To test for the effect of instructional methods on race, a 4 X 2 X 2 factorial design with repeated measures was used on the pre- and post-test scores. The variables were a) race, b) instructional methods, and c) both test scores. Race did not interact significantly with either the pre- or post-test scores \[F(3,178) = 1.47, p = 0.2235\]. The 3-way interaction between race, instructional methods, and the pre-test and post-test scores was also insignificant \[F(3,178) = 0.48, p = 0.6975\], showing the significant difference found between the two instructional methods was not caused by race (see Table 3).

Gender
The effect of instructional methods on gender was analyzed using a 2 X 2 X 2 factorial design with repeated measures on both test scores. The variables were a) gender, b) instructional methods, and c) the pre- and post-test scores. Gender has no significant interaction with both test scores \[F(1,182) = 0.11, p = 0.7415\]. The 3-way interaction between gender, instructional methods and the test scores was also insignificant \[F(1,182) = 1.40, p = 0.2383\] (see Table 4).

Discussion
Race and gender did not affect achievement significantly. However, the difference in achievement caused by instructional methods poses a few fundamental questions to ESL teachers.

Although teacher ineffectiveness is relative, the MCALL program appears far more effective than conventional teacher-taught classes in increasing the English proficiency of the students as measured by the TOEFL. If the MCALL Program had not existed, the conventional classes’ performance would have been commendable. The 26-point average improvement over a 16-week period is a significant result that many institutions would be proud of. However, this improvement pales in light of the 39-point average increase achieved by the MCALL students in 11 weeks. Simply put, the MCALL program yielded a 50% improvement over teacher-taught classes in 31% less time at potentially 83% less cost.

The difference is likely to have been caused by a variety of factors. The MCALL’s learner-centered environment is...
supremely conducive to language learning. Providing greater motivation, responsibility for learning was transferred to students. Students themselves set the learning goals at the start of the course (with the researcher) and decided when and what they needed to learn. In short, they should fail, they only had themselves—not the teacher's teaching—to blame. To learn, the students had only themselves and the multimedia computer to depend on.

The multimedia computer does not have the intelligence to teach anyone. This proved a boon. When teachers were present, they could always be relied upon to supply the correct answers in good time. Without teachers, students were forced to rely on their innate analytical skills to find solutions, which ultimately proved a more productive way to learn. What the computer lacked in intelligence, it made up for in storage capacity. It had an enormous database of authentic language use that students could use to model and scaffold their learning. In this particular instance, this scaffolding facility was all the students needed to pull themselves up by their bootstraps.

The students were given a task they believe in—earning an internationally recognized English proficiency certification. The task sufficiently challenged their abilities and improved their proficiency by a fixed quantum. Although the TOEFL is not a perfect test or even suitable for evaluating English proficiency in some circumstances, it is set up and graded externally, so students perceived a greater sense of 'fairness' or objectivity because there is no possibility of teachers influencing the outcome in any way. No longer could they depend on the final evaluation being set to reflect their norm because the TOEFL is set to reflect the norm of the world. One tends to be more motivated when competing against the world.

Teacher-taught students were required to be in class at fixed times even when they were tired or distracted. In the MCALL program, students could choose to learn only when they felt fresh and able to concentrate. Sometimes this freedom was abused, but the student-mentor system and the teacher's monitoring kept this in check. Should a particular student not comprehend a certain learning point, the teachers in class only had that many minutes to correct the problem because they had a responsibility to the other students too. In contrast, the computer could repeat the same point to one student for hours if need be, without holding up or boring other students.

Language is more skill than content and is learned more with practice than by abstract reasoning. No one has ever learned to speak by silently reading a passage. The computer proves to be a more tireless model to the students than any human teacher ever could. The limitation of this is that, not having any judgmental capability, the computer cannot decide the 'appropriateness' of the students' oral and written production, but in scaffolding students' acquisition of listening and reading skills, its strengths outweigh its weaknesses. Asian students are more risk-averse in situations where 'face' can be lost. A class is a potential face-losing situation because a student is at risk of being corrected by the teacher in front of the whole class. When asked what they liked best about the MCALL program, the students' answer was frequently "No teacher!"

The creation of an effective learning environment would have been made much harder without appropriate software. It is often said the computer is merely a tool and what makes the difference is how it is used. However, how a computer is used depends partly on available software. Traditional software has been little more than rote drills promoting low-level rather than higher-level learning. In creating the MCALL program, a deliberate decision was made to use interactive video because it is more authentic. Rote drills were eschewed for interactive multimedia because the latter is infinitely more flexible, and the flexibility conferred by the software should not be underestimated because with flexibility comes freedom to create a more powerful learning environment. Until true artificial intelligence is achieved, the computer's abilities to teach are limited, but the appropriate application based on sound learning principles can create a learning environment where teachers and computers work seamlessly together, each covering the weaknesses of the other. Although such a learning environment enhances the capability and value of effective teachers, it can also replace ineffective teachers.

Ineffective teachers use ineffective teaching strategies often stemming from viewing language teaching as "information dissemination." This leads to a teacher-dominated learning process emphasizing rote learning and automaticity. Such an orientation is self-defeating because it nullifies creativity, the hallmark of humanity, and prioritizes automaticity, the hallmark of computers. In disseminating information, computers are bound to be more effective. We should re-examine what we mean by "knowledge" and "learning" and whether our learning theories, teaching strategies, and classroom practices truly support learning.

Teacher-training has been the main culprit of ineffective ESL programs. Reform in this area is urgently needed. Technology not withstanding, the MCALL program was created, maintained, and managed by experienced human teachers who harnessed the computer to enhance their effectiveness by effectively blending learning theory, practical teaching experience, and computer expertise. Without the right human teachers, learning environments such as the MCALL program cannot be sustained, a tragic loss to future generation of language learners. Although computers cannot replace the "right kind" of teachers, the remaining question is whether enough teachers of the right kind exist.

Limitations

The results need to be confirmed by replicating the program. A bigger sample size would have allowed more powerful tests in the analysis stage. Sample size is a particular concern with the teacher-taught group. The 77 students in this group came from four classes. In effect, the MCALL Program was tested against only four teachers. It may be that with other well-trained teachers, the outcome may be different. On the other hand, the MCALL Program suffered a few setbacks placing it at a disadvantage. Due to technical problems, the MCALL students began learning five weeks after the teacher-taught classes had begun regular classes. In short, the MCALL students had a significantly shorter learning time, and the impact on their motivation during that time of inactivity could have been significant. During the course of the 11-week experimental period, a few software bugs (discovered including one that prevented some students from reviewing their progress online) were discovered. Such incidents would surely have impacted their motivation although the effect on their achievement could not be ascertained.

Conclusion

The results show that properly-used computers can be effective 'language teachers. Clearly, technology has become so powerful and flexible that, properly used, can replace ill-prepared people. Language teachers can only continue to ignore technology at their own peril. The onus is on teacher trainers in language teaching to incorporate this powerful tool into teachers’ arsenals. The language teaching profession at large must start asking itself some hard questions as to its roles and cost-effectiveness. The computer is neutral; it can as easily be a friend or a rival to the language teacher. Ultimately, the choice is ours. But the time to make the choice may be running out.

Since the announcement of Faculty Cultivation Code of the Republic of China on February 7, 1994, it established the diversified development direction of the faculty cultivation of R.O.C. in Faculty Cultivation Code, the regulations governing the students of normal college in the future through education and practice in obtaining conforming teacher qualification would require the students to fulfill prior-to-function educational program who, through conformity of preliminary teacher appraisal, shall obtain practice teacher qualification (Article 7). A practice teacher shall go through one year of education practice; the one with conforming performance record and secondary teacher qualification appraisal shall obtain conforming teacher qualification (Article 8). One who wishes to obtain conforming teacher qualification shall go through preliminary appraisal, education practice and secondary appraisal; the teacher certificate system is therefore confirmed and established. (Ministry of Education, 1996)

The teaching practice and simulation of a student of normal college during schooling stage, and the practical teaching of the same student after fulfilling studies and assigned to a school for practice, shall form profound impact on his/her later teaching proficiency development. However, during the study program of the current normal college, the integral planning of combination of practice and theory and each education subjects is in lack that the practical experience of the students of normal college is insufficient. Therefore, how to integrate the education subjects and practical program for teaching from freshman year to senior year in a normal college in the future, to strengthen the practical experience of a student; how to improve the function of practice guidance sector of a normal college and assist a student graduated from a normal college to develop his/her proficiency to successfully become a conforming teacher with proficiency; how to establish a sound mode of teaching practice system of a student of normal college in order to upgrade the faculty qualification of the high schools and primary schools.

Research Objectives

- Analyze the educational practice system of advanced nations to compare the difference of the education practice system of R.O.C. normal colleges.
- Analyze the appropriateness of the existing educational practice system of R.O.C. to serve as reference to improve education practice system.
- Provide a feasible mode for the framework and execution policy of the education practice system of the normal colleges of R.O.C.
- Propose substantial opinions of improving the education practice system of normal colleges.

Research Methods

Literature Analysis
This research mainly solicits the domestic/overseas periodical journal, magazine, academy report, and research report and paper, about the related education practice system data of a new teacher, and perform analysis and comparison of their characteristics.

Site Interview
Site interviews of the executive officers of the education and administration authorities of 12 normal colleges, teacher research institute, and school for practice, etc. to further understand the current condition of distributed practice of the students graduated from normal colleges and their difficulties.

Expert Symposium
Such related personnel as scholars, headmasters, directors and teacher representatives, educational adminis-
tation personnel, etc. are invited to hold symposium. The obtained conclusions serve as reference for preparing questionnaire and research.

**Questionnaire Investigation Method**

This research, based on the self-edited "Research on Chinese Normal College Education Practice System" investigation questionnaire as the main research tool, divided into Questionnaires A, B and C. Questionnaire A is for the personnel of high school and primary school; Questionnaire B is for the scholars and experts; Questionnaire C is for the educational administration personnel. The research unit designs questionnaires, experts are recruited to perform review and comment, through pre-test and revision, the formal questionnaire investigation is carried out.

**Conclusions**

1. The main conclusions of expert symposium and site interview part shall be divided into the following items:
   1. Education practice target.
   2. Education practice organization.
   3. Education practice program.
   4. Education practice strategy.
   5. Assigned practice in the 5th year of college.
2. The main conclusions of questionnaire interview part shall be divided into the following items:
   1. Preparation education stage (freshman and sophomore years).
   2. Practice education stage (junior year).
   3. Comprehensive education stage (senior year).
   4. Assigned practice stage (the 5th year).

**Recommendations**

1. Construct education practice system, develop characteristics of normal education.
2. Propose education practice guidance strategy, reinforce contact of various sectors, actualize education practice guidance work.
3. Review education practice goal of normal college, actualize education practice function.
5. Improve prior-to-job cultivation education practice program, supplement basic capacity of normal college students, unify the education practice content of various years, supplement practical experience of the students of normal college.
6. Prudently select outstanding faculty to perform functions of teaching and guidance, upgrade teaching quality.
8. Improve education practice guidance measures, actualize education practice guidance work.
9. Reinforce the communication contact and compliance among practice unit (office), practice school, Hsien/city education guidance corps, guidance professor, develop integral cooperation and guidance function.
10. Prepare and print related practice information manual, provide for reference to the graduate students and guidance professors.

ine art and craft teaching is a teaching activity dealing mainly with visual form, aided with various types of materials to engage in creative performance and evaluation. During teaching, the application of practical situations, object, picture, photo, slides various teaching media is very necessary. Due to the comprehensive scope of information, data collection is not easy. Besides, due to the restriction of traditional media, application and maintenance, the application and performance of teaching media is also doubtful. The operation of computer multimedia becomes simpler, but the functions become stronger. The application of the multimedia with digital style, rich information and active interacting function to fine art & craft teaching as teaching source or learning source is one of the feasible alternatives.

From the angle of the epoch, the Ministry of Education has been active in promoting computer education in primary and high school recently and the computer application has been more and more popular to help the children of the new generation to possess the capacity of using computer to process information since childhood. Therefore, as an educator to cultivate the citizens of the new generation for the 21st century, the application of computer as education resource or teaching tool is necessary. In the epoch of new media and traditional media, how to apply computer digital information to plan for a feasible mode the integration of new and old media to effectively upgrade the quality of fine art & craft teaching is the motivation of this paper.

Research Objectives
The main purposes of this study were as followes:
• to analyze the feasibility of computer multimedia digital information as a resource for fine art and craft teaching in primary schools.
• to analyze the feasibility of integrating computer multimedia with traditional media for the fine art and craft teaching in primary schools.
• to analyze the number of applicants relative and teaching requirements of the fine art and craft teachers of primary schools concerning computer multimedia.
• to submit the recommendations on the application of computer multimedia for the fine art and craft teaching in primary schools.

Research Methods

Literature Review. In order to attain research objectives, the literature review was used to analyze the feasibility of computer multimedia and its alternative strategies for fine art and craft teaching in primary schools.

Questionnaire Investigation. In order to attain our third research objective, an investigation questionnaire, Applying Computer Multi-Media for the Fine Art & Craft Teaching in Primary Schools was designed to explore the number of the fine art and craft teachers who would use the technology and their educational requirements.

Research Conclusions
There are five main conclusions of the study:
1. Application of computer multimedia in fine art and craft teaching activities in primary schools shall be necessary for an educator.
2. Applications of digital information relative to computer multimedia in the processes of fine art and craft teaching are feasible in primary schools.
3. The integration of computer multimedia with traditional teaching media is of worth in the application and promotion of current fine art and craft teaching.
4. The recognition, capacity, and teaching skills of the fine art and craft primary school teachers on the use of multimedia are insufficient and shall be upgraded.
5. The intent of computer multimedia teaching of the fine art & craft teachers in primary schools is high; therefore, the sound inservice study shall be duly planned by the educational administrative authority.
Recommendations

The study suggested that applying computer multimedia for the fine art & craft teaching of primary school in the future. This study mainly recommends its system structure is listed as diagram 1.

INFORMATION TECHNOLOGY USED IN FOREIGN LANGUAGE TEACHING IN SECONDARY EDUCATION

Weiguo Feng  
Tongji University

Yi Lu  
Shanghai School of Chemical Technology

Yuren Wu  
Tongji University

Maochang Que  
Shanghai School of Chemical Technology

Shanghai is the biggest city in China. As the industrial and financial center and the foreign liaison window for China, Shanghai is in great need of qualified personnel with a good command of foreign languages. During the years of open policy, the requirement and training for all sorts of people with good English capabilities have both reached an unprecedented degree. There are more than one hundred thousand people who have successfully passed the Rank Examination in Proficiency in Commonly Used Foreign Languages of the Citizens of Shanghai with fairly fluent primary English and Japanese, communication English and Japanese, and intermediate English and Japanese, and so forth. And there are quite a number of people who have passed the qualification test for high-ranking English interpreter positions. Thus, foreign languages teaching (taking English as the dominant factor) in secondary schools, which are crucial in providing all sorts of talented people, has also attracted a whole lot of attention.

Secondary schools, including senior secondary schools, junior secondary schools and secondary technical schools, pay great attention to English teaching, which is indicated by the big amount of improved teaching equipment. As the degree of the technical advance in each school varies, so does the teaching result, due to lacking of funds; but the developing trend is very obvious. The following general characteristics are found in several schools.

- Shanghai School of Chemical Technology is a full time technical school. It has been acknowledged by the authorities as one of the grade “A” top ranking technical schools in China.
- Attached Secondary School of Shanghai Jiaotong University is one of the key schools in Shanghai. It has only senior secondary school students.
- Shanghai Guangming Secondary school is one of the key schools in Luwan District, Shanghai.
- Shanghai Secondary school No. 51 is an ordinary school.
- Quyang Secondary School No. 2 is an ordinary school that has only junior secondary school students.

The results of our investigation of the information technology equipment available for use in English teaching in the above-mentioned schools are listed in Table 1 on the following page.

From the result of the investigation, we know that there are considerable differences among these schools in their ability to make use of information technology. The teaching equipment is comparatively advanced in key schools, because of the considerable investment from the government and the help and support from the society. Because of the value placed on foreign language degrees, key schools often regard teaching equipment as the component part of school construction.

In those schools the use ratio of sound laboratories is high and there is a television set in each classroom. The students there have good conditions of learning English. For example, Attached Secondary School of Shanghai Jiaotong University sets up a special-purpose audiovisual teaching and research section that is specifically in charge of the management of sound laboratories, classrooms with electrical audiovisual aids, and computer rooms as well as some related teaching activities. Every student registers in English listening comprehension for one semester.

Market Calculation of IT in Secondary Educational Fields

What is happening in advanced schools of today is going to be seen in other schools tomorrow. With the social economic capabilities rising, and the price of semi-

</table>

Attached Secondary School of Shanghai Jiaotong University includes some rural students, so the ratio of the families owning video recorder is comparatively low. The ratio of the senior school students owning computer is higher than that of the junior school. The ratio of the families from two schools owning computer is about 15%. It can be found from the investigation that there is not much difference among the family conditions of the students of various schools. The levels of their desire to understand advanced technology are almost identical.

It is estimated that the ratio of Shanghai families that own computers will go up to 20% next year. It looks as if the ratio of the families of senior school students owning computer will be higher than it. The increasing interest in home computer not only forms a new demand on computer course, and therefore, with the assistance of computer, supplies favorable conditions for English teaching, it also provides a huge market base for English teaching software.

The exhibitors selling sound equipment and computer took up about half of the exhibition hall of the September 1996 laboratory instrument and equipment in Shanghai. It is estimated that in next ten years, newly built key schools will put comparatively advanced sound equipment and computer networks into teaching; the already existing key schools will put the emphasis on building multimedia computer network while safeguarding the former sound equipment at the same time. A new type of sound laboratory which is controlled by computer is gradually but warmly received by schools, too. The installation of computer network will become imperative in other schools as well. All the schools are looking forward to more advanced and yet practical equipment, and combining sound equipment with multimedia computers.

In English teaching, the effects of audiovisual education technology are well known to the public. Tape recorders have become the tools that English learners can’t be short of. In order to sharpen the listening ability of students, using tape recorder in English class has been greatly promoted in many secondary schools. English teaching programmes on radio and television have been effective instructor and helpful friend to millions upon millions of people. There is no doubt that most parents want their children to watch such programmes. In schools with good labs, sound laboratories become welcome study places of instructors and students. But at present, as far as English
teaching of secondary schools, the pity is that mediums to provide visual stimulation seem not to have been made full use of. Some English teaching films can be made and shown properly in class without much change, and some other suitable English movies can be produced or purchased for students to watch after school. These visual aids will play an important role in students’ English learning. It is estimated that, if there is a large quantity of suitable VCD teaching materials, the call “VCD Enters Classroom” will probably be raised in near future in schools where each classroom is provided with TV set, which will be more practical and convenient than letting computer software goes directly into classrooms.

The development of hardware will certainly bring along that of software. Both purchased and produced English teaching software is valued extensively.

The quantity of existing software for English study is so large that it has become difficult to add up. These existing software for English study may contain word study, reading comprehension, listening comprehension and multiple exercises training. Some software is used in one single school, while others have been exchanged among schools. Some software is popular and has gone through many reprints, and some has been upgraded as multimedia version recently.

One of the authors has helped to develop the software about English word structure. That courseware, which contains the entire texts of English textbooks for students of senior secondary schools, teaches readers how to distinguish the prefix, root, and suffix of a word, and learn to remember the words according to the three parts of meanings. We had some students been tested on it, and found that the number of the new words that could be memorized by the students per hour can add up to about one hundred when they were tested using the software for only fifteen minutes, after learning the courseware for an hour.

Quite a number of editions of learning software on different subjects of secondary education, including English, have appeared in recent years. Gold Disk English, the first set of laser disk of English teaching material for students of senior secondary schools, teaches readers how to distinguish the prefix, root, and suffix of a word, and learn to remember the words according to the three parts of meanings. We had some students been tested on it, and found that the number of the new words that could be memorized by the students per hour can add up to about one hundred when they were tested using the software for only fifteen minutes, after learning the courseware for an hour.

In Shanghai, in the past few months, the software of “National Audio-Visual Educational Experimental School” held in Xuhui District Central Primary School No. 2, Shanghai Committee of Education made the following demands: enthusiastically advance the modernization of educational mediums such as projectors, televisions, videocoders, computers and so on, gradually have them take the place of traditional teaching tools such as chalk, blackboard, instructor’s pointer etc., further promote the reform of the basic education and the all-round improvement of the knowledge of students in secondary schools and elementary schools.

In order to advance the modernization of the education, the Audio-Visual Educational Committee of National Committee of Education has lunched a project of National Audio-visual Educational Experimental School. In Shanghai, 52 schools have applied for it, and through experiments, over 70 percent of the experimental schools will become model schools of Shanghai, where the level of carrying out education with electrical audio-visual aids and the degree of modernization of education are both quite high. Shanghai Committee of Education will select a few from among those schools for applying for national audio-visual educational model school. By means of using the experience of selected units to promote work in the entire area, the level of the modernization of the educational mediums used in English teaching in secondary education of Shanghai will certainly be raised by degrees.

Prospects for English Teaching Technology

In foreign languages teaching, various schools have used information delivery methods to different extents. Both instructors and students are looking for the information technology that is more suitable for teaching and learning.

Different kinds of information technology have been accepted by schools. The whole process can be described as a fixed course of “Saddle-shape Process” (also called “U-Process”). Sound equipment has experienced its peak period and indifferent period, and now it is beginning to step into an improving and moderately developing period. Multimedia computer network is advancing towards its first peak period.

In November, 1996, at the mobilization meeting of “National Audio-Visual Educational Experimental School” held in Xuhui District Central Primary School No. 2, Shanghai Committee of Education made the following demands: enthusiastically advance the modernization of educational mediums such as projectors, televisions, videocoders, computers and so on, gradually have them take the place of traditional teaching tools such as chalk, blackboard, instructor’s pointer etc., further promote the reform of the basic education and the all-round improvement of the knowledge of students in secondary schools and elementary schools.

Multimedia computer network is advancing towards its first peak period.
Features of Future English Teaching

Classroom teaching mediums are varied by degrees. Different kinds of mediums such as tape recorders, TV set, videocorders, multimedia computers and sound equipment will be applied increasingly in classroom teaching, instead of using blackboard and chalk only.

Study channels are gradually varied. It is no longer only from classroom that students obtain knowledge of foreign languages. Now they can also find supports from families and community. The increase of information mediums used in families, community and schools makes the classroom teaching lose its importance, while at the same time sets a higher demand on the efficiency of classroom teaching.

Individual study is strengthened. Students have the ability to prepare hardware and software themselves and study them individually. There will be more and more excellent students, and the overall level of students will be raised, too.

The work of instructors has changed to some extent. An increasing number of instructors divert some of their energies to the development and application of advanced teaching mediums.

By the year 2000, the value of the output of electrical computers of Shanghai will add up to two thousand million yuans, of which the value of software will amount to five hundred million yuans. We should catch this juncture in English teaching, make full use of new technology, and foster a good ability of English listening, speaking, reading and writing for our students.

MASSIVE DISSEMINATION OF INFORMATION TECHNOLOGY THROUGH TESTING IN SHANGHAI

Julie Bao  
Shippensburg University

JoAnn Lan  
University of Alabama, Birmingham

Chen Xin  
Shanghai Television University

With the rapid development of electronic technology, the world has entered a new era of the information age that is exerting an increasing impact on our life styles, paradigms, and the modes of production. Yet, this impact reveals a huge inequity of technology access between the economically advanced nations and developing countries. Consequently, how to make the information technology benefit people of all countries becomes a new challenge in the information age. Furthermore, how to let information technology reach a developing country of 1.2 billion people makes the challenge even tougher. Due to the facts that there are very few technology dissemination programs that can be readily applied to China, the human resource engineers of China have to create their own. Among the successful out-research programs they have developed is the “Disseminating Information Technology through Testing” in Shanghai.

This paper analyses the Shanghai computer test program from the following four aspects: a. the background of the program which introduces the current stages of technology development in China and discusses the necessity of the program; b. the curriculum of the program which delineates the content and sequence of the program, c. the testing procedures and results, which deal with the operational aspect of the program, illustrate the results of the first 10 tests, and describe the demographic characteristics of their participants, and 4. the discussions of the model which put the initiation and success of the program in the social and cultural perspectives of the Chinese society.

The Background of the Program

Very few statistics are available regarding the current status of distant learning facilities and computer availability in Chinese schools and society. People’s Daily reported in 1995 that by 1994, there were 7,100 educational television stations (including relay stations) and 53,000 TV viewing sites. They were mainly used to train 1,200,000 school teachers and provide agriculture technology for 20,000,000 farmers (People’s Daily, 1995). According to the “Feasibility Study of the State Major Tasks for the 9th 5-Year Plan” of the Chinese State Education Commission, China has currently equipped 30,000 schools with computer labs and has a total of 300,000 computers used for the elementary and secondary schools (CSEC, 96). That indicates 30,000 labs out of 800,000 schools and one computer lab out of 25 schools. Most of the citizens have never used computers and will not likely possess one in the near future. Nevertheless, the world has entered an information age, and computing skills are required in almost all careers. With the booming industry in China, and especially in her most industrialized city of Shanghai, the need of information processing skills for a new generation of workforce is becoming increasingly demanding.

Shanghai is one of the largest cities in the world with a population of 12 million people. In spite of its rapid growth in industry, it is still a developing city in a developing country, which greatly limits its access to financial resources. In view of the great disparity between the need of economy and the exiting information skills of her citizens, how to disseminate technology among her enormous population is a daunting challenge to its human resource engineers. Searching around in the global technology market, there were hardly any technology outreach programs that could be readily applied to the economically booming, yet populationwise most burdened city of Shanghai. Therefore, the leadership of Shanghai decided to design its own programs of human resource development for the 90s, including training at least 10,000 much needed personnel for the key positions of Shanghai economy (Shanghai Education, 94). Naturally, information technology should be part of the training curriculum, yet Shanghai was short of both instructors and facilities for the grand task. Consequently, the Shanghai Educational Commission gathered its 8 experts in the educational computing field in 1993 and called for creative solutions to the challenge.

The Shanghai Television University (STVU) took on the challenge of massive dissemination of technology in
Shanghai with a creative approach involving a unique testing program. STVU was an open university under the Shanghai municipality to engage in distance learning by modern technology. It was one of the earliest radio and television universities in China. The President of STVU, Professor Huang Qingyuan headed the newly established Computer Application Testing Office that initiated the "Teaching Technology through Testing" program in 1993 to massively disseminate information technology to much needed specialists for Shanghai economy (STVU, 96). The outcome of the program greatly exceeded the expectations of the designers, and the past three years have seen a great success in this unique program.

The Curriculum of the Program

The designers of the testing course were very conscious of the classical tendency in Chinese training programs, which, in the computer field, would have started from the binary systems or the BASIC language for the beginners. Nevertheless, the designers of the course made it very clear this time that it was the functional knowledge of computer and hands-on skills that were required for this program. Therefore, the learning objectives for the Basic Computer Course were to demonstrate the skills to use DOS, WPS (a Chinese word processing program), and the FoxBASE Database system. It was so designed that approximately 100 hours would be needed (50% of time in reading, and 50% hands-on experience) for an equivalent of a secondary school graduate to complete the course. After 4 months of joint efforts, the textbook for the Basic course was completed in 1993. The need for the course was so great that 900,000 copies of them were sold within 2 years (STVU, 96).

The Intermediate Course selected the upgraded version of DOS, Window, and FoxPro as their major software for training. Its textbook was completed by the faculty of STVU in 1994, and 100,000 copies of them have been sold since. Apart from the textbook, STVU also provided video tapes (34 sessions and 25 minutes each) for both Basic and Intermediate courses. These training sessions have been repeated many times on the Shanghai Education Television since 1993.

The Testing Procedures and Results

All tests were conducted on computers and each test lasted 2 hours. Of all the disks (21,000 for the first and 62,000 for the second) that were made for the first 2 tests, not a single one became problematic. The content of the Basic Computer Test was divided into 2 parts. The first part tested the functional knowledge that consisted of 25 multiple-choice questions which accounted for 25% of the total scores (25 points). The second part was divided into DOS Operation (10 points), Inputting Chinese Characters by Using WPS (20 points), Word Processing (20 points), and Using FoxBASE (20 points). The Intermediate Computer Test also consisted of two parts: The first part tested the foundation knowledge with 40 multiple choice questions (40 points), and the second part assessed the operating ability by asking students to demonstrate their skills to use DOS, MSWindow, and FoxPro database on computers. Each category in the operational part accounted for 20 points.

Due to the limited testing facilities and the enormous numbers of people that had applied for the test, the first test lasted 5 days with a total of 15 testing sessions. The second lasted 8 days with 24 sessions. As a result of this, evaluation software had to be developed and improved. The evaluation software currently used was a product of a comparative study of computer and manual evaluating on the basis of 1000 testing samples.

Because of the enormous population involved, it was impossible for STVU to offer all the hands-on training programs, therefore, it facilitated all the qualified adult learning institutions to accomplish the task. Before the first test, 140 training sessions with 4,000 computers were organized to prepare 15,000 participants. This number of training sessions increased to 250 with 7,000 computers to prepare 50,000 participants for the second test. Currently, 400 training sessions with more than 10,000 computers are preparing 300,000 trainees. Table 1 illustrates the number of participants and the passing rates of the first 6 tests for the Basic Computer Courses (STVU, 96).

Discussions
There is little argument that the “Disseminating Information Technology through Testing” is a highly effective program in Shanghai. Its success can be attributed to, among others, the following 4 reasons: First, there is an urgent need for a new generation of workforce for the booming economy in Shanghai. The computer dissemination program is called upon by, and falls right into the essential curriculum of, the human resource training plan of Shanghai. The development of Shanghai economy demands millions of people who will be able to use various computer programs.

Second, Shanghai excels and leads the Nation in its distant learning and adult education programs. Currently, there are 258 adult learning institutions in Shanghai with a total student population of 160,500. Together with correspondence courses and other forms of training, approxi-

mately a million people are trained annually by one or more varieties of adult education programs (Shanghai Education, 1994). To many adult learners, the Computer Training Program is just one added curriculum requirement.

Third, there is a Testing Complex in the Chinese culture. From the Ancient Mandarin tests to the current competitive school exams, the test is always one of the central components of the curriculum. People are used to it. They readily accept it and work hard for it. Tests have more legitimate authority in Chinese culture and can generate more motivation in China than many other nations.

Lastly, the success of the program involves the team work of many people and organizations. After the course was designed, the formal notice of the course was passed on immediately to employees by all major related organizations. The Shanghai Education and Health Commission, Shanghai Personnel Bureau, and Shanghai Adult Education Commission jointly required their employees and all the administrators and technicians in Shanghai under the age of 50 to pass the Basic Computer Course. The Administration of Shanghai municipality recognized the two levels of computer certificates and connected them with employment qualifications and promotions. All the conditions mentioned above help create an environment that is conducive to the success of the program.

With the achievements of the Basic and Intermediate Computer Courses, the STVU recently released an Office Automation program that included basic knowledge of office automation, information processes in the OA system, OA hardware and software, Microsoft Windows 3.1 Chinese version, Microsoft Word 5.0 Chinese Version, Microsoft Word 5.0 Chinese version, and Chinese Star 2.0. Twenty testing sessions have been conducted on a server controlled network that no longer needs any separate disks. The server controlled network will replace all the disks in the future tests.

Together with the dissemination of technology among adults, the State Education Commission has just released a feasibility report in the Computer Aided Instruction field, which recommends 8 challenges as major tasks for the computer education in Chinese schools for 1996-2000. These 8 CAI tasks include:

1. Design software for the key courses in higher education,
2. Develop assessment software for higher education and test banks for key courses,
3. Design courseware for the secondary schools,
4. Develop courseware for the elementary schools,
5. Enhance the software engineering and development environment for educational software,
6. Increase the CERNT application and the distance learning.
7. Experiment the Local Area Network for elementary & secondary schools, and
8. Develop multimedia educational software. All projects will work hand in hand with the current adult technology dissemination programs and together they will make technology more accessible to the Chinese people.

The experience of the Shanghai computer training program demonstrates that disseminating technology in a development country calls for creative approaches and joint efforts of many fields. It is an achievable and a worthy cause. In spite of the fact that outreach programs may develop very unevenly in a developing country, and the curriculum of the Shanghai Computer Test Program is far from perfect, yet, it does reach people by hundreds of thousands in a very efficient and economical way. It is a highly successful program in Shanghai, and it has certainly brought information technology a giant step closer to the Chinese people.

China 5000 is the first and by far the only truly hypertext chronological timeline of Chinese history in the Internet community on the World Wide Web (WWW). It incorporates Chinese culture, art, education, science, and government reference related to China, Taiwan and Hong Kong. The user can simply click on one of the dynasty in the timeline to view materials related to that particular dynasty (Figure 1). Beside being a centralized site in the WWW community, China 5000 is further enhanced for educational purpose due to its Distributive Query Handling (DQH) system. DQH utilizes the Internet “reflector” feature to forward questions and requests received through China 5000 to appropriate experts in the Internet community. These experts can then assist in answering questions in different subjects. To date, China 5000 has received China-related questions and helped distributing these educational requests from/to Singapore, Canada, France, US, and Mexico (Chang & Tsao, 1996).

Information Technology and Chinese Studies

This year, under the author’s recommendations, the University of Maryland hosted the 38th American Association for Chinese Studies (A.A.C.S.) conference with two major innovations: first, a never-before conference theme - “Communicating in the Chinese-Speaking World”; second, a newly-added discussion topic - “Information Technologies”. A theme provides focus on the presentation materials while new topics will provide new thoughts to the conference participants. The author is also happy to see both suggestions being well-adopted by A.A.C.S. board members and the conference participants, resulting more than twenty panels targeting on the conference theme and three panels on science and technology issues, particularly information technologies.

This discussion panel, “The Role of Information Technology (IT) in the Chinese-Speaking World”, was also proposed by the author. The purpose is to present to the audience the importance, potential, and application of many aspects of IT in the Chinese-speaking world. Since this is one of the very first attempts to link IT into future A.A.C.S. conferences, the author decided to use the exact panel topic, with the traditional 6 W method, to elaborate on IT and its link to Chinese studies and the Chinese-speaking world. Throughout this paper, a project named “China 5000”, an Internet World Wide Web (W.W.W.) based project initiated by the author in 1995, will be used as an example to support the author’s points.

The 6 W method, is a rather old-fashioned way of discussing and analyzing different subjects. However, the simplicity and clarity of such method makes it a very useful way of presenting newly-established concepts. The author is conducting the 6 W method in a questions-and-answers format. The first 5 W’s (What, Why, Who, When and Where) are intuitively acceptable. While the last W (how) will be somewhat controversial, the audience should understand the author’s assertions were derived from his own professional and scholarly viewpoints.

What (shall we do about Information Technologies and Chinese Studies)?

The questions derived from the word “What” can not be considered narrowly as “What is Information Technologies?” or “What is the Chinese Speaking World?” They should be rephrased as “What shall be done for information technologies” or “What shall be accomplished for the Chinese speaking world?”

“What shall we accomplished for the Chinese Speaking World (Chinese Studies)”? Below are three major directions proposed by A.A.C.S.:
1) encourage the study of subjects related to China, especially in American educational institutions;
2) advance such study and teaching through the exchange of information and scholarship across disciplinary lines;
To promote understanding and communication between Western and Eastern scholars involved in Chinese studies.

Figure 1. Sample WWW Home Page for China 5000.

“What shall be done for Information Technologies?”
The answer can be generated by replacing the word “Chinese studies” with “information technologies” in the above three statements. In short, the application of information technologies needs to be promoted.

Why (do we want to associate IT with Chinese Studies)?

IT handles large size, long distance and provides high speed (relatively, in comparison to post-mail) in an inexpensive way. Table 1 contains an electronic message regarding “China 5000” delivered to the author in US from Singapore — an example for long distance and high speed communication. (Ron, 1996)

<td>Dear Sir, I was doing a research on ancient China and in the course of my research I came across China’s “legendary age”. According to the book (History Of Asian Nations by Zaide), the unknown centuries prior to 2205 BC were known as China’s legendary age. According to the legend China was successively ruled by “Five Good Rulers” namely Fu Hsi, Shen Nung, Huang Ti, Yao and Shun. I consulted another book (An Outline History of China by Bai Shouyi), it never mentioned the names of Fu Hsi and Shen Nung. Although it mentions the name of Huang Ti, Yao and Shun but they were only tribal chiefs. Can you enlighten me on this? Thank You.</td>

Who (should be involved in such effort to link IT with Chinese studies)?

This task will not be limited to a small group of scholars anymore. Whoever familiar with IT and is interested in Chinese study will be able to join the task force. Table 2, 3, and 4 contain E-mail message about China 5000 from different group of people. Such variety of participation proves the important role of IT to the enhancement and enrichment of Chinese studies. (Grunfeld, 1996; klstewart@gnn.com, 1996; benson@gsilink.com, 1996)
When (should all these activities be happening)?

With the help of IT, Chinese studies will be a 24 hours activity! CHINA 5000 can serve as a typical example. (see Table 5; Goldman, 1996)

Table 5.
China 5000 (Chinese studies) a twenty-four hour activity

How (could we accomplish what we want)?

Is the answer simply the word “Internet”? No, it is not just “Internet”! The author proposes the need for greater efforts in the following three directions:

1. Chinese Language Unification (in spelling and writing)
   a. Character reunification: a follow-up of Emperor Chin’s contribution thousands of year ago
   b. Pin-Yin or Phonetics?
   c. Both will simplify technology advancement and improvement in Chinese language

2. Chinese Studies Net (C.S.N.)
   a. Organizations like A.A.C.S. should take the lead in organizing Chinese-related materials on the WWW
   b. Scholarly involvement is the most essential topic

3. Information Technology Advancements in Chinese Language
   a. Chinese Speech Recognition
   b. Chinese Handwriting Recognition

Implications for Teacher Education

China is more than 4000 years old, while Information Technologies has no more than 100 years of history (Hafner & Lyon, 1996). To strengthen the link between IT and Chinese studies is like strengthening the relationship between a 100 year old lady and a two year old child. It is not impossible; it needs people’s participation, time and effort. Having three science and technology related panels among the twenty-two panels in the AACS conference is an excellent start and a good example of people participation in linking IT with Chinese studies. Successful promotion and adaptation of an IT oriented educational project like “China 5000” will be a strong step in the direction of acceptance and advancement of IT in teacher education.

INSERVICE TRAINING THROUGH ODL ENVIRONMENTS: FROM USER NEEDS TO FUNCTIONAL SPECIFICATIONS

Christos Bouras  Petros Lampsas  Paul Spirakis
Computer Tech Institute  Computer Tech Institute  Computer Tech Institute

Open and Distance Learning (ODL) can be regarded as learning by means of telematics (the combination of means of telecommunications, information technology and multimedia), which identifies as necessary to the learning process all interactions between learners, teachers and courseware, all accessible and readable information and knowledge (in different representations), and a high degree of flexibility regarding place, time and pace of learning.

The ODL has four main objectives: to develop teaching frameworks and methods suitable for the use of technologies in different educational environments; to not only improve the organizational environment in which these new methods of education are applied but to enhance the quality and user-friendliness of multimedia applications and online services; to increase the skills of teachers and trainers in devising and using models for training relevant partners at all levels; and to encourage the recognition of qualifications obtained using multimedia materials and distance learning services.

The ODL’s purpose is to develop and promote methods and techniques designed to increase the quality, efficiency, and flexibility of education. ODL is to be understood in two senses—the improvement and development of teaching methods in the educational system and the supply of distance learning services using information and communication technologies.

ODL does not necessarily mean that a student must study alone (at home, at school, or in the working environment) under the guidance of a teacher who is at a remote site. ODL can be best combined with other forms of education such as cooperative or distance learning. Using telematics is not a target itself, but one means of realizing educational goals such as renovation of the pedagogical methods and environments in educational institutions, stimulation for the dissemination of information among educational institutions all over the world, encouragement of collaboration, a very good educational technique, motivation of students through the use of effective and current technological equipment, and effective transmission and delivery of knowledge to students.

The educational systems must be urgently supported by effectively introducing the use of Information and Communication Technology (ICT) and by installing flexible teachers’ training techniques that ensure equal opportunities for all without restrictions such as distance and time; cost effectiveness; and continuous improvement of teachers’ skills and capabilities.

The TRENDS Project

At the time of this writing, in Europe, an attempt is being made through the TRENDS project to use ODL environments to reach these goals (Telematics Applications Programme - ET/1024 EC). The TRENDS project aims at the development and efficient delivery of inservice training to school teachers, thus improving the quality of the educational services of public interest and, at the same time, stimulating the creation of new jobs in the education and training sector. The methodology focuses on the enhancement of existing ODL techniques in the area of multimedia telematics by practicing the latest methods of Information Services Engineering in measuring the application as well as the socio-political feasibility in the domain of lifelong learning. The objectives of the project are:

- The development of an inservice, school based teacher training system based on multimedia telematics to support the continuous improvement of teachers’ skills and capabilities in European secondary education.
- The implementation of distance learning techniques to provide viable and cost-effective school-based training.
- The establishment and operation of a European Teachers’ Training Network to provide the distance training.
- The validation of the distance training services by training 2,400 teachers from 120 European public secondary schools.

Methodology to Determine User Needs

A very important phase in the lifecycle of a project relates to determining user needs. Since TRENDS is a trans-European project, the task of establishing user needs
is even more complex and requires a great deal of organization and planning. Failure to identify the user needs is almost certain to lead to the project’s failure. It is, therefore, imperative that utmost care is taken to determine all user needs at the onset of the project.

Determining user needs was adopted in the context of the TRENDS project by the participating countries with slight variations as dictated by the educational systems’ differences. The method included:

- Questionnaires sent to key persons and experts (indirect users of the TRENDS project) from the fields of Education, Information Technology, and ODL about topics related to the teachers’ work, initial training, inservice training, needs for support, and their new role as a teacher incorporating new technologies into the learning process. Master guidelines were based on the responses to the questionnaire.
- Organization of discussion panels/workshops with marginal extension of the numbers of these key persons and experts for brainstorming and discussion of the aforementioned topics.
- Questionnaires addressed to potential end users (school teachers) who were divided in two groups: users with and without experience in using ICT for educational purposes.

The justification of the outcomes for each of the participating countries was ensured by the involvement (discussion and/or questionnaires) of end users (teachers) to some extent and the involvement of indirect users (such as education policy makers, ODL and ICT experts, teacher training experts, and decision makers) by interviews and discussion panels/workshops.

User Needs for the TRENDS Project

The user needs as expressed by the end users fall into two categories. The first contains needs expressed by those having little or no experience in the use of modern telematic technologies for improving the educational process. The second contains more detailed needs expressed by those who understand the possibilities offered by the use of telematic technologies. Following are, in brief, user needs:

- Acquaintance with the various tools offered by ICT and how these can be uniformly and readily used for improving the overall quality of the learning process.
- Creation of interdisciplinary courses on a national or international basis.
- Personal communications among teachers, school administrators, and curriculum experts to exchange ideas, information, plans, and techniques concerning the educational process.
- Additional scientific knowledge pertaining to particular subject matter (expressed by nearly all countries with only slight variations). This knowledge should either fill ascertained gaps in the initial training of teachers or contribute to their further education in the subjects they teach (Italy, Portugal, Spain).
- Participation in discussion fora dealing with educational issues to exchange information/opinions on educational matters with trainers and colleagues all over the world.
- Further education and updating for teachers on the new didactic methodologies developed and applied to each subject matter. The aim is to familiarize teachers with these methodologies and their contribution to the learning/teaching process with particular emphasis placed on those which help solve special problems facing teachers.
- Access to resources containing educational material (such as the Web).
- Transfer or exchange of educational material between teachers all over the world.
- Access to services offered by already established educational networks for using already existing, evaluated resources.

TRENDS Educational Network Services

To meet end users’ needs, the following services will be offered in the context of the TRENDS project:

Interpersonal Communication Services

The following are the interpersonal communication services offered through the TRENDS project:

- **Off-line contact with a trainer.** This service will offer the ability to register questions concerning the material they studied. The trainers will be able to answer and clarify any difficult points. This service will be implemented by employing already existing network services such as contact through e-mail with other educators and trainers. The e-mail service, enhanced by supporting multiple data formats (multimedia support), offers a fast path for the exchange of messages with other colleagues participating in the TRENDS project as well as personal contact with the trainer.

- **Access to multimedia information.** Widely known Internet technologies will be used for implementing the access to multimedia information and for storing and making available the information that the TRENDS project will produce.

- **Creation of fora.** These fora will exist in the form of newsgroups in which educators can participate. Also, the newsgroups can offer up-to-date information on educational subjects and policies adopted by each of the participating countries. The TRENDS project will produce its own fora for discussion and debate on subject matters mainly concerning the audience of the TRENDS project.

- **Access by trainers and educators to curriculum-related information.** This will be accomplished by having access to other educational networks through TRENDS’s educa-
tional network to already existing educational networks. This will facilitate the introduction of ICT in the educational process by enabling teachers to use already existing educational material and share experiences on similar approaches.

**Multimedia Tele-training Tool**

This tool will allow online delivery of remote training sessions from trainers to teachers. A training session offers both the trainers and the teachers the following services:

**Preparation of the training session.** This service will allow trainers to prepare training material containing multimedia information, making training sessions more attractive to educators. In this way, the immersion of the trainees is more complete and results in a better understanding of the material. The trainers will be able to customize the material, thus increasing effectiveness and making the material easy to update and reuse.

**Participation in a lesson.** Educators will be able to register in available services and to join an already-started training session at any time.

**Automatic distribution of the training material.** Educators who registered for the session will have access to training material that will not only reside in their workspace but will be available for later review.

**Coordination of the training session.** Trainers will be able to actively control the training session’s speed to accommodate. It will also give educators to register questions concerning the session’s material, and the trainer will be able to answer them online, thus aiding the clarification of difficult points.

**Review of the training session’s material.** Those participating in a session will be able to review the training materials outside of training time. Thus educators will be able to prepare or review material after the training session to achieve a better understanding.

**Distribution of Lessons Through Multimedia Distance Education Tool and Video**

These tools offer a way to access off-line lessons residing in remote servers. These lessons will contain multimedia information and will offer the equivalent of an electronic textbook. The services include:

**Lesson preparation.** Trainers will use appropriate equipment and software for preparing lessons. The distance education tool will offer trainers the ability to create lessons containing multimedia material that may reside in various hosts. Also, trainers will be able to define the navigation flow that educators accessing this lesson will follow, thus guiding them to a better understanding of the lesson’s material.

**Searching for lessons.** Educators accessing various lesson servers will be able to search for a lesson using search criteria such as key words, exact titles, and cross-references. This service will help the educators easily focus on lessons that interest them.

**Access to a chosen lesson.** After selecting a lesson, educators will be able to connect to the appropriate server and browse through it.

**Navigation with the use of hypermedia semantics.** After retrieving the lesson, educators will be able to use hypermedia semantics to browse through it. They will be able to either follow the trainer’s predetermined lesson flow or to randomly access those parts of the lesson that are of major interest to them.

**Continuation of a lesson.** Educators will be able to quit browsing through a lesson and to save it for future review. In this way, educators will not waste time and can be more productive. Problems arising from limited in-service time may be overcome in this way.

**Progress supervision.** An evaluation tool must be available for multimedia distance education. The trainer will issue test to check trainees’ absorption of lesson material. Educators will be presented with individual success statistics for reforming the lesson and will be informed about their success ratios, helping them to better review the lesson.

**The TRENDS Educational Network**

TRENDS services will be implemented as a set of software tools abiding by the client/server model. The use of the client part of the software tools will be through a common look graphical user interface (GUI) customized to fit each users’ language.

The TRENDS project will establish a network based on existing technologies of EURO-ISDN. The connections will have a minimum bandwidth (such as 64 Kbps) to guarantee the proper delivery of the services. The underlying network will support various services aimed at training of educators. The implementation of these services is based on using existing software tools (modified for the purposes of the project) that are integrated under a common user interface and that give them the added value needed for the purposes of the TRENDS project. These services are complemented by the organization of already existing education material and the implementation of new material mainly concerned with educators using ICT.

Due to the nature of the planned services and applications, TRENDS network infrastructure will offer:

**High speed.** The proposed services and applications transmitting large amounts of data require a minimum network speed to provide timely responses to the user.

**Multicasting.** The nature of the distance training and education tools requires that the trainer’s node must send data to the trainees’ multiple nodes.

**Trans-European interoperability.** Trainees and the trainers will be distributed in various European countries, so the network infrastructures must admit a high degree of interoperability.
Certified quality of services. Since some of the educational services offered by the tools cannot function properly, if network services are not meeting certain criteria, the network infrastructure must guarantee these criteria are fulfilled.

Since the same services will be offered by the TRENDS Project on a pan-European level, the six national sites in Greece, Italy, Spain, Portugal, France and United Kingdom will be interconnected through mature network technologies (Euro-ISDN, TCP/IP protocol suite) providing service to teachers in their schools.

In each of the 120 participating schools, client software will be installed, giving a significantly large number of European school teachers the ability access valuable information available in cyberspace in a friendly, time-efficient way. These teachers will also participate in teletraining courses as well as interactive work sessions. The national site configuration consists of the following:

The Training Centre, the location of TRENDS servers. Concerning information providers, some of the TRENDS partners and the sponsoring partners (Ministries) will provide multimedia information (courses) through different servers. Although its implementation may differ depending on interests, this configuration is compatible with the model of the strongest network operators.

Participating Countries' Training Centres. Schools connected to their country's Training Centre where the necessary client for the TRENDS network is installed.

Conclusions and Future Work

The development and availability of high-quality equipment and software, the service environments in which these tools are used, and teacher training are a few of the many conditions studied in six European countries within the TRENDS framework. The use of distance learning technologies makes possible virtual mobility and widespread access to educational services. The greatest possible number of educators will eventually be able to benefit from an intercultural and multilingual education as part of their personal and professional development.

The aim of the TRENDS Project is a trans-European educational network working with already existing advanced network technologies. This educational network will provide a set of elementary and advanced services comprising the Distance Learning Environment of the project.

The implementation of these services will be based on the use of existing software tools (modified for the purposes of the project) integrated under a unified GUI. These services should be supplemented by the organization of already existing educational material and the creation of new material mainly concerned with educators using ICT as part of the learning process.

As a result of the TRENDS project, an educational network called the European Teachers Training Network (ETTN) will be developed based on Advanced Telecommunication Infrastructures.

Acknowledgments

This work was supported by Telematics Applications Programme under project TRENDS(ET-1024).

Recently a new tendency has appeared on the labour market, timidly in Belgium and in Italy, more in other countries: telework, through the use of linked computers. There are estimates that more of 60% of the work implied in the production of goods is processing of information. This information is increasingly computerized. The possibility of teleworking is therefore huge in principle. The employer can benefit from savings in investments and consumption in buildings and furniture and a largest flexibility. For the worker, one invokes also the flexibility that allows for better conciliation of work, family obligations and leisure. The diminution of travel is to the advantage of the whole society by decreasing the pollution and bottlenecks and to the advantage of the worker in avoiding the loss of time and money, the fatigue and the stress. The different advantages for the worker also benefit to the employer that can hope increased productivity and quality of the work.

For persons whose handicap reduces the mobility, telework is an obviously attractive solution. For those whose mobility is reduced or that ask frequent assistance and cares, telework from their domicile or the institution where they reside or pass the day is practically the only solution to participate in the economic life by an active contribution and to find at the same time a broader socialization. For a mobile person, telework can involve less social relationship compared with what working in the premises of the company could offer. But for some handicapped persons isolated by the impossibility of usual work relationships, telework allows a huge socialization compared to their isolation (Volpentesta, 1995). For these handicapped persons, telework offers therefore a unique chance to break barriers of their handicap.

Of course teletraining is the first necessary step to prepare disabled people to telework. As a matter of fact it makes trainees familiar with technologies, methods and organizational structures for teleworking activities.

EXPERTISE (EXchange and Promotion of TElematic and Robotic Technologies for vocational training and employment of the dISablEd) is a transnational project to promote high level formation and employment of handicapped people in the HORIZON/EMPLOYMENT Initiative of Europe Union. It involves many regions of different European countries (Spain, Germany, Austria, Belgium, Italy) and its main objectives are:

- to provide effective tools and innovative methodologies for the vocational training and employment of disabled people using the most recent technologies, and
- to promote exchange of technology and knowledge among all European regions involved in the project.

In particular in Wallonie in Calabria we’ve focused our attention on teletraining and teleworking.

In the rest of paper we discuss the technological infrastructures used at Le Réseau (Wallonie - Belgium) and at Brutium (Calabria - Italy) to support project activities; telematic services which are used either as communication media for distance education and as means for teleworking; and didactic methodologies and some considerations about first results.

Technological Infrastructures

Regional occurrences of the project in Wallonie (Belgium) and in Calabria (Italy) are based on the same starting architecture that has led to similar infrastructures even if they differ for some tech implementations. Project activities are hosted in a vocational center, where most training activities take place, and in some peripheral nodes (no-profit organization and trainees’ home) for distance training and net services delivery.
The main center purpose is to have a place where trainees can meet and configure telework modules. As shown in figure 1, a digital laboratory has been set up in the center and can be accessed physically or virtually, with a remote access, by trainees. A coordination staff is always available to a trainee for tech or medical assistance. In the digital laboratory, a set of Web/FTP servers are installed for local Intranet and world-wide Internet users; the purpose is to make available a group of services to the trainees and to disseminate project results and some works developed by trainees themselves.

The labs aims to give many different kinds of support to disabled persons:
- selection and integration of new software/hardware technologies and useful aiding tools;
- as vocational guidance site;
- as an interface to possible interested enterprises which need teleworker;
- in coordination of training and work activities;
- in management of tech infrastructure;
- to arrange a physical place for periodical meeting and socialization;
- to make available a place where trainees can deploy part of their working modules;
- to make available computing and telecommunication resources;
- as a router and gateway to ISDN and Internet;
- to activate base network services as file transfer and e-mail;
- to promote local services;
- to disseminate information on available technologies;
- to adapt workplaces for disabled people; and
- to create job opportunities for qualified handicapped people.

Both centers, in Wallonie and in Calabria, use multimedia personal computers and workstations to enable audio/video interaction. Listed below there are some brief characteristics of each tech solution; you can note some little differences in technological implementations.

At Brutium we have installed a LAN extended all over the rooms in the laboratory building. The LAN is a Fast Ethernet 100Mb/s to allow video/audio conferences inside the lab. A gateway to Internet at 64Kb/s. We’ve plugged in to the LAN 15 Win95 Net Clients PC all with audio capabilities, two of them have speech recognition software, three have video grabbing cards, two have CD-R drivers for multimedia production. We’ve also configured three Internet servers one Intel Linux, one Intel Windows NT 4, one PA-RISC HP-UX. As additional accessories we make available digital cameras, color printers, scanners, VGAtoPAL converters, VCRs, and a LCD projector. Moreover, all recent Multimedia Technologies and Intranet and Internet facilities have been set up. We have provided the possibility for people with severe handicaps to remotely attend lab activities (teletraining) via HFTV and Intranet technologies.

At Le Réseau we’ve given each student at the site where he/she is receiving the teletraining (home or institution) a PC Pentium 133 with 16Mb RAM, CD-ROM drive and sound card, Windows 95 and a printer. In our center, (where we are also providing vocational training in classrooms) all the (about 40) computers (trainees, trainers, administration) are linked in a LAN Thin Ethernet 10Mb/s. At the software level, it is a mixture of Windows 3.11 and Windows 95, with a Windows NT 3.51 server. Our server is equipped with a DIVA Quadro ISDN card from Eicon Technologies, providing 8 channels (four 2-channels Basic Accesses). The remote students also have a Basic Access to the phone company and an ISDN card in their computer.

We do not use Internet or other private networks. People can get relatively cheap Internet Access through analogue telephone lines but ISDN Access is only proposed at corporate rates which are still rather expensive. Instead, the remote students call directly the phone numbers of our server. Belgium is a small country. Even with (not so long) long distance calls, we pay less that what we would pay to the Internet Access providers (plus local calls).

In both training centers we focus on coming out professional profiles in these sectors:
- digital audio-visual production;
- system and network administration;
- office and home automation;
- software design and prototyping; and
- CAD, computer graphics.

Telematic Services
Some basic and advanced telematic services have been made available to TEACHERS, TUTORS, TRAINEES AS SUPPORT IN TELETRAINING AND MANAGEMENT/COORDINATION PROCEDURES and to promote socialization through entertainment. Such services have been based on the usage of suitable telematic software tools.

The first set of tools integrates Internet technologies. In particular it essentially consists of some Internet modules and interfaces between them (Fasano, Frega, Greco, Volpentesta, 1996). On the Internet side we’ve built-up a Mailing List (to broadcast e-mail messages among Internet Horizon subscribers) and a Web Board (to let users browse all messages and bulletins from WWW).

Other tools, we’ve called WebRobots (Frega, 1995), let users publish full HTML pages without requiring HTML knowledge at all Della Gala, Frega, & Volpentesta, 1995)(Frega, 1995); they consist in a pages slider/randomizer and a HTML editor on line with preview and upload utilities; another tool is essentially a multi-user program
that allows anyone with a Java-capable browser to draw on the same canvas for collaborative drawing.

At Giuda Lab. we've developed an entertainment shell where we inserted on line a couple of interactive card games (Frega, Greco, Pisculli, Volpentesta, 1996). The system may be regarded as an environment that allows users to communicate each other by a chat service, while they are playing some card game on a virtual table.

We have also developed a tool for collaborative drawing, called CODEE, it is essentially a multi-user program that allows anyone with a Java-capable browser to draw on the same canvas (Frega, Greco, Pisculli, & Volpentesta, 1997).

The last prototype we have developed and used in EXPERTISE is MAGDA: a multimedia collaborative agenda (http://tre7.deis.unical.it/magda/magdafrm.htm). At a local level the agenda is used as a support tool to project management; to coordinate teachers, tutors, trainees and their teletraining activities; and didactic collaborative work to let trainees groups to create and present multimedia material about topics selected and scheduled by teachers and tutors.

At a transnational level the agenda is used to setup european partners meetings; to give each subscriber a view at meeting schedules; and to multicast messages to pre-defined workgroups.

We do not use videoconferencing. As mentioned below, our training is largely practical. Trainees and trainers interact mainly by sharing directories and files, by e-mail and by phone. We thought that videoconferencing was not the priority in our situation. Another issue related to videoconferencing is that this medium is most appropriate to broadcast real-time teaching. On the contrary, we want to allow our remote disabled students to adapt their time schedule to their particular situation and their learning rhythm.

**Didactic Methodologies**

In the starting phase of the project most of the trainees didn't have a clear view of what computers are, what they are used for in the economical world, and how they themselves will fit in. Still, if they did come to us, they had a project or some hope to find a job after training. It is along their training that we're examining and developing their project with them. We help them to gradually better understand where they go and what training is needed to go there. There is no a priori program (except for the first weeks). The program is tailored to each individual following his (her) needs, inside what the centers is able to offer.

In regard to the didactic method we use, it is very different from classical one-way knowledge transfer from one teacher to all students; it's quite individualized anyway. Trainers give few classical lessons. They give explanations on some points and then tasks that allow students to try by themselves. This is the method that we are transposing in teletraining, providing multimedia materials instead of spoken informations and instructions: the trainers give to distant trainees, through the network, explanations and instructions to allow them to work autonomously, in principle for one day. These works are retrieved, through the network, to be evaluated by the trainer who decides about the next step. Of course, writing information and complete instructions is a huge work and we are searching for all existing pedagogical tools that could ease us from part of this task. It is true also for the work in the center: all the time that the trainers can save by using the existing pedagogical tools, is more time devoted to individual follow up. Individual training on the job and group collaboration are also encouraged by providing network application and communication tool for promoting exchanging with other EXPERTISE partners.

Trainees are also encouraged to use e-mail between them. Distant and in loco trainees keep tracks on the agenda to record all their training activities. This diary can be accessed at any moment by the staff. Meanwhile, a recording software traces all actions on the computer.

**Formation**

Since we deal with persons with more severe handicap, we think that the training could be slower. Some of them receive cares that take a good part of their daytime. For its content, the training benefits from the competence that both centers have developed. Globally, the objective is to master the use of networked computers and traditional software in business work (word processing and electronic publishing, spreadsheets, databases, accounting software) giving access to a large variety of jobs in the tertiary sector. Other possible training orientations are analysis and programming, the computer-assisted design (DAO) or computer graphics. Possible basic training shortcomings are taken in account in the project to make it accessible to the largest number, including the most disfavored.

**Conclusions**

In this paper we have discussed some technological and methodological solution we have adopted for the execution of teletraining actions in a eupean formation project. Issues about such solutions have dealt with:

- a telematic infrastructure (Internet/WWW/BBS) linking all interested sites and relevant public and private institutions (for ex. HANDYNET nodes) involved in the project;
- experimentation of teletraining and other distance education activities;
- usage of telematic software tools in order to support teletraining and management/coordination procedures; and
- providing technical aids to prepare people with sever handicaps to telework.

FIRST STEPS OF NEW INFORMATION TECHNOLOGIES IN A RUSSIAN TEACHER UNIVERSITY

Sergey Kramarov  
Rostov State Pedagogical Univ.

Irena Rozina  
Rostov State Pedagogical Univ.

Dmitry Mezhevikin  
Rostov State Pedagogical Univ.

Rostov State Pedagogical University (RSPU) and affiliated science organizations such as South Department of Academy of Education (SDAE), Don Division of Academy of Informatization of Education (DDAIE), train teachers for all stages of education - for Nursery Schools, for Primary Schools, for Further Education Colleges and advance the science and education level of the magistral staff, graduate and post-graduate students. One of the ways to advance this level is the using of new information technologies such as telecommunications in education and training.

The team of Nets Technologies are included to the University program for students of some faculties. It is focusing on the using metropolitan (MAN) and global (WAN) nets at the lessons, for researches and the professional growth of school teachers. Unfortunately, the practical learning of nets is applied for the local University net (LAN) only for our students, because of the low technical provision of computer classes. For some graduate students (Magistrants), which specialize on Informatics, there is the add entire course with the practical opportunity to work in global nets. The goal of this courses is provide a starting point for the future teacher.

Magistrants are working with one of e-mail curriculums and at first are accessing with Internet services by e-mail. This skills are very important for future teachers because most of schools and colleges in Russia don’t have a direct connection with Internet resources today. At beginning new users learn the network with newsgroups in the Usenet hierarchies (most of them there are on the newsserver of our service provider) and choose one or more groups for subscribing. Looking through the articles from these newsgroups (especially the moderated newsgroups) students obtain appropriate information for future search or retrieval - addresses of FTP sites with necessary files or programs, URLs of WWW sites with the indication of the path to necessary files etc.. Then they learn to access various Net resources using E-MAIL SERVERS (FTPMAIL, WAIS, GOPHERMAIL, WWWMAIL, LISTSERV, MAIL-SERVER) by specified commands in the message (Krol, 1995). Throughout this course Magistrants develop knowledge on the global network, with identified search tools for the navigation in the Internet and material for the execution of their science work. We hope that our students as Network specialists after graduating from University will advance the new information technology in education or in spheres other than teaching, for example in industry and government.

The University theoretical research project which involved the creation of the educational net among regional pedagogical colleges entering our University system, has developed some practical steps for advancement of educational telecommunications. There are part time University students, who work as administrators or teachers of Informatics in regional colleges. The University information technologies laboratory is the place to receive technical and practical support (books, shareware and interchange of information) in the fields of pedagogical information. This project is the first step in creating an information and provider center on based at the Pedagogical University.

For the nature and humanitarian post-graduate students and teacher educators of our University there are a number of teaching methods, using interactive communication technologies. Students and educators have opportunities for full Internet access, which is one of the best methods for quickly finding appropriate information for their science researches, development and professional growth. The task of University specialists in telecommunications is to provide instruction on search techniques both off-line and on-line accesses. The University specialists recommend a starting point for items of scientific interest (Lambert and Howe, 1993). Educators in the Humanities have specific problems with telecommunications, because they are far removed from the computers' terminology and also often don’t know English. There are a few special guides for humanitarians which have been written or translated and published in Russian and also some Russian nets with electronic versions. Tutoring begins with checking and/or improving definite computers and English language skills.
The second step is determining a chain of keywords of science interest and tools for beginning a text search on the Internet. Usually 5-10 lessons are allowed for new users to work individually with popular WWW, FTP and Gopher search engines and hypertext links.

Recent social and political changes in Russia have lead not only to radical transformation in the other countries, but in Russia as well. New educational paradigms realized today in these institutions and in teaching preparation programs determine the major goals. These goals include development of not only the students’ personality and creative ability, but also the ability to solve scientific, practical, educational, and social problems through technology to meet the needs of a developing and changing world. educational systems in secondary schools and universities.

Aspects of the Educational Process

These new paradigms affect three aspects of the educational process: content, structure of programs and technology. The reorganization of the first and second aspects made after rapid social changes of the late 1980s and early 1990s has stabilized, and the development of content and structure, although slow, is extensive. The development of the technological component in education is the subject for intensive research and projects at Federal and regional levels. Technology is becoming the leading and most important aspect in determining educational strategies and concepts. Utilizing computers to work with databases, global networks, multimedia, and other software gives students and professors more opportunities to analyze information and to work with more complex decisions and problem solving. The ability to design and simulate phenomena and learn multi-processes are important in all aspects of Russia’s educational changes, and the technological direction is rapidly becoming a priority, especially in terms of developing an open society.

Description of the Situation

In the past, Russian educational institutions had a few computers made in Russia; however, they were not compatible with computers made and/or used in other countries. Much progress has been made in this area since the 1980s. Today Russia is 6th among the European communities and second only to Germany in using computer technology. Schools and universities in St. Petersburg, Russia now have access to computer laboratories. Herzen State Pedagogical University has recently connected to the Internet and Runnet (a network among twenty universities in several regions of Russia). At this time, IBM compatible hardware is used more often, but other manufacturers, i.e., Mcintosh, are becoming available.

Problems, Trends, Perceptions

Using Herzen State Pedagogical University in St. Petersburg, Russia as an example, it is possible to show general current situations and trends in Russian educational settings. In order to determine the use of computers and the types of software used in major content areas by university staff, professors and lecturers from the departments of Science and Humanities took part in a survey questionnaire and participated in personal interviews.

Analysis of data collected from the participants indicate that currently the main use of computers is as a word processor. However, such a one-sided use of modern technology cannot be considered completely effective. This situation is common, not only in Russian schools, but in other educational institutions as well (Mims & McKenzie, 1995). Perhaps an understanding of why this is common practice among faculty in universities and how to alleviate the lack of computer use should be the starting point for further studies and in deciding how and what to teach university personnel.

According to the data collected from the questionnaire, computer use by university teaching personnel most often involves the following: word processing- 9%; qualitative and statistical data -5% each; although the staff are aware of e-mail, few have direct access on a daily basis. The majority of university professors have not been trained in the various aspects of multimedia and other more modern technological uses. The main direction of computer use by university faculty is in training perspective teachers of mathematics and computer programming. This may be due to the fact that those professors seem to know more about mathematical implications than their colleagues in more humanities-based courses; however, more faculty are beginning to give lectures based on computer learning, and they are using, when possible, computer in their disciplines.
Teachers of subjects to be taught in English are the current leading users of software. This is explained by the fact that there is a strong motivation for students to study English as the language of international communication. Also, there is more English language programs available due to gifts to local schools by visiting American educators. The percentage of use in computer labs by faculty and students in teacher preparation programs is low. For example surveys indicate that 5% of the Math and computer teachers use the labs. One percent use the lab for training in computer skills for other majors, and 1% of the lab use laboratories for software training for specific areas. Science and Humanities faculty and students account for 5% of the lab use. Also, 95% of teaching in this discipline is devoted to the teaching and learning English as a second language.

Problems

The use of computers in teaching other disciplines is determined by availability and the amount or lack of quality software. The greatest number of educational software programs (made by known international companies such as Microsoft), are most used in the areas of English and Business. Conversely, professors in the area of Science education, at this time, must write their own programs. Perhaps the primary reason for this is because of the popularity of English and Economics as majors most often selected by students at Herzen University as well as other Russian universities, and these students’ awareness of international uses of these subjects. Therefore the demand for software in these areas is great, but there is a great need for software in other disciplines as well.

In summary the use of computers in specific academic disciplines, where there is available software either self-designed or commercially produced, is in the areas of Math, Science, Humanities, English, and Business.

Other Concerns

Certainly the use of educational software is not the only direction being realized in the educational process. University professors and personnel would like more access and availability of computers for their own research. The majority of professors would like to have the ability and resources to integrate their teaching with computer technology and a variety of software programs.

Data from the survey and interviews with selected faculty and staff at the university indicate that there are many expectations for future use by university teaching personnel. These university personnel listed the following as their perceptions of how technology could help them in the immediate future:

- improvement of technological qualification
- work with "local network"
- CD ROM
- multimedia
- Internet
- e-mail
- use educational software
- learn to use different software program
- work with word processor

Future Training

Advanced educational technologies require appropriate qualifications. In accordance with the problem of running effective programs such as in-service training regarding use, and in overcoming barriers for use is most urgent. Data from the survey also indicated that a majority of professors would like to learn more about the integration of multimedia. Barriers, or more precisely, the main reasons for non-use of computers included the categories of psychological and professional qualifications: lack of motivation, and a lack of both computers and appropriate software. Most faculty indicated that the number one "Barrier" to computer use is "not enough personal qualification."

Implications

Education in the former Soviet Union is rapidly changing. New standards and goals are slowly being met by individual regions, and there is a growing pride in the accomplishments of students as they prepare to take their place in a global society. On the other hand, political uncertainty and related economical concerns continue to plague the minds of educators who are eager to use the most modern equipment possible. While computer labs do exist, more powerful computers with CD-ROM capability are scarce. It is imperative that sponsorship and funding be found to assist Russian university faculty in educating students using up-to-date equipment and relevant software. Without the proper equipment, the training of higher education personnel will continue at a slow pace and possibly place students in a position far behind other countries in the use of technology.

EXPERIENCING THE VIRTUAL CLASSROOM AS A TRANSLOCAL FIELD

Heikki Kynäslahti
University of Helsinki

Because of the recent developments in information and communication technologies using video conferencing and audiographics, Finland has been experimenting with joining separate classrooms in an educational environment where classes situated at different sites participate in the same lessons through a video link. In autumn 1994, the lower secondary school of Kilpisjärvi, a small isolated rural village in the Finnish Lapland, was linked with the Teacher Training School of Helsinki University, a large urban school in the Helsinki metropolitan area (Kynäslahti & Salminen 1995). Although the teacher is usually situated in the Helsinki classroom with a group of pupils, the Kilpisjärvi teacher has taught several lessons. As a result of this and several other collaborations with Finnish schools, student teachers at the Teacher Training School not only practice the use of communication and information technologies in education but support the delivery of education to small schools. The results presented in this article are based on participant observation and interviews of pupils, teachers, and parents during a period of over two years.

Virtual Classroom

Like other terms popular in academic and social discussion, the concept of virtuality has both specific, narrow definitions. Many people, especially in the field of technology, regard virtuality as something relating only to advanced technology like data helmets and suits. Others, however, defined this word in a much broader sense. For them, the pompous and richly decorated baroque churches are examples of the virtual feeling of Heaven (Huhtamo, 1992).

The word virtual is derived from the Latin word virtualiter, used in metaphysical discussions in the Middle Ages concerning the dilemma between our worldly experiences and the true state of the entities. Martin Kusch explains this as the relationship between our world and (other) possible worlds (Kusch & Hintikka, 1988, p. 15). Possible worlds can be thought of as alternatives for our real world, or, on the other hand, our experienced world can be considered as an alternative from an endless number of options (e.g. Kusch, 1989, pp. 93-102). When constructing possible worlds, we can construct them with recognizable elements from our real world; as a result, the possible and real worlds seem similar. However, it is possible that other worlds are completely different from our real world; in this case, constructed worlds are very different from what is familiar to us.

The idea of possible worlds is interesting when considered within the context of virtuality and the virtual classroom. Many experts in this field consider the virtual classroom a version of virtual reality and replace the word virtual with the phrase as if. Because of illusion, we experience the virtual reality and environment as if we were actually within that environment. In contrast, Tiffin & Rajasingham (1995, p. 3) emphasize that virtual means reality in effect, not in fact. This interpretation suggests virtual reality and virtual environments work well when dealing with subjects such as virtual buildings and cities.

But what about social environments and virtual communities? Reid (1995), asserting that virtual environments are a question of imaginative experiences, approaches virtual reality as cultural constructs that emphasize users’ experiences in the virtual world. The illusion of a real environment, she claims, depends on “the user’s willingness to treat the manifestations of his or her imaginings as if they were real” and the degree to which users relate the virtual to their real world environment, an important point in experiencing virtual reality (Reid, 1995, p. 166). In the Multi-User-Dimension systems Reid investigated, users created an imaginary social and cultural world where they reacted to other users’ moves. Towne puts it, “Typically, VR implementations attempt to maintain a realistic representation of some segment of a real or imaginary world as a participant moves about and operates upon that world.” (Towne, 1995, p. 12). It is true that those who experience the virtual environment tend to emphasize elements resembling real situations and want to act as if they were in real life circumstances.
we override silence by constantly talking to maintain the illusion of being together. How does this apply to the virtual classroom?

The term virtual classroom originates from using computer-mediated communication to establish an electronic environment where classroom communication, like discussions and lectures, are possible (Hiltz, 1986, p. 95). Similarly, Tiffin and Rajasingham state that in a virtual class everybody can talk, be heard, and be identified as well as see the same words, pictures and diagrams (Tiffin and Rajasingham, 1995, p. 6). “The virtual class is a meeting place for virtual communities of learners with a shared interest in the same subject.” (Tiffin & Rajasingham, 1995, p. 177). Before I try to answer the question I posed previously, we should consider virtual environments as an ethnographic research field.

Translocal Fields

Traditionally, in ethnographic research, a field has meant a geographical area, its people, and its community or culture. In the context of educational research, the field is often one or more classrooms or schools. However, Marcus and Fischer break with tradition and use the term multilocale ethnography rather than field (Marcus & Fischer, 1986, p. 93). In these cases, no interaction between the localities is required. While conducting my research, I faced the problem of defining the ethnographic research field, the virtual classroom. In a way, this field has no location. In my case, field referred to two groups of pupils (one in Lapland and the other in Helsinki) lived 1200 kilometers apart and a teacher who worked within a “non-location” field, the virtual classroom.

Dahlén, Hannerz, and Lindquist (1995) speak about translocal fields based not on geographical areas or localities but on common ideas, interests, and interaction between the sites. Another uniting element of this field type are social relationships for creating social order. The role of some active persons, agents who take care of the performance of the field as mediators between the different localities, is important. They are the heroes of the field.

During my research, I used an approach derived from the ideas of Dahlén, Hannerz, and Lindquist to investigate the experience of the virtual classroom.

Virtual Classroom as a Translocal Field

The idea of bringing together the Kilpisjarvi and the Teacher Training School is to enhance the quality of the rural students’ education (Kynäslahti & Stevens, 1996). Because the Lapland school does not have enough resources to deliver competent education in a variety of subjects, joining the rural classroom with the university classroom enables pupils to participate in lessons taught by teachers who are experts in their field. In this experiment, teachers and the rural and university students actively participate in the virtual classroom, but the rural pupils and the teachers are completely engaged in the program. Both student groups are focused on the teacher and the instructional process, so the teacher, who actually serves as a type of mediator between the students, becomes a significant element in the quality and maintenance of the virtual classroom. Using the vocabulary of translocal fields, the teacher is the hero of the virtual classroom.

The teachers’ pedagogical approach is characterized by the intention of uniting the two student groups into one virtual class. The link between the teacher and the pupils in the remote site is intense, and the telepresence of the teacher is obvious when the experiment is viewed from the remote students’ perspective (Salonen & Kynäslahti 1996). The pedagogical goal of joining the two groups into one adds new elements to the instructional process and to the virtual classroom. As stated before, in virtual environments people tend to emphasize those elements that creates an illusion of real world. In virtual classrooms, teachers try to manage the situation as if the pupils were in the same room. In this process teacher’s role becomes more verbal as they guide students by often asking questions to reinforce student learning (c.f. Husu, 1996). In their efforts to create one virtual environment all participants, the teachers seem to enforce unintentionally their role as an uniting element (Kynäslahti, 1996, p. 131).

Linking two classrooms as one is not an easy task, especially if the groups differ in their cultural or social background. Therefore, a teacher in a virtual classroom may be in a situation similar to that of a teacher in a multicultural classroom. However, the virtual classroom can be even more complex because students cross two borders: first, they move to a virtual environment, and second, they are placed in an environment where they face people who come from different life experiences. For the Lapland pupils, the virtual classroom represents not only a version of their classroom but a different (other) world. Sensing this, teachers recognize the cultural differences and the distinctively different environments where the pupils live. In uniting student groups with respect to cultural and other differences, teachers risk segregating the pupils if they overly consider the local circumstances, needs and interests of each pupil because by doing so they simultaneously emphasise the students’ differences (e.g. Schiffauer, 1996). Perhaps this phenomenon is an example of politics’ difference with respect to education where the “guiding principle would be openness to differences rather than the urge towards sameness” (Nicholson, 1991, p. 47).

The relationship between the pupils at the different sites is a bit problematic and reflects the research discussed above in regard to students becoming segregated (McHenry & Bozik, 1995). The lack of spontaneous interaction between the two groups confirms the teacher’s central role in this educational process. The students do share common Self with the teacher viewed as Other. Rather, each student
group seems to be its own Self with Other being the other student group. The teacher exists somewhere between Self and Other. Interestingly, because the students have now participated in the mutual virtual classroom for over two years, they have a common history, which is very important in developing a sense of community (Nicholson, 1991).

During the experiment, other heroes (usually the class clown or students with distinct personalities) emerged through the use of humor, which seems to be an important uniting element both for the pupils and for the teachers as evidenced by the repetition of inside jokes. This factor seems to have contributed to the students' emerging sense of the common Self in the virtual classroom.

Conclusion

In general, this virtual classroom resembles the traditional classroom because it is a virtual version of the “real” classroom with which they are familiar. The virtual classroom, a possible world, enhances the quality of education in the Lapland school by linking rural students with teachers who are experts in their fields. Because the virtual classroom is similar to a traditional classroom, participants recognize those elements that remind them of the real classroom and easily adapt to the virtual classroom.

Despite the similarities between the traditional and virtual classroom, the virtual classroom creates new environments with community patterns and forms of socialization, which until recently had been unknown. People from different environments and distinct cultures are brought together by common interests. Virtual classrooms, unknown possible worlds ready for educators to explore, are full of opportunities for developing social relations and new virtual educational communities unfamiliar to the context of traditional classrooms.

During the past few years, the transition from print and postal-based materials traditionally used in distance education with adult learners to the more interactive and technology-based systems has been apparent. Modern technology used in classroom settings seems to open new possibilities for teaching and learning. Although there has been discussion about the use of telecommunications in education (e.g. Mason 1995), further research in different instructional and institutional settings is still needed.

The basic approach of this study focuses on three education families—conventional classroom education, distance education, and virtuality in education. The basic approach of the study comes mainly from conventional classroom education. However, it should be noted that the concept conventional is used to relate the dominant educational format both with the distance education and the emerging forms of virtual classroom. Conventional does not include any value aspects or preferences and conventional education is neither good nor bad. According to Keegan (1989, p. 13), the idea that distance education can correct what is “wrong” with conventional education is “a dangerous cul-de-sac for distance educators and should be abandoned.”

Tiffin and Rajasingham (1995) emphasize that virtual classes are not intended to replace conventional classrooms. In fact, they can not do that because both the established and the emerging modes of education have a particular communication system for learning. Besides their differences, they do share similarities, particularly in interaction.

This paper presents an interactive framework which brings together parallel features of these three educational modes: conventional education, distance education, and the emerging forms of virtual classroom. Furthermore, the framework aims to integrate and balance the elements from these three education families of education into one experiment where new ideas and technologies in teaching and learning in a school environment are tested.

Coming to Terms With the Case

Practically, this paper is based on a three-year pilot study where two schools are linked together for common instruction with the help of video conferencing and audiographics. The project began in 1994 between a group of four pupils at the Kilpisjärvi school in the northwest Finnish Lapland and a group of thirteen pupils in the Teacher Training School of Helsinki University 1200 km away.

Parents and local authorities in geographically isolated Kilpisjärvi wanted to establish a secondary school (grades 7-9) in the village so children could stay at home instead of living in a boarding school 180 km away. In the village, a modern primary school could offer support to the secondary classes. As the resources of subject teachers available for secondary stage instruction were limited, a cooperative project with the Department of Teacher Education, University of Helsinki, was planned and implemented.

The Training School of Helsinki University, one of the two training schools belonging to the Department of Teacher Education, University of Helsinki, agreed to become the cooperative agent in this venture. With modern communication technologies these two classrooms—one in a large urban school, the other in a small rural school over one thousand kilometres away—were joined to form one virtual classroom.

The kind of arrangement where one teacher simultaneously teaches two groups of pupils, a local and a distant group, can be defined various ways. Previously we have used the term classroom focused distance education (Husu et al. 1994; Husu 1996a; Meisalo 1996) to distinguish between distance education occurring in a school environment from distance education occurring on higher and adult educational levels. The study focused on the question how these two groups of pupils can be handled simultaneously by one teacher.

Theoretical Approach

In this project, the elements of distance education are integrated into the conventional education taking place in classroom settings. The theoretical framework tries to capture key features of conventional education, distance education, and virtual reality. The approach is twofold; first, this chapter describes essential and common characteristics of these three families of education, and, second,
in the following chapter, these key features are related to each other within the interactive framework.

**Education at a Distance**

Distance education in school settings is a strange phenomenon. According to Keegan (1989, p. 9), within distance education there is a strong tendency to separate two distinct dimensions—conventional group based-education and individually oriented distance education. Conventional education is mainly associated with children and adolescents in school settings while distance education is usually associated with adults and their professional training in its various forms. While school education is mainly compulsory, distance education is usually voluntary. Keegan (1989, p. 13) argues that this distinction has led to a crude dichotomy according to which pupils either attend educational institutions or study from a distance.

With the emergence of modern information and communication technologies, conventional education teachers and pupils find fewer practical concerns with delivering education at a distance. Consequently, the methods used in distance education are becoming more like those used in modern conventional group-based education. For example, the technology used in this project, video conferencing, can be viewed as a group method of teaching and learning providing real-time interaction between the teacher and pupils in a manner similar to traditional classroom instruction.

The blurring of boundaries has made it more evident that the major and the most common feature in both forms of education is the process of interaction among teacher, pupils, and subject content. The main difference is that the majority of interaction between teacher and pupils is mediated by communication technologies. According to Shale and Garrison (1990, p. 31), “education and distance [between teacher and student, implied] are concomitant features but it is clear in practice that we are attempting to provide educational opportunities for pupils who just happen to be physically separated from a teacher” (or from other pupils). They argue that the definitions of distance education usually tend to reverse this emphasis and are preoccupied with various features of distance. Therefore, Shale and Garrison (ibid.) argue that “viewing distance education from the perspective of the technological media used to achieve it obscures the fact that in all instances the goal is education.”

This kind of definition does not necessitate a reconceptualization of the educational process itself. Rather, it emphasizes the basic feature of the educational process—how interaction between the teacher and pupils as well as among pupils themselves can be facilitated. Whenever the teacher and pupils are physically separated, distance education must rely on technologies to mediate the interaction process between both parties. Reviewing the literature gives the impression that considerable attention has been given to the use of technological media while less attention has been paid to the nature of interaction processes and the role of technologies supporting it. However, it is not the technological solution in itself that can be regarded as education, in most cases not even educational, but the subject content and the appropriate pedagogical use of the medium applied.

**Virtual Classroom**

The term virtual classroom originates from the use of computer mediated communication to establish an electronic environment where communication forms of a classroom, like discussions and lectures, are possible (Hiltz 1986). Hence, the basic patterns of virtual classroom are technology and communication (Tella 1995; Tiffin & Rajasingham 1995). Technologies such as video conferencing allow a virtual class where teacher(s) and pupils can see and hear each others in real-time.

The issue of virtuality is interesting. Its background comes from the linguistic and philosophical problems of the Middle Ages to explain the relationship between the actual reality and other possible worlds. Virtual means an interpretative and mind-mediated version of the surrounding world as it is experienced by the individual. In other words, virtual reality is individually constructed in much of the same ways as our ‘ordinary reality’—if we accept the basic lines of constructivism. Following Bruner (1986), both are ‘possible worlds’ constructed by our ‘actual minds’. Reid (1995) points to the imaginative aspect of experiencing virtual environments. She claims that the illusion of reality lies in the willingness of the participants to “treat the manifestations of his or her imagining as if they were real” (Reid 1995, p. 166).

Today, the term virtual has gained a more specific meaning where the aspect of replacing is also present (Huhtamo 1992, p. 38). Virtuality has some sort of capability to replace something that isn’t physically present. Something in virtuality ‘triggers’ an interpretation in the individual, and this interpretation then dominates individual’s experience of that virtual situation, event, or object. Accordingly, virtual classroom creates an illusion as if we were in the real classroom. Rajasingham (1996) states that virtual in this context means reality in effect, not in fact.

Going back to Hiltz’ definition, the virtual classroom is created by communication, and the use of technology gives an illusion of a “real” classroom. When two separate classrooms are linked together, as in our case, to form one virtual classroom by using video conferencing and audiographics, means that the virtual classroom “feels” like a “real” classroom. The question is about the factuality, not the physical situation, of the experience.

In sum, our approach can be described as experience-oriented and interpretative (Husu 1996b). When defining our virtual classroom, we acknowledge with Rajasingham
(1996, p. 33) that a classroom is a communication system making it possible for people to come together with the intention of learning something. According to her (ibid.), "the idea of a virtual class is that everybody can talk and be heard and be identified" during the course of the instructional process. Consequently, the concept of interaction is crucial.

**A Network of Interactions**

The importance of interaction in education these three education families is practically taken as a "given." Theoretical statements in both forms of education emphasize this. In its most basic form, education is a process of interaction between teacher and pupils to provide the subject content of teaching. It is clear that these three "poles" of interaction - teacher, pupils and subject content - cannot capture the total complexity of the instructional process taking place in various educational settings. At first sight this stance seems to be quite reductionistic but, as Moore (1989, p. 100) states, interaction is a term that "carries so many meanings as to be almost useless unless specific submeanings can be defined and generally agreed upon."

Both in conventional and in distance education the interactions between the named three 'poles' can be conceptually and empirically analyzed not only from a theoretical and philosophical perspective but also from a practical and functional perspective. According to Wagner (1994), the functional perspective is important because different variables of interaction need to be empirically examined to discover the impact of interaction in different educational contexts.

**Interactive Framework**

Interaction during the instructional process can be either intentional or unintentional. Whenever interaction is connected with some purposes or a set of purposes for which teaching occurs, it can be viewed as intentional. Teachers' and pupils' intentional communication is often tied to practical activities—teaching is the activity of teachers, and studying is the activity of pupils.

In our approach, the addition of a distant classroom to the instructional process changes the scene of interaction. The instructional process is extended for two reasons: 1) another group of pupils at a distant place is added to the process, and 2) a new dimension of interactions, the mediated interactions of distance education, occur simultaneously with local interactions of conventional education. The research focuses on the question of how these two communicational elements—local interactions and mediated interactions—between two remote classrooms can be handled simultaneously. Because of the importance of interaction in educational processes, in general, it is necessary to investigate how the mediated forms of interaction can be fitted into the instructional process of virtual classroom.

It must be noted that mediated interactions differ from interactions taking place in conventional face-to-face teaching. The medium mediates, and anything that mediates changes what it conveys. In terms of instruction, it is not only a question of transmitting content knowledge from teachers (encoders) to pupils (decoders), but rather the establishment of an effective two-way communication dynamics in the circumstances created by the medium. With the use of the term "mediated interactions" instead of "distance interactions" it is intended to emphasize the aspects of communications over the aspects of physical distance between the two classrooms. Still, we should not forget that even the physical distance itself brings a significant impact to the elements of the instructional process, because it has implications for the teaching role, teaching methods, pupils' studying methods, and pupils' expectations. The extent and the meaning of this impact is also an important research task. In our case, the virtual classroom consists a network of interactions (Husu 1996c) when mediated interactions are integrated with the basic elements of conventional education.

The basic elements of the instructional process—teacher, pupils, and subject content—are embedded in the interactions of the virtual classroom. Although there are now two types of interactions handled concurrently by the teacher and pupils, the classroom where the teacher is situated is primarily an area of local face-to-face interactions. However, in our case, the teacher is simultaneously connected to another classroom. As Figure 1 shows, the two forms of teaching, local and mediated, are simultaneous versions of the same teaching act. In the remote classroom, the pupils' studying acts are mediated to the teacher. The teacher in the local classroom and the pupils in the remote classroom only meet virtually. Further, there are two kinds of pupil-pupil interactions occurring in both classrooms: 1) pupil-pupil interactions within both groups and 2) pupil-pupil interactions between the groups.

In sum, the instructional process of the virtual classroom consists of two classrooms with a different interactive network in each one. This means that both the teacher and the pupils must cope with these two distinct networks of interaction. This kind of teaching and studying practice especially emphasizes the role of the teacher because, according to our experiences based on this testing case, the teacher seems to be the main critical factor in the success of distance education.

Towards the end of this year about 6000 German schools will be connected to the Internet (Initiative: Schools on theNet, 1996). This initiative is sponsored by the Federal Ministry of Education and Deutsche Telekom. 40 millions dollars will be spent in the next three years. Simultaneously the federal state of Northrhine-Westfalia has founded the initiative Media NRW (Northrhine-Westfalia, 1996). Many teachers do not have any experiences in using this new technology. This is one reason why the World Wide Web is not very accepted by teachers (Goldberg, Salari & Swoboda, 1996). Furthermore, a great number of courseware are made for universities and not for schools.

We developed a WWW-supported course about graph theory, which can be used in two different contexts at two different levels. The teachers or prospective teachers are able to use our course to get familiar with graph theory and WWW-based courseware. Additionally they can use a light version of this course in the classroom.

We have designed this course as a WWW-supported course for several reasons. Teachers cannot participate in a regular university course, because of lack of time. Updates of the courseware can be delivered to the user very easily. Beyond WWW-based learning material, we integrate electronic mail and bulletin-boards to improve the communication within the learning group and to support teamworking.

Conception of the Course

Graph theory plays an increasing role in German schools. We have chosen this subject, because it meets with a good response from the students and graph theory finds its way into the curricula in Germany. In our course we study some basic problems in graph theory from an algorithmic point of view.

The contents of our course are the following:

1. Basic definitions.
2. Basic graph algorithms (e.g. depth first search, breadth first search).
3. Shortest-path algorithms (e.g. Floyd's algorithm, Dijkstra's algorithm).
4. Graph planarity (e.g. path addition, vertex addition).
5. Network flow (e.g. Ford's and Fulkerson's algorithm, Dinic's algorithm).
6. Tours in graphs (e.g. Euler paths, Hamiltonian tours).

The course is split up into three phases.

First Phase: Learning the Basics

In the first phase of our WWW-supported course the teachers use the learning environment to acquire basic knowledge in graph theory in individual work at home or in their schools. The content of the courseware is modularized into small pieces of information, called learning units. A learning unit consists of a presentation of a learning subject by text, illustration, animation, and simulation of dynamic models. Further learning units contain exercises (see Figure 1). Static exercises deal with problems which require a special constructed example to explain special cases. Randomly generated exercises make it possible that learners make the same exercise with little variations several times to improve their skill. In user defined exercises learners can adapt the degree of difficulty appropriate to their knowledge. Every learning unit ends with an automatically generated test which gives an immediate feedback (VanLehn, 1996).

The high degree of interaction and the final test in every learning unit improve the motivation and enable the self-control of the learner. Guided tours help the teachers to navigate through the range of learning units in an ingenious order. But due to the fact that teachers are skilled in self-organized learning, the teachers have no restrictions moving within the courseware. Already in this early phase of the course, the cooperation between the participants is supported by integrated electronic mail and bulletin boards (Chee, 1995).

We have implemented the courseware in Java. The underlying data structures are adopted from LEDA, a library of efficient data types and algorithms already used by a great number of research groups (LEDA, 1996); hence our courseware can be easily extended to related topics like geometric or search algorithms.
Second Phase: Compact Seminar

In the second phase, the teacher should acquire a deeper knowledge of some special subjects of graph theory. To achieve this, small groups of three or four participants elaborated seminar papers to special subjects and their pedagogic issues. During the preparation of the seminar papers, the learning environment supports the communication between the users in case they do not have the possibility to meet each other. For questions concerning their special subject every group has its own bulletin board. Afterwards a compact seminar at university takes place where the seminar papers will be presented to the whole course.

Third Phase: Completion of a Common Document

At the end of the course all the groups have to work together to create a final hypertext document about the elaborated subjects. There must be common notions and the interfaces between the topics of each group have to be brought into a line. The more communication in the group takes place, the smaller are the problems concerning coordination and decision making (Gruenfeld, Mannix, Williams & Neale, 1996). The application of the communication facilities of the learning environment can be useful here. The final document will be published in the World Wide Web. In this way the pedagogic knowledge increases from course to course (Boys, G., 1996).

Time Schedule

We suggest the time schedule, which is shown in Table 1, to carry out the course. During the whole course the participating teachers have to be present at university only for the few days when the compact seminar takes place.

Using the Courseware in School

The WWW-based learning environment is appropriate to teach graph theory in school. To acquire basic knowledge in graph theory the students can use a light version of the courseware. It differs from the teachers version in some aspects. The content of the course is reduced to topics of a level of difficulty which is adjusted to the students capabilities. The possibilities to move around the learning units are restricted in the student version of our system, because students do not have the necessary previous knowledge to choose an appropriate tour through the course.

When the students have learned fundamental principles in graph theory, we suggest that they get the opportunity to apply their new knowledge in a project. An example of such a project might be an information system for the local public transport. The communication facilities of the learning environment open the possibility that students from different schools work on common projects. So, for example, students from different schools might combine their information systems to a single information system for the regional public transport. The World Wide Web provides an opportunity for students to publish the results of their work.

Conclusion and Future Work

We have described a WWW-supported course for teachers and prospective teachers in graph theory. The teachers can use a light version of this courseware in school. We are working on a visual software developing tool which enables the learner to program graph algorithms independent from a specific programming language. A transfer of other subjects in mathematics and in computer science to our WWW-based course concept is in work or planned. A next major step would be the integration of an authoring tool which enables the teachers to develop new learning units and to embed them in our courseware in the third phase of our course.

540 — Technology and Teacher Education Annual — 1997
Chatham College is a small liberal arts college for women in Pittsburgh, Pennsylvania. In a small college, access to research materials is vital to the academic enterprise, more important indeed than the simple acquisition of data. At Chatham College, technology now provides an equalizing tool in keeping the college community current with developments in all fields. Providing across-the-board access to all members of the college, Chatham has recently invested in developing a strong campus network using fiber optics and Microsoft NT networking software, installing a new telephone system by Siemens-Rolm, and placing high and multimedia PCs in faculty offices, student computer labs, and classrooms. The entire college community now has electronic mail available as a resource as well as full network access to the Internet. Furthermore, resident students can access the campus systems from their own rooms as well as through more public computer clusters.

Applying Technology to Curricular Programs

A vital part of the undergraduate program includes the Junior Interim Abroad, offered during the January term, which gives Chatham juniors the experience of living and learning abroad with faculty and classmates. Chatham Abroad is a series of academic courses focused on interdisciplinary topics, enabling students from every field of study to integrate a travel experience into their education. The courses, topics, and foreign sites vary from year to year, depending on faculty interest and expertise, the global economy, and international political conditions.

In recent years course offerings have included Spain: Past and Present; Women in Public Life: Dublin, Ireland; Morocco: Cultural Crossroads; History, Art, and Literature of London; and Belize: Reefs, Ruins, and Rainforest. Students have also traveled to the Galapagos Islands and to Egypt. Prior to their study abroad experience, students participate in classes where they learn about the customs, language, and lifestyles of the country they will be visiting. They also undertake research projects to be completed or presented on site, and maintain personal journals. With the exception of a small administrative fee, Chatham Abroad is offered at no extra cost to all full-time students. A timely enhancement to the Junior Interim was, however, added for the January, 1997 trip to Scotland: the instructors incorporated Chatham’s technological advances into the program of study.

Junior Interim Abroad

For the last two weeks of January, 1997, professors of education and modern languages led a group of students to Scotland on a course entitled, Castles, Clans, and Culture of Scotland. The destination was chosen because of Pittsburgh’s cultural legacy. Many of Pittsburgh’s influential philanthropists during the Industrial Revolution came from Scotland and the students and faculty have been eager to learn more about the ethnic heritage of Pittsburgh’s founding fathers. The college students began their intercultural living experience in Edinburgh, where they spent some days with a family before traveling north to Inverness via Dunfermline and Stirling. Andrew Carnegie, the founder of Pittsburgh’s first public library which opened in 1895 (Gangewere, 1995), and of over 2000 libraries in the United States, was born in Dunfermline and emigrated to the United States at the age of 11. His birthplace, now a museum, documents his family’s journey to the United States and details his role in the steel industry and his meteoric rise to international prominence. Pittsburgh is home to Carnegie Mellon University, Carnegie Music Hall, and the Carnegie Museum which includes natural history, science and international art collections. After Edinburgh, the students traveled to Inverness, where they were received at Skibo, translated from the Celtic as “place of peace.” Skibo is the summer retirement homestead purchased by Andrew Carnegie in 1898 after the birth of his daughter intensified his desire for a Scottish Highland family home.
The trip was enriched throughout by university lectures and school visits in Edinburgh and Glasgow, stops at castles and cathedrals, tours of parliamentary and city chambers in Edinburgh and art museums of Glasgow. As part of the pre-trip preparations, students worked together on individual projects of their own choice and presented part of their research to the other participants before departure. Topics included comparisons of the educational systems, the history of the music and dance of Scotland, family and clan structure, medieval history, and the history of England and Scotland. In their personal journals, the students documented their perspectives and experiences of the trip abroad.

While we felt that this program of study certainly had academic value for our 24 college juniors, we decided that with the technology's aid we could take more students along on our trip to Scotland...albeit not in a suitcase. And for this, they did not even need a passport. By infusing technology into our trip planning and the actual Junior Interim Abroad, many could experience Scotland along with us.

In preparation for the course of study abroad, we relied heavily on technology to communicate with the students and with our connections in Scotland. We used faxes, e-mail, and voice mail with all members of the group. In order to more quickly survey the students’ areas of interest and apprise them of meetings, Scottish events in Pittsburgh, or a new article on reserve in the library relevant to their research, we used e-mail to communicate with them promptly and efficiently. They also replied, equally promptly—there seems to be no doubt that students read their e-mail. We also created a site on the Chatham College homepage (http://www.chatham.edu) on the Internet to announce the course expectations and syllabus, post reminders of passport deadlines, and alert all participants to any other information relevant to the upcoming trip. Later information on the homepage included biographies and pictures of all the participants and their particular area of interest, a detailed itinerary, and summaries of student research.

Access to the Internet enabled others participate in the Scotland trip. With this availability through technology, we invited classrooms whose curriculum included studies of Scotland to “come along” on our trip. Prior to the departure, one professor visited a sixth-grade elementary classroom and introduced the students to Chatham College’s homepage on the Internet and to Websites that our college students were accessing for research and information about Scotland. The elementary students could learn what preparations had been undertaken, see what it is like to visit there, and ask questions directly of Chatham students before departure. During the trip, the elementary students daily tracked the itinerary and viewed photographs of the group in Scotland and even communicated with them via e-mail. Biographies about the travelers on Chatham’s homepage enabled the elementary students to be personally connected via technology.

For the trip itself, we carried a digital camera, a Macintosh laptop computer with adapter for the local power supply. We needed only a network connection to the Internet once we were in Scotland. During the trip pictures were taken and transmitted back to the Chatham web server, which then made them available with their accompanying narrative to all network citizens. There was then opportunity for direct interaction not only between the college students and faculty at home and abroad but also between classrooms in both countries—with the proviso that schools both in Scotland and the USA had e-mail accounts established for them and access to the Internet. Any schools so equipped may access Chatham College’s own homepage and any other information there on other programs of study abroad, including that for the two other trips to Belize and the Bahamas that were also taken in January, 1997. The transmitted documents were saved as they were sent and copies are available from the authors.

**Pre-Trip Travel on the Superinfo Highway**

Students were also encouraged to explore Internet Web sites to prepare them further for their research and travels. Some favorite web sites included:

**Scotland:** (http://www.autumn.scotland.net) This beautifully designed homepage of the Scottish Tourist Board offers practical information about traveling in Scotland, including places to stay and travel tips. Also included is a weather map.

**Scotland:** (http://www.scotland.rampant.com) This web source offers a large index of “the best” of Scotland, including whiskies and haggis, rugby and golf, clans and tartans, Gaelic and Celtic culture, and history, castles, and museums.

**Scotland:** (http://www.biostat.wisc.edu/~cuthill/) This homepage on the web was designed by a Scot living in Wisconsin. From this site, one can link to other locations for information on castles, ancestry, history, Edinburgh, famous Scottish people, and inventors. It offers a wide variety of topics.

**Scotland:** (http://www.scotland.org) This electronic signpost for Scotland, funded, managed, and built entirely on location, provides an extensive directory of electronic resources relevant to Scotland which are accessible via the Internet. A variety of topics from education to culture, commerce, government, society
and politics and tourism. By clicking onto education, one reads that in 1492, the Scots introduced compulsory education, the first people in Europe to do so. A link from this site connects one to “personally Scottish,” where people of Scottish heritage can be found in all corners of the globe.

Scotland: (http://www.geo.ed.ac.uk/home/) Provided by the University of Edinburgh Department of Geography, this site offers interactive maps of the country, including details of suburban and rural areas. On-line newspapers, information about famous Scots, Edinburgh, local time, and even the Royal Scottish Geographical Society’s upcoming programs and other topics of interest also may be accessed from this site. The Society has an e-mail address for membership information.

Scotland: (http://www.lonelyplanet.com.au/dest/eur/sco.htm) This site has reader-friendly information about the people, history and many places, including off-the-beaten-path destinations. Make a stop at this site and take a “virtual trip,” viewing slides and maps of Scotland.

Scotland: (http://www.expressmedia.co.uk/) At this web site, world renowned golf and leisure resorts such as the Turnberry Hotel and The Carnegie Club are reviewed. Information about ticket and bookings is given.

Andrew Carnegie: (http://www.clpgh.org/exhibit/carnegie.html) This site gives a biographical sketch of Mr. Carnegie, including a scanned-in image of the man. Physically, he is described as a man standing between 5’2” and 5’6” but with determination and discipline that made him a giant. A man of contradictions, committed to the notion that education is the key to life, he was a shrewd and tough businessman who lived through the industrialization of America.

Conclusion

This paper provides a paradigm for infusing technology into study abroad. Such a model can undoubtedly inspire more educational professionals to investigate the possibilities for technological enhancements of their own curricula. Furthermore, it addresses the interests of a diverse audience of educators by linking elementary schools in the United States with comparable classrooms and teachers in Scotland, through the technology provided by a small college. Indeed, technology may be used effectively as a tool to change the educational process, to link students of different cultures while they are actually abroad, and to take everyone along “in the study abroad suitcase.”

USING THE INTERNET TO EXTEND OUR HORIZON: FROM E-MAIL TO GLOBAL VIDEO-CONFERENCEING

David Brunner  
University of Southampton

Debra Resch  
Russell O. Brackman Middle School

Since the earliest days of the Internet, there has been an almost universal interest in finding ways in which “The Net” can be used to enhance education and children’s knowledge of the world in which they live. Interest in other cultures dates back to early pen-pal schemes, that are still very much alive right the way through to sophisticated data communications that we have available to us today. The challenge that we face as we prepare to enter the next century is to have a clear vision of where the technology is going, how the children of today relate to that technology and how we prepare our intending teachers to make effective use of it. In doing so we may also need to reappraise our own view of technology and the way in which we as both teachers and teacher educators respond to its challenge.

I challenge you, the people in this room, to connect all of our classrooms, all of our libraries, and all of our hospitals and clinics by the year 2000. We must do this to realize the full potential of information to educate, to save lives, provide access to health care and lower medical costs. (Vice President Al Gore, Royce Hall, UCLA Los Angeles, California January 11, 1994)

It is evident from the comments above made by both American and British governments, who appear - certainly in the latter case, to have little understanding of what they are talking about or proposing. Once again, as with the emphasis on programmed learning of 20-30 years ago, technology is being hailed as a universal panacea for the perceived failings of the education system as a whole. Here, we have governments talking about installing networks capable of transferring data in the Mbit/second and above ranges, and yet there is still little real understanding of what the technology can be used for.

Information superhighways offer the potential to deliver widely and cheaply a vast range of services, including education. …network capable of transferring very large amounts of information - including video, still images, audio and text between users. (DfEE, 1995)

Having set the scene for the U.K., the paper then goes on to consider how schools are placed to deliver an information technology entitlement to pupils, but by its own admission it states:

Evidence from HMI… and independent sources indicates that schools are not finding it easy to offer all pupils appropriate opportunities for using IT in
the curriculum.... It is readily possible to identify exciting educational possibilities... but in each case decisions have to be taken about whether the value added justifies the cost in money and time involved. (DfEE 1995)

The consultation paper finishes with a consideration of the I. S. as a vehicle for offering both initial and in-service teacher training, and as a management tool. Clearly governments see many possibilities. the Information Superhighway is paved with good intentions!

**Where are We Now?**

If the concept of video on demand from an educational information service is beguiling, it is also some way off. Fundamental questions about who will provide the service, who will pay for it, the equipment needed and the infrastructure to support it have not been adequately addressed. Many schools in both the UK and the US are still pitifully equipped with computer equipment that is out of date or simply not generally accessible; teachers themselves find that they are under increased pressure to deliver more curriculum materials with less resources, and the children are disillusioned with the teachers and the equipment. This is especially so in more affluent areas where the students may have far better facilities at home than the school, what signals does this send to them?

At present, the emphasis on the Information Superhighway can be thought of as building motorways when few have cars, those that do can’t drive, and the ones who can drive cannot afford the petrol! It will be great at some point in the future, but not yet for the majority. The National Information Infrastructure (NII) promoted by the current US administration integrates computer, television, telephone and telecommunication technology with a promise that every school, library, hospital and clinic in the US should have access to the network. But, has any consideration been given to how this impacts on the school curriculum and teachers in general, indeed how long will it be until teachers have both the resources (equipment and time) to integrate this vision into the everyday life of a classroom.

**Some Fundamental Questions**

How many teachers make regular use of the existing communications channels that are available to schools with the equipment that they currently have in their classrooms?

What can we do to promote good practice and the development of skills that will be invaluable when someone gives them access to the highway?

It is obvious, but worth restating, that in order to utilise technology, we must first know that it exists, we must understand both its potential and its limitations and we must have a vision of what we wish to achieve with it; having got thus far, we must then have both the skills and the equipment in order to realise that vision.

Technological change continues at a breathtaking pace, hardware becomes both cheaper and more powerful, software becomes more sophisticated and easier to use. New communications channels are being opened up and the advent of cable modem technology will increase the available network bandwidth to a level enjoyed by those on Local Area Networks (LAN’s) and new ‘providers’ are currently giving the everyday user cheap and effective access to global communications.

**How do we as Teachers and Teacher Educators Respond?**

Since many of today’s schoolchildren have a grasp of this technology already, many have access to equipment that is more sophisticated than that found in their computer labs in school, many are linked to the Internet at home and have a better understanding of how to use it and of its implications than the teachers themselves:

- How does this leave the teachers feeling?
- How are we, as teacher educators, responding to these developments?
- Are we taking on board the new communications medium, or are we ignoring it?
- Worse still, are we just not aware of it? and
- Do we believe that it is of no significance to us as teacher educators?

This study is about how teachers and children use worldwide communications in the classroom and attempts to push the existing (as in 1996) technology as hard as possible, to find out what can be practically achieved and what the training and resource implications are for schools and teacher training institutions, and then to look ahead 5 years.

**What Can Existing Technology Offer in the Classroom?**

In order to appreciate how the technology may facilitate worldwide communications, it is first necessary to understand what is possible and what follows lists what can be done now, with equipment and telephone lines that are currently in place. What the project set out to achieve was a model of classroom practice for teleconferencing, and worthwhile curriculum activities based around such a model.

E-mail. There have been many schools that have communicated using e-mail, right from the early days of Compuserve until the present time. Software allows files to be ‘attached’ to e-mail documents to allow the transfer of images, word processor documents and programs to take place, and is the most widely used way of transferring files between users.
Telnet. The facility to remotely access one computer from another in order to access files or e-mail from a remote computer, not very user friendly.

Usenet News. Newsgroups appeared in the late 80s, allowing groups of like minded individuals to “Post” messages to other members of the group. The users were then at liberty to read the heading and ignore, or to look at the whole posting, which could also include encoded files.

Chat or Internet Relay Chat. Can be considered as analogous to the multiparty chat lines that are available over the telephone, where a group of people join in a group discussion. The ‘chat’ is text on a screen that a l can see, preceded by the name of the person who made the comment, with the opportunity to chat on a 1 to 1 basis, to send files and to launch sound events, that will play a predetermined audio file on each person’s machine. The text appears in ‘real time’ with typically a sub 10 second lag, users may be from all over the world, and at any one time there may be 7000+ chat channels.

Audio. As technology has advanced, the possibility of sending live audio across the Internet became a reality, and in the past 18 months there have been a number of developments in this area. The most important of these has been the “Internet Telephone”, allowing users from around the world to talk to one another for the cost of a local call. The audio quality is very variable depending upon the line quality and the computer’s capability to encode and decode sound into Internet data packets. More sophisticated software allows users to interact through a shared white board, to transfer files and to chat, useful when spelling is important. This same technology allows audio to be broadcast from a central location, with software such as “RealAudio” it is possible to listen to a conference or even a radio station across the net.

VideoPhone. There are two approaches to sending video from point to point, the first is to use a dedicated videophone, a major expense in itself, and an ISDN line. The line will cost in the region of £400 per annum in rental before call charges are added, and this alone puts such equipment outside the reach of many schools for whom the expense could not be justified.

Video and the Internet. The second approach is to add a video capture card and video source to an existing multimedia computer and use the Internet to transfer the images.

Software to do this has been under development for the past few years with Cornell University taking the lead with its CUSeeMe software, now being marketed commercially by “White Pines” software, features of the software include a “whiteboard”, file transfer and a text based chat mode. A number of participants to a single site, allowing for a multi user conference to take place.

Classroom Activities

Since the school in NJ was communicating successfully with the University using e-mail, it was decided that we should attempt to use “Chat”, “Internet Telephone” and “Internet Video” with a group of 8th grade pupils, giving them the opportunity to ask questions regarding life in the UK. They felt this would be most valuable - having in the first instance, an academic online to talk to and answer specific queries; and once an understanding of the technology had been achieved links would then be established through the university’s partnership scheme to local schools in the UK.

This had to be done using existing resources in order to see what the current technology could offer, and to help shape future activities and subsequent bids for funding, without the hype and rhetoric of the Information Superhighway.

Chat - This is the simplest of the facilities, and had the advantage that the whole class could see by using an overhead projector and a projection tablet. In all, three sessions were organised with questions ranging from school through to politics and pop groups. The time delay of 5-15 seconds made little difference to the activity, and in the end whoever was asking the questions simply asked the next question whilst waiting for a response. This gave a very real feeling of conversation taking place, with low cost equipment and a local (free) telephone call to the provider.

Internet Phone - At the time, this was less successful, but was used with the same 8th grade group in order that they could “hear” what the person they had previously chatted to sounded like. The technology has improved but really needs a Power PC or a fast multimedia PC. It has the great advantage that it will work across platforms, and even with a 14.4k modem the results are acceptable. As before, the class room activity was kept to a question and answer format, with students taking turns to use the microphone, and the whole class could hear the replies.

CuSeeMe - Was the most ambitious attempt at linking the school and the university, and as with Iphone met with varying levels of success. At its best, using a Dual ISDN line at a local high school it gave acceptable levels of voice and slow scan image (approximately 5fps), along with a facility to jointly edit a document using a shared white board. On a regular phone line it was very frustrating, and a way of working using both “text chat” and “video” was developed, in order to prevent the lines being swamped with data and the system grinding to a complete halt.

From an academic point of view, we pushed the technology to its limits, but what about the view from the classroom?
Teleconferencing - A Classroom Perspective

Debra Resch, Computer Teacher:

As an educator, I have found the Internet to be a valuable, exciting and sometimes overwhelming environment, and after stumbling about for almost a year with a popular commercial service called America On Line, I finally became aware of other provider options that were far less expensive, but required a little bit more computer savvy on my part! Through the necessity to keep up with some of my more able students and with the trends in computer education, I was forced to spend the time and effort to learn about various areas of telecommunications and the Internet, this has been a voyage of discovery over the past year.

During this time I have learned how to utilize e-mail to communicate with friends, colleagues and students, as well as using Netscape Web Browser to access Internet sites. I was amazed to find that much of the basic Internet software I needed could be found somewhere on the net. I learned to use a list serve and to access news groups to get the most up-to-date information on a specific topic and was astounded that I could talk to people all over the world by using an Internet chat program. I was now able to talk to my students about the Internet and all it's amazing possibilities (at least the ones I know about!)

As students become more proficient in their basic computer usage, it becomes more of a challenge to keep up their level of interest and enthusiasm in the basics. The Internet opens new doors for students to be able to locate a wealth of information and to utilize the skills they have learned in order to arrange this information in a presentable, understandable, and orderly fashion. The search for information on the Internet requires language and cognitive skills equal to or greater than those required to locate information in a library. As a result:

- students must possess adequate keyboarding and language skills;
- they must learn to narrow their topics, be specific in their searches for information; and
- how to focus and discriminate information that is relevant or irrelevant to their topic.

Although these search techniques require skill, training, and teacher guidance, the payoff is the quality of information obtainable. Students will have electronic access to an almost limitless amount of textual, graphical, audio and video resources regardless of their physical geographic location. Teachers should find that students who participate in online telecommunications will eventually demonstrate improved writing skills because they will be writing to an audience made up of other students and adults who can be from anywhere around the world. This will make the task of writing more important and relevant to the student, who will also take pride in their work (art, writing, etc.) when it is published online for all the world to see.

But, searching the net for information is just one aspect. Through e-mail, teleconferencing, and chat, students may have the opportunity to learn about people from anywhere in the world. Rather then just read about the customs and traditions, races and religions of other countries, it is amazing to actually talk and correspond with a person who lives in that country. The friendships that can develop are invaluable in understanding and accepting the world as it will be in the 21st century. I am still somewhat surprised sometimes at the lack of knowledge, understanding and tolerance that students of middle school age have of people from other countries and cultures. They may have learned the geography (hopefully) and maybe a few facts but that is not enough to cultivate true understanding and tolerance in today's world. This is evident to me and my colleagues through observation of student behavior, interaction, and reactions to material discussed and presented in our schools.

Through the recent advances in technology, students have many more options than the pen-pal format of the past since they can now speed up their correspondence with e-mail which may include sending attached documents, photographs or artwork. They can also have real time conversations through chat programs which require typing or through 'Internet Telephone' software which allows the user an inexpensive way to speak with people around the world. The final extension is video-conferencing programs such as CuSeeMe which allows the users to actually do video conferencing which involve both seeing and hearing the other person along with the possibility of sharing files - providing the line is both fast and good enough.

In my own school, we have a PowerMac connected to a regular phone line at 28.8k and use one of the local New Jersey Internet Providers, this enabled me to see if e-mail, chat and video conferencing could be achieved. I have demonstrated some of these features to my 6th, 7th and 8th grade classes, even allowing them to ask questions and have controlled interaction in a telecommunications setting such as chat, e-mail, and even teleconferencing. This type of activity required planning, preparation, and follow-up activities in order to be successful. Teacher's who attempt this need to find reliable contacts who will be able to contribute and interact in a positive and productive manner with their students. An introductory lesson is imperative to teach students proper net etiquette as well as to have a basic background understanding of the culture and geographic location of the participants on the other end. It is important that students have input in the planning of such an activity.
and spend time in advance formulating questions and ideas for meaningful correspondence.

Two of my 8th grade students in particular, Scott Hayes and Kathleen Whalen, were very interested and helpful in setting up and evaluating this process. As Scott and Katie became more experienced with the Internet, they advanced from just e-mail to the most up-to-date features of CuSeeMe. We all profited greatly from CuSeeMe because it includes real time audio and video conferencing by way of a user-friendly interface with many useful features. Although it will work on a 28.8 kbps line under ideal conditions, it really an ISDN line to get video and audio on a satisfactory level.

With CuSeeMe, my students have communicated with David Brunner at the University of Southampton in England. They found this technology very exciting and interesting. They were anxious to have other teleconferencing experiences with students from other countries and expressed to me that they felt it was an exceptionally motivating educational experience in which they could improve their communication skills and learn about other cultures and lifestyles firsthand.

Of course, it is possible to get inappropriate responses from other people, just as it is possible, even with the aid of ‘filtering’ software, to come across negative information on the net. The person who teaches or supervises Internet usage will have to deal with such issues. Students will need clear direction, constant supervision, and motivation to stay on task. Class rules will need to be very specific and appropriate sanctions will need to be enforced without delay should a rule be broken. Hopefully, the climate of such a classroom will be a positive one where students are too busy and excited with the task on hand to stray to the less desirable aspects.

All of these possibilities are exciting but they require teachers to take the time and initiative to learn how to use the hardware, the software, and to calculate ways to integrate these possibilities into busy schedules and overburdened curriculum guides. It also requires that boards of education, administrators, and people of the community to understand the financial commitment that must be made. Of course it can and must be done, money spent on Internet training and access in a school is worth an amount that cannot be measured by a dollar value. The access to these resources will open up a world of information, arts, literature, culture, etc. The quality of these resources are not only immeasurable but we cannot even begin to make any comparison with the current resources of the most affluent up-to date school library. Dollar-wise, telecommunications technology is the best educational investment that a school can make at the present time; however, the financial funding commitment at the National as well as state level (at least in New Jersey) continues to be one of large volumes of verbal rhetoric with relatively small amounts of real dollars allocated to the educational levels Pre-K to Grade 12 and even to the higher educational institutions. The words alone will not replace the dollar amounts that are needed to prepare students at the various education levels for the “technological 21st century.”

Technology now offers many possibilities for students and educators alike - it is an especially exciting time to be a “Computer Teacher” and have the joy and occasional frustration of trying to share a vision of the “Global Village” of the future with others in the field of education. I can see people coming around slowly but many are still resistant, frightened and easily overwhelmed by the technology and the opportunities it provides. Fortunately and unfortunately, the children are not usually the ones who are frightened and overwhelmed - they are excited and anxious to discover! The only things holding them back are the financial restraints, a lack of commitment to teacher training and resistance on the part of many teachers.

Teachers must be given the time, encouragement and support to feel comfortable and less threatened by technology, the curriculum of the past and present must be integrated with the technology of the future, and as educators we have an obligation to really make it a “small world” after all!

David Brunner:

Providing an Infrastructure and Developing a Curriculum Model

In any project, there is a need to establish the ground rules and common goals and objectives. This was highlighted by Meadows in 1992:

Teachers and tutors may need to spend a long period communicating with each other before being ready to start work with their pupils or students on a twinned project - patience and commitment are important here, and so is support within the school...

Having established that transatlantic telecommunications was indeed possible, the fundamental question arises, “what do we do with it?” This may best be illustrated by the project proposal outline from another NJ elementary school:

...a theme of “Lifestyles” will be the topic for study, a monthly topic will be established and researched by each school. Classroom time will be devoted to the development of the questions and answers while computer lab time will be devoted to their production (artwork and text) and subsequent communication. The theme of Lifestyles provides a broad spectrum of activities: School & Home (students details), Geography (Local Industry), Recreation, Holidays & Festivals, News & Current Affairs,
Language (Meanings, Differences, etc.) covering the whole curriculum.

Goals:
- The underlying theme of this proposal is enhancement of the curriculum and school resources; not only in terms of equipment available but through developing teachers’ skills and understanding of computers, and by offering students a wider view of the world.
- By incorporate telecommunications technology into the classroom in a meaningful way in order to extend teachers and students understanding of computers in general and their application to communications in particular.
- To improve the skills base of the teachers within the school through training and the opportunity to become involved in an exciting and motivating activity.
- To give students a greater opportunity to understand and explore the Internet.
- To enhance the provision of the schools computer lab for the production of a wide range of computer based activities throughout the whole school, this will have an impact on the school in general and enhance the quality of teaching an learning.

Objectives are to:
- Establish the communications links by providing the hardware, software, Internet provider
- Undertake necessary staff training and development - and enable both sets of teachers to communicate.
- Develop suitable curriculum materials for use by, and using computer technology.
- Maintain a weekly dialogue with a UK school, initially through e-mail, that will enable files to be transferred between the two schools.

This has provided a focus and a starting point for activities that are both practical and attainable within existing resources and curriculum constraints, and it is hoped that it will allow for the development of a wide range of activities and sharing of curriculum materials.

Issues to Be Addressed
Social and Moral. Providing access to the Internet and online resources can have many and varied benefits, but there are fundamental questions about how contacts are established and maintained, who exactly are students talking to and what exactly is being discussed. This can be controlled in a text-based e-mail environment, but just as with the 1-800 telephone SEX LINES, WE ARE NOW BEGINNING TO SEE THE ADVENT OF VIDEO BASED INTERNET PORNOGRAPHIC material. How do we prepare our children and educate our teachers to be aware of the potential risks involved in accessing the Internet, and to promote values that will ensure that it does not become an issue?

Training. There are a number of states in the US that have well developed training schemes for existing and trainee teachers alike. Research shows that unless teachers are given the opportunity to use teleconferencing in a very real way, then they are unlikely to continue with its use (Schrum, 1995). Teachers need to be shown how to access data, how to incorporate it into their existing schemes of work and how to make use of one of the most valuable resources that will ever been available - other like minded individuals.

What Lies Ahead? The Information Superhighway promises much, but before we begin to contemplate its use, we must first understand and use the Internet of today. The skills of data handling and retrieval learned today will prove to be invaluable tomorrow, the conceptual framework and principles remain the same whether data is sent at 3k or 100k bytes per second. Classrooms will not change radically in the next 3 years as we approach the new millennium, but our perceptions, and those of our students can and should.

546 International — 549
South African educational institutions' Information Technology (IT) departments are not providing enough African IT graduates for the South African industry. This paper investigates this situation and highlights the fact that, although more African students are enrolling for IT studies, the failure rates are very high. Some of the major reasons why many African students fail their IT studies are their previous schooling, and their social and cultural background. In facing the challenge the Department of Computer Science and Information Systems at the University of Port Elizabeth has implemented some practical steps. In addition to this the department has also identified some research areas. These include academic development and support, the influence of home language, methods of lecturing, the psychometric profile of students as well as the training of teachers in disadvantaged schools.

In many aspects of their lives South Africans have experienced some kind of change, accompanied by new challenges, expectations and difficulties. The Information Technology (IT) industry has not escaped this. The lack of computer literacy in the African community is alarming, and the IT Industry is expected to do everything in its power to train many more African IT professionals (Van de Werken, 1994). The politicians are appealing to the IT industry to use technology in uplifting people's socioeconomic conditions. Ofir (1994) states that the importance of technology in improving daily life must be visible especially in rural or poor areas.

The predicament of the South African IT Industry is highlighted by the fact that in 1995 it had less than 1000 nonwhites out of approximately 20000 personnel, with no real expectation that this ratio could change considerably within the next 5 years. (Kun, 1995). This racial balance is obviously far from desirable in a country which, through affirmative action, is attempting to correct the racial imbalances of the past.

Because affirmative action candidates (African candidates) are in tremendous demand, they tend to change jobs frequently, causing additional skill development difficulties for companies. To add to the human resource problems of the South African IT industry, local businesses must compete with much bigger international companies. Ten surveyed companies lost 1254 skilled IT workers to international competition in 12 months (Gary, 1996). The industry is thus depending on universities and technikons to supply them with IT graduates and, more specific, African IT graduates.

A Rapidly Changing Environment

As a result of the social changes throughout the nation, higher education has become much more available in South Africa. As a result of this, universities and technikons have seen tremendous changes in their student populations. They are going through a process of rapid transformation with immense new challenges (Fish, 1996).

The University of Port Elizabeth (UPE) is also experiencing dramatic changes in its student population. In 1987 less than 10% of all freshmen were African students. This has changed dramatically to the current scenario where more than 50% of freshmen are African (UPE Academic Records, 1996). This increased African enrollment is also experienced at other South African universities (Brummer, 1996).

According to projected headcounts, the number of African students who pass their matriculation exams will increase from 190,000 in 1995 to 470,000 in the year 2005 (National Commission on Higher Education, 1996). This will definitely create a further influx of African students to universities and technikons.

UPE is also experiencing a growth in African first year enrollment in IT courses. The Department of Computer Science and Information Systems recorded 13% (98 out of 767) African first year students in 1995. This figure has nearly doubled to 24% (174 out of 715) in 1996 (UPE Academic Records, 1996), and predictions are that the figure could again double in 1997.
The Lack of African IT Graduates

Despite the ever increasing number of African students enrolling for IT courses, South African universities and technikoners are not producing enough African IT graduates. A very high failure rate is experienced amongst African IT students (Venter, Blignaut, 1995). In 1995 the white first year students in the different IT courses at UPE had a pass rate of 80%, while the African pass rate was 30%. Of the 53 African students who enrolled for the first year programming course in 1996, only 10 passed the course at the end of the year (UPE Academic Records, 1996). The major challenge facing many, if not all, South African university IT departments, is therefore the problem of increased African student enrollment, with consistently low pass rates.

Major Reasons African Students Fail IT Courses

Schooling

It is generally accepted that African students in South African universities come from a disadvantaged schooling background, as a legacy of the Apartheid era. The old African education system in South Africa has been described as a “national catastrophe” (Mazwai, 1990). Some of the problems experienced at historically African schools include the following (Verwey, 1990):

- textbook shortages and poor textbook management;
- inadequate school management;
- poor qualifications of teachers;
- financial disparity and inequality, compared to white education.

Garson (1995) reports that the first national teacher education audit to be conducted in South Africa, uncovered alarming inadequacies. The quality of teacher education was found to be very poor, with a dire shortage of teachers in mathematics, science, and technology. Of specific importance to IT departments is the underachievement in mathematics by African students. Maree (1995) points out that for every 1000 African scholars entering school at grade 1 (first school year), we can expect only 1 to matriculate successfully in mathematics. Although the different education departments throughout the nine provinces of South Africa are no more racially segregated, the above mentioned problems will definitely not disappear over-night.

Psychometric Profile

Holland’s profile of successful South African IT personnel identifies them as being investigative, enterprising and realistic (Prediger, Swaney, & Mau, 1993; Taljaard & Von Molendorf, 1987). Although research at UPE has found that this profile has changed (Calitz, 1996), the investigative skill is still highlighted as very important.

In light of the above, Castle’s (1992) observation on the African schooling system in South Africa is alarming. According to him, the school system for African students emphasizes rote learning, strict discipline, and one-way communication (teachers to learners). Students are discouraged from asking questions and using their initiative or imagination. Clearly such a learning culture in schools will limit scholars’ investigative skills.

Social Background

Again, because of South Africa’s past, most of the African students come from a disadvantaged social background. Many of these students come from communities where they have very little exposure to technology in their daily life (Venter, Blignaut, 1995). The influence this has on their ability to cope in the computer world was strikingly emphasized in an exercise done in 1996 at UPE with first year programming students. The students were asked to come forward with a specific problem in their daily life which could be addressed by writing a simple C++ program. The examples chosen by some of the African students indicated a lack of frame of reference in which they could place the use of a computer in their daily life. The following are only two of these examples:

- Write a program which asks you how many children you are in your family. The program must then tell you whether you are a big family or not.”
- Write a program which asks you what your life expectancy is. If you say less than 80, the program informs you that you will live longer than that. Otherwise the program will inform you that you will die younger than you think.”

In addition to a lack of frame of reference, computers are perceived by black students as a “white thing”. According to research done by Ofir (1994) technology is seen as a tool of the white community to ensure their superiority.

Cultural Background - First Language

Research in the Department of Computer Science and Information Systems at UPE, found that a student’s ability in English is a good predictor of success in IT studies (Calitz, 1996). Most of the African students in the department have the ethnic language Xhosa as first language with English as a second language. It is interesting to note that for most of these students English was officially the medium of instruction for many of their senior years at school. Strevens (1980) points out that in such a situation, where English is not the mother tongue, the scholars learn and use it as a general or cultural language. A student in science, and in this case Computer Science, however, needs to be skilled in scientific or technical English. The obvious problem that African students experience concerning language is simple mutual communication. In addition to not being able to follow the contents of the lectures, they have difficulties articulating the problems they experience.
with the course content. This is mainly experienced during one-to-one discussions with lecturers as well as with communicating with their assistants during practicals.

When being taught science in a foreign language, the problems are more complex than the difficulties in mutual comprehension between lecturer and student. These problems also include (Strevens, 1980):

- the absence, in the student's own language, of a word or expression;
- the absence, in the student's own language or culture, of a necessary concept e.g. infinity or gravity;
- the indifferent use of key words such as "if", "when", "whenever" etc.;
- the counting system used in the student's own language.

Selection of Students

Matriculation (school-leaving) results have widely been accepted as good indicators for identifying successful students in IT (Calitz, 1992; Butcher, Muth, 1985; Evans, Simkin, 1989). Various studies have identified specific subjects as good indicators for success. Of these, Mathematics has been identified as the most important (Kovalina, Wileman, Stephens, 1983). Other subjects such as Science or a combination of subjects have also been identified (Calitz, 1992).

In recent research done at the University of Port Elizabeth (Calitz, 1992, 1996), candidates' ability in English, in addition to the other subjects mentioned above, was also identified as one of the most important indicators. Table 1 shows the subjects entered into stepwise regression analysis for identifying successful programming and computer literacy students.

A disturbing find in this research was that matriculation marks of students from historically African schools are not as good indicators of performance as those of white students. Because of limited numbers, this must be viewed as an initial finding. Obviously this creates new challenges for IT departments in South Africa. Without being able to use matriculation marks as good indicators of success, two obvious errors could be made in the selection process:

- selecting students who have very little chance of success, resulting in even higher failure rates and creating a negative atmosphere in class; and
- disallowing students who actually have the potential of being successful.

Facing the Challenge

It is clear to us as a university, and as a department, that the problems mentioned above need to be addressed if we want to achieve success in the challenge of a new South Africa. Certain practical steps have been taken by the department as well as the Faculty of Science in to address some of the problems mentioned above (Greyling, 1995). These include the following:

- Extended IT first year - students may do their first year over two years (Department of Computer Science, 1994);
- Summer and Winter Schools - students who fail their first year, are given the opportunity of redoing the course material during their recess periods (Wesson, 1994);
- Extended BSc Curriculum - in their first year students do credit bearing courses such as Mathematics Special, Technical English, Life Skills and Computer Literacy Special.

In addition to the above steps the IT Department at UPE has also identified the following research areas:

Academic Development and Support

A research project has been proposed on the academic development and support in the Science Faculty of UPE. This research would entail establishing the current state of academic development and support in South African universities, designing a structure of academic development and evaluating the implementation of such a structure in the Department of Computer Science and Information Systems.

Language and Its Influence

As mentioned earlier, most of the African students at UPE have Xhosa as their first language. This language is in many ways very different from a typical Western language such as English. This was illustrated in an experiment with first year students where they were asked to translate a simple while loop into their home language. The Xhosa speaking students had difficulty in translating this concept and programming structure into Xhosa.

Many solutions have been proposed to the problems of teaching science in a medium of instruction which is not the student's home language (Kotecha, Rutherford, & Starfield, 1990). There is definitely a possibility for a linguist to do research on the influences a language such as
Xhosa has on a student’s ability to program. Such research could assist us in bridging the language gap in university IT courses.

**Different Methods of Lecturing**

The obvious solution to the language problem we experience would be to have Xhosa speaking lecturers and assistants in the department. Up to now we have, unfortunately, been unsuccessful in obtaining either. The department should have a few senior Xhosa speaking students soon who could be used as assistants. The author, however, is not so positive concerning lecturers. Because they are in such demand in industry, it is very unlikely that African IT graduates would choose a less-profitable academic career.

Eliminating the lecture method in favour of self study modules for discussion in cooperative learning groups is being investigated. This will allow students from the same cultural and linguistic background to discuss problems in their own language.

An experiment at group work in the first year classes proved to be very successful and interesting. During these sessions it was natural that students speaking the same language would gather together. It was exciting to observe how especially the Xhosa speaking students would explain certain programming concepts to each other. The best example was explaining the if statement by using the analogy of a man standing at a door, asking people a question in order to decide whether they were allowed into the room.

**Psychological Research on the Reasons for Success and Failure**

In cooperation with the Department of Psychology at UPE, as part of their honors program, we are doing research on the different aspects which might cause success/failure amongst first year Computer Science students. This includes the following:

- Quantitative tests on the 1997 first years. These tests include a new test on simultaneous and successive processing skills, which we feel might be correlated to the ability to program;
- Qualitative research on 1996 first years, through interviews. The focus of these interviews would be to determine students’ perceptions and experiences of computers as well as their backgrounds (personal, social, cultural etc.) and how this influences their interaction with computers.

**Computer Literacy of African Teachers in Disadvantaged Schools**

The department is involved in computer literacy training of teachers at several disadvantaged schools in Port Elizabeth as well as in the surrounding rural area. In addition to the practical assistance given, this is also seen as a potential research area. The aim of this research is the development of an effective introductory Educational Computing course for disadvantaged teachers, using global Educational Computing models (Cowley, 1995).

**Conclusion**

The Africanization of South African universities has been in the spotlight for the past decade. This concept embraces the integration of universities into the culture of Africa, reflecting the changing needs of Africa and commitment to the needs of the whole community (Farquharson, 1990). South Africa needs more African IT graduates, and to the industry it is of utmost importance that standards are not dropped.

Responding pro-actively to socio-political changes in the country and the imminent restructuring of the tertiary education system, the University of Port Elizabeth has adopted far-reaching policy resolutions and taken a wide range of action steps to promote the institutionalisation of the process of change in South Africa (Kirsten, 1996). In correspondence with the changes of the new South Africa and the general atmosphere at UPE, the Department of Computer Science and Information Systems is ready to face the challenge. It is very important to the IT industry and the economy of South Africa as a whole, that we, as well as our colleagues at other universities, are successful.

PEDAGOGY OF INFORMATICS:
PREPARING EDUCATORS TO FACE THE CHALLENGE

Ana Cristina L.A. Jurema
Federal University of Alagoas

Mary C. Dalmau
University of Oregon

Maria Edite Costa Lima
Institute of Technology in Informatics

Merval Jurema Filho
Institute of Technology in Informatics

Through this presentation, we will discuss the challenges facing educators to incorporate informatics (we have used that term because it represents information and automatics, all together, placing computer education in the broader context of information and technology) into the curriculum, the capacitation—neologism for continuing professional development which enables and empowers teachers to action—of teachers to face these challenges, and review a new educational program in Northeast Brazil. We will present a package of teaching and student materials which formed the basis of a course in informatics for K-12 students. These materials which were developed in Portuguese are currently being translated into English at the University of Oregon.

Perspectives/Theoretical Framework

In Brazil (as in USA), computers were introduced into educational programs for children with the promise or belief that through the computer students would learn more, read better, and work more creatively and cooperatively. However, the computer, reified in this way, has not corresponded to people’s expectations of its potential in the learning and teaching situation. Recent research in the US, Japan, Israel and some countries in the Europe Union shows that the main focus of computer education in schools has been on computer skills, e.g. word processing or information management, and little attention has been given to developing a pedagogy which integrates the teaching of computer skills with an understanding of informatics and its place in our society. Little or no attention has been given to a Pedagogy of Informatics which takes into consideration learning and teaching processes, organization of curriculum, and reflection on people/machine relationships in learning and in the wider community, as well as developing children’s ability to use computers competently. In addition, the responsibility for computer education and use in schools has been left in the hands of technical experts working from computer labs, rather than incorporated by classroom teachers into the curriculum (Pelgrum & Plumb, 1991; Anderson, 1993; Lund & Wild, 1993; VISION TEST, 1990; Office of Technology Assessment, 1995).

The challenge facing educators today is not just to use computers at school, but to use computer education and informatics to mediate improved social and learning relations in schools. The introduction of informatics into the curriculum can assist schools to change from a traditional way of teaching and learning, to one that provides students with an ever more cooperative apprenticeship in the learning and teaching process, and prepares them to be lifelong learners, explorers and integrators of learning and experience. Key factors in assisting teachers to respond to these challenges, are (1) the production of resource materials which express didactically the basic educational concepts that will facilitate the processes of working, teaching, communicating, and learning, and (2) the capacitation of teachers (Jurema & Costa Lima, 1993).

Foundational premises for developing a program based on the Pedagogy of Informatics include:

- The interdisciplinary nature of informatics knowledge involves a range of subject areas and processes, including but not limited to mathematical, historical, linguistic, logical, conceptual, and graphic.
- Learners are active participants who in the course of their learning structure their experience and knowledge.
- The cooperative work of students and teachers creates a new cultural resource which is greater than the knowledge and understanding that any of the individuals possessed before.
- Approaches which are based on the social and cognitive reality of students will develop learning experiences that are challenging and open-ended, enjoyable and playful, cooperative and socializing.
• Computers are a means not an end. In the educative process they do not replace people but assist them in reorganizing interactions, thus reorganizing the teaching and learning process (and the play).

• The content of knowledge and its daily application are intrinsically related. Therefore teaching and learning programs in addition to providing information about computers and information technology, must be functionally constructed (authentic learning), and also challenge learners to reflect on social impacts and implications (i.e. the relations of people with the machine and with one another).

• Informatics in schools are not an appendix to the educative process, but an integrated element of the school curriculum which must enrich the teaching and learning situation.

• The capacitation of teachers is essential. An approach based on the pedagogy of informatics requires teachers to develop their knowledge and understanding of informatics in our society, to rethink their roles and practices, and base their teaching on their students' curiosity and active involvement in their learning (Jurema, Costa Lima, Dalmau & Jurema, 1995).

Developing a Pedagogy of Informatics involves collaboration in learning at a number of levels, i.e. the collaboration of educators as they work together on the conceptual and operational changes required if they are to teach both about the computer and with the computer; the collaboration of students as they learn together through activity-based and challenging learning opportunities; the collaboration of schools and communities as they come to terms with the role of education and schooling in the information society; and interdisciplinary collaboration in the development of curricula and educational programs.

**Methods and Data Sources**

A computer education program, produced by the Institute of Technology in Informatics (ITECI), based on this emerging pedagogy of informatics has contributed to our knowledge about the use of computers and information technology in education. These materials were developed by a cooperative, multidisciplinary working team of professionals from the areas of informatics, cognitive psychology, education, visual programming (graphics), history, and production of didactic materials. They were trialed through an intensive course, and then successfully used for more than five years in seventeen Elementary and Middle Schools, with approximately 20,000 children and adolescents in the states of Alagoas, Pernambuco, Rio Grande do Norte, and Ceará. With some adaptations the course was also taught to a group of children with special needs (Jurema, Jurema & Longman, 1992). Our observations are based on the conceptual framework on which the program was based, the multidisciplinary and collaborative approach to the program development and implementation, and the follow-up evaluation of ITECI's methodology and courses. The program integrated three key objectives:

• Informatics education: to provide students with access to systemic knowledge about computers and information technology;

• Educative informatics: to use computers and information technology as an educational resource for students and schools;

• Capacitation of teachers: to assist teachers to become users and teachers of informatics, through understanding the philosophy, ideas and skills on which the program was based.

The program. The Introductory Informatics Course for Children and Adolescents (Jurema & Costa Lima, 1993) included both, a methodology for teaching informatics to children and adolescents (K-12), and a series of teaching and learning programs across the age-range. It was designed (1) to assist children and adolescents develop the abilities, understandings and values necessary to participate effectively in a society infused by computers and information technology, and (2) to assist schools and teachers to develop informatics as an integrative element across the curriculum. The course was designed around three thematic nuclei:

• Foundations of Informatics (history, functioning and uses of the computer),

• Informatics and Society (social impact and vocational and work market analysis),

• Interest centers (workshops on many topics, including but not limited to, art, games, literature, mathematics, pedagogical support, library).

The program materials include a kit of didactic materials: text books (reference books for students and teachers), activity challenges for students, manuals of methodological orientation and educational programs for teachers, and a support kit of educational software. The software developed are simple, requiring the teacher to explore the ideas they represent and integrate them into the learning program. The teachers' manual presents, besides suggestions for activities, some alternative suggestions about ways to work with students within each subject, and the integration of the program across the curriculum. Collaborative processes are built into all activities of the program so that the cooperative and cognitive elements are intrinsically united, e.g. when children work in teams to create databases, they generate findings which have to be discussed, analyzed and communicated, and require their active involvement in the reasoning process.

Capacitation of teachers. The capacitation of teachers is the key to the success of the program. If informatics is to become and intrinsic component of schooling, it will not be enough for schools systems to merely train computer
experts. All teachers must be given the opportunity and the encouragement to develop the conceptual understanding and technical skill necessary to integrate the computer into their educational programs. The Teacher Capacitation Program developed by this project assisted teachers to develop their own knowledge and understanding of informatics in our society, to rethink their roles and practices, and base their teaching on their students' curiosity and active involvement in their learning. It is an ongoing process, including a practical course of informatics (40 hours), monthly teacher meetings (3 hours), and end of semester workshops (6 hours).

**Educational Importance of the Study**

As stated above computer education in schools has not lived up to the high expectations with which it was introduced. In many cases as the speed with which the technology is developing simply means that teachers and schools get left further behind. The emphasis has been given in equipment. We propose a shift, building a pedagogy of informatics in a permanent program of teachers capacitation. This project has been successful in both, the capacitation of teachers, and the development of a Pedagogy of Informatics—assists students to conceptually understand the structure and functioning of computers and software in both historic and contemporary contexts, and be able to infer, take risks and face new challenges creatively. It is important that educators are given many opportunities to discuss and contribute to the emerging Pedagogy of Informatics, and to learn from successful programs such as this one.

The Monterrey Institute of Technology at Mexico City (ITESM-CCM) has faced a great challenge creating a department whose aim is to offer service to faculty who want to create educational technology materials for their courses and to direct instructional technology projects that enhance students' learning. This effort brought together people from several backgrounds including computer engineering, instructional design, graphics design, psychology, and the humanities as well as academics and administration. The result is a well organized department that continues growing and producing better results in terms of the administration, faculty participation from several disciplines, and the creation of interdisciplinary groups in the generation of instructional technology projects.

The Virtual University Department at ITESM-CCM began as the Educational Technology Center two-and-a-half years ago. Originally, its purpose was to provide the equipment for high school and undergraduate students to work on technology-based aids for their classes. The end products included PowerPoint presentations and Magic interactive programs to work with laser disks, computers, VCRs and projectors. Today, this department houses the Instructional Technology Department, which offers services to academics and directs projects in the area, and the Distance Education Department, which manages the administrative and academic functions of receiving courses from our system's main campus.

The Instructional Technology Department, previously called the Multimedia Lab, consisted of a coordinator and two assistants who helped faculty create class projects and use multimedia tools for making better materials for their classes. Although the general administration had asked the department's director to incorporate multimedia applications into the everyday classes and encourage using the equipment in classrooms, few teachers used the facilities because not only did they know little about this department, but they also claimed they were too busy with classes and did not feel the use of technology in their classrooms was very important.

First, to promote the department, teachers attended several seminars where ideas for using interactive multimedia programs as part of their regular classes were presented. A contest was held for other classroom applications, and the winner would receive the multimedia center's support for making the program a reality. It was emphasized, however, that such developments would have to be of a multidisciplinary nature in order to succeed. For example, the notion of instructivist vs. constructivist vs. cooperative education, where the well-known dispute over teaching-learning vs. learning prevails, was introduced to build a debate that would allow the faculty to evolve. However, no leave time or money was offered to those participating in the program.

Almost at the same time, the school's system launched a program for financing educational technology projects, and several professors at our campus submitted proposals. Since many projects proposed creating interactive tutorials or multimedia programs for their classes, the administration asked the multimedia center to concentrate its efforts on one project that encompassed the submitted proposals. The center began an organization of an interdisciplinary group to devise Toward the Virtual University (TVU), which focused not only on the creation of multimedia programs but also in the pedagogical validation of the products and in the technological investigation.

The Educational Technology Center support area, still consisting of only a director, and a coordinator with two assistants, administered the project. As the administrative base of the project, they concentrated their efforts on the faculty who were to create the projects, investigate in the pedagogical area, and assess the technological needs for establishing the Virtual University.
Initial Difficulties

At the beginning of the project and at the implementation of the new department's administration, several difficulties arose:

1. The initial inability for defining a virtual university, and thus for creating a predictable plan for the project in terms of its financial, managerial, and operational essence.
2. The faculty's cultural resistance for using computer technology.
3. The financial difficulties for finding funds for the new technologies.

Although the term virtual university is quite fashionable, it is still undefined in terms of its technical-soundness, standardization-procedures, and educational-potential assessment. From the start, the team refused to adopt the simplistic view of the virtual university as a distributed multimedia and hypermedia environment. Therefore, research and practical results were necessary to make our grant sustainable, and the group decided to assume the risk of an experimental-oriented focus. It was unclear how the final programs and released products would be implemented, and although the scenario presented uncertainty in both financial and operational aspects, the work started.

Lack of defining the virtual university prevented the TVU project from implementing a defined publicity campaign among the faculty, which resulted in misunderstandings about the project's purpose. Many professors thought that the new paradigm would destroy teaching—that the computer would be used a substitute for the real teacher. Therefore, it became increasingly important to erase these myths. However, the cultural resistance was, as it is now, resistant to the program.

Another stumbling block to the TVU project was Mexico's economic crisis in late 1994, which pushed the national computer industry to its limits. It became obvious that a sophisticated laboratory and development software/hardware infrastructure was required for the research to be successful. The team started to work with a limited set of resources, using campus-supplied computer equipment, appropriate only for general purposes as it is not configured for the project's specific needs. This has caused operational and logistic problems in the long run. However, since the project is so important and its future so prominent, the team adapted the available resources. Because of this crisis, the project and the team learned to use only necessary materials, equipment, and human resources.

Cultural Shock Before the TVU Project

Once the multimedia-equipped classrooms were inaugurated, professors were expected to use a PC or Macintosh computer and standard multimedia software to enhance their courses. The campus administration launched a complete training effort, and a campaign was begun where teachers could purchase desktop computers.

The technological aspect of this training was complemented with aspects of a permanent program, Professor Training Program, which emphasizes courses aimed at enhancing the faculty's potential and profile improvement. There was, however, a lack of synergy between the computer and the educational enhancements, probably due to the lack of understanding of the concept virtual university. As a result, the cost-benefit usage of the multimedia classrooms deteriorated because the technology was used simplistically or because its educational, pedagogical, and social values were ignored.

The System-wide Virtual University

The Instructional Technology Department is not alone as a project. The system’s policies have recently shifted for the Virtual University to happen, and a generalized acceptance of the constructivist school (Reeves, 1994) where discovery, self-administration, and learning-to-learn are key factors for a paradigm change has been accepted.

ITESM fosters through its distance education programs and virtual courses new learning paradigms. It offers courses on the high-school, undergraduate, and graduate level. In the distance education programs, depending on the level, students attend class from one to three times a week, and they are responsible for their learning. A teacher who instructs from the main campus and a classroom facilitator guide student learning. However, in some classes, students, especially those on the graduate level, are by themselves.

Virtual courses focus on the idea of teachers acting as advisors. The programs developed at our campus fall into this category, and other system locations will use them next semester. To develop these courses, teachers go to our department, and we give them technical, pedagogical, and instructional design help and produce the computer programs.

To function, the Virtual University at ITESM works as an interdisciplinary group. People who work in this new area come from different backgrounds and different campus locations. To renovate and improve the teaching-learning paradigm, faculty, administrators, technicians, and many more work together to save and improve available technology. The Instructional Technology Department follows this structure and way of working. Although it developed independently and fulfills other needs, this department fits perfectly in the new management guidelines where improvement in the use of resources, teamwork, and interdisciplinary groups are the basis for its functioning.

Retraining Within the TVU Project

It became necessary for professors to adapt to the new methods of teaching. Of the 17 professors who began the
project in 1994, few had notions of multimedia computing; some others had notions of instructional technology; and almost none had combined notions. A leave-time scheme was planned as shown in Table 1.

Table 1. Leave-time Scheme.

<table>
<thead>
<tr>
<th>Human resources</th>
<th>#Professors</th>
<th>Professor Salary*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Leave time (1 group)</td>
<td>17</td>
<td>$639.20</td>
</tr>
<tr>
<td>Total</td>
<td></td>
<td>$10,866.40</td>
</tr>
</tbody>
</table>

*Figures shown in US dollars.

Although $639.20 is about seven times the minimum wage, or enough to pay for retraining, the learning curve was too steep for professors to adapt to multimedia programming, instructional design, and testing (an average of more than 16 hrs/week). The conclusion was that faculty needed additional support strategies for effective teamwork. The teachers used seminars to offer feedback on current development and on pedagogical and social issues. The first meetings centered on adapting to basic multimedia concepts. Today, the faculty has shown a higher level of criticism toward the use of multimedia. One of the main conclusions reached was that technology alone would not trigger educational development.

The Next Step

As a result of the project’s success and the new needs, the Educational Technology Center turned into the Virtual University Department at ITESM-CCM, and the Multimedia Lab became the Instructional Technology Department (DTI) with the laboratory assistants becoming part of expert development teams who familiarized and tutored professors with the new technology. Because the development of the project involved not only technology but also pedagogy, instructional design, and graphics design, the interdisciplinary teams became one of the most important characteristics of the work.

The DTI itself has not grown in terms of full-time people. As part of the budget for the project, we hire graphics designers, an instructional designer, an educational psychologist and a couple of programmers. This allows the Institute to minimize costs and the results, up to now, have been very positive. We have proved that there is no need of a large full-time staff when good planning and teamwork are emphasized and promoted. In addition, the academics who participate also allow us to do without hiring experts in certain areas. They help us and share their expertise not only in general knowledge but in specific topics.

Financial Issues

With an initial budget of $108,000.00 USD, the project has been able to produce great results in the development of:

1. Three virtual university software programs.
2. One complete in-class social, educational, pedagogical validation of all three programs.
3. Six international and six national publications.

This project demonstrated that it is possible to have an increased $/man/hour throughput when a good administration strategy is applied. Given the high cost of technology, we reduced purchases but effectively used existing expertise and resources. Although some people were hired to become part of the development groups, most program participants were already part of the Institute. It is important to mention that the administration and academic departments gave professors leave time for participation. This can be considered a great achievement in terms of administration, and the conjunction of these factors allowed the project to handle its finances more efficiently.

Conclusion

The TVU project has helped us to innovate administration techniques which at the same time helped us to consolidate the new Virtual University at the ITESM-CCM. The experience we gained has allowed us to contribute to the new scheme where interdisciplinary groups, teamwork, and effective use of available resources are vital and necessary.

In examining this year's papers it was fascinating to observe the emergence of several themes which have been present in the process strands of Mathematics education in general. Since their inception in 1989 the NCTM Standards for Curriculum and Evaluation have been quietly (and in some cases quite vocally) changing the face of what constitutes mathematics and how we think about its teaching and learning. This is not, in and of itself, surprising. What is surprising, however, is the degree to which these themes parallel larger themes within Instructional Technology.

At the risk of sounding like a content chauvinist it does indeed seem to be the case that good thinking in mathematics is good thinking in general. To see what we are referring to, consider the following: mathematics is communication; mathematics is reasoning; mathematics is problem solving; and mathematics is connections. These statements are drawn directly from the process strands of the 1989 Standards document. Now, let us consider how the following sounds: technology is communication; technology is reasoning; technology is... somewhat eerie, isn't it?

Taking a cue from this observation we are organizing this year's papers around these strands from the standards: communication; reasoning; problem solving; and connections. Admittedly we have had to "stretch the envelope" a bit beyond what a literal reading of the standards might suggest but we have found this to be a helpful organizing device for this year's crop of papers and hope that you find it to be, also.

Communication

A key part of the communication process lies in insuring that the same mental referent is present in the minds of both parties to the communication. One of the places in mathematics where this rule is most easily violated is in the visual display of quantitative information. Unless clear understanding are present regarding what the data is intended to represent — coupled with standard presentations — it is unlikely that successful communication will take place. Hosticka and Clark take this issue head-on in their paper. This paper is a must read for all of us interested in using graphs effectively. Halpin describes efforts at promoting the dual goals of increasing computer literacy and in preparing teachers to effectively use computer applications in the elementary classroom via a technology integrated methods course. The findings of this study should be carefully examined by all looking at course and program revision.

Of course one must also look at what it is that is being communicated. The role of communication is much different when the students role is to commit items to memory than when the role is to be an active sense maker and problem solver. Connell looks at two broad categories of technology use, Artificial Intelligence (AI) and Intelligence Amplification (IA), and describes impacts upon teacher and student communication which follow from each type of use. These categories have shown to be especially useful groups for opening communication with preservice teachers in their examination of educational technology and its impact upon teaching and learning mathematics.

One of the more fascinating aspects of communication in mathematics lies in the symbol systems used to create representations of mathematical situations. The role which technology might play in this process is detailed by Prokhorov who describes a fascinating object oriented environment within which such representation may be built. This system is well worth a careful investigation. As an added bonus, the supporting software PYTHAGORAS is included on the CD-ROM edition of the annual.

Reasoning

In Wentworth's paper we are reminded to expect a J-shaped change curve in moving teachers toward the standards. Change clearly takes time and this should be...
planned for and it is far too easy to shortcut reasoning by expecting a quick fix. A goal of reasoning is to give the teacher candidate the tools for self-reflection. The described approach to video tape usage can be helpful in this effort as it provides a context within which to reason. As a part of this process the teacher candidate was expected to observe and analyze a range of approaches, examine and revise existing assumptions, work with diverse thinking, analyze existing thought, and examine dispositions toward teaching mathematics.

If we are to expect our future teachers to employ and teach mathematical reasoning effectively we must also adopt new approaches in their preparation. One such approach, MATH-PLACE (Measuring, Analyzing, and Training Heuristically: Professional Learning Assessment, Computer and Equity Education), is described in Freeman's paper. This project and the technology and manipulative rich environment it creates are worthy of note. In particular, the teacher candidates are given the opportunity to reason with the same tools which they will later be expected to teach with. Such an approach is highly important, as it is doubtful that teachers could effectively reason and teach with a tool which they have not experienced.

An environment for teaching linear algebra to preservice teachers, MATLAB, is described in Bouniaev's paper. Here we read a thorough description not only of what was done but of crucial importance as to why it was done. Although the content analyzed in this paper was linear algebra, the sections describing the manner in which actions are developed at various stages of instruction offer insight into the learning of mathematics in general and the application of technology in this process in particular.

Finally, unless teachers can help their students to reason mathematically, we cannot claim success in our efforts in teacher preparation. Vidavocik, Berenson, and Blanton provide an excellent description of a course which was both technologically intensive and geared toward giving teacher candidates specific methods for later use. The creation of the "complex" investigations and activities described in this paper are well worthy of emulation.

**Problem Solving**

Technology changes the playing field of mathematical problem solving in a significant way. Problem solving methods shift from the passive and algorithmic to interactive and generative. Kennewell explores how improvements in learning mathematics may be made by inclusion of technology in problem solving. In doing so he lays out a clear picture of the ways of knowing which are developed by the use of technology and provides well thought out advice and caveats for technology implementation.

One of the problems which must be squarely addressed in applying technology in the mathematics classroom is the alignment between the technology usage and the underlying instructional philosophy of the class itself. Connell presents results from two classrooms sharing a common constructivist philosophy who had agreed to use technology in different fashions. Although significant gains were made in both classrooms, the data clearly supports the need to align the technology use with the instructional strategies.

The beginning teacher faces many problems to which technology could be a helpful ally, but often lack the experience to know where and how. In Milligan and Robinson's work we see how many of the typical tools of technology can be helpful in addressing these very real teacher concerns. In particular, use of the Internet as a resource; effective use of such tools as databases and spreadsheets; technological enhancements for teaching algebra and geometry; and the more staid uses of technology for classroom management purposes. Clearly technology has a place in problem solving — bringing the context of the problems to those relevant to a beginning teacher will go far to helping them realize this potential across the curriculum and teaching process.

**Connections**

In Bloom and Handler's work we see a process described wherein connections are made, not only within the mathematics content, but within one's circle of professional colleagues. Clearly the integration of technology into methods courses will require a team effort which cannot be limited to mathematics experts. A team approach between IT and content is not only helpful it is essential. As we are reminded in their closing statements: "Spread the word about what you are doing. Open communication with other faculty and encourage their efforts at integrating technology." We also see the importance of making connections between the needs and requirements of a single course to the larger program of teacher education to which it is a part.

This connections theme continues in Aotani's paper where we learn of a program which takes the theme of connections and expands it to include connections between institutions. Mathematics educators planning similar programs should read this carefully as a possible guide for their own efforts. In today's increasingly "virtual world", a key element of this success appears to be making an old-fashioned "physical" site visit. This institution-to-institution and person-to-person connection must not be short cut.

One of the major ramifications which technology has made in mathematics lies in the connection between the tool used to think with, in this case technology-based, and the content itself. Algebra provides a compelling case in point where we see radical changes proposed in both content structure and recommended teaching methods. This interaction between content and technology is
carefully examined and analyzed by Williams. We see in this paper a strong argument that inservice and preservice teacher preparation must prepare teachers to make regular use of technology in their own methods. If this is not done it is doubtful that their students will succeed in the changing algebra content which the technology has enabled.

Math Central is a World Wide Web site designed as a meeting place for mathematics teachers and students from kindergarten to grade twelve. Here connections with other professionals may be made to share resources and information. In Maer's, Weston, and Hanson’s paper we read of this site's history, structure, and use since its founding. This site will quickly be added to the bookmarks of our browsers!

Finally, in her description of SkyMath; Lynds remind us that although connections in mathematics education generally refers to mathematics itself there are many other “educational” connections that enhance the learning process. In particular, this paper describes the connections made possible by this project between middle school teachers and university faculty, SkyMath and the Internet, and with SITE itself.

Summary
We hope that this use of the process strands from the standards will prove useful to you in your reading of these papers. Now, as was done in the Standards, let us each remember the content themes which we are each responsible for teaching. This year's papers contain a wealth of information to draw from in this effort and should certainly be carefully examined concerning the light they bring to bear on each of our course and program responsibilities in teacher education.

Michael L. Connell is the Director of the Center for Mathematics, Science and Technology and an Associate Professor of Curriculum and Instruction at the University of Houston, Houston, Texas 77204-5872. Voice: 713-743-8677. E-mail: Connell@cite502.coe.uh.edu

Susan E. Williams is an Assistant Professor of Curriculum and Instruction at the University of Houston, Houston, Texas 77204-5872. Voice: 713-743-4969. E-mail: SEWilliams@uh.edu

Ruth Gannon Cook is a doctoral student in Instructional Technology at the University of Houston, Houston, Texas 77204-5872.
The new educational reforms in mathematics (NCTM Curriculum and Evaluation Standards) and science (AAAS Benchmarks) focus on the improvement in understanding of the content and the integration of technology into instruction. An area of content in mathematics, the display and interpretation of statistical data, is a tool in science to display information resulting from data collection. With the advent of graphing packages and data base and spread sheet programs with graphic capabilities, many teachers are using graphic generation as an integration point for technology. These packages help the user make graphs attractive, accurate in their measurements and eliminate much of the tedium of creating a graph. With the increased use of graphs in information dissemination the need for understanding the correct use of the graphs, the type of information they display, and the likelihood of misinterpretation becomes increasingly more important.

Graphs can do much more than simply substitute for numeric information. At their best, graphs are instruments for reasoning about quantitative information. Often the most effective way to describe, explore, and summarize a set of numbers is to create a graphical representation of those numbers. Of all methods of analyzing and communicating numeric information, well designed graphs are usually the simplest and at the same time the most powerful.

Reporting of data is used to influence people in areas from politics to consumer choices. When this data is reported with inappropriate graphs it is misleading. Misleading information gathered from inappropriate graphs then leads to uninformed choices. This misleading data can be presented either intentionally or accidentally. The two graphs that follow both present the same data, yet the messages received by the viewer are very different, as indicated by the titles.

Creators of graphs and interpreters of graphically presented data, both need to be informed of graphic principals in order to protect against misinformation being disseminated and acted upon.

When using a graphic package to construct graphs the user is given many choices of types of graph and special features within each type. Making poor choices when using the graphic packages often leads to graphs that are easily misinterpreted and are created in such a manner that may inadvertently misrepresent the information contained in the data. The special skills and understandings necessary to insure that data is accurately transformed into graphic format at a level of sophistication accessible to the user is both an art and a science - and a skill that all makers and consumers of graphs should posses.

This paper will discuss and illustrate principals of graphic design, and the issues and concerns in making choices in types of graphs used to present data.

Principles of Graphic Design

In order for graphs to be effective, students need to know how to convey quantitative data. Quantitative data may be presented in bar and column graphs, line graphs, pie graphs, and pictorial graphs. Each graph type has its restrictions, advantages, disadvantages, and data that is appropriate for it's use. It is these mathematical considerations and how they translate to the use of graph producing software that will be the focus of the following discussion.
Graphical Integrity

Graphics for presentation have one of the following purposes (Clagett, 1989): to show component proportions, item magnitudes, trends or time series, frequency distribution of items over ranges or relationships. Incorrect choices and/or decisions in graph construction can produce graphs that present erroneous information and lead to misinterpretations. To address this issue, Tufte (1983, p 77) developed six principles of graphical integrity to ensure that graphs tell the truth about the data:

1. The representation of numbers or axis intervals, as physically measured on the surface of the graphic itself, should be directly proportional to the numeric quantities represented.

2. Clear, detailed, and thorough labeling should be used to defeat graphical distortion and ambiguity. Write out explanations of the data on the graphic itself. Label important events in the data.

3. Show data variation, not design variation.

4. In time series displays of money, deflated and standardized units of monetary measurement are nearly always better than nominal units.

The importance of the data is lost in all the bells and whistles of the graphic display. The interpreter need to works harder at getting the information than should be necessary.

5. The more vertical the slope the more one believes that the change is great. In the first graph, the slope is greater than what the data would suggest. In the second just the opposite is true. There seems to be no change. By changing either scale the physical appearance of the graph and the visual impression of the data is changed.

6. Show data variation, not design variation.

When one reads this graph the horizontal axis interval is unclear and therefore the pattern represented is unclear. Is the information gathered quarterly, yearly, or over the decades.

The rising cost of a hamburger has increased, the graph suggest a much larger proportion of the resources going toward the item than in fact is true. If the cost and income are adjusted for inflation the data suggest that the percentage may have increased only slightly or in fact may even have decreased.
5. The number of information-carrying dimensions depicted should not exceed the number of dimensions in the data.

Languages Spoken by Students

At first glance of this three dimensional graph, the section of the graph that shows the depth looks like a larger portion than the one where the depth is not shown. This is due to the fact that the third dimension on the graph is incorrectly read as part of the area that represents the data. In the above graph the 27% and 23% are much closer numerically than the area of the graphic suggests. Third dimensions should not be used if the data is two dimensional.

6. Graphs must not quote data out of context.

In looking at the graph above the reader would assume a drastic decline in traffic deaths occurred. The interpreter does not know what came before, after or the cause of this decline. Looking at the larger graph (above, right) the interpreter sees that this is an anomaly and that in fact the deaths have not significantly declined over previous years.

In addition to not distorting the data, graphical excellence for Tufte consists of communicating complex ideas with clarity, precision, and efficiency.

**Type of Graphs**

The most commonly used graphs include bar, line, pie, and pictorial and their variations. The choice of which type of graph to use is dependent on the type of data and the kind of comparison to be shown. While the data should determine the types of graphs that are valid to use, research and experience suggests some types of valid graphs are more effective than others.

**Criteria and Consideration in Choosing a Valid Graph Type**

The major criteria in choosing valid graph types is the type of data to be displayed and the interpretation to be shown. Data types are discrete - things that can be counted to be quantified, (item magnitudes, frequency distribution of items), and continuous - things that must be measured to be quantified (trends or time series, frequency distribution of items over ranges or relationships). Interpretations of discrete data, answer questions of the type: how many? how many more? ... Continuous data, is used to show trends, predict future situations, and interpret data between two represented data points ... When the interpretation, is related to part / whole information, what is greater / less, then the graph choice is not solely dependent of whether the data is discrete or continuous.

**Picture graphs** are used for displaying discrete data. This display uses pictures or symbols associated with the subject matter to show quantity. They are less abstract than other types that may show the same data. When picture graphs are used the author must be careful that the representation of numbers, as physically shown on the surface of the graphic itself, should be directly proportional to the numeric quantities represented. i.e. 3 dimensions of a picture should not change for a simple additive or multiplicative numerical difference. In picture graphs, keys always need to be presented. When an icon represents more than a unit, and a part of the icon is shown, the graph will give a general feel for the quantity expressed, not an exact amount.

**Bar graphs** are used when discussing discrete data in exclusive categories. Their strengths lie in their versatility and effectiveness, especially for showing item comparisons. Bar graphs are the easiest to read and interpret when data is being compared. However, **segmented or stacked bar graphs** which are a variation of bar graphs, are often used when subcategories within a data field are to be shown. While they show the subcategories they lose the common reference line for the subcategories and make comparisons among the subcategories for all but the bottom segment difficult. This makes interpretations of the complete graph problematic.

**Line graphs** are used for showing continuous data such as time series and frequency distributions. When discrete data is represented on a line graph connections between categories that do not exist are often mistakenly made.

**Pie graphs** are used when we are comparing parts to a whole. Generally they are good for gross comparisons. Many people get confused when a large number of segments are used or exact quantities of data are desired.
Pie graphs with more than three or four segments can become ineffective in communicating the information desired. The human eye has a hard time discriminating between small angles and comparing the many segments.

Three-dimensional displays are available on many of the graphic packages and are appropriate for use when the data has three or more variables that needs to be represented on a two dimensional graphical display mode. Many of the graphing programs that give a 3 dimensional display option are not true 3 dimensional graphs. To be a true graph you need a third axis that can show variability. This three dimensional feature is inappropriate to use for cosmetic aspects of the graph and can lead to misinterpretations.

Classroom Considerations

Graphing packages allow for any type of data to be displayed in any type of graphic format. Technology is making the problem more pronounced by offering so many choices with a simple click of the mouse. The decision making necessary for correct use of graph types must become a main topic of instruction.

When teachers use graphic packages in classroom instruction the focus of instruction in mathematics can shift from how to draw the graph to how to interpret and display information for quick retrieval and through understanding. The choices we have when presenting data, the display features to best convey information, the titling of the axis and the graph all become the topic of the lesson. Students learn that transforming data into useful information is both an art and a science - and an essential skill. This knowledge of graphing will then be available to the student as they gain information in other areas from graphic representations. Uses of graphs for propaganda purposes will become less effective and the public more informed. Unfortunately, these skills are rarely taught in public school classroom and teacher education programs.

Teachers must also be careful when using and selecting teaching materials. Commercial materials often violate these principles and teachers need to be comfortable in identifying when graphs are inappropriate and helping students to make the same identifications. The following graph was taken from commercially available elementary teaching materials. One wonders what the points on the line graph between the zebra and the bear represent and just how fast that hybrid animal is.

This paper has presented considerations and examples for both teacher consideration and translation into curricular issues when teaching about and using graphic output.

INTERDISCIPLINARY APPROACH FOR INTEGRATING COMPUTER LITERACY IN ELEMENTARY MATHEMATICS METHODS

Regina Halpin
Mississippi State University

The National Council of Teachers of Mathematics Curriculum Standards states “...today’s society expects schools to ensure that all students have an opportunity to become mathematically literate, are capable of extending their learning, have an equal opportunity to learn, and become informed citizens capable of understanding issues in a technological society. As society changes, so must its schools.” (1989, p. 5)

Importance of Computer Literacy in Elementary Mathematics Methods

The recent reform in mathematics education to include the use of computer applications in mathematics instruction has been led by the National Council of Teachers of Mathematics (NCTM). The effective use of computer applications has become a focal emphasis in K-12 schools. Because of this emphasis, teacher education programs are expected to provide future teachers with an education that includes an understanding of how to effectively use computer applications. Across the nation, teacher education programs have addressed this challenge in various ways and at different rates. NCTM publications such as the Curriculum and Evaluation Standards for School Mathematics (NCTM, 1989) and the Professional Standards for Teaching Mathematics (NCTM, 1991) provide guidelines for preparing inservice and preservice teachers to teach mathematics so that precollege students are provided with the skills needed to successfully compete in the 21st century workforce. The new standards focus on teachers encouraging students to explore and discover information using computer software such as wordprocessors, spreadsheets, electronic mail, and network browsers. Given this current emphasis for computer integration into precollege classroom instruction, the question arises whether the use of computers as an instructional resource should be taught in a separate course or integrated into the current courses. Some researchers have supported the integration of technology across teacher education courses (Brownell & Brownell, 1991; McEneaney, 1992; Schmidt, Merkley, Strong, & Thompson, 1994; Russett, 1995; Wetzel, 1993). The integration across the curriculum provides preservice teachers an exploratory and discovery environment to become confident in their ability to use different computer applications for instructional purposes as opposed to viewing computers as an isolated part of instructional resources. One concern that needs addressing is if the use of computers is not connected to the subject matter, will preservice teachers understand the value of computers as an instructional resource?

Researchers have found teachers’ attitudes toward computers affect their willingness to use computer applications in their classroom instruction (Boone & Gabel, 1994; Kluever, Lam, Hoffman, Green, & Swearingen, 1994; Hunt & Bohlin, 1993; McEneaney, 1992; Okinaka, 1992). Therefore, educators must remain focused on how computer applications can be incorporated into the current curriculum. A set of guidelines has been identified (Niess, 1990) that can be applicable to all teachers, regardless of grade level or subject matter, for integrating computer-assisted instruction into the curriculum:
1. Fit the computer to the curriculum rather than the curriculum to the computer,
2. Use the computer as a personal and professional tool, and
3. Use the computer in the learning of subject matter.

These guidelines are important as preservice teacher training programs are modified to incorporate components for training teachers to use computer applications. Such changes will be more effective if the computer becomes a familiar supplemental tool that the teacher considers useful and applicable in their classroom.

Purpose and Objectives

The purpose of this study was to evaluate the effectiveness of preservice teachers’ ability to use various computer applications and apply these applications for teaching mathematics, science, social studies, and language arts after completing an integrated senior-level Block of method courses. In order to provide a problem-solving environment in the mathematics classroom, elementary teachers must feel confident in their ability to use com-
puter applications as tools for solving problems. Thus, the primary focus of this study was to produce preservice teachers who were computer literate and confident in their ability to use several computer applications as an instructional tool and gather data in an effort to determine how to effectively prepare preservice teachers to use computer applications in the elementary mathematics classroom. Research studies have reported that most preservice teachers entering today's teacher education programs are familiar with using a word processor (Fox, 1996; Sheffield, 1996) more than any other computer application. However, there has been a need to investigate the most effective approach for integrating computer training into preservice education (Waugh & Rath, 1995); specifically, elementary mathematics education. Therefore, the objectives of this study were to expand the current research and (1) assess elementary preservice teachers' computer skills when they enter into the integrated mathematics methods course, (2) determine if elementary preservice teachers' computer skills improve after completing a technology integrated mathematics methods course, and (3) evaluate preservice teachers' ability to develop an opinion of how technology should be used in the elementary classroom.

**Method**

During two semesters, pre- and post questionnaires were administered to the preservice teachers completing an integrated elementary method courses in mathematics, science, social studies, and language arts. These courses were taught as a Block each semester. A questionnaire was designed to assess students' use of computer applications prior to entering the senior Block. Students were asked to choose from the following computer applications and to check all that they felt comfortable using: word processor, spreadsheet, e-mail, and World Wide Web browsers. This pre-information was used by the faculty to develop interdisciplinary instruction and assignments emphasizing the effective use of computer applications in the elementary classroom. As part of the course, all students were provided an e-mail account to be used during the semester. At the end of each semester, students completed a post questionnaire. They responded how frequently they used the computer applications during the semester, their post-comfort level on using the computer applications, and their opinion of how they would use these computer applications in the elementary classroom.

During each semester, the students used computer applications to complete assignments in all four method courses. These assignments ranged from using the word processor for lesson plans and spreadsheets for graphing to communicating with peers and completing assignments via e-mail. As an example of an interdisciplinary assignment, an observational experiment and graphing assignment was designed by the mathematics and science instructors. During the Fall semester, the students conducted an observational experiment as part of the science methods and graphed the results as part of the mathematics methods. All of the students were shown how to use spreadsheets and required to use the computer application to complete the assignment. During the spring semester, the same assignment was given and the students were introduced to spreadsheets but were not required to use the computer application to complete the assignment. The purpose was to assess if the students would transfer their computer skills and choose to use spreadsheets even though it was not a requirement of the assignment. At the conclusion of each semester, the post-questionnaire provided the preservice teachers the opportunity to describe their perception of the role of technology in the elementary classroom based on their experiences during the semester.

**Results**

The students' responses prior to the class and at the end of the class concerning their level of comfort in using the various computer applications are given in Figure 1. As reported in the research, a majority (76%) of the 73 students reported they were comfortable using a word processor when they entered the semester. However, only 31 (42%) reported they were comfortable using e-mail and only 23 (31%) were comfortable using a World Wide Web browser. After completing the Block of method courses, the students were more comfortable using all three computer applications.

![Figure 1. Students' Reported Ability to Use Computer Applications.](image)

The students' pre and post responses for using spreadsheets are given in Figure 2. The purpose for reporting the preservice teachers' use of spreadsheets separately was to compare their reported ability to transfer the use of spreadsheets for instructional purposes based on whether they were required to use the application to complete an assignment.

During the fall and spring semesters, 18 of the 40 students (45%) and 6 of the 33 students (18%), respectfully, reported they were comfortable using a spreadsheet when they entered the Block. During the fall semester when the students were required to complete the graphing assignment using the spreadsheet, 78% reported they were
comfortable using the computer application by the end of the semester while only 45% responded in the same manner after having the option to choose their method of graphing. Of the 33 students during the spring semester, 13 (39%) chose to use the spreadsheet as a graphing tool even though it was not a requirement. The remaining students turned in hand drawn graphs.

![Spreadsheets](image)

Figure 2. Students’ Reported Ability to Use Spreadsheets.

The students’ were asked how frequently they used the computer applications during the semester. It was not surprising that all of the students reported they used e-mail and wordprocessors often because so much of their work required them to do so. However, the students’ responses to their frequency for using spreadsheets supports the results previously reported. During the fall semester when the students were required to use spreadsheets for an assignment, the frequency of use was higher than during the spring when the use of a spreadsheet was optional. The use of a World Wide Web browser was approximately the same during both semesters and this was expected considering the primary use was to option lesson ideas and plans to use in the classroom. The application was not used by the preservice teachers as an instructional tool with the students in the elementary schools.

Summary

The results of this study can assist other preservice education programs as modifications to elementary teacher education programs are made for incorporating the usefulness of computer applications so preservice teachers can enter the 21st century classroom with the positive attitude and confidence needed to teach mathematics in a technological society. The data suggest that it was important to integrate the use of computer applications into the already existing preservice methods courses as opposed to teaching the computer applications as a separate course without connections on how to use the technology in the elementary classroom. Furthermore, the interdisciplinary approach provided the preservice teachers with the much needed emphasis on the importance of teaching mathematical concepts as an integrated topic with other subjects in order to provide precollege students with the understanding and appreciation for mathematics. Based on the preservice teachers’ responses, they entered student teaching with experience and knowledge of how to use computer applications in the elementary classroom. Some of the preservice teachers gave more than one purpose. The results are given in Table 2. The results suggest that the preservice teachers responded based primarily on what they had observed and experienced during the semester. However, the responses relating to using computer applications as an enrichment, remediation, or research tool was not discussed during the semesters. Therefore, these responses reflected the preservice teachers’ ability to transfer their knowledge and think about other purposes for using the computer applications in the elementary classroom. Based on informal discussions with the students, a note should be made that the students probably responded based on one or two applications that they felt were most important. All of the preservice teachers reported that they felt technology has a place in the elementary mathematics classroom. Even though the question was not asked, many of their responses included a sentence explaining the importance of teachers entering the classroom with confidence to use these computer applications if they expect the students to learn how to use computers.

A content analysis was conducted to determine the preservice teachers’ perception of how they would use the computer applications in the elementary classroom. Some
computer applications in the classroom based on their own experiences and the demonstrations used during the semester. The author is presently collecting follow-up data to determine how frequently the preservice teachers are applying their computer skills in the classroom as an instructional and management tool and transferring their knowledge in order to discover new ways they can use the computer applications.

A note should be made concerning the importance of having an accessible computer laboratory for the preservice teachers to use. This was a major problem during the fall semester because the preservice teachers found the computer laboratory closed at 5:00 p.m. and was normally reserved for instructional purposes during the afternoons. For the spring semester, this problem was slightly improved when the computer laboratory extended the hours of operation until 9:00 p.m. However, the preservice teachers still commented that they do not have easy access to the computers during the afternoons. This is an important concern and should be addressed by preservice education programs before the use of computers are incorporated as a major component of the curriculum.

AI or IA: The Choice Is Yours!

Michael L. Connell
University of Houston

In this paper I would like to propose two major categories to use when considering instructional software for use in mathematics education. I have found them to be simple to remember and reflective of much of the current thought regarding uses of technology in mathematics education. Furthermore, they make for an easy way to describe organizing systems for use by in-service teacher candidates. The first of these categories is Artificial Intelligence (AI). The second proposed category is Intelligence Amplification (IA). The same two letters, but reversed, and oh what a difference that reversal makes!

AI and IA: A Working Definition of Terms

AI in Education

AI in education has a lengthy and prominent history. Thanks to the significant impact from the cognitive advances of the last 15 years we are now able to provide integrated learning systems (ILS) of great complexity and power. As systems become more and more powerful, the justification for their use as a teacher replacement model of instruction gains in popularity. It is ironic that some of the findings from the cognitive flexibility lab, which stress the importance of a personal interaction with the material and the role of the teacher as guide and mentor, have been used to create ILS systems with the explicit goal of teacher replacement.

Given the strength of parent perceptions supporting the computer-as-teacher replacement model (Wentworth & Connell, 1995; Harnisch & Connell, 1991), it is not surprising that growth in this area is inevitable. In part this growing trend can be directly traced back to the AI and cognitive philosophy which undergirds much of the AI and computer-aided instruction (CAI) program development. Despite an interest in inner mental representations, most educational AI programs have focused on how to guide a learner across a complex domain area in the same fashion as an expert in that field would guide them. As will be shown, this is diametrically opposite from the IA perspective.

IA in Education

IA in education takes a fundamentally different approach. In IA, the roles of the machine and the user are reversed. Instead of having a system in which the user responds to the machine, you have a system where the user uses a set of provided software construction tools to actively construct more powerful personally meaningful representations of problem spaces, and tools to work within domains.

Examples

If we take an information-centered perspective, what tools and abilities are necessary to succeed in an information society? How can educational technology be used as...
software may obscure rather than clarify this difficult problem. Because the variable and constants switch roles in the functions' parameters. In other words, the involvement and leaves the student active control only over the functions' parameters. In other words, the variable is not variable for the student but the constants are. The computer assumes the role of an active listener that will attempt to do exactly what it is told, as opposed to a pre-programmed instructor requiring a specific type of answer. Furthermore, idiosyncratic working styles and representation techniques may be created and serve as tools for leveraging the user into a knowledge creation mode, as opposed to the knowledge replication mode fostered in ILS programs. In addition to providing the students with an opportunity to share their developed expertise, the computer in these settings becomes a tool which encourages the student to engage in sense-making and self-reflection.

If we fail to carefully identify exactly what our desired educational outcomes are, the computer can lead to unexpected problems. In particular, the representation modeled in the system may not be one which is advantageous in the broader picture; furthermore, the representation selected by the AI modelers may bear little or no resemblance to that actually used by the learner. This is a weakness in almost every ILS program in education.

Typically what is done is to model expert performance, which does not include all the dead ends and muck which the expert went through to develop it. The learner in such a system is presented with what represents the end level trace of an incredibly complex act of meaning construction. It is little wonder that so many students tune out of ILS programs.

To see one example of this trend, consider a graphing module used in an ILS system described in Goldenberg (1988): "Software that graphs automatically from left to right sweeps over a domain in x without any student involvement and leaves the student active control only over the functions' parameters. In other words, the variable is not variable for the student but the constants are. Because the variable and constants switch roles in many graphic packages, the unthinking use of such software may obscure rather than clarify this difficult concept. ... there is also the possibility that a novice to graphs would dismiss graphs completely as How the computer behaves when you type x's into it."

Although well-intentioned, this proved to be a non-trivial intervention likely to have significant implications, not all of which are advantageous. The very features which contribute to a computer package suitable for a skilled user - speed, accuracy, flexibility, etc. - make it unsuitable for a beginning student attempting to construct an understanding of what is meant by a graph. The computer must be more than a black-box which always gives the right answer or provides the optimal path. The box itself must be transparent and its methods understandable to the student. In an IA system, the students' would have designed the graphing module for themselves (using admittedly a carefully guided construction of meaning) and have a deep understanding of all the assumptions made and the implications thereof.

**Discussion**

Typically AI programs take a product-centered approach toward instruction and adopt the view that "faster is better" as in "get the student to replicate the expert level of performance as modeled in the AI program as accurately and efficiently (ie, fast) as possible. Within this orientation, educational programs are designed in a fashion to take full advantage of the computer's speed in enabling a student to "produce" the end product as quickly as possible. In fact, such a perspective is clearly reflected in many of the general CAI models of feedback utilized in available educational software. In such programs, the computer provides immediate feedback to students responses to pre-determined questions from within a specified content domain. The tremendous speed of the computer makes it possible for the student to know within milli-seconds whether or not the question was addressed correctly. In general CAI models, this type of immediate feedback is preferred and planned for.

On-the-spot responses may be desirable for learning in content domains that are very restricted and require a high degree of memorization such as learning spelling lists and building vocabulary. However, the immediate feedback produced by implementing this model of instruction is not effective for developing higher order thinking skills. Although the student knows whether or not the answer provided was right or wrong nearly instantaneously, the basis for the decision does not belong to the student. Rather than the justification for the problem's solution being internal to the student, it has become external to the student and belongs to the machine. The computer, in this case, does not provide sufficient time for the student to think about the implications of the problem or to do self-confirmation - two of the more important skills in an information society. To put it bluntly, the computer has...
done away with the time necessary for the student to think and internalize.

If a student is to internalize and construct meanings from experiences, there must be time to reflect upon the nature of the experiences and how they connect with the students' existing knowledge base. When a student knows within a split-second whether or not a given answer is correct, there is no need for further reflection concerning one's own beliefs, intuitions, prior experiences, relation to other units of knowledge, and so forth. We do not want to reinforce the assumption that all that counts is the correct answer, and yet this viewpoint is being presented literally millions of times each day in numerous CAI programs.

Issues resulting from an inappropriate use of the computers speed of response are not the only items which should be considered in adoption of computers in an educational setting. Programmed learning as typically implemented in AI shells has the unfortunate characteristic of breaking down concepts into bits and pieces to facilitate presentation. From a product-centered viewpoint, fragmentation of curricular elements is viewed as a positive attribute as it contributes to a high rate of correct responses and enables the machine to ascertain right/wrong immediately and to make decisions regarding optimal path of presentation quickly and efficiently (Harnisch and Connell, 1991).

However from an IA perspective great care must be taken in selecting what knowledge units and connections to other knowledge units are presented. In an IA system, the user would construct their own knowledge units and representations, and establish the linkages with other (also student-constructed) tools, representations, and concepts. Despite their ability to model expert performance, AI models often fragment broad conceptual areas into a number of seemingly unrelated special cases to the novice mind. When this is done, we often succumb to the illusion that we are making progress when in actuality all we are doing is memorizing bits and pieces and forfeiting the greater power derived from an understanding of the coherence and relationships between ideas.

Conclusions

The range of problems which are being addressed by computer applications have steadily increased with its uses limited only by the imagination of those who would be users. Concurrently with this general technological growth, there has been an increasing view that the use of technology, in and of itself, will solve many of our problems. However, unless we ask the difficult questions concerning at what point technology enters into educational efforts and the effects upon desired educational values, we run a great risk of misapplication which could seriously damage the educational enterprise; on the other hand, when the goals, values and assumptions of education including a careful examination of the role of the teacher

- are carefully considered the adoption of technology may well live up to its promise as a powerful educational tool.

Michael L. Connell is director of the Center for Mathematics, Science and Technology and an Associate Professor of Curriculum and Instruction at the University of Houston, Houston, Texas 77204-5872.

E-mail: Connell@cite502.coe.uh.edu
The effectiveness of computer environments in mathematics education is often directly related to the conformity of objects provided by a language to the educational task at hand. But the potential uses of computer technology application are extremely varied. Furthermore, different mathematical models may be mixed when describing complex problems and the objects used to investigate them. This paper will not discuss general problems of using complex objects in development of corresponding models, scientific languages, and representations. We will assume in the paper that the objects are already created and the problem consists in their computer description.

So, there exists a problem: what language paradigm should we use for description of complex many-sided systems? Solution of this problem influences all attempts to reduce natural descriptions to a computer form. In particular questions such as how to work with the software, etc. There are different approaches which have been used to solve this problem. The main one is based on plurality of classes of models that could be represented in some programming paradigms. For example, extremely wide variety of models may be represented in algorithmic paradigm (Wirth, 1981). So, one approach might be to teach everyone to reduce descriptions in various applied areas to algorithms.

This is characteristic of classic programming approaches. For example, we can use a single language, say, C as general purpose tool to be adapted to each situation. It is very easy to teach a single language, but then we must study rules for transformation of any models' provided objects to forms we actually use in addressing problems. This can be pictured by imagining the processes necessary to create a program useful for reducing differential equations to a program in C. The algorithmic paradigm could be changed in the reasoning to functional or logical one with the same success.

An alternate approach would use a specialized languages' object set, and software, which would correspond to various paradigms (Floyd, 1979), (Gulliksen, Jonson, Lind, Nyargen & Sandblad, 1993). Then the users can choose the best match between paradigm, language, and software based upon what is most convenient for any given task at hand. This can result in great increases in efficiency. For example, it is faster to code a paper manually in TeX style, then to do it in C, but not so fast, as in WYSIWYG-based languages.

Further development in this direction includes ideas of integrated problem solving systems and a multiparadigm approach as advocated by Budd and Pandey, 1995 and Hailpern, 1986. In this case, the variety of different possible combinations makes it is very difficult to teach and to master different software. But it becomes very convenient to use software system developed for a specific area if one is already working in the field.

**Microcontext Approach**

The application of System Analysis theory and Object Oriented Design approaches to creating complex objects is becoming more commonplace. Such approaches are now widely used for document's organization (HyperCard and similar), and for linking of relatively big items in modern operating systems (as OLE in MS WINDOWS and others). In this paper we apply a similar idea to languages' and models' hierarchy Prokhorov, 1992-1995.

The essence of the approach might be viewed as:

1. Any information specification (except atomic ones) is regarded as a hierarchic structure, a superposition of more simple ones.
2. Each of the sublanguage-layers is oriented towards a much narrow class of operations, and its set of rules is much compact.
3. For every sublanguage-layer we have: (a) an independent internal idea of the sublanguage, and, (b) an independent form of external representation of the sub specifications (including media type).
4. A few universal actions are presented for each layer, such as (a) creating/viewing/editing, (b) interpreting or/ and translating/compiling, etc.
5. Independent (a) hardware, (b) software may correspond to each phase.
6. There are treaties supporting the multipurpose use of every language-layer, the multiplicity of couples of micro languages, for which the components mentioned in V can be used together.

So, the main idea of the microcontext approach is that we should not find or create "the best language." It is better to use a set of specific sub-languages, forming for a particular task a problem-defined hierarchical language. Software corresponding to each of micro-languages should support the descriptions at all stages of the description's life (preparation, interpreting, etc.), dynamically forming software environment for the composite language (as compound editor, compound interpreter, etc. Note, that from this viewpoint, even the simplest programming language (as Pascal, LISP, PROLOG, language of interaction with text processor, etc.) is a complex structure. It would not be considered as procedural, logic, or functional, ... language, but a multiparadigm one.

This nested object approach is very effective for application in education. One can imagine the study of common languages consisting of dissecting common languages to single-paradigm atomic sublanguages. The basis of that part of curriculum may be a study of basic paradigm principles' set out of particular languages. Further, it is useful to search identical basic sublanguages in common languages to better understand a particular language's nature. Furthermore, it is fruitful to consider the set of basic language paradigms when hierarchical task's model or representation is developing.

Ideally one would have software supporting the layered approach with independent layers, so we could connect each with other in arbitrary combinations. Note, that this unifying idea may be applied to all levels of models hierarchy consideration, from low to top-level philosophy about complex problems (Figure 1).

**Pythagoras Media**

The main elements of such a microcontext layered technology are realized in the PYTHAGORAS media. This program has currently been developed in two versions, for MS DOS and WINDOWS. This media provides ease of use for the beginner plus extreme power for the more experienced user.

Characteristic features of PYTHAGORAS include:
- support of several programming paradigms on the top levels (algorithmic, functional, and syntactical ones),
- support of the microcontext multilanguage technology, that allows to use sublayers of the language, supported by another environments.
- inclination to graph descriptions with animation, speech, and sounds,
- wide use of a game component,
- high success of use the same software by both little kids and Academy researchers.

Depending upon the available hardware, PYTHAGORAS supports several internal layers (algorithmic, formulae and syntactical languages, language for descriptions of data types, turtle graphics, etc.), and is open to attach arbitrary external software to form sublanguages. Note, that attached software, supporting a sublanguage, may operate on far computer, accessible through Internet or/and LAN.

Included in the supported graph languages are methods for structured descriptions of algorithms, data types, formulas and syntax in the media with both internal and user-defined objects denoted by icons. Some simple programs might be built without use of any text descriptions at all. So, a student could handle PYTHAGORAS based solely upon visual thinking (Stooder, Taylor & Macie, 1995), (Raeder, 1985).

---

**Figure 1. An example of a general chart of languages' relations.**

Depending upon the available hardware, PYTHAGORAS supports several internal layers (algorithmic, formulae and syntactical languages, language for descriptions of data types, turtle graphics, etc.), and is open to attach arbitrary external software to form sublanguages. Note, that attached software, supporting a sublanguage, may operate on far computer, accessible through Internet or/and LAN.

Included in the supported graph languages are methods for structured descriptions of algorithms, data types, formulas and syntax in the media with both internal and user-defined objects denoted by icons. Some simple programs might be built without use of any text descriptions at all. So, a student could handle PYTHAGORAS based solely upon visual thinking (Stooder, Taylor & Macie, 1995), (Raeder, 1985).
PYTHAGORAS orients student to use a top down approach to design (Reek, 1995) as their primary approach. Nevertheless, the bottom up approach is still possible: a student may use early developed modules (for example, procedures) for new modules’ creating later, more powerful representations which could be modules created in another environment.

Applying the open microcontext technology in PYTHAGORAS allows the use of the algorithmic language of PYTHAGORAS as meta-language for any external languages. If we have properly defined the sublanguage, then we can use objects created in any sublanguage as common operators of the program. PYTHAGORAS will automatically starts the corresponding editor when we edit the operator, it will then start the corresponding compiler and initiate the corresponding interpreter during the execution phase.

Algorithmic and Formulae Language Layers

Two kinds of operator sublanguages are currently available. The first one is the language supported by built-in compiler and interpreter. A student could easily use a graphic algorithmic language as top layer of PYTHAGORAS (Prokhorov, 1988), (Parker, 1995). The second currently available supported language produces a graphic version of C. Development of the software to support graph versions of C++ and JAVA is currently in progress.

The algorithmic layer of PYTHAGORAS supplies visualization with animation of the next objects and processes:

a. a chart of a program (scenario),
b. a process of the program’s creating,
c. a process of the program’s execution in a program’s chart;
d. a process of environment’s change during the program’s execution, for example, results of a turtle’s activity, as in LOGO (Papert, 1981).

When a program is running in the ordinary mode, the program will be executed as in common programming environments. If a program is running in a mode with executor’s visualization in children metaphor, the turtle graphics’ commands will be executed with moved turtle or pencil, and will be accompanied by corresponding sounds.

The Game Component in PYTHAGORAS

Gaming components increases students interest (Kolling, Koch & Rosenberg, 1995). PYTHAGORAS currently allows many enjoyable metaphors to be used for the algorithmic chart’s representation. These include math graph, railroad, catacomb and others. A student can choose various metaphors of representation of the same program in different times, as he/she likes. For example, railroad metaphor is very fascinating for young children: in this metaphor, an algorithm is represented as aggregate of road-beds with railways switches, stations and so on (see figure ). Creating a program is accomplished by using a set of tools, associated with the used metaphor. For example, a
Experience of the Approach’s Application in Education

The multi-metaphor layered approach was applied over five-six years in curricula in Ural State University (Computing Mathematics), Ural State Tech University (System Engineering, and Information Technologies), Regional Evening and Summer Schools for Talented Children, Ural Institute of Humanities, and others. The approach is used as the base of curriculums.

PYTHAGORAS was used to teach pre-school children. Kids of five or six years old enthusiastically mastered the media. The experience shows, that use of PYTHAGORAS for children really transforms boring “programming” into a very fascinating game; actually, children sense the media handling as kind of game. However, even young children understood basic ideas of algorithm programming at this earliest stage of interaction and created relatively complex programs during this “game.”

A version of the media was used as the only environment at the National Team Olympiad in Computer Science. Mastering PYTHAGORAS was one of the main problems at that 12-hour Olympiad. Participants (four high-school students per team), had to develop the popular Russian game TETRIS in PYTHAGORAS, but no student was familiar with this environment before the competition. Participants had demonstrated a progress in utilization of the approach and media, including usage of sub-systems. A quarter of the teams had developed working versions of the game.

Concurrently, a version of the media is used for development of complicated multiparadigm multi-component complexes. As example we would refer to a system for airplane’s flight modeling (including atmosphere, plain dynamics, control system, etc.) in multi-machine distributed computing environment on the base of PCs, local network, INTERNET, and powerful multiprocessor computing machine. Hence, students may to create distributed programs in PYTHAGORAS, using LAN and INTERNET resources.

So, the same software might be used successfully by different groups of users: pre-school children, scholars of all ages, university students, and Academy researchers.

Acknowledgments

The author would like to acknowledge and thank the team of the PYTHAGORAS programmers: Serge Kalugin, Alex Kopelev, Roman Pekhov, Serge Puzhevich, Dmitry Smirnov, Dmitry Toropov, Denis Zuyev.

580 — Technology and Teacher Education Annual — 1997
This study investigates students' beliefs about the teaching of mathematics as revealed in their review of the video tapes made of lessons they taught. The results indicate that video taping had an impact on preservice teachers' ability "to examine and revise their assumptions about the nature of mathematics, [and] how it should be taught?" (NCTM, 1991). As part of a larger study involving a cohort of elementary education preservice teachers, students in an elementary mathematics methods class were videotaped three times, in their first lesson, a middle lesson, and their last lesson. The first tape identified one student as using constructivist methodology in her work with elementary students. When interviewed during a review of the video tape she expressed concern that she was "not doing 'it' right." She felt that her lesson was a failure because the students were having a hard time learning the concept she was teaching. The researchers reviewing the video and the preservice teacher's interview about the video were surprised at her reaction to her instruction. They felt that she was using constructivist practices that had been taught in the mathematics methods courses. This study follows this preservice teacher through her three video sessions and talk-alouds to see if her beliefs about her practice change towards the Standards or if she begins to change her practice away from the Standards.

Theoretical Framework

Since the National Council of Teachers of Mathematics (NCTM) published the Curriculum and Evaluation Standards for School Mathematics (Standards) (1989) and Professional Standards for Teaching Mathematics (Professional Standards) (1991), preservice programs for teachers of mathematics have been reevaluated in terms of how well they meet the specified goals being proposed. The Professional Standards for Teaching Mathematics (1991, p.160) states as objectives that preservice programs for teachers of mathematics should:

a. examine and revise their assumptions about the nature of mathematics, how it should be taught, and how students learn mathematics;

b. observe and analyze a range of approaches to mathematics teaching and learning, focusing on the tasks, discourse, environment, and assessment;

c. work with a diverse range of students individually, in small groups and in large class settings with guidance from and collaboration with mathematics education professionals;

d. analyze and evaluate the appropriateness and effectiveness of their teaching; and

e. develop dispositions toward teaching mathematics. (p. 160)

Videotaping has been shown to help with these objectives. Over a decade ago McConnell and Fages (1980) found that the self-confidence of pre-service teachers increased after receiving videotaped feedback on their teaching. Anderson, Frager, and Boling (1982) found that students who viewed videotaped sessions of reading instruction demonstrated more effective teaching techniques than those who had used role playing to improve instruction. Volker, Gehler, Howlett, and Twetten (1986) used videotaping instructional modules to help their students evaluate the behaviors of classroom students. The review of videos has been shown to increase the depth of reflection and self-analysis using the ideas and questions of others (Lasley & Matczynski, 1995). Sweeder and Bednar (1995) saw videotaping as an aid in reducing student anxiety and promoting student achievement. This study seeks to analyze the use of videotaping lessons of preservice teachers and the value of having the preservice teachers review the tapes with their instructor to examine what they saw in their instruction. Does this process change the preservice teachers beliefs about the NCTM Standards and their instruction?

Method

At the onset of an elementary mathematics methods course, 18 cohort students completed a Likert-type instrument designed to measure beliefs towards mathemat-
ics, specifically towards Standards-based reform ideas, the Standards’ Beliefs Instrument (SBI) (Zollman & Mason, 1992). All students were videotaped (Erickson, 1986) at least three times for their mathematics methods class. The lessons videotaped were initially with a small group of elementary students and then with a whole class of elementary students. Mathematics lessons were taped later when the preservice teachers were actually student teaching. All students were asked to talk-aloud (Kagan, 1992) immediately after the interview (Mishler, 1986) immediately after the videotaping had on the change in students beliefs. The talk-alouds and the final interviews gave some insight into the importance of the videotaping in the changed beliefs of the students.

During the talk-alouds students made several comments about their dislike of the videotaping. They mentioned being self-conscious during these lessons. They did not like having the video camera in the room as they taught. It made them worry about things other than the lesson they were teaching. One student said, “There was a problem with the tape. We were trying to figure how to get it taped over, and we couldn’t tell if it was recording or not. The light wasn’t on, that is usually on when it is recording. And yes, I do look odd. We’ll try not to think about that.” Another student worried about how the elementary students responded to the camera. She said, “I think the kids are talking so quietly today. Maybe it’s because of the video stuff.” At the end of one talk-aloud one student commented, “Well it’s no fun watching yourself. You get caught up in watching your physical appearance and you are thinking ‘Oh my gosh, I shouldn’t do this and do that.’ But, um, I guess I felt positive about it.” Most of these types of comments were made at the beginning of the talk-alouds. After the preservice teachers and elementary students became accustomed to having the equipment there, they seemed to forget about it. Then the preservice teachers were able to focus on their instructional practices.

The SBI scores of the students in the cohort group are listed in Table 1. (The line in bold is of a student who will be discussed later.) In all but one case the scores dropped indicating that the students had improved beliefs about the NCTM Standards. (Lower scores are a positive response to the Standards.) The highest change in score was 12 points and the lowest positive change was 2 points. One student had a score that went up 6 points indicating a negative effect of the class. The student with this score had been the most resistant to the videotaping and other assignments in the course. The mean change was 6.2 points and a two-tailed t-test comparison of the pre- and post-test scores was significant.

Because videotaping was not the only aspect of the class, a major question of this study is what impact the videotaping had on the change in students beliefs. The talk-alouds and the final interviews gave some insight into the importance of the videotaping in the changed beliefs of the students.

During the talk-alouds students made several comments about their dislike of the videotaping. They mentioned being self-conscious during these lessons. They did not like having the video camera in the room as they taught. It made them worry about things other than the lesson they were teaching. One student said, “There was a problem with the tape. We were trying to figure how to get it taped over, and we couldn’t tell if it was recording or not. The light wasn’t on, that is usually on when it is recording. And yes, I do look odd. We’ll try not to think about that.” Another student worried about how the elementary students responded to the camera. She said, “I think the kids are talking so quietly today. Maybe it’s because of the video stuff.” At the end of one talk-aloud one student commented, “Well it’s no fun watching yourself. You get caught up in watching your physical appearance and you are thinking ‘Oh my gosh, I shouldn’t do this and do that.’ But, um, I guess I felt positive about it.” Most of these types of comments were made at the beginning of the talk-alouds. After the preservice teachers and elementary students became accustomed to having the equipment there, they seemed to forget about it. Then the preservice teachers were able to focus on their instructional practices.

The preservice teachers had many comments about the videotaping in their final interviews. Most students did not see value in the videotaping. One student commented to the interviewer that she didn’t like the videotaping and having to watch herself on video. She didn’t see any purpose in this at all. She felt it would have been more helpful to have an “expert” sit with her, so she could learn something from it. Or she would have appreciated more direction for critiquing herself. This student, in her first
talk-aloud did not mention mathematics at all. She commented on the students, discipline, how she looked in front of the group, but nothing about the subject of the lesson. Her comment to the interviewer was that she didn’t understand the purpose for the videotaping or the talk-alouds after them. She, along with the others in the course felt like guinea pigs—just running through mazes and seeing no purpose in what they were asked to do. One student did seem to understand that the videotaping was done not just for research purposes, but as part of her learning when she said, “Videotaping was not just part of the research. But that’s part of the educational process, although the professor would use that for research later.”

This same student did not always enjoy the videotaping. She also said, “A lot of people resented doing [the videotaping] because it was like a video factory, video cameras everywhere. It disrupted the students because there were cameras in their classrooms.”

The comments from the talk-alouds and interviews do not support a positive change in beliefs about the Standards coming from the practice of videotaping. However the researchers noticed that the practices of the preservice teachers supported Standards-based instruction as the course progressed. A look at one student helps to explain how the videotaping and talk-alouds encouraged the preservice students to change their instructional practices.

**Importance of Talk-Alouds in the Change in Beliefs**

In viewing the first video tapes, the researchers determined that the instructional practices of the preservice teachers matched their belief in the Standards. This was not true of Ann. Ann was a student identified early as having average feelings about the Standards in the original SBI survey. Ann’s SBI score of 31 was just at the average of the 18 students, expressing beliefs neither strongly for nor against Standards-based reform. Her final score was 21, a strong change of 10 points. The review of Ann’s first video identify her as using the Standards in her instruction, and her talk-aloud identified her as one who thought she was “doing it wrong.”

Ann’s first taped lesson was one that she had prepared only 30 minutes before she presented. In the lesson Ann asked the students to discover the concept of equivalent fractions through manipulatives. On the video the students were comparing shaded parts of a circle. One circle was divided into two equal pieces with one piece shaded and the second circle is divided into four equal pieces with two pieces shaded. Ann asked the students which shaded part of the two circles is bigger. She asked one boy, “If both of these circles were pot pies which shaded part of one of the pies would you want?” When Ann was talking about this part of the tape she said, “I could have probably done a better job of explaining why two-fourths is the same as one-half. I didn’t deal with the numbers very much, I just dealt with the size.” Later she said, “Here they understood what they were saying, but I think that if I could have shown them that six-twelfths was a half of a whole bar, just like a half bar was a half of a whole bar, I think that would have been more effective in helping them understand equivalent.”

The researchers who viewed Ann’s initial tape in this study commented on how well the lesson met the NCTM Standards. During her talk-aloud Ann was concerned that she did not tell enough. However the researchers agreed that her lesson allowed the students to discover the concept. She seemed to know that the students understood the concept, but she was concerned that she did not explain the concept to the students.

As the semester continued, Ann taught another lesson and talked about it. The researchers looked at the video to determine if she had changed her instruction to telling. They also listened carefully to her talk-aloud to see if she had become more confident in the students’ abilities to construct an understanding. The researchers and cohort leader spent much time discussing how to help this preservice teacher recognize the Standards in her instruction and value the methods that were so natural to her. In her second talk-aloud Ann talked about what she saw in her instruction, and she began to comment that the students did not need to be told everything. Ann said, “Mary wanted me to tell her the name of that shape, but I wanted to stress the point of the lesson which was that they look at the shape. At the end I wanted them to know the attributes of the shapes, not just the name, but why some shapes are the same, have the same name. I find that in teaching I have to make so many decisions in teaching about what to tell students and what not to tell”. She expressed the concern that she could not listen to every group of students as they discussed the shapes. She knew that some students were working on task thinking and discovering the ideas of the lesson. She also worried about the social noise. At the end of the talk-aloud she said, “They saw a lot about the shapes. There was good participation.” The preservice teacher began to trust her students’ abilities to discover. The researchers felt that Ann was moving in the direction of changing her views of the Standards. Early in her lessons she taught by the Standards but did not trust what she was doing. Later Ann continued to let students work in groups to discover meaning and she valued the process. She trusted the ability of the students to discover. She trusted the process of the Standards.

**Conclusions and Significance**

Most students’ videos showed a match between their instruction and their beliefs in the Standards. Ann’s story was unique in the class because she was strong in her methods initially, but only average in her belief of their value. Her SBI score started in the middle of the class, neither strong nor weak, but in reviewing her lessons from
the videos, she felt she should teach against the Standards. As she continued to view her videos, she expressed delight in the methods of the Standards, in the discovery that her students could make. As the researchers and cohort leader discussed the possible factors that helped the preservice teachers change their views of their practice, they began to believe that one key factor in the change was self evaluation. Telling Ann how to teach would not teach her what to do any more than her telling the elementary students about fractions would teach them about fractions. Conceptual understanding for the pre-service teacher occurred in the same way conceptual understanding occurs for her students, with hands-on, discovery learning. The combination of investigating both concepts of mathematics and concepts of instructional practice together may have aided the conceptual change of the pre-service teacher in both areas more than learning about just one or the other separately.

Standard’s Beliefs Instrument

The items in this questionnaire refer to the teaching of mathematics. For each item, fill in the mark for the response that describes your opinion. Work quickly, but be sure to consider each item individually. Any item you do not understand, please leave blank.

Mark "A" if your answer is STRONGLY AGREE
Mark "B" if your answer is AGREE WITH RESERVATIONS
Mark "C" if your answer is DISAGREE WITH RESERVATIONS
Mark "D" if your answer is STRONGLY DISAGREE

1. Problem solving should be a SEPARATE, DISTINCT part of the mathematics curriculum.
2. Students should share their problem solving thoughts and approaches WITH OTHER STUDENTS.
3. Mathematics can be thought of as a language that must be MEANINGFUL if students are to communicate and apply mathematics productively.
4. A major goal of mathematics instruction is to help children develop the belief that THEY HAVE THE POWER to control their own success in mathematics.
5. Children should be encouraged to justify their solutions, thinking, and conjectures in a SINGLE way.
6. The study of mathematics should include opportunities to make connections of using mathematics in OTHER CURRICULUM AREAS.
7. The mathematics curriculum consists of several discrete strains such as computation, geometry, and measurement which can be best taught in ISOLATION.
8. In K-4 mathematics, INCREASED emphasis should be given to reading and writing number SYMBOLICALLY.
9. In K-4 mathematics, INCREASED emphasis should be given to use of CLUE WORDS (key words) to determine which operation to use in problem solving.
10. In K-4 mathematics, skill in computation should PRECEDE word problems.
11. Learning mathematics is a process in which students ABSORB INFORMATION, storing it in easily retrievable fragments as a result of repeated practice and reinforcement.
12. Mathematics SHOULD be thought of as a COLLECTION of concepts, skills and algorithms.
13. A demonstration of good reasoning should be regarded EVEN MORE THAN students’ ability to find correct answers.
14. Appropriate calculators should be available to ALL STUDENTS at ALL TIMES.
15. Learning mathematics must be an ACTIVE PROCESS.
16. Children ENTER KINDERGARTEN with considerable mathematical experience, a partial understanding of many mathematical concepts, and some important mathematical skills.

Nancy M. Wentworth is an assistant professor in the Department of Teacher Education, David O. McKay School of Education, Brigham Young University, 110K MCKB, Provo, UT 84602, voice: 801 378-5617, fax: 801 378-4017. E-mail: nancy_wentworth@byu.edu
The approaches for solving mathematical problems have changed with technological advances and there is a need for reform in teaching techniques, the curriculum, and student assessment procedures. The MATH-PLACE: Measuring, Analyzing, and Training Heuristically: Professional Learning Assessment, Computer, and Equity Education - project was funded at Mississippi State University through the Learning Training and Networking Teacher Design Center Program offered through the Institutions of Higher Learning. MATH-PLACE was designed to provide inservice teachers in grades K-4 and 5-8 with instructional strategies to address the integration of technology and alternative assessment methods in the mathematics classroom.

During the past decade, research results have confirmed that a new direction for mathematics education is needed - a direction that empowers students with critical-thinking skills to reason and to solve problems more efficiently and effectively. For example, researchers have reported that students learning mathematical concepts using computer applications such as spreadsheets (Dugdale, 1994) score higher on tests and are more interested in learning mathematics (Palmiter, 1991). In order to prepare students for the 21st century, teachers are experiencing changes in mathematics curriculum and instruction to include manipulatives, computer applications, and open-ended assessment techniques. Unfortunately, there are inservice teachers who have not been provided the opportunity to receive the proper training in educational reform methods and strategies for implementing the instructional techniques as described in the National Council of Teachers of Mathematics Curriculum and Professional Standards (NCTM, 1989; NCTM, 1991, NCTM, 1995) and Goals 2000 (1994). Thus, the basis for the project described in this paper was to provide inservice teachers with opportunities to improve their mathematics instruction in kindergarten through the eighth grade using manipulatives, technology, and alternative assessment strategies.

Just as students should be provided a problem-solving environment (NCTM, 1989), it is essential to provide inservice teachers a problem solving training environment for learning how to identify, explore, and solve problems using manipulatives and technology. As teachers begin to learn how to redefine the kinds of tasks students do in the classrooms and employ hands-on materials, calculators, and computer applications, adjustments in alternative assessment techniques must follow (Hembree & Dessart, 1992). Assessment (testing) as practiced today arose because very efficient methods were found for assessing large numbers of individuals at low cost (Mathematical Sciences Education Board, 1993). Rather than the traditional objective test (short-answer, multiple choice, or true-false test), teachers must be trained to develop and implement new alternative assessment models to reflect that students have learned to reason, create models, prove theorems, and argue points of view (Carl, 1995). According to the Mathematical Sciences Education Board (1993), assessments that allow for a broad focus on technical criteria and are appropriately rich in breadth and depth provide opportunities for students to demonstrate their deep mathematical understanding.

Objectives

Inservice teachers may be aware of the research results; however, they are still overwhelmed and have difficulty integrating new teaching techniques into the current curriculum while meeting required school goals and assessment requirements. Therefore, the objectives of this project were to:

1. Develop a teacher training and networking center for Mississippi school districts in order for teachers to improve their professional skills.
2. Provide intensive professional development for grades K-4 and grades 5-8 teachers on using and incorporating hands-on instructional manipulatives, computer and calculator applications, and alternative assessment methods in an integrated approach.
Inservice Teacher Training

MATH-PLACE was the beginning of a mathematics teacher training center and resource laboratory at Mississippi State University. In order to meet the objectives stated above, the center provides inservice training on the latest issues in mathematics education and serves as a resource laboratory for teachers to borrow manipulatives and portable computers for use in their classrooms. The center provides inservice training on the latest issues in mathematics education and serves as a resource laboratory for teachers to borrow manipulatives and portable computers for use in their classrooms. The center provides inservice training on the latest issues in mathematics education and serves as a resource laboratory for teachers to borrow manipulatives and portable computers for use in their classrooms. The center provides inservice training on the latest issues in mathematics education and serves as a resource laboratory for teachers to borrow manipulatives and portable computers for use in their classrooms.

The preservice teachers use the resources during practicum methods courses and student teaching.

During the summer, a brochure describing the project and containing an application was sent with a cover letter to school principals within a ninety mile radius requesting their recommendations and endorsements for three of their teachers to attend the MATH-PLACE workshops. A total of 32 inservice teachers in grades K-8 and 16 inservice teachers in grades 5-8 participated in the project. The workshops were scheduled on the first Saturday of each month, alternating between the two groups of teachers. It was important to provide separate workshops for teachers in grades K-4 and 5-8 in order to effectively address the teachers' needs and provide the participants an opportunity to network with other colleagues from various school districts. If a teacher attended all three workshops for their appropriate grade level, they received a stipend, continuing education units, handouts of classroom activities and alternative assessment strategies involving manipulatives, calculators, and computer applications, and a manipulatives sample kit. The instructors for the workshops were teams consisting of university professors and inservice teachers. This was an important component that served as a "bridge" between the university and elementary schools. Even though it was beneficial to provide training to the teachers based on grades taught, the enrollment of teachers in grades 5-8 was lower than anticipated. In an effort to address this issue, future recruitment efforts for recruiting teachers of these grade levels could include one hour presentations or inservice professional development sessions at the schools to demonstrate the topics to be explored during the workshops.

Workshop Content

It was not possible to simply demonstrate new instructional tools and expect the teachers to be able to effectively integrate these into their instruction. The integration of hands-on manipulatives and technology in the classroom was necessary and, as a result, the proper training of teachers included modeled instruction using the instructional tools for teaching specific concepts that could be transferred into the teachers' real classroom of instruction. The use of hands-on instructional tools such as Cuisenaire rods, pattern blocks, and base ten blocks provided the teachers with new ideas of ways to provide students a problem solving environment in the mathematics classroom. The teaching strategies implemented during the workshops were focused in the areas of geometry and algebra because these topics are often neglected yet the applications are much more meaningful in the presence of technology.

Technology

The technology training consisted of computer-aided demonstrations on how to use selected computer applications, followed by the participants being actively involved in hands-on exploration using the various computer applications. The model used to train the teachers was a self-regulatory model that allowed the participants to work at their own pace. The technology training was based on the IDEA (Identify, Define, Explore, Assess) Model developed by Cardelle-Elawar (1993), which focused on elementary students having the opportunity to identify and define the problem, explore the software for solutions, and access the needed tools for solving the problem. This approach was selected as a model for training inservice teachers because the strategies reported in the research were successfully used in the elementary classroom. Therefore, it was feasible to use the same model for training inservice teachers in hope they would be more likely to transfer the methods into their own classroom instruction.

Computer-aided instruction and strategies for promoting a problem-solving environment using computer applications in the mathematics classroom were provided. It was not enough to demonstrate to the teachers how to turn on the computer and use an application or piece of software in an isolated activity without demonstrating how to incorporate the application into lessons that were designed to promote problem solving. It takes time to develop and become effective in learning not only new teaching strategies but also in modifying current teaching and alternative assessment strategies to meet local, state, and national goals. Therefore, the instructional component of the workshops consisted of "modeled" lesson plans using various spreadsheets, the World Wide Web, and educational software. In addition, the teachers learned how to use the spreadsheet as a gradebook and an instruc-
tional tool. Following the demonstrations, the teachers explored their options and completed selected activities using their choice of calculators and computer software.

Because technology has become a common component in the classroom, it was essential to provide the teachers with an evaluation process for selecting appropriate software for their instructional purposes. Based on prior experience, the workshop leaders selected educational software that had been rated favorable and non-favorably by preservice teachers based on the user-friendly capabilities. The purpose was to provide the inservice teachers the opportunity to compare and contrast the characteristics of educational software and report why they would or would not select the software for use in their classroom. Each teacher was provided a software evaluation form for rating the usefulness and user-friendly characteristics of the software.

**Alternative Assessment Strategies**

As closure to each training session, teachers were provided the necessary training in implementing more open-ended assessment techniques as recommended by the NCTM Standards. Initially, alternative assessment methods were discussed and participants identified the methods they felt would be most successful in their own classroom for meeting the new challenges involving the use of manipulatives and the ever-changing technology in the mathematics classroom. Then, each teacher completed various alternative assessments based on the instructional components presented during the workshop. A follow-up will be sent to the teachers during the 1997-1998 academic year to determine whether the teachers are implementing in the mathematics classroom the instructional and alternative assessment methods discussed during the workshops.

Although it is important to consider how differences in opportunity can affect students' success, it is equally important to be aware of how the integration of technology and assessment methods can affect students' opportunities to learn important mathematics. The current mathematics educational reform involving the integration of technology has resulted in different teaching and assessment strategies being randomly implemented in classrooms without a central focus on different grade levels. Thus, the uses of alternative assessment results of technology should be scrutinized for their impact on both students' opportunities to learn and schools' capacities to provide instruction consistent with the vision of mathematics education. The ever-changing developments in technology, cognitive psychology, and mathematical pedagogy will continue to create challenges for teachers as they attempt to modify their teaching techniques to include the use of different teaching tools and methods.

LINEAR ALGEBRA WITH MATLAB PACKAGE IN PRESERVICE TEACHER EDUCATION

Mikhail M. Bouniaev
Southern Utah University

The psychological theoretical foundation of this paper is the theory of stage-by-stage development of mental actions (SSDMA theory) elaborated by the Russian school of psychology (Leontyv, 1972; Galperin, 1979; Talizyna 1975, 1979). In the paper presented by M. Bouniaev (Bouniaev, 1996) at the 7-th International Conference of Society for Information Technology and Teacher Education the general ideas of applying fundamental ideas of the SSDMA theory to computer based instruction (CBI) were discussed. It was also shown by M. Connell and M. Bouniaev (Connell & Bouniaev, 1996) that recommendations for CBI based on the ideas of modern constructivism and SSDMA theory are very similar.

In this presentation we dwell on the applications of this general approach to the particular case of teaching linear algebra with MATLAB package to preservice teachers. Since a lot of linear algebra concepts can be traced back to K-12 mathematics, it is important for preservice teachers to learn about different software packages along with psychological foundations of developing learning strategies that can be used for teaching such topics as systems of linear equations, matrices etc.

Unfortunately, the SSDMA theory, experimentally proven and universally accepted in Russia is practically unknown in the USA. So we have to explain at least very briefly some notions and ideas of the theory. The SSDMA theory determines methods of analysis of the instructional process and selection of appropriate strategies. According to it, a major goal of instruction is developing mental actions with objects of the studied field.

All actions can be referred to two categories: general logic actions and specific actions. Examples of such type of actions are qualification (quadratic forms qualification) or break up into classes (break up all matrices into two classes: singular matrices and non-singular matrices), comparison (compare symmetric entries in the matrix), etc.

Specific actions are basically inherent to a given subject field. For example, in linear algebra they are: finding a solution of the system of linear equations, finding eigenvectors and eigenvalues, etc. We’ll consider here in greater detail the action of finding eigenvalues and eigenvectors.

As a rule, the performed actions themselves consist of other, more primitive actions, which in their turn can be part of other actions. Actions that are part of a given whole, are called operations. For example, action of finding linear combinations of rows is an operation of the action of finding solution of a system of linear equations. That is, operations are also actions, hence the term “operation” implies only the hierarchical subordination among actions. Goal of an action and an action object are attributes of any action.

Analysis of component operations of any action shows that they perform different functions. Some part of performing an action is taken up by preliminary work, a plan or preparation for an action in a certain sense. This preparatory part is called orientation part of an action. The performance itself is called the executive part of an action. Analysis of actions and experiments carried out in this regard shows that there also exists a control part which takes place after the executive part is performed and the student compares the results achieved in the executive part of the action with the goals of the action and the draft plan of the execution planned in the orientation part.

In this presentation we consider as an example the development of action of finding eigenvalues and eigenvectors. It is natural that performance of any action depends on environment and tools allowed to be used. Our assumption is that students perform the action in MATLAB Notebook. MATLAB Notebook is a combination of MATLAB package and Microsoft Word wordprocessor. Working in the MATLAB Notebook environment students can use MATLAB commands as well as write and edit explanation on the same screen. They can save results of their work and use them for future studies. In the process of developing the action of finding eigenvalues and eigenvectors we use not only MATLAB commands, but also M-files (Leon, Herman & Faulkenberry, 1966; Hill & Zitarelli, 1966)
mance we have to rely on a textbook. We used the textbook of Steve Leon (Leon, 1994). We also used MATLAB syntax, for example the matrix \([4 -2;1 1]\) is a matrix with the first row 4 -2 and the second row 1 1.

**Actions Of Finding Eigenvalues And Eigenvectors In MATLAB Environment**

In this section will discuss the structure of the action of finding eigenvalues. The object of this action is square matrix \(A\), let us say \(A=\begin{bmatrix}4 & -2 \\ 1 & 1 \end{bmatrix}\). The goal of the action is to find all scalars \(m\) such that for some \(x Ax =mx\) (definition of eigenvalue). Bellow we give the operational composition of the action of finding eigenvalues. We also give substantiations for all operations because we need them for the further discussion. We do not discriminate such suboperations as creating objects in working environment.

**Scheme 1. Operational Composition Of The Action Of Finding Eigenvalues.**

1. **Orientation Part Of The Action - Plan Of The Action.**

   **Operation 1.** We substitute the problem of finding all scalars \(m\) such that for some \(x Ax =mx\) with problem of finding all values of \(m\) such that \((A-mI) x =0\) has a nontrivial solution. This operation has the following substantiation. The theorem (Leon, 1994) states that \(m\) is an eigenvalue of \(A\) if and only if \((A-mI) x =0\) has a nontrivial solution.

   **Operation 2.** We find all values of \(m\) such that \(\det(A- m*I)=0\). Since the action of finding conditions under which \(Bx =0\) (in this case \(B=A-mI\)) has a nontrivial solution was developed earlier, the following theorems (Leon, 1994) are substantiation of this operation.

   **Theorem 1.4.3.** Let \(A\) be a square matrix. The following are equivalent: a. \(A\) is nonsingular. b. \(Ax=0\) has only trivial solution 0.

   **Theorem 2.2.2.** A square matrix \(A\) is singular if and only if \(\det(A)=0\).

   **Operation 3.** Evaluation of \(\det(A- mI)\) will give us polynomial \(ChP(A)\) - characteristic polynomial of \(A\).

   **Operation 4.** The solution set of characteristic equation \(ChP(A)=0\) forms the set of all eigenvalues.

   **Operation 5.** Creating object of the action in working environment. In our environment we type MATLAB command \(A=\text{sym}([4 -2;1 1])\).

   All other operations are developed according to the plan of action.

2. **Executive Part Of The Action.**

   **Operation 1.** Substitution of expression \(Ax =mx\) with expression \((A- mI)x =0\). The objects of this operation are: matrix \(A\), matrix \(mI\), matrix \(H=A- mI\). We have to create this object using MATLAB commands.

   **Operation 2.** Determining for what values of \(m\) \(Hx=0\) has a nontrivial solution (this action was developed earlier). As well as in the previous operation the major part of this operation consists from creating objects of the operation in the working environment. Operation’s objects are: matrix \(H\), \(ChP\) - characteristic polynomial of \(A\), \(ChE\) - characteristic equation of matrix \(A\).

   Performance of the executive part of this operation (substituted with MATLAB command “\text{solve} ChP”) shows that 3 and 2 are eigenvalues of matrix \(A\).

**Teaching Linear Algebra In MATLAB Environment**

Analysis of the linear algebra course and MATLAB package shows that a lot of actions to be developed in the process of instruction have their computerized representations (or models) as MATLAB commands or M-files.

Teaching linear algebra based on SSDMA theory and using MATLAB package consists of developing at each stage of instruction a particular group of actions in the assumption that their operations are already developed at a sufficient enough level and therefore may be substituted by appropriate MATLAB commands (M-files).

Regarding the example of action of finding eigenvalues we can state that all the operations of the executive part of the action have already being developed at the previous stages of instruction. Actually the most important part of the action to be developed is the orientation part of the action including substantiation, and of course, the action itself as a whole. Developing the action as a whole we first should expose and develop it in the operation-by-operation mode.

The SSDMA theory gives prescriptions for subject content analysis, how to organize and structure the learning material, as well as the algorithm for developing the action itself. One of the important and hard parts of subject content analysis to do for CBI is organizing the hierarchy of actions to be developed: actions of lower level are operations for actions of higher level, and creating their computerized models.

Thus for developing the action of finding eigenspace for the given eigenvalue, the actions to be developed (an action of lower level in the action hierarchy) and have computerized models are the following.

1. Action of finding eigenvalues of given matrix. Computerized model in MATLAB - command “\text{eig}(A)”.
2. Action of entering different matrices into MATLAB .
3. Actions of performing arithmetic operations with matrices in MATLAB.
4. Action of finding nullspace of a given matrix \(H\). Computerized models in MATLAB - command “\text{null}(H)” or M-file “\text{homsoln}(H)”.

In the assumption that all the operations listed above were developed at the previous stages of instruction, developing the action of finding eigenspace for a given eigenvalue consists mostly of developing the orientation part of the action (including substantiation). Let us
illustrate it with an example of operational composition of the action of finding eigenspaces.

Scheme 2. Operational Composition Of The Action Of Finding Eigenspaces.

The action object is square matrix \( A \) (let us say \( A = \begin{bmatrix} 4 & -2 \\ 1 & 1 \end{bmatrix} \)). The goal of the action is to find all linear independent vectors \( x \) such that for given eigenvalue \( m \) \( Ax = mx \).

I. Orientation Part Of The Action - Plan Of The Action

**Operation 1.** Find all eigenvalues. MATLAB command `eig(A)` can be used. Fix one eigenvalue \( m \).
**Operation 2.** Find the basis for the solution set of system \( Ax = mx \). Substantiation: definition of eigenspace corresponding to the given eigenvalue.
**Operation 3.** Substitute \( Ax = mx \) with \( (A - mI)x = 0 \). Substantiation: system \( (A - mI)x = 0 \) is equivalent to \( Ax = mx \).
**Operation 4.** Since solution space of \( (A - mI)x = 0 \) is equal to nullspace of matrix \( H = (A - mI) \) we find nullspace of \( H \). Note that this operation was developed earlier and therefore may be substituted by MATLAB command “null” or “homsoln”.
**Operation 5.** Creation object \( A = \begin{bmatrix} 4, & -2; \\ 1 & 1 \end{bmatrix} \).

II. Executive Part Of The Action.

**Operation 1.** Performance of MATLAB command `eig(A)` gives value \( m = 3 \).
**Operation 2.** Substitution system \( Ax = mx \) with \( (A - mI)x = 0 \). The operation’s objects are: matrix \( A \) and matrix \( H = A - 3I \) created in working environment by typing MATLAB commands \( I = \text{eye}(2) \) and \( H = A - 3I \).
**Operation 3.** Finding nullspace of matrix \( H \) (M-files “null” or “homsoln” are used). As the result of performing this operation we obtain vector \( v = (2.1)^T \) that forms a basis of eigenspace corresponding to eigenvalue \( m = 3 \).

Now we fix \( m = 2 \) and repeat operations 2 and 3 with this value of \( m \).

III. Control Part Of An Action.

Objects of action are matrix \( A \), vector \( v = (2.1)^T \), and number 3.
**Operation 1.** Evaluation of \( A^*v \) (in MATLAB)
**Operation 2.** Evaluation of \( 3*v \).
**Operation 3.** Comparison of \( A^*v \) and \( 3*v \).

Development Of Action At Different Stages Of Instruction

The SSDMA theory singles out 5 stages in the process of instruction. Here we will briefly outline them.

First Stage Of Instruction

At the first stage the student gets necessary information about goals, objects and operational composition of the action to be developed. The orientation, executive and control parts of action are defined as well. SSDMA theory specifies four independent characteristics of any action used to judge the level of development of an action. One of them is the degree of completeness which indicates if all the operations that were to be performed have actually been completed, including the operations of the orientation part of action with substantiation. This demonstrates the ability to perform any action in operation-by-operation form. Therefore in presenting the material to the students we must do it also in operation-by-operation form.

Let us consider further the example of developing the action of finding eigenvalues and eigenvectors. At the first stage of instruction it is important to connect abstract notions with the images and hand-on activity. For this purposes we can use ATLAST M-file “eigshow” (Leon, Herman & Faulkenberry, 1996). The program gives graphical demonstration of geometric eigenvalue/eigenvector relationship. Working with the program students can find eigenvalue and eigenvectors belonging to this eigenvalue before they have formal definitions.

Based on the graphical demonstration the instructor gives the formal definitions of eigenvalue, of eigenvector, of eigenspace corresponding to \( m \), characteristic polynomials, characteristic equation.

Then the instructor provides students with the operational compositions of the actions of finding eigenvalues and eigenspaces (Scheme 1 and scheme 2). The first action to be developed in the operation-by-operation form is the action of finding eigenvalues. The second action to be developed is the action of finding eigenspaces. Since the action of finding eigenvalues is an operation of the action of finding eigenvectors, the action of finding eigenvalues can be substituted by MATLAB command `eig(A)`.

Second Stage Of Instruction

As we have already mentioned the SSDMA theory specifies four independent characteristics of any action used to determine the level of development of an action. We have already discussed the completeness of an action that is the ability to perform all operations in operational composition of action without skipping any operation.

Probably the most important characteristic of an action is the form of an action. An action can be in the materialized (material), speech or mental form. The materialized form of action is connected with manual activities (manipulation, hand-on activities, etc.). Objects of action (or their models) are presented in the material form, results of action should be real transformations of these objects or their models.

The second stage of developing an action deals with students performing actions in the material or materialized form. Therefore in presenting the material to the students we must do it also in operation-by-operation form. For this purposes we can use ATLAST M-file “eigshow” (Leon, Herman & Faulkenberry, 1996). The program gives graphical demonstration of geometric eigenvalue/eigenvector relationship. Working with the program students can find eigenvalue and eigenvectors belonging to this eigenvalue before they have formal definitions.

Based on the graphical demonstration the instructor gives the formal definitions of eigenvalue, of eigenvector, of eigenspace corresponding to \( m \), characteristic polynomials, characteristic equation.

Then the instructor provides students with the operational compositions of the actions of finding eigenvalues and eigenspaces (Scheme 1 and scheme 2). The first action to be developed in the operation-by-operation form is the action of finding eigenvalues. The second action to be developed is the action of finding eigenspaces. Since the action of finding eigenvalues is an operation of the action of finding eigenvectors, the action of finding eigenvalues can be substituted by MATLAB command `eig(A)`.

Second Stage Of Instruction

As we have already mentioned the SSDMA theory specifies four independent characteristics of any action used to determine the level of development of an action. We have already discussed the completeness of an action that is the ability to perform all operations in operational composition of action without skipping any operation.

Probably the most important characteristic of an action is the form of an action. An action can be in the materialized (material), speech or mental form. The materialized form of action is connected with manual activities (manipulation, hand-on activities, etc.). Objects of action (or their models) are presented in the material form, results of action should be real transformations of these objects or their models.

The second stage of developing an action deals with students performing actions in the material or materialized form. Therefore in presenting the material to the students we must do it also in operation-by-operation form.
form. As we wrote students can use M-file “eigshow” in combination with formal calculations. In MATLAB Notebook environment they can also use a mouse for pasting the objects-blocks and transferring them to a different place on the screen. This enables students to perform transformation actions with models of objects of the studied actions.

Since it is important for instructional process at this stage that students discriminate all operations as well as objects those operations are aimed at, we give them for homework traditional exercises that can be found in any textbook but insist that actions be performed in the operation-by-operation mode.

Example Of Homework Problem. Find eigenvalues for each of the following matrices. Then find all eigenspaces. You can use the copy features of MATLAB Notebook.

Students can copy all the theorems and definitions that already exist in their own notebook. We give the students the hard copy of scheme 1 and scheme 2 and computerized schemes 1Home and 2Home. Since schemes 1Home and 2Home are interactive versions of scheme 1 and scheme 2, we give here an example of just one of them. We put three question marks to show that this is the students’ working space where they are supposed to copy or to type the answers. In the parentheses we write comments whenever appropriate.

Scheme Home. Action Of Finding Eigenvalues Of A Given Matrix
   Action object: ??? (let us say A=[4 -2;1 1]
   Goal of action: ??? (to find all scalars m such that for some x Ax =mx )
   Substantiation of action goal ??? (definition of eigenvalue, students are supposed to type it here for the first exercise and copy for others).

Orientation Part Of Action - Plan Of Action.
   Operation 1. We substitute the problem of finding all scalars m such that for some x Ax =mx with the problem of finding all values of m such that (A-mI)x=0 has a nontrivial solution.
   Substantiation: ??? (Students create their own MATLAB notebook in the process of developing any action and therefore usually they have all theorems that substantiate actions of the lower level in the action hierarchy. Students are supposed to copy all the theorems that substantiate the operation from their own notebook).
   Operation 2. We find all values of m such that det (A-m1)=0.
   Substantiation: ???
   Operation 3. Evaluation of det(A- mI) will give us polynomial ChP(A) - characteristic polynomial of A.

Executive Part Of Action
   Operation 1. Substitute expression Ax =mx with expression (A -mI)x=0. What are the objects of this operation: ???
   Operation 2. Determining for what values of m Hx=0 has a nontrivial solution. ??? What are the objects of this operation: ??? (matrix H, ChP - characteristic polynomial of matrix A, ChE- characteristic equation of matrix A)
   What MATLAB commands or M-files do you use: ??? (MATLAB command “solve ChP”).
   What conclusion did you make: ???
   Control part of the action can be substituted with M-file eigshow.

The Third Stage of Developing an Action
   The third stage of developing an action is that of speech form, both in its oral and written variant. And the possibilities provided in this case by MATLAB Notebook are hard to underestimate. It not only enables students to express their thoughts in a written form but also connects them with models of the action constructed at previous stages of instruction. It should be noted that “show” or “proof” exercises of Leon’s textbook provide good material to develop actions in the written (speech) form.

   For the same lesson the following types of exercises that require written explanations can be assigned.
   1. Show that the eigenvalues of a triangular matrix are the diagonal elements of the matrix.
   2. Let A be a square matrix. Prove that A is singular if and only if 0 is eigenvalue of A. etc.

Students write the explanation, if appropriate they do some experiments. To substantiate proves they copy in appropriate places statements of the theorems and definitions they use.

Fourth And Fifth Stages Of Instruction
   The fourth and fifth stages are very similar. At the fourth stage the action should be developed in the inner speech form. It must be developed in the operation-by-operation mode with all the operations performed separately. Thus it is essential in organizing instruction to provide the students with the opportunity to describe in a compressed form the operations performed. MATLAB commands and M-files may play this role of compressed expression of an action performance.

   The fifth stage is development of an action in the mental form. The action at this stage becomes an inner mental act with only the product of this action explicitly

591 Mathematics — 591

BEST COPY AVAILABLE
evident and observable. Assimilation of the action at a given level of compression and generalization becomes a matter of top priority in developing the action at this stage. At this stage of instruction students are supposed to make conjectures based on the experiments in MATLAB environment. There are some special matrices in the ATLAST Computer Exercises for Linear Algebra (Leon, Herman & Faulkenberry, 1996) that provide good material for these experiments. Computer can perform certain operations at the student’s command. Therefore performance of this time consuming but necessary action can be taken over by a computer.

Another function a computer can be assigned is presentation of the same type of problems and control over their solutions (drill-and-practice). It is important to remember that at this stage the action should be developed in the compressed form. And, finally, MATLAB Notebook provides new forms of recording students activities thus substantially increasing motivation at a given stage.

**Conclusion**

1. MATLAB Notebook is a very convenient (and important from the standpoint of SSDMA theory) tool to develop actions in both written and materialized forms. The result of each computer session is fixed in the Notebook as a meaningful text with MATLAB commands or M-files.

2. Basic ideas of the SSDMA theory can be implemented successfully in teaching linear algebra using the software package MATLAB and the related published materials such as Linear Algebra Labs with MATLAB”(Hill & Zitarelli, 1996) and ATLAST Computer Exercises for Linear Algebra (Leon, Herman & Faulkenberry, 1996).

This paper describes preservice teachers’ ideas of how technology can be used to help high school students develop an understanding of the mathematical concept under consideration. The subjects in the study were the five preservice teachers enrolled in the methods course, Teaching Mathematics with Technology. The analysis of the lesson plans developed by the subjects revealed the differences in preservice teachers’ ideas of the role of technology in their lesson planning. Some teachers planned to use technology to enhance their lesson while others planned investigations in which students would use technology to explore mathematical ideas.

Introduction

The NCTM Standards (1989) maintains that the appropriate integration of technology will “transform the mathematics classroom into a laboratory...where students use technology to investigate, conjecture, and verify their findings...[and] the teacher encourages experimentation” (p. 128). In this context, teachers often become students as they struggle with understanding technology and its pedagogical implications (Norman, 1993). Indeed many universities address this need by offering preservice teachers methods courses in learning how to use technology to teach mathematics.

We teach such a course to preservice middle and high school mathematics and science teachers as part of their professional preparation. During the past several years, we have observed through their prepared lesson plans that preservice teachers have considerable difficulty in successfully integrating technology into instruction so that students are able to construct their own knowledge of the mathematical concept under consideration. Too often in their planned lessons and activities, these novice teachers did not fully utilize the additional power that technological tools offer the mathematics classroom, focusing instead on automated manipulations that served only to keep students occupied.

Klimick-Schoaff (1993) suggests a step-by-step procedure that may help teachers to develop lessons that effectively use software or calculators in the classroom. This procedure includes (i) analyzing technology to determine its attributes; (ii) finding corresponding problem-solving strategies and then deciding on the types of questions that can be answered through the use of the technology tool; and (iii) studying the syllabus to determine what topics might benefit from this approach. Based on our experience, it is Klimick-Schoaff’s second step that has emerged as a common obstacle among preservice teachers. Therefore, this study focuses on preservice teachers’ ideas and choices of problem-solving situations and investigative strategies, as well as their decisions on how technology can be used to help high school students construct their knowledge of mathematics.

Method

Subjects

Five preservice teachers who took the methods course, Teaching Mathematics with Technology, at a large southeastern university participated in this preliminary study. This methods course addresses three important areas of technological competence for preservice middle grades and high school mathematics teachers. 1) The use of technology to support and enhance professional productivity, information access and transfer, and collaboration and communications. 2) The use of technology to support and enhance student-centered learning by actively involving students in mathematical investigations and problem solving activities that promote mathematical reasoning and critical thinking. 3) The use of technology to promote conceptual understanding of content specific knowledge found in the middle grades and high school mathematics curricula. Computers and calculators are used with a variety of tools including the Internet, Geometer’s Sketchpad (GSP), NuCalc, EXCEL, Claris Works, HyperStudio, and Calculator-Based Laboratories.

All of the preservice teachers in this methods course were within two semesters of their student teaching practicum. During the semester the participants were asked...
to write a lesson plan to teach a particular mathematical concept or the concept of their choice. Based on one of the objectives of the course, the expectation was that they would incorporate technology into a lesson plan of their choice. These lesson plans were collected and analyzed to determine the preservice teachers' ideas of the role of technology in their teaching. In particular, their ideas of using a spreadsheet, GSP, the Internet and the graphing calculator were analyzed in depth. Because of the space limitation we chose to report here only the analysis of the teachers' lesson plans using the GSP software.

**Analysis and Results**

It was our purpose to analyze the investigative activities developed by the preservice teachers as part of their lesson plans. Frobisher (1994) has classified general investigative processes into four categories. These four categories of investigative processes are Communication, Reasoning, Operational, and Recording. Frobisher (1994) described these categories as follows: Communication processes involve students in explaining, talking, agreeing, and questioning. Reasoning processes have students engaged in collecting, clarifying, analyzing, and understanding within their investigations. Operational processes included those of collecting, sorting, ordering, and changing. Recording processes were described as drawing, writing, listening, and graphing.

These four categories contribute to Frobisher's (1994) final category, Mathematical processes, that involves the students in guessing, pattern-searching, interpolating, extrapolating, predicting, conjecturing, testing, hypothesizing, generalizing, or proving.

We adapted Frobisher's (1994) five categories of investigative processes by adding some additional descriptors to code our data. A code of Communication Process was assigned to the part of a preservice teacher's lesson plan if it required the student's involvement in explaining, talking, agreeing, questioning, discussing, or writing. Reasoning Process was assigned if the lesson plan required the student's involvement in classifying, comparing, contrasting, analyzing, understanding, defining, or organizing. Operational Process was used when the lesson plan engaged the student in collecting, sorting, ordering, changing, dragging, transforming, constructing, or selecting. Recording Process was assigned when the student was required to engage in drawing graphs and figures, writing (numbers, words, symbols), listening to information, creating tables, measuring, observing, or labeling. Finally, Mathematical Process was assigned to a piece of data if the student was asked to engage in guessing, pattern-searching, interpolating, extrapolating, predicting, conjecturing, testing, hypothesizing, generalizing, or proving. Each sentence of the preservice teachers' lesson plans was analyzed for evidence of any of these five processes. From our definition of the categories, it is clear that more than one code could be assigned to the same sentence of the lesson plans.

After coding the data for each teacher, we summarized the number of times the students were asked to engage in each of the five processes. From that summary, two distinct groups of lesson plans emerged, casting technology in the roles of lesson enhancer or investigative tool. Qualitative analysis of the relationship among the investigative categories further clarified preservice teachers' ideas on the role of technology in designing investigative activities:

1. **Preservice teachers plan to use technology to enhance the presentation of information in their lessons**

The lesson plans in this category were characterized as teacher-centered plans, with technology used as a lesson enhancer. The data from these plans were categorized as requiring students to predominantly record information (listen, watch, and/or write) generated by the teacher and the computer. There were few operational processes included in the enhancer plans, and these operational processes were controlled by the teacher. Little or no communication processes were included in this type of plan, and the few reasoning processes that were included were judged to be disconnected from the recording and operational processes of the planned activity. An example of an enhancer lesson plan is shown in Figure 1, where technology is used as part of the teacher's lecture about circumference and area of a circle.

2. **Preservice teachers plan investigations for their students to explore mathematical ideas**

These lesson plans involved the students in a learning context that reflected their active involvement with the technology to pursue investigations related to learning mathematics. The students were engaged in more operational and recording processes than those plans in the enhancer category. To a lesser degree, the investigation plans involved students in communication processes, reasoning processes, and mathematical processes. Further analysis revealed two main subgroups that were distinct from each other based on the complexity of the lesson plan. Complexity was defined by the number of times the students were asked to engage in reasoning processes or mathematical processes. Complexity was further defined by the connections established within the lesson plans between the operational/recording processes and the reasoning/mathematical processes.

Simple investigations. Lesson plans in this subgroup mainly asked students to use technology to construct figures. Simple investigations involved students in making just one conclusion or observation from the constructions. Some of these simple investigations were somewhat trivial. Others required students to draw a conclusion that was somewhat disconnected from the preceding operational
Circumference and Area of a Circle

The first topic we are going to discuss is the circumference of a circle. What do you think of when you hear the word circumference in dealing with circles? For instance do you think of the interior or exterior of a circle? Most of you would probably say the exterior which is correct. What is the difference between the circumference of a circle and the perimeter of a polygon? Well yesterday we defined the perimeter of a polygon to be the sum of the lengths of its sides. It is rather obvious that a circle has infinite sides, so we are unable to call it a perimeter. To give you an example of this here are several polygons inscribed in a circle. You notice as the polygons have more sides it looks more and more like a circle.

As we said before circles have infinite sides. This limiting number of sides is defined to be the circumference of the circle.

The next topic we are going to discuss is the area of a circle. Now that we have concluded that the circumference deals with the exterior of a circle and area deals with the interior of the circle. What do you think of when you hear the word area? What does it mean when someone tells you to stay in your own area? It means you have that entire section, but no more. Basically, everything included in the boundaries that are set forth. What do you think is the difference between finding the area of the circle and the area of an inscribed polygon? The philosophy is very similar to the difference in perimeter and circumference. The areas of inscribed polygons get closer and closer to limiting number, and this limit is defined to be the area of the circle.

What would you expect to happen to the perimeter and the area as we increase the number of sides of the polygon? Remember what we talked about earlier. A circle has an infinite number of sides. For example using some trigonometry we found that a 4 sided polygon has a perimeter of 5.66r and an area of 2.001. What do you suppose the perimeter and area would approach as we increase to a 20 sided polygon? We are going to approach the circumference and area for a circle which are approximately 6.28r and 3.14r2. The exact values are given by the formulas below.

Circumference: 2πr
Area of a circle: πr2

Note: 3.14 or 22/7 are only approximations so, be careful when solving problems if the problem asks for an exact value.

Complex investigations. Investigations were deemed complex when there were a number of different processes that were planned to engage the students. Figure 3 presents a complex investigation of polygons with respect to pattern finding and generalizing a formula for the sum of the measures of angles in a polygon. The plan required students to construct, measure, and make a conjecture several times in succession, beginning with a triangle. Plans that characterized more complex investigations required more reasoning and mathematical processes and these processes were sequenced to follow an episode of construction and recording. [i.e. operation - record - reason/mathematical; operation - record - reason/mathematics; etc.]

Discussion

Given the dual role of computers as a computational and instructional tool, it is important to understand how preservice mathematics teachers plan to use technology in their teaching. Some preservice teachers see the computer as a drawing or computational tool to enhance their lectures or class presentations. Others envision a classroom where technology is used for students to investigate mathematical ideas. However, this preliminary study finds...
that preservice teachers’ ideas about investigations are qualitatively different. The simple investigations for students tended to emphasize constructions and measurements using the GSP, with few instances of communication, reasoning, or mathematical processes. Less common among preservice teachers’ ideas of investigations was the notion that each construction and the related measure(s) were tied to an instance of reasoning and/or mathematical processes. Also, we conclude that communication processes are not seen as important in the plans in comparison with the other four processes.

Figure 3. Complex investigative activity.

The translation of this research to our practice is the next step in our preliminary study. More specifically, we plan to have the preservice teachers use these five processes to evaluate lesson plans written by other preservice teachers, as well as their own plans. We conjecture that these teachers’ pedagogical investigations may prove to be another powerful learning experience on how to teach using technology.

THE INFLUENCE OF TECHNOLOGY ON TEACHERS' WAYS OF KNOWING MATHEMATICS

Steve Kennewell
University of Wales Swansea, UK

During the early stages of an investigation of the integration of technology into teacher thinking using Shulman's teacher knowledge framework (Shulman, 1986), it became clear that the ways in which teachers know their subject are an important influence on their teaching approaches, that learning with technology is likely to produce a change in ways of knowing, and an understanding of this change can form a useful part of a teacher's pedagogical content knowledge.

The variation in ways of knowing amongst different individuals may be studied in relation to many factors. One set of factors concerns the individual's identity in terms of, for instance, gender and culture. Another set concerns the educational environment experienced in terms of school ethos, curriculum, pedagogy, resources, and relationships with other learners. Of particular interest at present is the study of variation in ways of knowing according to the extent and nature of technology use in learning. For many years now, teachers have been encouraged to use technology in their teaching for a variety of reasons, the main ones being to bring about improvements in learning traditional subjects, to reduce the number of qualified teachers needed, and to improve learners' skills in applying technology to worthwhile problems.

We shall explore the first of these reasons, and in particular, how improvements in learning mathematics may be brought about by exploiting technology's power to support more powerful and flexible ways of knowing mathematics. We shall also consider the implications for teachers' knowledge if they are going to be able to use these ideas in the classroom.

Ways of Knowing

Most epistemological positions in current research into the learning of mathematics allow for individuals to know the same piece of mathematics in different ways. What makes a group of people feel that they are talking about the "same" piece of mathematics is a relational structure which is common to the ways in which they individually represent the knowledge. They can communicate these relationships amongst the members of the group by means of a shared system of terminology and notation. This feeling of sharing and agreement is sufficiently strong amongst expert mathematicians that many believe that the piece of mathematics exists independently of their individual mental representations, their social interactions and the physical signs they use. However, all the research evidence concerning the difficulties which novices have in understanding mathematics indicates that they do not easily gain a feeling that they share the expert's knowledge of mathematical structure. In fact, for any particular concept or technique, learners exhibit different ways of knowing, not just different amounts of knowledge. Experts are likely to know a concept in multiple ways, and are able to switch their thinking to the most appropriate form of knowledge when solving problems. In particular, expert teachers of the subject are able to switch amongst the several possible ways of knowing which their students may possess, in order to try to understand each student's thinking and work towards the objective of a shared understanding.

These different ways of knowing are characterised by the variation in conceptual relationships, the imagery, the analogies, the learned facts and the algorithms which each individual uses to make sense of the piece of mathematics, both in pure mathematical terms and in terms of its applications to problems in other domains. I suggest a number of categories of ways of knowing a mathematical process or relationship:

- static verbal (SVe): the knower can state a relationship in words
- static visual (SVi): the knower can visualise a relationship or recognise it in a visual image
- dynamic visual (DVi): the knower can represent the generality of a relationship or process through the visual perception of variation
• passive algorithmic (PA): the knower can follow a procedure for carrying out a process (this may involve conscious attention to the process, or the process may be carried out as an automatized routine)
• active algorithmic (AA): the knower can construct a general procedure for carrying out a process
• inductive (I): the knower can recognise a relationship from a pattern of values
• deductive (D): the knower can deduce a relationship from the structure inherent in a situation

These categories have been identified by analysis of detailed published findings from the UK (Hart, 1982; Assessment of Performance Unit, 1984) and of my own observations in class rooms (Kennewell, 1996) and when working with student teachers. Only some of these will be applicable to any particular piece of mathematics, and the appropriate categories will depend on the nature of the mathematics involved. In order to illustrate these categories, the following topics have been chosen randomly from a typical curriculum for mathematics. The suggested ways of knowing are either drawn from the sources given above, or are derived from the theory and represent possibilities to be investigated.

Examples

Rational Numbers. These may be known as the division of a whole object into parts (DVi); as a subset of a set of objects (SVi); as the result of a division calculation (PA); as a pair of numbers with called numerator and denominator (SVe).

The Area of a Triangle. This may be known as the number of unit squares and parts of squares (SVi); as a rearrangement of two copies of the triangle to form a parallelogram or rectangle (DVi); as a formula to be applied (PA); or as a relationship which is necessarily true between the length of any side and the corresponding altitude (D). It may also be known by making many different triangles by cutting and arranging copies of a piece of paper with known area, and then calculating \( \frac{1}{2} \times \text{base} \times \text{height} \) for each one (I).

The Distributive Law in Simple Algebra

\[ a(b+c)=ab+ac. \]  
This may be known as an algebraic rule: removing brackets (PA), as a concrete rearrangement of manipulatives/dots/shapes (DVi), or visual combination of them (SVi); as the fact that if one adds together two numbers, and then multiplies the result by a third number, the result is the same as if one had multiplied each of the two numbers separately by the third, and then added the two results together (SVe); as a pattern of results from many separate calculations (I); by writing a Logo program to systematically evaluate each expression and compare the result for different combinations of numbers (AA); or as properties of numbers and operations which can be deduced from definitions/axioms (D).

Pythagoras’ Theorem/Rule. This may be known as a procedure, viz., to find the longest side of a right-angled triangle, square the lengths of the two other sides, add together, and square root the result (PA). A further, separate algorithm for finding one of the shorter sides may be known as well. Alternatively, it may be known as a relationship expressed verbally, such as: the square on the hypotenuse is equal to the sum of the squares on the other two sides (SVe). The same relationship may be known geometrically, by means of a dissection of the largest square to form shapes which can be rearranged to make the two smaller squares (SVi); or even as a dynamic image whereby the smaller squares undergo isometric transformations so as to form components pieces of the large square (DVi). It may be known inductively from many drawings and measurements produced within the class (I); and may even be known by a proof using Euclidean axioms and inferences (D). A few may know it as a special case of a more general principle concerning regular shapes drawn on the sides of a right-angled triangle (D).

Maximum and minimum values of a quadratic expression such as \( x^2 - 4x + 3 \). Again, this may be known algorithmically, either as a procedure involving completion of the square of a linear term in \( x \) and then merely identifying the constant term (PA); as an application of differential calculus involving the equating of the derived function to 0 and then substituting the resulting value of \( x \) (PA); or as a situation which is susceptible to the weak method of trial and improvement (AA). Alternatively, it may be known graphically - the function is symmetrical about its minimum value, and so its minimum value is therefore obtained by substituting the value of \( x \) which is half way between those at which it cuts the \( x \)-axis (SVi).

Of course, the same individual may know such a piece of mathematics in multiple ways. Indeed, the development of mathematical expertise is characterised by an increasing richness of conceptual structure, rather than merely an increasing extent of knowledge.

Objects of Mathematical Thought

In addition to the ways listed above which all involve an articulated representation of the relationship or process, a piece of mathematics may be known as an object of mathematical thought (Sfard, 1991) or a “procept” (Tall, 1995). This is a encapsulated, holistic mental representation of a relationship or process which the knower may operate on as a single item within a more complex problem or structure, yet will still be able to articulate the process or relationship when appropriate. Thus a person who knows the particular processes and relationships listed above as objects of thought will be able, without working through algorithmic procedures, to:

• recognise that a rational number may be represented as a position on a number line;
• find the area of a complex shape by splitting it into separate triangles;
• interchange expressions of the form a(b+c) with their equivalent form;
• write an expression for the modulus of a vector;
• write down the value which makes an expression maximum or minimum.

This way of knowing has been named reification (Sfard, 1991), and is of great importance in developing more advanced concepts which subsume the relationship or process in question. For our five example topics, the more advanced concepts might be measurement of continuous quantities, finding the area of a circle, factorisation of algebraic expressions, vector algebra, and graph sketching, respectively.

Accordingly, reification is the aim of much teaching effort. However, attempts by teachers to convey knowledge of such mathematical objects directly lead to inappropriate ways of knowing which I would describe as premature reification. One example of this “fruit salad algebra” (Küchemann, 1978, p. 26) where learners are taught simplified expressions such as

5a + 3b - 2a + b by thinking of a as an apple and b as a banana. It has been suggested by Küchemann and others that such ways of knowing do not form a good foundation for the desired progression in mathematics. It seems likely that the reification of a mathematical relationship results from integrating multiple experiences involving more than one way of knowing the relationship.

Influences of Technology on Ways of Knowing

Returning to the examples, the following are afforded when technology is used in studying the topic:
• Rational numbers can easily be changed from a division operation to fraction form and to decimal form, facilitating the perception of equivalence across the three representations which correspond to static verbal, passive algorithmic and reified.
• The area of a triangle may be calculated using dynamic geometry software. The triangle can then be manipulated so that the learner can explore the effect of moving the vertex parallel to the base, which gives better dynamic visualisation of the dependence of the area on the height. Mason (1995) describes this as knowing through muscular sensation, and this “mouse mathematics” may constitute a different way of knowing from one that involves cutting and arranging. The same idea may be extended to Pythagoras’ Theorem. The active algorithmic approach can also be used for the application of Pythagoras’ Theorem and trigonometry by challenging students to model the solution of right-angled triangles using a spreadsheet.
• The distributive law may be studied by inductive and active algorithmic methods using, for instance, a spreadsheet. The learner may be given first a number of different expressions and asked to explore which ones are equivalent using replication of the formula and testing with many values. Next they can be asked to suggest a rule for removing brackets, then to test their rule on an expression containing parentheses by typing in an equivalent expression without parentheses, and finally to check their results by replicating the expressions over many cells and evaluating them each for many different values. A computer algebra system (CAS) may be used for the first stage of this, of course, but may less valuable in learning as it does not demonstrate visually the equivalence of the expressions.
Graph plotting software may be a better alternative for showing equivalence visually, although this is less dynamic than when the learner builds a table of values.

The method of trial and improvement for finding turning points of a function may be made much more efficient with technology at various levels from simple calculator through to CAS. The graphic calculator also provides a dynamic visual approach through graph tracing. In addition, its ability to plot a family of graphs obtained from the variation of one parameter, and even to cycle through them dynamically, may offer an effective path to reification of the relationship between a function and its turning points.

Technology thus affords a change from ways of knowing which are static verbal, static visual and passive algorithmic to those which are dynamic visual and active algorithmic. These new ways are potentially more powerful in solving problems and in providing a foundation for more advanced learning. They support structural rather than operational thinking (Sfard, 1991). However, technology also affords a change from deductive to inductive ways of knowing. Whilst this shift to weaker, more general methods increases access to important mathematical ideas, it constitutes a loss of power in solving particular types of problem. We must be aware of the danger of losing the deductive element which is the essence of advanced mathematics.

Indeed, we must ensure generally that learners do not miss out on traditional ways of knowing which they will need in addition to the new ways afforded by technology. Effective problem solving in a domain requires multiple ways of knowing. Teachers, therefore, need to set specific tasks for students which require switches in ways of knowing, to discuss the solutions with students in order to stimulate them to make switches for themselves.

It is not yet clear whether the technological means of carrying out algorithmic procedures (graphic calculators, CAS) provide an alternative to reification as a foundation...
for more advanced concepts, or whether the value of the technology is in supporting the process of reification by providing a powerful way of knowing the process. This is a key question for further research, because the answers we find will indicate how technology may be exploited most effectively in teaching and learning.

**Implications for Teacher Education**

If the suggested benefits for learners are going to be realised, it is not enough for students just to be presented with the activities suggested. Studies such as those detailed by Hoyles and Sutherland (1992) have shown that effective learning depends on careful structuring of challenges, intervention by teachers at particular points in a task, and reflection by students on their approach to the work.

For most teachers at present, activities involving technology have the status of curricular knowledge rather than pedagogical content knowledge, and Shulman's (1987, 1986) theories of knowledge transformation for teaching suggest that what is needed is for technology to be part of teachers' own subject knowledge. It will be hard for teachers to integrate technology into their teaching if they do not themselves know mathematics in the ways supported by the use of technology. The alternative is for applications of technology to be seen as optional extras which may be adopted in order to motivate students rather than to develop their understanding of mathematics.

Student teachers may or may not know various aspects of mathematics through technology. Those who do have the opportunity to develop their pedagogical content knowledge with technology integrated, but they will need encouragement from their mentors (we must accept that mentors of student teachers may not have integrated technology into their pedagogical thinking at present). Those student teachers who do not know mathematics in this way must quickly gain the experience themselves of learning (or re-learning) some aspect of the subject with technology. These learning experiences may be fragmentary, however. Just a small part of their mathematics may be known through technology, and there is a danger that student teachers will only be able to use technology in teaching those particular pieces of mathematics they have studied with the aid of technology. They need, therefore, to discuss their experiences, to attempt to generalise from them and to form principled knowledge. As teaching with technology thus becomes part of their general pedagogical knowledge, we should find that they can apply it to new situations.

Experienced teachers should also be able to change the way they know some of their mathematics. The greater their experience of teaching without technology, however, the more automatized will be their repertoire of traditional teaching activities, the more entrenched will be their beliefs about teaching, and the more difficult will be the process of change (Noss & Hoyles, 1993). Some work on mathematics itself using technology away from the classroom may be an important stimulus to this process which must be continued in the classroom. Teachers' early attempts at applying technology in the classroom will not be very effective; but their subject knowledge and pedagogical content knowledge will develop together as they try out the use of technology with students and reflect on their experiences. Encouragement and advice from colleagues and other agents of professional development will be important during this process.

Once the constructivist philosophy is adopted day to day life in the classroom is profoundly and significantly altered for both teacher and students. This goes far beyond such superficial aspects such as the physical arrangement of workspace within the classroom, or heavy use of 'manipulatives' — two features which are most often noted by casual observers. With the constructivist adoption comes changes in some very foundational views of what constitutes knowledge itself. Even such basic notions as what an acceptable student product or the nature of the mathematics which is constructed should be must be carefully reexamined. Enabling in-service and pre-service teachers to successfully use technology within such classrooms is a major challenge for the teacher educator. The results of this study identify some factors which have proven to be helpful in this effort.

The research was done in two classrooms from the same school in a rural school district over a one year period. Both classrooms were taught by different master constructivist teachers who had each previously participated in one year of inservice, support, co-teaching and collaborative curriculum design prior to this work. These two teachers agreed to implement technology within their classes in markedly different fashions to investigate potential roles technology might play in enhancing a constructivist approach. Although each of these classrooms would easily be classified as technology intensive, one mathematics classroom utilized the computer as a student tool for mathematics exploration - in line with the instructional philosophy of the class. The other classroom utilized the computer as a presentation tool - more in line with a behaviorist approach. In each of these two classrooms total time utilizing the machine remained relatively the same. Within these contexts, this paper will address the question: Given two classrooms from the same school, both of which are taught by master constructivist teachers, is there an added value which might be expected of technology when it’s usage is aligned with the instructional philosophy?

The conditions leading to these findings were first, that the technology was "tightly linked" with the underlying instructional philosophy and approaches. Secondly, the technology in the constructivist orientation was used as a tool for student use in creating their own personally meaningful representations - not as a delivery system. And third, opportunities were presented for the students to create computer based tools for use in solving their problems.

Technology Through a Constructivist Lens

The technology in this project made use of an object oriented computer authoring language - in this case HyperCard and its' scripting language Hypertalk. The object oriented nature of this language allowed for a wide range of powerful tools - such as drawing and painting - to be available for student use, and yet still had relatively simple syntactic requirements conducive to creating expressions in algebraic terms. The computer was used in the technology aligned classroom as a bridge between the sketch and the abstraction.

In actual practice the students did not proceed to the computer until they had become immersed in the problem they were working on via physical materials. The students did their initial sketching on the computer until they had constructed a working representation of the problem space they had encountered. They then identified what the relevant information should be through creating appropriate input and output fields. The developing representation at this time had many features common to both sketches and mental pictures. The entry into the realm of abstraction began as they constructed their method of procedure and expressed this in algebraic terms through scripting the
Subjects consisted of a total of 52 students completing a year of instruction at a rural western elementary school. These students had been randomly assigned into one of two conditions. Of this total 25 students were assigned to the technology misaligned classroom (TMC) and 27 students were assigned to the technology aligned classroom (TAC) [The N’s are end-of-year and account for attrition]. The teachers covered a common core of mathematics curriculum and instructional sequence, although each individual teachers’ curricular emphasis varied in response to the needs and strengths of the students. This school serves a broad predominately Caucasian, lower-middle class population. Based upon district provided data this school was at, or above, district mean achievement scores in mathematics.

Subjects

Methods

Subjects consisted of a total of 52 students completing a year of instruction at a rural western elementary school. These students had been randomly assigned into one of two conditions. Of this total 25 students were assigned to the technology misaligned classroom (TMC) and 27 students were assigned to the technology aligned classroom (TAC) [The N’s are end-of-year and account for attrition]. The teachers covered a common core of mathematics curriculum and instructional sequence, although each individual teachers’ curricular emphasis varied in response to the needs and strengths of the students. This school serves a broad predominately Caucasian, lower-middle class population. Based upon district provided data this school was at, or above, district mean achievement scores in mathematics.

Measures

Parallel forms of the Morgan Mathematics Inventory were used to gather student pre and post data. This fifty item inventory was the result of an earlier extensive cooperative effort between the author and a district level evaluation team (Connell, 1991) and was structurally similar to standard assessments such as the California Achievement Test (CAT) or the Iowa Test of Basic Skills (ITBS). During this test construction process an extensive item analysis was performed to select the best items and establish the item to objective mapping used in this study. The items making up each form of the test were subsequently mapped onto each of the state mandated curriculum objectives of Numeric Operations, Ratio, Measurement, Pre-Algebra, Geometry, Graphs, and Estimation in mathematics. Validity controls were constrained to face and content validity as determined by the teachers and investigators taking part in the study. Reliability estimates using Cronbach’s Alpha were calculated for both pretest (alpha=.85) and posttest (alpha=.81) versions of the test as taken by this group of students. A 25 item geometry pretest from the McGraw Hill Mathematics series was used as a covariate. This assessment was structurally identical to the pre and post measures in construction and administration procedures.

Procedures

This project had been in place for a year when this research was performed. During this year the student growth and progress observed by the participating teachers as a result of their informal observations led to a refinement and stronger adoption of the project ideas and goals as described in the introduction. By the time this research began the following teacher characteristics were observed: instruction was student centered and constructivist in nature; the instructor’s role was that of question asker and problem poser; and problem solving, and persistence and resourcefulness on the part of the students were highly valued by the participating teachers.

The pre-test was given during the second week of September as a part of the instructors beginning of the year assessment of the students. Conditions in both classrooms were controlled with both instructors following a previously agreed upon standard administration format. An existent Geometry pre-test was administered during the first week of October to serve as a covariate. As had been the case for the pre-test conditions in both classrooms were controlled with both instructors following the same standard administration format.

The treatments for this study were the day to day instruction given by the instructors. Both teachers had been identified as exemplary by the district administration and were observed by the author to have reached a master level prior to the beginning of the intervention. Classroom instruction in both classes was constructivist as described in the introduction. Technology was present in both classrooms, but only used as an integral portion of the mathematics instruction in the technology aligned classroom. Student time on computer as reported by the teachers was the same for both groups over the course of the day with the technology misaligned condition’s use primarily as a delivery system for pre-packaged instruction.

The post-test was given during the last week of May as a part of the instructors end of year assessment of the students. As was the case for both pre-test and covariate data collection sessions, conditions in both classrooms were controlled with both instructors following the same standard administration format.

Design

There were two primary quantitative analysis which were performed for this study. The first is more traditional and uses standard ANCOVA techniques to ascertain which, if any, of the observed differences in student performance over the course of the year were significant. The second analysis will not be reported here due to space considerations, but used SP curve theory to find out just what lives in the variance observed in the ANCOVA (See Harnisch, 1995; Harnisch and Connell, 1991).

The data was analyzed using a pre-post repeated measures design utilizing a subset of geometry knowledge as a covariate. As parallel significant improvements were found in each of the mathematics sub-continent areas identified in the item to objective maps, the total mathematics scores will be used as the outcome measure for the results section to eliminate the need for nearly identical multiple parallel discussions.
Results

Due to space constraints this discussion will be limited to the results of the repeated measures ANCOVA. It should first be noted that both the Technology Misaligned Classroom (TMC) and the Technology Aligned Classroom condition (TAC) showed a significant improvement over the course of the year (t(23) = 6.13, p < .0001; and t(25) = 13.24, p < .0001 respectively). Although heartening, this finding must be tempered with the realization that this intervention took place over the course of an entire year. Had a significant difference not been found it would have been cause for great alarm on the part of the investigator, not to mention the local school authorities.

Although a quick examination of the data shows the TMC condition (60%) to be initially performing better than the TAC condition (54%), this observed difference was not significant (F = 1.03, p < .3151). Fortunately for this study, the observed differences at the end of the intervention, in which the TAC condition (81%) is observed to be performing better than the TMC condition (71%) were significant (F = 6.42, p < .0152). The time by classroom interaction effect likewise proved to be significant (F = 15.62, p < .0003).

Discussion

It is important to properly situate this study within the broader context of the research program of which it is a part. By the time this study took place these teachers had a years worth of experience with the materials, methods, and in dealing with implementation issues. I would doubt that the significant differences technology made would have been possible without the prior assurance that both classrooms were utilizing a similar model of constructivism at a master level. The previous year had allowed sufficient time for the teachers to construct a united set of epistemic beliefs and for these beliefs to impact their practice to a significant degree. Mathematical Constructivism involves too many counterintuitive practices to expect a simple two week intervention or inservice to suffice to reach the level of mastery necessary for the commonality of beliefs and practices across classrooms in this study to occur (Connell, Peck, Buxton, & Kilburn, 1994).

In examining the results of this study, some very interesting observations may be made. To begin with, it must be noted that the students in both classroom were successful in meeting both state and district goals relative to their mathematics instruction. This was true in each of the required content areas as indicated by the district. This is an important observation which transcends the t-test significance which was reported under results. A significant t, obtained without a commensurate success in meeting mandated content requirements, might work well for writing an article or paper but does little in providing an effective example for project dissemination. Within this context, i.e., the success of both groups in learning the required grade level mathematics, it is clear that both constructivist approaches to instruction utilized in this study were effective. Although this is not surprising to those who employ such methods, it does serve to document for the literature once more the often surprising power of this different approach toward instruction (Buxton & Connell, 1994). The entire process of putting the teacher in the role of question asker, and then letting questions and not answers guide the instruction is often counterintuitive to many practitioners.

Given the fact that both classrooms had adopted a common constructivist mathematical pedagogy and used the same or highly similar set of materials, the question really boils down to what impacts technology might make in such classrooms. Implicit in this study was the notion that the technology usage must be tightly linked with the instructional program. The technology was, therefore, used in a constructivist fashion. The introduction of the computer was not an afterthought. Rather, the technology had a well defined theoretical place in the curriculum which was made explicit to the participating teachers. This notion of having the usage of the technology be “tightly linked” to the underlying instructional theory is of key importance in efforts to apply these findings.

The fact that technology, used in such a tightly linked fashion, does indeed have an impact is clearly demonstrated by the significant differences in performance found over the course of the study. Despite an initial non-significant advantage held by the students in the TMC condition the use of technology enabled the TAC students to not only overcome this handicap, but to surpass the TMC group to a statistically significant extent. Furthermore, the significant time by classroom interaction suggests that the length of time in which technology is used in this fashion the greater the impact.

One possible interpretation of this finding might be that for technology use to be effective it must map onto the underlying instructional practices in the classroom. This interpretation is problematic in that it assumes that any particular method for learning is equivalent to any other and that all we need do is to match technology implementation to the instructional approach at hand. This is not the case in elementary mathematics. This study differs from this simple interpretation in that the approaches to which the technology use was aligned reflected the thinking presented in the NCTM Standards (1989) to the maximum extent possible based upon the experience and beliefs of the participating teachers. As these Standards identify, not every instructional approach is equal in terms of its effects upon student beliefs, systems of justification, and developed problem solving processes. Doing a better job at meeting inferior goals can hardly be seen as a step forward.
Conclusion

This study, at one level, serves as another testimony that a constructivist approach to instruction can be highly effective in the area of elementary mathematics. If this was all it had to offer, however, it would be of little impact upon the field. There are numerous examples documenting the power, effectiveness, and difficulties associated with such approaches. At another, more significant level, it begins to address some very difficult issues surrounding how technology might play a supporting role in such implementations. As a result of this study the following suggestions seem in order:

1. The technology should be utilized in a "tightly linked" fashion and supportive of the underlying instructional approaches. Educational problems are not likely to be solved by merely throwing CPU's (central processing units) at them.

2. The technology should be used as a tool for student use in creating their own, personally meaningful, representations. The presence of the computer alone as a delivery system of static expert representations does not guarantee, and indeed may inhibit, the development of student "re-presentations".

3. Opportunities should be presented for the students to instruct the computer, using algebraic notation as dictated by the authoring system, general systems of solution to the problems they encounter. This enables the computer to serve as an active critic of the student's work and forces a presentation in a more standard format than otherwise took place.

When these suggestions are taken to heart by experienced teachers, as was done in this study, computer technology has the potential to be a powerful mediating influence in the ongoing student construction of mathematical meaning.

604 — Technology and Teacher Education Annual — 1997
There is a special excitement that comes with the opportunity to develop a new course which spurs reflection on basic beliefs for teaching and learning as well as particular goals for the specific course. This course was the result of such reflection, beginning with the planning stages and continuing to the closing evaluation. As the course progressed, we attempted to document the development of the course, and the impact of the course on the participants. These became the components of our action research project.

Colleges of education are faced with the task of preparing preservice students and inservice teachers to become effective users of technology. This task takes many forms, from separate distinct computer literacy courses to full integration of technology into all teacher education courses. Separate technology courses require a computer expert and focus on developing technical skills. A criticism of these courses is that they do not provide a good model for how technology can be used in a classroom. Additionally, these courses have been criticized for not providing opportunities for students to examine the place of technology in society and its effect on education (Davis, 1993).

Another approach for introducing technology is through integration of technology in existing methods courses. In another study, Copley (as cited in Davis, 1993) found a higher use of the computer with elementary preservice mathematics students who were allowed to explore mathematics and technology together than students who were in separate instructional technology courses. Nicaise and Barnes (1996) describe the process of integrating technology into an undergraduate secondary mathematics education class on teaching geometry. The purpose of the course was to prepare students to understand different instructional methodologies, tools, and textbooks and their application. The course was designed with technology as an important component in the creation of an information rich classroom based on constructivism. These instructors employed several instructional techniques. The first phase of the course consisted of learning theories, geometry curriculum for secondary schools, and technology demonstrations. There was hands-on training of geometry software and Internet tools, including e-mail and the World Wide Web (WWW). Students explored a variety of instructional software including The Geometer's Sketchpad (Jackiw, 1991). The learning activities for the course revolved around the authentic task of designing a theory-driven geometry curriculum. Students worked in groups to build a curriculum that integrated at least three subject areas. The students shared their curriculum by building a WWW site. Informal reports of the students note high satisfaction with the web development part of the course.

At Lesley College Graduate School of Education the computers-in-education faculty developed a program to integrate technology into teacher education. Such integration is not an easy task and requires rethinking of course content by teacher education faculty that may not have sufficient knowledge of technology. The computers-in-education faculty found that team teaching courses in which professors of subject area methods courses were paired with technology faculty or teaching assistants with strong technology backgrounds was extremely effective (Roberts & Ferris, 1994).

A specially focused course on the use of technology in a specific subject area is another way of introducing technology into teacher education. Many of these courses began as summer workshops for teachers. Steen and Taylor (1993) describe a working conference for teachers at Teachers College, Columbia. The conference consisted of two components: software evaluation and lesson creation. In the software evaluation component, the participants worked in groups to carefully evaluate mathematics software including a discussion of the kinds of lessons for which the software would be an effective teaching tool. In the other component the participants created original lessons using the software, including time for practice and discovery exercises for the participants. At the conclusion of the working conference the participants were able to select software for their school or institution and to
develop lessons utilizing that software. Morris (1992) also describes a preservice course that developed from a summer workshop. Students participated in experiments designed to introduce software that allowed them to become familiar with principals behind mathematical concepts.

In the Computer Application and Manipulative Mathematics Program at the University of North Carolina at Charlotte, teachers learned to use computer software to develop ways to make the transition from concrete manipulatives to manipulation of symbols (Piel, Green, & Gretes, 1994). Informal interviews with the participants determined that they had decreased their use of textbooks and increased their use of manipulatives and technology. Using technology helped teachers rethink mathematics and consequently change their teaching methods.

**Course Development**

The idea for the course came from a need to prepare mathematics education students at the University of Tennessee, Knoxville to use technology in the classroom. Like other courses found in our literature review, this course sought to provide opportunities to explore the use of technology. Further, it sought to implement many of the ideas present in the literature.

The course was developed by a mathematics education professor and an educational technology graduate student (Roberts & Ferris, 1994). This was a successful match. Development began with a discussion about the goals of the course. We wanted to provide an opportunity for students to learn mathematics with technology. It was our idea that until teachers have had an opportunity to learn with technology they would not be able to teach with technology. We wanted our students to develop a vision of what a classroom with technology could be even though many of them will not immediately teach in such a classroom. We also wanted to provide a model for teaching with technology for our students (Nicaise & Barnes, 1996). Teaching with technology provides instructors and students the opportunities to explore different roles. During class presentations the instructor not presenting information interacted with the students in the class. During lab and exploration days we served as facilitators. We shared in the preparation of the lessons and labs. Our goal was that our model of collaboration and facilitation would help the students think about instructional techniques for their own classroom.

To further model the integration of technology, we decided to make the course paperless. We began by making the syllabus available on the world wide web. This offered unexpected opportunities. Each day we were able to clarify assignments and ideas by creating other pages linked to the syllabus. The students’ work also became a part of the syllabus. The students were patient and willing to keep trying when technical difficulties occurred.

Continuing with the paperless aspect of the course, students turned in their assignments via the local area network. Evaluation of student work was provided by way of a word processing file that was loaded on each student’s computer. The students could then copy that file and remove it from the hard drive to ensure privacy. As the course progressed students developed electronic portfolios.

**Conceptual Framework for Course Activities**

The course was organized into five modules: (a) teacher and student use of the Internet; (b) productivity tools for instruction, databases and spreadsheets; (c) technology for teaching algebra; (d) technology for teaching geometry; and (e) management and evaluation of technology. Each consisted of three types of activities: developmental, experimental, and instructional. Developmental activities provided opportunities for participants to become familiar with specific technology resources. Experimental activities provided opportunities for students to expand their knowledge of mathematics through technology. The main objective for the participants was that they use the mathematics software to learn something new about mathematics. The students selected individual lab activities to explore mathematical concepts. Instructional activities provided opportunities for participants to apply what they had learned about the individual software packages to develop instructional materials. Students worked in pairs or individually to complete activities. We used class discussions of assigned readings to tackle issues like classroom management with computers and the effect of computers on teaching.

**Portfolio Development**

A central feature of the course was the means of assessment. Students created an electronic portfolio consisting of activities that they had created within each module. They also created word processing files that explained what they learned or how they would use the materials they created. Students kept a personal copy of their portfolio on disk. About half way through the course the participants learned how to use Hyper Text Markup Language (HTML) to create WWW pages. They created their web portfolios using basic HTML tags and a simple text editor. They made screen shots of their explorations and lessons completed in the modules and converted these to a web acceptable format.

This aspect of the course offered both the instructors and the students opportunities for authentic problem solving. Posting the files to the WWW server required the development of consistent file naming schemes. Another technical problem the instructors faced was limited allotted file space for the student portfolios. Obtaining file space which would remain available for an extended length of time for a class was a new procedural issue for the university.
There were several design issues that the students and the instructors faced in WWW page development. Instructors had to design a method for linking the course syllabus to student work. Students faced several decisions about the design of their portfolio. For example, one student designed her portfolio as one long document in an outline format with internal links to sections. Another student choose to make her portfolio as text with hypertext links to examples of her works. Still another student made her portfolio several pages that linked to each other allowing one to choose items to view. As students gained skill in HTML development they added graphics and ideas from other sources on the WWW.

Results: Participant Reflections

The culmination of the research aspect of this project was the written evaluation from the participants. They expressed their perspectives on the ways in which technology acts as a change agent in their attitudes, skills, knowledge, and behaviors in the mathematics classroom. The anecdotal analysis of professional growth is seen in the following excerpts of student comments and corresponding examples of their use of technology from each module.

As indicated above, each module provided the students opportunities to learn new software, learn mathematics in a new way, and apply both to the design of lessons for their own students. In the Internet module one student represented her new knowledge of the Internet in an innovative concept map.

Another student used the computer to make creative worksheets. Although typically a productivity tool, her use of databases took a different look. As she learned about databases and spreadsheets, she applied that knowledge in ways useful to her since she did not have access to a computer in her classroom.

One student who saw herself as a “slow learner” in this class gained “many insights and a huge amount of information.” She related her own computer anxiety to students’ mathematics anxiety As she expressed, “readily available assistance and experience go a long way to alleviating both.” Her use of spreadsheets to explore the Central Limit Theorem is an example of her willingness to use technology in innovative ways, beyond her previous view that these programs were “limited to clerical types of teacher chores like averaging grades.”

An elementary school teacher felt that “the more knowledge and experience a teacher has with technology causes him/her to have positive attitude about, and feel comfortable working with, whatever is available. It helps to see the vast possibilities of how to incorporate these materials into the regular curriculum ... for the entire instructional process.” Within the Algebra module, she portrays this positive attitude in innovative instructional ideas for her students by using the technology in conjunction with manipulatives to “guide students from concrete to abstract.”

A high school teacher, worried about students losing essential skills by using the computer, found that “computers allow students to go straight to the heart of the problem instead of getting bogged down by the time consuming computational work.” He used The Geometer’s Sketchpad (Jackiw, 1991) to create pie charts by rotating angles to make the sections of the chart.

A variety of concerns were expressed during the discussions in the management and evaluation of technology module. Several students discussed opportunities to apply for grants for technology classrooms such as Tennessee’s 21st century classroom: “I will not do that [discard application] the next time I am offered the chance to bring my students the technology they need to learn so that they will be successful in their future.” Another student stated, “With all I’ve learned this summer about technology, I could feel confident in applying for a 21st century classroom next spring.” Recognizing that access to technology in the classroom was an important issue, students expressed valid concerns regarding the equitable use and availability of computers one student wrote, “Not every school is equipped with them which hurts the students;” and “the gap between the education of the low economic areas and the middle to upper economic areas will widen even more.”

At the conclusion of the course students reflected on changes in knowledge, skills, and attitudes. This allowed students to rethink their philosophy of instruction and assessment. “By using technology in a classroom, one’s philosophy of instruction and assessment has to change....The assessment of students with computers has more to do with the process rather than content. I think students feel like they have more control about what they are learning...” Assessment alternatives are certainly available with computers, but not limited to the technology. “Two examples of how students can show their understanding of the material are (a) students writing paragraphs explaining what the numbers mean and (b) one student explaining the mathematical process involved to a fellow student.”

The obvious area of growth was in participants’ attitudes, skills, and knowledge regarding the use of technology in the mathematics classroom. In the words of one student,

This class has changed the way I think about teaching. Having experience with the computer gives new ways to design lessons and activities, even without an available computer. Now, I will think to imitate many of the activities with paper and pencil instead of pouting that I do not have any computers in my room. Now, I’ll consider what
happens when I rotate this shape or drag this corner. ...My philosophy of computer technology has changed, because I have had an opportunity to explore different software and the internet with guided help.

Participants expressed changed beliefs and behaviors about the class environment, teacher and students roles, and instructional strategies. They perceived the nature of mathematics and its possibilities with their students as more exploratory, interactive, and authentic. What they said and what they did reflected the idea that technology had the potential to change what mathematics is taught, and how mathematics is taught.

Discussion

One of our major goals was to create an innovative course that integrated mathematics and educational technology and embodied features found in the literature. Another goal was for students to learn some mathematics using software as well as to use software to create lessons for their students. Evaluation of the course based on student work, student reflections, and our informal analysis indicates that we met both of our goals to a large extent. Within the course design, we would readdress the assessment of student work, especially the use of the portfolio, using a best-work rather than all-inclusive portfolio of student work. We would also reconsider assessing multiple aspects, such as creativity, substance, form, and design. We also would develop a means to incorporate student progress as well as mastery of materials.

Examples of student work and reflections indicate that students were able to reconceptualize their own learning of mathematics. Moreover, the process of learning with the technology was important to the design of lessons for their own students. We would hope to strengthen these opportunities even more for students to learn the content in new ways through the use of technology.

It is our hope that, by sharing the process and product of our action research regarding our course, other teacher educators will also be encouraged to develop and implement means for integrating technology into the mathematics education curriculum. As we attempt to impact students' beliefs and behaviors, we too must reflect upon our own beliefs and behaviors, and respond accordingly. Designing innovative instruction in a collaborative effort makes partners of people as well as partners of disciplines.

Technology in Mathematics Education: A Model for Revisioning Preservice Courses

Stephen J. Bloom
Butler University

Marianne Handler
National-Louis University

It is no longer a question of whether or not technology experiences need to be an integrated part of a preservice teacher education program. The question now focuses on identifying those processes which will best help us put those experiences in place. Teachers & Technology, the 1995 report from the Office of Technology Assessment, clearly identified several real concerns in the area of technology and the preparation of new teachers. Two of these findings that provided the impetus for this project were: 1) graduates of teacher preparation programs are entering the field with limited knowledge of how technology can be used in their own practice and 2) teacher education faculty are teaching about technology, not with technology. The ISTE Foundation Standards as presented in the Curriculum Guidelines for Accreditation of Educational Computing and Technology Programs (1992) also identify the skills new teachers should have when they complete their preservice program. Additionally despite the calls for including technology experiences as a part of preservice teacher education programs articulated by national and state organizations and groups such as the National Council of Teacher of Mathematics (1991), Interstate New Teacher Assessment and Support Consortium (1995), Simpson and Wallace (1996), Molina and Schielack (1996) the concerns noted above are found in the preparation of teachers of mathematics.

Faculty involved with preservice students should provide experiences that include real-world instructional problems where technology can be a solution in solving those problems (Rodriguez, 1996). Our previous collaborative work, Bloom and Handler (1993) has lead us to believe that collaboration among university faculty in planning a systematic integration of technology across the full preservice experience, as well as, in the revisioning of particular course offerings can be successful.

Project Goals

This project addressed two main goals. The first was to integrate meaningful technology experiences within the mathematics methods course. The second goal of this project was to develop a model that would assist faculty as they revision existing courses and explore ways to assist student attainment of the objectives of those courses through the use of information technologies.

The partnership for this project included a member of the Technology in Education Department and a member of the Mathematics Education Department. We acknowledge that our previous collaborations, as noted earlier, make us somewhat different than new partnerships that might attempt to use this model. In any collaboration the element of trust is key and we had already established that in our working relationship. Others might find the process developing more slowly as the working relationship is established.

In the National-Louis University undergraduate elementary education program preservice students are required to complete an introductory Computers in Education course prior to admission to methods courses or student teaching. A course that includes clinical experiences in classrooms is a prerequisite for the computer course. Through this sequence, the students are able, to some degree, to place the experiences of the Computers in Education course in a school-based context. The placement of the computer course in the program means that methods course faculty can expect students to have the basic computer skills necessary to accomplish the assigned technology based tasks. The computer course provides 'how to' knowledge and skills and some application, but the continued application and development of skills to meet the ISTE Foundation Standards takes place throughout the program.

Building the Model

As we approached building the model we examined the “Innovation-to-Practice” process model described by Yessayan(1992). The phases of the model include exploring the possibilities that exist, gathering information toward implementation, planning for incorporation into
instruction (Yessayan referred to this as “innovate and experiment”) and reflecting for modification.

Our first step in the process was to identify the course with which to explore and build the model. The Methods for Teaching Elementary School Mathematics course was chosen. It was to be offered two quarters in a row providing us opportunity to continue to build the steps of the model during the first quarter and move through the cycle again as we planned for and implemented the changes in the second quarter. While Bloom was a comfortable technology user and had integrated some technology experiences into his courses, he was not familiar with the range of software available to him and his students. Handler brought this expertise to the project. That was how we had envisioned the model developing. One partner would bring the technology know-how and awareness that the instructor of the course being revised had not yet perfected. This partner might be a department colleague who has gone through the process or a colleague from another department who believes in the importance of the technology integration process. What the collaboration needs is at least one partner that has a personal comfort level with technology, uses technology in her/his own instruction, and is willing to be a mentor.

Starting from Where You Are

Starting from Where You Are

During the first quarter we began with the extant technology experiences. Bloom reevaluated technology experiences from previous course offerings and considered their effectiveness in terms of desired and actual student learnings. Previous student experiences had included a CAI software evaluation and the in-class use of the Geometer’s Sketchpad (1995) and Data Insights (1990). In our planning process we considered what the student experiences would be and what kinds of modeling could be done by the instructor. We determined that we would build in several new experiences during the first quarter, assess their value and success, and use that information in our planning for the second quarter.

Our brainstorming at this point also focused on another vehicle to expand student understandings. In previous offerings of this course, students had been required to interview a mathematics teacher using questions that were linked to the mathematics topics in the course. The interview was revised to include questions that focused on the teacher’s use of technology tools in his/her own instructional practice.

During the first quarter Handler observed Bloom’s class as well and demonstrated several pieces of software. One of the pieces of software demonstrated was Math Blaster Mystery (1989) (MBM). Previous demonstrations of the software focused on the problem solving steps and the ability for teachers to create their own files of problems using the provided template. During this demonstration of the software, Bloom led a discussion on how specific course objectives could be met through the use of MBM. He showed the students how the answers chosen by children could help the teacher identify misconceptions held by those children. This approach to using the software was new and one that worked well in subsequent demonstrations and discussions of MBM.

Meetings throughout the first quarter focused on how to revision the course in terms of both instructor and student learning experiences that support the objectives. These changes were then reflected in the second quarter’s course syllabus. We aimed to develop both new technology experiences for the students and ways the instructor could better model technology as his own instructional tool. With that two-pronged approach as our guide we prepared for the second offering of the course.

Looking for New Opportunities

Looking for New Opportunities

During each quarter the first step was to brainstorm the opportunities. These included:

- student activities during class
- revising of the instructor technology interview
- technology-based assignments
- options for instructor modeling
- opportunity to learn new software and use for instruction.

We took into consideration the time needed to learn new software and included some pieces with which Bloom was familiar. As it was important for us to add one new experience for the instructor, he chose to learn how to use the slide show component of ClarisWorks (1995). We also created an assessment activity to determine how the students perceived this new focus on technology experiences.

Our plans had to be adjusted following the first meeting of the methods block faculty. As the four faculty
members shared their plans for the quarter it became obvious that each was planning to provide students with technology-based learning experiences. We then reexamined the pedagogical knowledge of the students' technology knowledge and skills. We had assumed that all the students had completed the required introduction to computers course prior to enrolling in the mathematics methods course. We later determined that this assumption was in error. Faculty wishing to incorporate technology experiences into their courses would be well advised to assess the technology knowledge and skills of their students and be prepared to include time for teaching students about the technology itself.

In implementing the revised course Bloom redesigned the Kid Pix assignment to look at both math concepts and mathematics pedagogy. Students had to consider the accuracy of the mathematical model being portrayed, the quality of the interactivity created in the screens, field test the screens with students and summarize that field experience. They were also required to write a summary describing the process they used throughout the completion of the project, and, as means for further assisting students in linking this technology experience with the course objectives, include a reflective statement describing how this task helped them attain those objectives.

In implementing the ClarisWorks slide show Handler was able to take the notes and create a template and an opening screen. The partners then sat down together, one dictating the content with the other modeling how the program worked. Changing positions and roles, Handler aided Bloom as he created the next several screens. With this assistance he was able to complete the slide show on interpreting and analyzing data: the shape of the data.

Building in New Opportunities

Three specific opportunities were identified during which the instructor could model the use of technology as an instructional tool. The first was to model, on his own, the use of MBM and lead a discussion similar to what had been done during the first quarter. The second modeling experience included the use of Inspiration (1992) as a concept mapping tool in class using a computer and a LCD panel. The last opportunity was to work with Handler in order to learn how to use ClarisWorks and develop one slide show to be used for instruction.

The final format for the course included three technology-related assignments. The first assignment focused on practitioners' current use of technology in their teaching of mathematics. Towards that end students were provided a protocol of interview questions. Each student interviewed a practitioner and the results of those interviews became the basis for an extended discussion of those responses. For the second assignment students could either construct an appropriate set of problems for MBM or create an annotated bibliography of technology-based resources available, including resources accessible via the Internet, for teaching elementary school mathematics. In the MBM assignment the students used the teacher utility component for creating problems. As they created the incorrect response selections for their problems, the preservice students had to indicate what error or misunderstanding in a student's mathematical thinking would be revealed as a result of the answer choices they had included. In the third assignment, students would create mathematics activities for children using Kid Pix (1994).

Implementing the Revised Course

A key component of the implementation process was to assess what we were doing as we looked at content and instruction of that content in a new way. We did not see ourselves as adding onto the course but rather approaching the content through new instructional strategies. The goal was to discover ways in which the technology could assist in introducing mathematics concepts and could also build pedagogical knowledge.

One problem we encountered was in relation to the students' technology knowledge and skills. We had assumed that all the students had completed the required introduction to computers course prior to enrolling in the mathematics methods course. We later determined that this assumption was in error. Faculty wishing to incorporate technology experiences into their courses would be well advised to assess the technology knowledge and skills of their students and be prepared to include time for teaching students about the technology itself.

In implementing the revised course Bloom redesigned the Kid Pix assignment to look at both math concepts and mathematics pedagogy. Students had to consider the accuracy of the mathematical model being portrayed, the quality of the interactivity created in the screens, field test the screens with students and summarize that field experience. They were also required to write a summary describing the process they used throughout the completion of the project, and, as means for further assisting students in linking this technology experience with the course objectives, include a reflective statement describing how this task helped them attain those objectives.

In implementing the ClarisWorks slide show Handler was able to take the notes and create a template and an opening screen. The partners then sat down together, one dictating the content with the other modeling how the program worked. Changing positions and roles, Handler aided Bloom as he created the next several screens. With this assistance he was able to complete the slide show on interpreting and analyzing data: the shape of the data.

Review and Further Revisioning

In order to assess what had occurred over the two quarters, we tapped several data sources. We collected feedback from the students, sent a survey related to course technology use to the other methods faculty, and we each had personal reflections concerning the process. In order to determine how well the ISTE Foundation Standards were being addressed, we examined all of the technology experiences the students had completed within all four of the methods courses. All of these data will be used in future program review and development and in identifying areas for faculty professional growth experiences in the technology area.

Student Feedback. Student feedback provided important information about the assignments. We were initially surprised when none of the students had selected to create an annotated resources bibliography. In their feedback the students clearly indicated that they had chosen not to select this assignment option because the directions had not been clear enough. Their previous experiences with the lack of access to the labs also provided concern that the assignment would be too difficult to complete. For them using Math Blaster Mystery or Kid Pix was far more comfortable. They had previously seen these programs in their introductory computer and mathematics methods courses.
The students had very positive responses to the Math Blaster project and the development of the Kid Pix screens. Bloom had already modeled the programs and showed how the mathematical concepts had been woven into the lesson. Then the students had a chance to apply these ideas in meaningful projects that could be used with children. Student feedback included comments such as “The method of focusing on the problem solving process instead of all the focus being on the answers was new to me” (from an MBM project), “I felt that working the program (from an MBM project) enabled me to understand children’s mathematical thinking more than I had in the past”, “This field test showed me that technology allows children to work at their own pace” (from an KP project) and “I learned to think about what students need to think about when they are involved in an activity” (from an KP project).

One of the assignments was a revision of the classroom teacher interview. The interview focused not only on teacher’s mathematics instruction, but also on the teachers’ valuing of technology as a tool, ways in which that valuing was communicated to students, decisions about and decision making processes for using technology, and assessing and evaluating mathematics learning and how technology assisted new mathematics knowledge. During the post-interview discussion in class the students found that the practicing teachers interviewed typically did not use technology in their mathematics teaching. The few that did tended to either use CAI software or word processing in connection with their students’ writing. Reflecting on these findings allowed the students to reexamine the types of technology experiences they had had in the course and the barriers to using technology in mathematics teaching and learning commonly faced by elementary school teachers. From this discussion and the students written summaries of their learning, the course instructor deemed that the goals for the assignment had been attained and that the teacher technology interview would be an assignment worthy of incorporating into the next offering of the course.

Faculty Surveys. We discovered that students had a variety of experiences but not all were of the same quality. In the science methods class they previewed laserdiscs and CDs that fit into the science curriculum. They also had an opportunity to go onto the World Wide Web and look for science resources. The social studies methods instructor had students evaluate software and list appropriate software in their Social Studies Unit project. As a part of their language arts methods the students helped children in classrooms develop word processing skills. Finally, all written assignments in the mathematics and language arts methods courses were to be word processed.

Collaborators Reflections on the Model

In examining the usefulness of this model in other settings, several questions arise. We will raise but a few of those. What if methods courses are not in the school of education? What if there is not instructional technology support? What if there is an integrated methods experience in a clinical site? These are a sampling of the questions that would need to be thoughtfully considered and planned for.

We learned that revisioning courses using this model is a process that takes time and commitment. If this process is important in the redevelopment of teacher education programs it must be supported administratively in some way. In our case, Handler was on sabbatical and so time was available however we had no other institutional support. We also learned the importance of preplanning equipment needs and arranging for access to the resources students would need for assignments, creating back-up plans in the event that the technology does not work, and, above all, we learned about the need to be flexible and trusting.

This project reaffirmed for us the pleasure of working in a collaborative relationship. It is important as faculty try this model that they build their partnerships carefully, taking time to talk about ideas, values, and beliefs. Don’t plan on making big changes right away. Find out where you are and move carefully. As you and your partner(s) work together, think course specifically and programatically. Spread the word about what you are doing. Open communications with other faculty and encourage their efforts at integrating technology. Open communications with students and provide them a first-hand view of peer collaboration at work. We think it is worth the effort.

TEACHER TRAINING IN COMPUTER-AIDED ALGEBRA INSTRUCTION

Masayasu Aotani
University of California at Berkeley

The University of California at Berkeley and Vista Community College, also located in Berkeley, share many instructors. As a result, the two institutions work very closely with each other. In fact many of Vista College's evening classes are offered on the campus of UC Berkeley. Vista Community College offered computer-assisted elementary algebra and intermediate algebra in the spring of 97 for the first time. This pilot project had been in preparation for about a year as of the fall of 96. Peralta Community College District which Vista College belongs to held a number of workshops for prospective teachers during the fall semester of 96. This paper is about the design and the goal of these workshops.

Rationale for the Workshop
1. Most mathematicians use computers only to typeset their papers. They need to get used to using them in different ways. In particular, many are against using calculators to learn and teach mathematics. They need to be shown the differences between a calculator and a computer in the ability to aid students in their learning and in the role they play in mathematics instruction.
2. Needless to say, computer-aided instruction did not even exist when they were students. Therefore, even the concept of computer-assisted instruction is entirely new to most professors. They need to get initiated in various senses; both theoretical and practical.
3. Instruction using computers requires an entirely new set of teaching paradigms. Chalk-and-blackboard professors from the old school need to learn how to modify their teaching.
4. As the method is new to the students as well, the professors should stay at least several steps ahead of the students in terms of both the knowledge about the equipments and the awareness of new learning methodology.
5. By making it a district-wide workshop and appealing to the power of numbers, the chance to get any grant will be maximized. Furthermore, this arrangement enables us to form, even loosely, a district-wide task force of computer-literate mathematicians.

Design and Goals of the Workshop
The workshop contains the following elements.

Organizational Meeting — Introduction
In this mandatory meeting, professors from different schools are introduced to each other. Unlike at four-year colleges such as the UC System schools, at community colleges the resources one college can afford are quite limited. This is the case both with man power and other resources. Therefore, it is crucial that all five campuses along with UC Berkeley can band together to create a common resource pool which any faculty at any campus can take advantage of. The fact that so many professors are graduates of UC Berkeley makes the process of getting to know each other and forming camaraderie quite easy.

Getting Started with Interactivity
Basics of the operations of the pcs delivered to the schools along with the necessary preparation both equipment-wise and otherwise are discussed.

As mentioned in the Rationale section, computer assisted learning is quite new for most faculty members. In particular, it is important to understand the difference between a typical lecture and computer assisted instruction since even a typical lecture is interactive to some extent. The instructors should learn the newly defined interactivity in the context of computer-assisted instruction. Needless to say, as the name suggests, Computer Assisted Instruction is not done exclusively by a computer. Human guidance, intervention, and reinforcement are very important ingredients of any successful CAI. Proper timing and extent of intervention must be learned. In this unit, the instructors learn the rather theoretical aspects of CAI. Our experience with mathematicians, including myself, is that they cannot feel comfortable unless the theory behind what they are told and supposed to do is presented to them alongside practical instructions.

Syllabus Workshop
Course design issues and issues surrounding effective use of each software are addressed. This is important as each software is designed for a specific set of tasks.

This is a unit in CAI practicum. The instructors study actual syllabi for a course built around CAI. Several types of syllabi are presented for comparison. The core of this
unit is the presentations by those who actually taught such courses out of the syllabi they are presenting and the ensuing brainstorming sessions with the professors who are being trained to use the systems. As some opinions and criticisms expressed by the participants were quite revealing and at times even eye-opening for the presenters. Both the presenters and the trainees gained much out of this session.

**Site Visit**

In some of our neighbor community college districts computers have already been used for mathematics instruction for a while. For example, Chabot College has been using technology in their instruction campus-wide. This visit keeps us from reinventing the wheel.

Seeing is believing. It is one thing to read about CAI, and it is quite another to actually try it oneself. But, seeing it in action in a real classroom is several notches above those in terms of the impact on the participants. For one thing, it makes a believer out of doubters. For another, they get to hear about their colleagues’ experiences including the problems they faced. It was quite convincing and encouraging when they told us the attrition hit the all time low at their school since the introduction of CAI. Many instructors took this opportunity to become students themselves and try out the softwares. As they use their computer to teach humanities as well, many mathematicians were able to experience firsthand what is it like to learn a new material from a computer interactivity. This also served well as sensitivity training as many experienced quite an array of unexpected problems including even failure to logout.

**Monitoring Student Progress**

As the whole point of computer-aided instruction is allowing the students to proceed at their own pace, each student will be doing a different exercise at any given moment. The issue of keeping track of the students’ progress is discussed with an emphasis on time management and effective use of laboratory assistants.

The students are allowed to move to more advanced sessions only after a successful completion of all exercises and obtaining a passing score on the exit quiz. Needless to say, this relieves the instructor of grading and recording duties. However, at this point our system can only act as a bookkeeping tool, and detailed analysis of difficulties and individual patterns of mistakes still have to rely on human instructors. This is often compared with machine translation. Machine translation equipped with artificial intelligence is quite powerful and impressively fast when translating a standard document. But, they fail miserably with nonstandard documents. Current learning theory emphasizes different learning styles exhibited by different individuals. Individualized teaching is, at least at this point, only possible by human instructors. As the questions on the quizzes and the grading scheme are somewhat simplified to facilitate fast grading and fast feedback by the computer, frequent human intervention is crucial. Half of the instructor’s job is to learn to analyze these quizzes in a new format, and the other half is to master the technique of complementing the CAI system. By complementing, we mean reallocating all simple jobs to the computer and concentrating on the tasks that can only be done by humans. For example it is quite difficult for a computer to teach effectively how to approach word problems. On the other hand, computers are very good at giving computational problems with similar features such as equations with fractional coefficients.

Speaking of reallocating jobs to others, an effective use of laboratory assistants is another area where the teachers need to be trained. At four-year colleges, most professors have experience with teaching assistants. But, community colleges, at least the ones in California, do not have teaching assistants. Furthermore, the functions performed by TAs are quite different from those of laboratory assistants. We have to remember that some mathematics professors have not had a laboratory of any kind even as students, and as such they have not even encountered a laboratory assistant in their life before. This is not unrelated to the fact that mathematics is basically a matter of individual efforts, and a common mistake first time teachers make is trying to do everything and trying to run the show all by themselves.

**Introducing Students to CAI**

The title says it all. This is as new for the students as for the professors. Some pointers as to what to teach the students and what pitfalls exist are provided.

**Getting Up and Running**

Instructors should know how to and from whom get help. Also covered in this session are various troubleshooting techniques.

This intensive session is run right before the semester in an environment that simulates the actual classroom very closely. As each college in the district has its own com-
puter facility, the workshops are run on the instructors' home campuses. By this time everything including support systems should be in place at each college.

**Difficulties Students Face**

During the course of the workshop, every participant is made aware of the following typical difficulties experienced by the students.

**Lack of Individual Attention**

The students who are more used to conventional lecture style teaching feel somewhat abandoned when they have to face the computer screen and interact with the machine by clicking and typing. They have to be told to take full advantage of the help available both from the laboratory assistants and the instructor himself.

Very low level of student-to-student interaction As each student proceed at his own pace, it is difficult for the students to discuss the problems they are working on with their classmates. This is why Vista College has a resident tutor for lower division mathematics classes. He organizes study sessions to promote group studying. Furthermore, the students are encouraged to post their questions to a computer bulletin board. This is precisely like the Usenet newsgroups except that it is just for Peralta students.

**Limited Student-Teacher Interaction**

Even though most students sit quietly in a typical classroom and do not ask too many questions, it seems to be comforting to know that the teacher is standing in front of them facing the students and is available to answer questions if one should decide to ask something. They should be told that they now have to take the initiative in their learning. The computer does not lecture to the students who just sit in front of it. Their computer lab is not a movie theater. They can not move forward unless they initiate the process. If they get used to treating the computer as a teacher, there is indeed much more interaction between the students and the teacher. However, for those who insist on learning it from a human teacher in a conventional classroom. That option is readily available. Most classes are still in the traditional format, and CAI is just an option for them.

**Concluding Remarks**

We have considered the content of the teacher workshop for computer assisted algebra instruction in the Peralta Community College District in Northern California. Even though this is a workshop for mathematics instructors, many features must apply to other subject areas as well. In particular, the difficulties the students face in learning from a computer is not limited to mathematics. After all, the reason for CAI is to let the students set their own pace and create their own learning style. If the conventional method suits the students, they should certainly be able to learn the material that way. It helps greatly to remember that CAI is not a cure-all, but is another alternative for those who do better if allowed to take the initiative in their learning and set their own pace. At the community college level, one of the major reasons for introducing CAI is to retain the students in the class. Therefore, if the student is not comfortable with CAI, there is no reason to force it upon them.

EFFECTS OF HAND-HELD COMPUTERS ON THE TEACHING OF ALGEBRA

Susan E. Williams
University of Houston

The publication, "Algebra for Everyone" (Edwards, 1990), suggested that all high school students need to study algebra. Several mathematics educators supporting this idea have noted that traditional algebra is approached in a manner that is too abstract for most students (Chambers, 1994; Hawkins, 1993; Heid, 1995; National Council of Teachers of Mathematics Board, 1993; Seeley, 1993; Silver, 1995; Steen, 1992; Usiskin, 1995). A recurring message in each of these articles is that traditional algebra often is taught using a rigorous approach that involves rote computations, meaningless manipulations of symbols, and acquisition of a predefined set of procedures for solving a fixed set of contrived problems. In addition, the algebraic understandings cultivated in traditional algebra are generally far removed from those needed by both employment-bound and college-bound students in a technological world. The challenge of creating an "Algebra for Everyone"—one that can provide all students with tools that allow them to advance in both academic and employment settings—has caused mathematics educators to rethink the structure of algebra as well as the teaching of algebra.

Three major issues must be addressed for the implementation of an "Algebra for Everyone" to be successful. One issue centers on the obvious need for the rethinking of the topics and the structure of the algebra curriculum. The second issue involves the role of technology in a reformed algebra curriculum. The major influence of technology in mathematics education is its potential to shift the focus of instruction from an emphasis on manipulative skills and algorithms to an emphasis on development of concepts, relationships, structures, and problem-solving skills (Corbitt, 1985). This is right in line with the goals for the reformulation of the algebra curriculum. The third issue revolves around the need for effective staff development to prepare both preservice and inservice teachers to teach a reformed algebra curriculum that makes regular use of powerful technology. The proposed changes in curriculum and teaching practices are a substantial departure from conventional practice, and considerable evidence suggests that reforms of this type are difficult to implement and hard to sustain (Cuban, 1990; Cuban, 1992; Fullan & Stiegelbauer, 1991; Sarason, 1990). Reform efforts aimed at changing the way we approach mathematics teaching cannot possibly succeed without the assistance of teacher preparation and training programs.

Need for Algebra Curriculum Changes

One of the major themes that permeates mathematics in algebra and the courses that follow is the study of function. In spite of this, traditional algebra has been organized around the concept of equation and methods of solving equations. The concept of function has been "patched in" at the end of the algebra course without providing substantial meaning or purpose. The algebra curriculum has typically approached functions as a more advanced idea and has treated functions in abstract and general ways which serve to make simple ideas difficult (Stanley, Molina, Seeley, & Williams, 1996).

According to Stanley (1995), the emphasis on number systems and equations in the traditional high school algebra course made sense years ago when the course served as the first step in the preparation for a college-level course in "abstract algebra." But today the topics and organizational structure of high school algebra make less sense as the goals shift toward the laying of a foundation for general understanding of technical ideas in science and business, or as preparation for the eventual study of calculus. Stanley suggests that high school mathematics in general (and algebra in particular) should take on a flavor of analysis (where the study of functions is the central focus) and not of abstract algebra (where the study of number systems and equations is central).

Placing the concept of functions in the central role of algebra makes sense for several reasons: (a) the concept of function arises naturally out of the study of patterns and formulas of earlier grades; (b) variables represent quantities that change, and functions provide a way of stating...
rather than the emphasis of algebra being placed on the special case, it would focus on the overarching idea of function; (d) the flow of algebra would be more natural—questions often arise from the study of functions that lead to simplifying expressions, solving equations, and working with inequalities; (e) with hand-held technologies, graphs of functions are easily constructed and compared; and (f) connections between multiple representations of functions become more accessible with the computer assisted symbolic algebra (CAS) capabilities of the newest hand-held computers (Stanley, Molina, Seeley, & Williams, 1996).

Heid and Zhiek (1996) propose that algebra should be reformulated so that the curriculum (a) centers on algebraic concepts such as function and variable instead of on paper-and-pencil algebraic routines, (b) focuses on mathematical modeling rather than on classic word problems, (c) replaces symbolic manipulation with symbolic reasoning, and (d) encourages the use of multiple representations and strategies in algebraic problem solving instead of mastery and use of one representation or strategy at a time.

Impetus for Algebra Curriculum Changes Provided by Technology

The algebra curriculum needs to embrace a functions approach using experiences embedded in the context of realistic and interesting problems (Chambers, 1994; Fey & Heid, 1995; Heid, 1995; Silver, 1995; Stanley, 1995; Usiskin, 1995). Graphing technologies support the change to a function-centered algebra curriculum—the language of graphing technologies quite naturally depends on the concepts of variables and functions. In addition, the technology makes the use of real-life data and contextual problem-solving situations more attainable. Without technology, students are limited in problem-solving situations to solving problems which predominantly use algebraic techniques. Classroom time and student algebraic skills become issues when technology is not present; problems must be carefully written so that there are "nice" solutions. Because real data rarely behaves in a "nice" manner, contrived data has been used in the past. When technology is made available, real data can be collected and used because the technology can handle the "tacky" computations and the time-consuming and tedious manipulations. The student is allowed to focus on process and the construction of understanding which allows for meaningful interpretation of the outcomes.

Mayes (1993) has found that graphing technologies have (a) broadened the class of problems that can be presented to students because the polynomials need not be factorable or limited to small degrees, (b) allowed for both algebraic and graphing approaches, improving students' understanding by furnishing multiple representations of a problem, (c) afforded the opportunity for discovery-learning episodes by reducing the burden of computation, manipulation, and plotting so that students can focus on patterns and relations, and (d) allowed a focus on heuristics for solving more realistic applications by reducing the time spent on mundane manipulations and graphing.

Hand-held computers have recently become more advanced. For example, the new TI-92 hand-held computer provides a first glimpse of inexpensive powerful technology that will be available on a regular basis to all mathematics and science students (Demana & Waits, 1996). It has built-in software for computer assisted symbolic algebra (CAS), computer interactive geometry, 3-dimensional graphing, sequence graphing, a partial spreadsheet, as well as all the traditional features of graphing calculators. The TI-92 can be linked to a Calculator-Based Laboratory System (CBL) to collect experimental data electronically. The full range of probes available for computers are also available for CBLs. The affordability of such a powerful tool for mathematics and science investigations should certainly assist in redirecting the focus of the algebra curriculum.

The use of sophisticated technology such as the one described above encourages change not only in how mathematics is taught (instructional component) but also in what mathematics is taught (curriculum component) and the setting in which it is taught (contextual component). Technology can play a powerful role, both as a catalyst for change and as a resource to facilitate the transformation of teaching and learning (David, 1990). Together, reform and technology create a far more powerful force for change than either is alone.

Need for Professional Development Training for the Teaching of Algebra Using Technology

To make "Algebra For All" a reality means focusing on fewer topics organized around central ideas while preserving mathematical integrity and rigor through the depth of study rather than the breadth of study. As we formulate this approach to teaching algebra, we must use the information that we know about how students learn best and apply that knowledge to our teaching. Students need to be involved in active learning situations with new information being connected to the information they already possess. Algebra students need to be provided with opportunities to experiment and collect data, to analyze that data, and to draw reasonable conclusions based on the findings. Algebra needs to focus on "ways to solve a problem" rather than "the way to solve a problem" so as to equip students with multiple solution strategies. A major obstacle in creating such courses stems from the fact that teachers have never been taught how to teach in a way.
that engages students in a variety of interesting and important learning activities structured to develop the inherent critical thinking and problem-solving abilities of all students (Seeley, 1993).

To assist in the development of an understanding of how algebra might be addressed from a functions approach, a professional development algebra institute (Williams, 1996) was created for secondary mathematics educators in the state of Texas. This five-day institute was produced with funds from the Texas Statewide Systemic Initiative in Mathematics, Science, & Technology Education and the Texas Education Agency and consists of student activities, presentation transparencies, and teacher notes for three areas of first-year algebra: foundations of functions, linear functions, and quadratic functions. Initial training of trainers began last March—an effort which trained more than 100 mathematics coordinators/specialists and regional service center personnel. Those 100 trainers have provided multiple training sessions in their regions during the summer and again this fall. Training was also provided in May for university teacher educators thus allowing the materials to be incorporated into preservice secondary mathematics methods courses and/or graduate mathematics education courses. In the paragraphs that follow, an opening activity which involves the use of handheld computers will be described to illustrate how teachers can be immersed in technology-enriched algebra experiments that demonstrate a different orientation for algebra with technology and function concepts taking increased "front stage" roles.

Example Activity

The Valentine’s Day Idea Problem: The school’s drill team has decided on a money-making project for February. They plan to take orders (and money) for roses in advance and deliver them to the designated students on Valentine’s Day. The drill team has contacted several flower distributors and has narrowed the choice to two companies. They need to determine the more economical option.

Classroom Setup: Participants are divided into groups of four. Two people are positioned so that they cannot see the overhead projector. They represent members of the drill team who are to make the decision about which company to do business with. One person is instructed to ask cost questions from a small school perspective, and the second person from the perspective of a large school. The other two people are positioned so that they can easily read information that is projected onto the overhead screen. One of these persons is to represent the Roses-R-Red Flower Distribution Company and the other is to represent the Flower Power Distribution Company. It is their job to try and convince the drill team to buy from the company they represent. All four participants are provided TI-92 graphing calculators.

The Constraints: The following information is projected onto the overhead screen. Option 1: Roses-R-Red has offered to sell its roses for a fixed charge of $20 plus an additional charge of 75 cents per stem. Option 2: The Flower Power has offered to sell its roses for a fixed charge of $60 plus an additional charge of 50 cents per stem. Which is the more economical offer?

Outcomes of Activity

Initially, the Roses-R-Red representative concentrates on the fact that their fixed charge is only $20 compared to the competitor’s fixed charge of $60. The Flower Power representative diverts the buyers attention to the fact that they sell each stem for 25 cents less. This situation provides for excellent discussion during the debriefing period. It draws attention to the fact that often students have a tendency to focus on certain parts of a problem situation while not attending to other parts. If allowed sufficient time to work on the problem, however, the context of the problem and the group discussion eventually lead students to address all the parts together.

Some buyers approach the problem by asking questions about the cost of a certain number of roses, and they build a table to keep track of the outcomes. For example, they might ask how much it would cost to buy 10 roses from Roses-R-Red and from Flower Power?, how much for 20 roses?, how much for 30 roses?, etc.

<table>
<thead>
<tr>
<th># Roses</th>
<th>Cost at Roses-R-Red</th>
<th>Cost at Flower Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>$20.75</td>
<td>$65.00</td>
</tr>
<tr>
<td>20</td>
<td>$35.00</td>
<td>$70.00</td>
</tr>
<tr>
<td>30</td>
<td>$42.50</td>
<td>$75.00</td>
</tr>
<tr>
<td>40</td>
<td>$50.00</td>
<td>$80.00</td>
</tr>
</tbody>
</table>

They note that the difference in cost is getting smaller as the number of roses purchased increases and generally continue to build the table to determine the point at which the difference is zero. They then understand that the most economical offer depends on how many roses are being purchased.

Other participants choose to write the functions that describe the two proposed deals and to graph them. The Roses-R-Red function is \( y_1 = 0.75x + 20 \) and the Flower Power function is \( y_2 = 0.50x + 60 \). By graphing the two functions and using the zoom and intersection features of powerful handheld computers, the groups can very quickly determine that the cost difference becomes zero when 160 roses are purchased. Careful examination of the graphs with the trace feature of the technology indicates that Roses-R-Red is more economical when less than 160 roses are purchased, and Flower Power is more economical when more than 160 roses are purchased.

Several groups have entered the two functions into the function plotter menu but then used the table generator feature of the handheld computers to investigate and compare the costs for the two companies. This provides
for nice discussion about an approach that combines the first two approaches.

Some participants simply set the two functions equal to one another thus creating an equation with one variable. They can even use the CAS features of the TI-92 to solve the equation $0.75x + 20 = 0.50x + 60$. This approach allows for excellent discussion on the roles of functions and equations in an algebra course. The approach exemplifies the point that equations are a special case of functions. The equation that is proposed is asking for the value of the common variable $x$ for which the output of the two functions is equal. Once again the solution to the equation ($x = 160$) signals that there is no economic advantage when 160 roses are purchased. More work is required to determine what happens when less than or more than 160 roses are purchased.

Occasionally a group gathers several data points for each company, creates scatter plots on the calculator, determines a line-of-best-fit for each data set, and investigates the graphs to make their decision.

The real richness of the activity becomes obvious during the debriefing period when participants share their approaches to the problem. Teachers are allowed to experience for themselves that algebra problems can be solved in many different ways, that one approach is not best, that real understandings come from viewing multiple representations (tables of values, graphical representations, algebraic symbolic representations) of the problem and connecting the meanings of each of these representations. They also are allowed to see how equations naturally arise from functions and give purpose for finding the unknown quantity.

Closing Remarks

Mathematics teacher educators need to understand algebra very differently than we did a few years ago. Success in algebra in the past has been judged by mastery of a set of manipulative skills presented in isolation. In contrast, the algebra of today is expected to eliminate artificial and meaningless exercises and to de-emphasize symbolic manipulation while at the same time giving students opportunities for exploration and conjecturing and discovering. But not only must we understand algebra differently, we must be prepared to illuminate others. The algebra reform movement put into motion by the NCTM Curriculum and Evaluation Standards for School Mathematics (1989) will not succeed if teacher educators are not (a) prepared to rethink the algebra curriculum and ready to model instruction that allows for personal construction of meaning, (b) armed with technology and an understanding of how to allow the technology to assist learning—not control learning, and (c) prepared to provide quality preservice and inservice training for mathematics teachers.

In September of 1995 three faculty members at the University of Regina implemented an Internet service for mathematics teachers and students from kindergarten to grade twelve. Math Central <http://mathcentral.uregina.ca/> is intended as a meeting place for teachers of mathematics to share resources, as a service to teachers, students and parents who may need an answer to a mathematical question, and as a facility to allow teachers to carry on a dialogue amongst themselves. In this paper we outline why this service was begun, its basic structure, how it has been used by faculty and students in the Faculty of Education and how it has changed the structure of teaching and learning in Mathematics Education classes.

History and Background of the Project

The site, which is very much an educational project in the pedagogical sense, had its beginnings outside of the Faculty of Education. Our university, the University of Regina, is a moderately sized (approximately 11,000 full and part-time students) research oriented institution in Western Canada. The first author is from the Faculty of Education. The second and third authors have their training as research mathematicians and are members of the Department of Mathematics and Statistics in the Faculty of Science. The eight-year involvement of the third author with a Provincial Mathematics Advisory Committee and a three year involvement of all three authors with the local Public School Board’s Mathematics and English Advisory Committee brought them directly into contact with teachers and students at all levels. In the case of the Provincial Mathematics Advisory Committee, the K-12 mathematics curriculum was being entirely rewritten with a problem solving approach, incorporating many of the themes from the NCTM Curriculum and Evaluation Standards (1989). Beyond the provincial level, a Western Canadian Protocol for Collaboration in Basic Education (1996), involving four provinces and two territories, was developing a Common Curriculum Framework for K-12 mathematics. The philosophy of the Provincial Education Department, Saskatchewan Education, is also reflected in this protocol. The Regina Public School Board Mathematics and English Advisory Committee was considering the interface between the secondary and post-secondary institutions and the problems students encounter at this juncture. This exposure not only emphasized the disparate views of research mathematicians with educators at all levels but exposed a gap in the maintenance of K-12 professionals and an complete breakdown or lack of communication between mathematicians on our campus with each of: K-12 students, student teachers in the Education Faculty, Faculty in Mathematics Education, and K-12 teachers. The introduction of new topics into the curriculum, the demand for interesting examples and applications, and the obvious lack of communication among K-12 teachers planted the seeds for the Math Central project. We envisioned a place where both students (at all levels) and teachers could share their questions and expertise, a site which would be theirs to develop, a site at which mathematicians from the Faculty of Science would act as a resource and as facilitators, and importantly, a site on which student teachers could develop and share resources while becoming literate in the ways of the web.

Relationship to the Curriculum

An important part of Math Central, other than the distinguishing feature that it was to be run by students, student teachers, and teachers, was that it actually support Provincial and Western Canadian philosophies of mathematics education. For example, the mathematics curricula (Saskatchewan Education, 1992, 1995, 1996) are centered around the philosophy of real-life problem solving, the active involvement of students, and the use of a variety of appropriate resources. The curriculum is designed to promote the following: the incorporation of problem solving in every strand of the mathematics program; the use of multiple resources; the application of mathematics to real life; the active involvement of students in their learning, including the extensive use of
Characteristics of the Site

The physical shape of the web site, as described below, was decided upon for a variety of reasons, many of them coming from our interaction with teachers in the field and from being on advisory committees. The problem of starting up a site without resources from teachers was somewhat delicate. It would not have been wise to have the site appear to be a university-driven site telling teachers what to do. A major facet of this site is the capability of teachers to share resources with teachers. Needing seed resources we adopted pseudonyms in some cases, while in others we directly addressed questions that we had encountered in our advisory capacities. Additional resources were obtained by inviting teachers into our advisory group for Math Central.

The Resource Room

The Resource Room is a facility to allow mathematics educators to store and retrieve resources. It is a place where teachers can share notes, ideas, lesson plans, or any other resource having to do with the teaching of mathematics. In the beginning, the Resource Room was seeded with resources written by those of us who started the project; now we are actively seeking submissions from teachers and student teachers. At the present time approximately 60% of the resources have been written by teachers or students and approximately 20% are in French. The resources are categorized by level, elementary, middle and secondary, and then by curriculum strand. A user is able to browse the database by level and strand and see title, author, and an abstract of the appropriate items. There is also a search mechanism that allows the user to search the database by keyword, author or title. The Resource Room also has mathematics glossaries, at the middle years level in English and at the elementary and middle years levels in French.

Quandaries and Queries

Quandaries and Queries is a question and answer service. Mathematical questions sent to us are automatically forwarded to a group of teachers and university faculty we call our Quandaries and Queries consultants. Input from the consultants is then formulated into a response which is returned to the person who asked the question. As in the Resource Room, the mathematical questions and answers are stored in a database that can be accessed by any user. This database is categorized by level and can also be searched by keyword, author or title.

Teacher Talk

Teacher Talk is an electronic mailing list for mathematics teachers. The intent of this service is to provide teachers with a place for an open discussion on mathematics education, with the topics as varied as the participants wish. Archives of the Teacher Talk discussions are maintained on the Math Central server and can be viewed by any user.

Bulletin Board

The Bulletin Board is Math Central’s information board. It includes information about conferences, newsletters and periodicals, and the site itself.

Changing Nature of the Site

In our original concept of Math Central we expected that questions to Quandaries and Queries would be mathematical in nature and that questions concerning the teaching of mathematics would be discussed in Teacher Talk. The usage is of course determined by the users and the division between Quandaries and Queries and Teacher Talk has blurred. The site has thus taken on a life of its own through user-driven modification. Some examples of non-mathematical questions sent to Quandaries and Queries will illustrate this point. These questions are quoted verbatim from submissions to Quandaries and Queries, with identifying information removed.

1. I’m looking for information on math anxiety. Any resources that you know of on the Net? Thanks!

2. I am the mathematics consultant and we are about to begin work developing performance standards to accompany recently produced curriculum outcomes for the end of Grade 10. I am interested in identifying documents/sources which may have already been produced along this line. Thank you for your help.

3. I’m a graduate student from ***** searching for journal articles or research on linking math and children’s literature in the primary setting. Could you direct me? I haven’t had much luck on the WWW. Thanks!!!!!!!

4. My name is ***** and I am a student at *****. I have recently chosen to do a science project on whether or not a calculator causes people to lose their knowledge of basic math skills because of increased use, in other words, if we become dependent on them. I have had great difficulty finding any information related to my topic. If you have any related articles or studies on this topic, I would greatly appreciate your help.

These and similar questions have underlined the importance of having a list of consultants with a variety of expertise. Those of us who are academics can supply the expertise in mathematics and in pedagogy but the real experts on many aspects of education are the teachers in the classroom. If Math Central or similar sites are to be
useful to teachers and students they must involve substantial cooperation among the various stakeholders.

**Education Student Involvement**

Since the conception of Math Central and its first appearance on the web in September of 1995, the site has employed education students to work on a variety of tasks such as transforming submissions from teachers or students into html format for posting in the Resource Room, demonstrating the site through workshops at the university and in schools, and compiling a cybibliography of math-related web sites. In addition to these paid appointments, mathematics education students contribute to the site by (1) submitting resources which they have personally developed, (2) asking questions in the Quandaries and Queries section, (3) subscribing to and participating in Teacher Talk, or (4) acting as consultants in answering questions that are submitted from the teachers or students.

**Pre-service Course Involvement**

The pre-service teacher involvement, particularly in the elementary (i.e., kindergarten through grade 5) and middle level (grades 6 through 9) mathematics education classes taught by the first author, has included the following:

1. One senior elementary and middle level mathematics education class was given an assignment which required them (1) to access and become familiar with Math Central, (2) to use Math Central's built-in links to explore other sites, and (3) to conduct a search for mathematics topics within Math Central and throughout the World Wide Web. In each case the students had to write a short description (and critical analysis) of the sites they visited, how the sites could be used, and by whom. These hundreds of sites were then collated, edited, and organized alphabetically (by our paid assistant) into our Cybibliography <http://mathcentral.uregina.ca/RR/cybiblio/cyberbib.html>. This was a massive project that began with some tears, much frustration as access was a problem for some students, a fair amount of one-on-one mentoring and peer support, and finally an acceptance that the Internet was here to stay and that this assignment was valuable for their professional growth as teachers. By the end of the assignment, and especially when students saw their work published on the web, they felt quite proud of their accomplishment; some became tutors for second year elementary pre-service teachers.

2. Another class assignment, this time for a second year, middle level class, involved the students, in groups of four, (1) locating and doing problems found on math web sites by use of a data projector and Internet connection in the math lab, (2) analyzing these problems for problem type, most efficient strategy, and curriculum integration, (3) creating a problem of a particular type, addressing a real problem situation, and becoming involved in the problem context, (4) giving their problem to other groups to solve, and (5) assessing the merit of their problem (self-assessment) and problems of their peers (peer-assessment). After about six class periods, the tested, evaluated and edited problems were ready for publishing on the Math Central web site (see "An Experiment in Problem Solving" <http://mathcentral.uregina.ca/RR/database/RR.09.95/maeers4.html>).

For most of the students this was their first electronic publication, so the experience helped them to better understand the importance of the web as an effective tool for teaching and learning mathematics.

Also, since the entire project was a class assignment, which carried course credits and grades, the students were strongly motivated to stick with the project and see it through to completion.

3. During the winter, 1997 semester, elementary and middle level pre-service teachers will become involved in Math Central through an assignment which will require them, in groups of four, to compile a resource bank to support different curriculum strands at different levels. For example, a group of four middle level pre-service teachers may decide to compile resources for data management and analysis, one of the middle level curriculum strands. They will begin with their curriculum guide to determine the extent of this strand at the middle level. Then they will visit Math Central to locate and explore any Math Central resources related to data management and analysis. From Math Central they may link to other sites and eventually they will produce an extensive resource list of web site information, text/print resources, non-print resources, computer programs, video and interactive CD-ROM resources, etc. Their assignment, when completed, will become part of a newsletter, which is distributed to all mathematics society members in the province, and it also will become part of the Math Central resource list for middle level data management and analysis.

**Changes in Course Planning and Implementation**

Dr. Maeers, in her course planning, is now incorporating into the assignment agenda opportunities for all students to (1) explore and become familiar with Math Central through an assignment (with credit attached to it) that requires of the students some contact with this site, and (2) contribute to the professional mathematics society of the province, either directly through the math newsletter, or through posting work on Math Central, whereby it can then be accessed by any interested party. From the exploratory beginnings to the final posting and publication,
the students become keen Math Central and general Internet users/surfers. They also locate other resources, which they share with the class, and develop group projects involving Internet access. For example, one group used the Internet to investigate fractals, located fractal images, animated fractals, played fractal music, etc. They created a fractal slide show, using downloaded images and sound, and portions of a video, which was imported into the slide show. All of this played in the background during their verbal presentation. This presentation did not involve Math Central directly, but before they created their project they had spent many hours exploring Math Central and this exploration or playing phase enabled them to expand their horizons to more sophisticated Internet usage.

Course assignment agendas have changed to include opportunities for all students to access and explore features of Math Central and other web sites, and for students to become familiar with software appropriate for their chosen level of teaching. Actual class teaching has changed to include frequent opportunities (1) to demonstrate Math Central and other web sites to students, (2) to introduce and model how to effectively use appropriate mathematics software, and (3) to deliberate on the effective integration of web sites, the resources from web sites, and to incorporate software into mathematics instruction. It is critical that pre-service teachers are knowledgeable and comfortable with technology so they can select which tools or resources would be the most effective in the classroom environment they are planning for their students.

Conclusion

The creation and implementation of Math Central has precipitated the development and evolution of an extensive knowledge base of types of usage of this web site—who has used it, for what purpose, what percentage of elementary teachers, secondary teachers and so on. We know, for example, that the web site use began locally among the pre-service teachers at the university and has expanded to being used extensively by teachers at all levels around the province and by teachers from other parts of the country and around the world. We have linked our web site with provincial and national mathematics societies through the Bulletin Board, either by making a link directly to their web site or by posting information from other societies on Math Central, thus making available to interested parties relevant provincial and national up-to-date information. Math Central has thus become an environment where information from mathematics societies may be stored and retrieved. It has also become a user-friendly environment for teachers of our province, and indeed for any teacher, to locate resources to integrate into their classroom environment. Math Central has facilitated an autonomous learning environment for the students and for the pre-service mathematics educators; it has become a place where both students and professors can share ideas.

The Math Central web site has acted as a prototype web site for all subject areas in the Faculty of Education. It has provided mathematics education students with a real forum for participation and has enabled them to become proficient at general Internet research and at being mentors for students and teachers just beginning their Internet journey. The impact of having what the students call their very own web site has engendered real interest in learning (1) how to contribute to a web site, (2) how to learn from it, and (3) how to teach mathematics differently, and more effectively, by utilizing many different resources, and by knowing which resources to use.

Support and Funding

In a research-oriented faculty such as our Faculty of Science, an unusual concession was needed to develop Math Central. The Dean of Science, with the backing of the Vice-President Academic, agreed to allow work on the proposed site as a legitimate academic pursuit, an academic pursuit that would be evaluated at Faculty Review time, in Science, in lieu of research and publications in mathematical research journals. The Deans of Science, Education and Graduate Studies agreed to provide funds for the equipment. External funding was required to make the project viable. We sought funds to hire students to help design and implement the site and were successful in attracting funds from the SaskEd Multimedia Program and from Industry Canada, a supporter of SchoolNet, an educational initiative supported by a variety of organizations across Canada.

MAKING CONNECTIONS

Beverly T. Lynds
University Corporation for Atmospheric Research

The University Corporation for Atmospheric Research (UCAR) has developed a program, Project SkyMath, that integrates science, mathematics, and technology in a middle school (grades 5-8) mathematics module, Making Mathematical Connections: Using the Science and Language of Patterns to Explore Temperature, based on the content standards of the National Council of Teachers of Mathematics (NCTM).

When discussing connections, the NCTM Standards often refer to making connections within mathematics itself or to applying previously-learned mathematical concepts to new mathematical situations. But there are many other “educational” connections that enhance the learning process. The SkyMath module provides a mechanism for connecting key mathematical ideas to a real-world scientific context. It connects classroom activities with technology by introducing sophisticated technological tools as needed during the course of the development of the mathematical ideas. The SkyMath activities move students into the realm of purposeful projects calling for reflection and communication; these serve as a good transition tool to assist those teachers who have only taught in the more traditional manner to connect to constructivist pedagogy. We have found that when used in a classroom, it has encouraged in-school teacher collaboration (between the science, mathematics, and technology teachers), connecting science, mathematics, and technology teachers.

The most interesting connections for UCAR are those between middle school teachers and university faculty. UCAR universities (62 research-intensive universities having Ph.D. granting programs in the Atmospheric Sciences) are beginning a program to introduce the SkyMath module into their undergraduate courses that serve future middle school teachers. Earth Science Departments are interested in diversifying their offerings and have expressed interest in focusing one section on future K12 teachers. The introduction of the SkyMath module to future teachers fits well into such a section and provides the future teachers with content that could be taken directly to the classroom.

The university scientists are also building connections to their education departments and are learning the teaching styles of the new pedagogy, implementing them in their undergraduate courses, and are offering their scientific expertise as a backup to the SkyMath module. Faculty and undergraduate students are serving as resources to the local middle schools in a collaborative effort to support mathematics teachers in the implementation of the SkyMath module. In one university, the SkyMath module has been introduced in the school of education's math methods course as an example of the use of technology in a middle school math classroom. Undergraduates responded very positively to this opportunity to get familiar with a module they could use directly in their classrooms.

Following a similar pattern, the Universities affiliated with NASA’s Minority University-Space Interdisciplinary Network (MU-SPIN) are connecting with local middle schools and encouraging them to introduce SkyMath into their curriculum. Seven minority universities have taken on the responsibility for building and maintaining Internet connectivity to minority institutions and predominantly minority-attended elementary and secondary schools in their areas. The SkyMath module provides math-content for the schools coming on-line.

A more general connection illustrated by SkyMath is that of connecting classrooms and teachers to the Internet. The SkyMath module is freely available for downloading from the SkyMath HomePage:

http://www.unidata.ucar.edu/staff/blynds/Skymath.html

The module is intended to be self-supporting for any middle school math teacher who has Internet connectivity — In addition to fifteen classroom activities, the module contains tutorials on accessing weather data, built in student assessments, “teacher stories” from teachers sharing their experiences with the module, reproducible masters that can be printed and copied for student activities, and an Internet SkyMath Mailing List for teachers to share experiences and information and to link up with a partner classroom.

SkyMath seeks connections with professional Societies like SITE in the hopes that the membership will assist us in communicating this opportunity for teachers to make mathematical connections.

Acknowledgements

SkyMath is funded by the NSF grant: ESI-9450248.

Beverly T. Lynds is with Unidata, P. O. Box 3000, Boulder CO, 80307-3000. E-mail: blynds@unidata.ucar.edu
It is always a pleasure to read articles about multimedia and hypermedia. Developments in this area of Instructional Technology are evolving so rapidly that, between the time these articles were written and their presentation at the SITE conference, new programs and applications will have enriched our understanding and documented our progress. This section describes a wide variety of multimedia and hypermedia projects which are rapidly expanding the ways we understand, manage and disseminate the information that contributes to both our teaching and learning. The authors of these articles demonstrate a commitment to using new media in two main ways. Several authors discuss the role of the teacher and developer in using and implementing hypermedia. Other authors discuss the development of multimedia products that can be used in educational settings.

The Role of the Teacher and Developer

Bartasis and Palumbo explore the role of instructional guidance to aid the development of search strategies in a commercially produced, situated, hypermedia environment. Their article provides valuable information for teachers interested in using similar technology-mediated environments as part of developing writing process skills in their students. Several factors such as the inclusion of graphics in the writing product and the related process of reflection about relevancy appear to enhance both the visual experience and cognitive efforts.

Lee presents the findings of a survey designed to identify the motivational factors and learning methods that influence users learning to use hypermedia authoring applications. Results indicate that a constructivist approach with hands-on experience and learning-by-doing activities were viewed as valuable and useful.

The Development of Multimedia Products

Mitchell and Smallie describe the development of multimedia lesson plans by preservice teachers at the University of Central Florida. These lessons plans are created with a multimedia authoring tool and incorporate text, graphics and video components. Other strategies designed to utilize multimedia for a variety of purposes with different audiences are explored in this article.

Proost and Elen discuss the development of DigIT, a hypermedia information system about the use, development, and evaluation of courseware. Teachers are able to obtain a systematic overview of types of courseware and concrete examples as well as answers to specific questions. In addition, DigIT may be used as part of a training program for future teachers by providing a digitized source of textual information as well as a working example of a hypertext database.

Herrington, Sparrow, Herrington, and Oliver provide a description of interactive, self-paced and instructor-supported learning modules which provide preservice teachers with a more complete range of mathematics teaching and assessment strategies. These modules consist of a multimedia CD-ROM and a manual which provides a list of optimum implementation conditions. Preliminary evaluation indicates that the motivation to learn from the experiences described in the modules has resulted in student teachers developing self-directed strategies that have resulted in quality learning.

Hwu, Tseng, and Pan discuss the planning and development of a hypermedia application designed to teach Spanish phonics. Their article describes the various phases of the development of the prototype and suggests that it is feasible to develop this type of application to enhance traditional teaching methodology.

In a close-up of a multimedia design team, Heath, Butts, Reed, Troutman and Varagoor, a group of graduate students from the Instructional Technology Program at the University of Houston, discuss their experiences in developing a product. Each student contributes a unique perspective of the design process and the role of collaboration, communication and cooperation in the success of both the team and the development of the product.
Ouyand and Holst present the development of an multimedia-based, instructional module designed to teach research writing. In this paper the authors present a description of the six phases of the writing module, discuss its potential effectiveness of teaching and provide teachers with suggestions for implementation which includes software. Both developer and user perspectives of the process are provided.

Stammen describes a two-year project designed to teach college professors and K-12 teachers how to use multimedia to enhance their classroom curricula. The project also involves pilot-testing the modules and related materials in four schools and at two universities. Information about the procedures and strategies utilized, as well as the systematic process involved is shared in this paper.

Strang and Schoeny discuss a software tool that allows teachers to prepare hypermedia lessons in virtually any content area. The three program modules, the authoring module, the instruction/testing module, and the feedback module, are described as well as field trials designed to assess the instructional phase's ease of use and student navigation.

The articles in this section provide a critical insight into current developments and future applications of new media. They offer a practical and useful resource for educators who want more information about this evolving area.

TEACHING AND LEARNING INFORMATION SEARCH STRATEGIES IN A SITUATED HYPERMEDIA ENVIRONMENT

Judith A. Bartasis
University of Houston

David B. Palumbo
University of Houston - Clear Lake

Information-based technologies have quickly become an integral part of American society (Cerf, 1996). Rapid technological changes in American society are affecting changes not only in the way we do business, but in the way we educate our students, and in the expectations of educational outcomes (U.S. Department of Education, 1991). Although we cannot precisely predict what form education will take in the coming years, we can begin to identify skills that will be needed in order to function in technology-mediated environments. Through a synthesis of knowledge of how people learn and how people use technology, educational researchers may be able to make recommendations regarding the relationship between technology and the learner that could result in the design of more effective and efficient learning environments.

Technology implementation is a problem that affects educators at all levels, sometimes in a most daunting way (Budin, 1991). Facilitating technology implementation in classrooms does not require teachers to become programming experts, or commit to expensive dedicated learning systems, or become savvy Internet surfers. It does mean that teachers need access to information and acquisition of skills that will aid them in adding technology mediated instruction to the palette of tools they currently use. Classroom implementation of technology needs to be addressed in a realistic, usable manner so that educators at all levels of computer competency can begin to push the envelope of experience technology offers and use its capabilities to provide challenging learning environments that can be used to develop higher order thinking skills and prepare our students to take their places in a technology rich society. As technology continues to change and improve, the development of quick and easy, yet effective, methods of implementation becomes more urgent.

Over the last decade new computer hardware and software development has increased at an extremely rapid pace. Hypermedia, multimedia, access to the Internet especially the World Wide Web, computer-mediated communication, development of groupware and other types of collaborative software, are opening the doors to new types of learning environments and new perspectives on the use of the computer (and related technologies) in education. In the midst of these new technologies, a new perspective on the role of computer in the classroom is emerging. This perspective involves using existing applications as “cognitive tools for engaging and enhancing thinking in learners” (Jonassen, 1996). Using this perspective, the challenge before educators and learning specialists is a critical examination of existing technology, and a determination of its possible use as a cognitive tool in the promotion of meaningful learning.

Hypermedia Environments

The successful implementation of any new tool in the classroom - whether it is a book, a manipulative, computer software or a particular perspective on learning - depends on the teacher’s awareness of the tool’s strengths and weaknesses, as well as its utility. In order for meaningful learning with technology to flourish, teachers need to understand the strengths and weaknesses of technology mediated learning environments. The focus here is on hypermedia (Nielsen, 1990) environments, as they are loosely structured and provide the opportunity for students and teachers to access and construct information in a variety of meaningful ways.

Research in effective uses of hypermedia identifies several possible problems for the user, including learner control and navigation issues. Learner control refers to a student’s ability to make content selection choices, to sequence objectives, and to control the pace of the learning (Merrill, 1980). At issue over the years in hypermedia research has been the determination of the appropriate amount of learner control. In a meta-analysis of 50 learner control studies involving computer assisted instruction, Goforth (1994) found many conflicting and/or inconclusive results, but also determined through the analysis that it is important that the learner have some control rather than none, that learner control is an effective strategy and that adaptive advice is a central element of it.
The nonsequential nature of hypermedia systems can create information interaction problems for the user. Most information interchanges that we experience are linear. Interacting with information in a hypermedia structure requires the user to fight a history of traditional presentation of information in a linear, sequential manner (Conklin, 1987). Research regarding navigation in hypermedia environments has shown that several problems can impede the search for information. The ability to choose any path through the information can limit the user's ability to understand his/her location in hyper-space (Dede, 1992). Some hypermedia researchers have attempted to overcome this problem by providing navigation aids, such as maps or indices, or constraints on paths that users can follow (Gay, Trumbull, & Mazur, 1991). Another navigation related problem lies in developing a means to ensure that the user will interact with all the information the designer intends, guarding against simple omission (Shin, Schallert, & Savenye, 1994) or purposeful exclusion (Harmon & Dinsmore, 1993).

In spite of the potential problems presented, hypermedia seems to have much to offer learners. It can provide an environment that engages the learner through interactivity, allowing the construction of knowledge in a meaningful way. It provides an environment that can enhance the learners' ability to accurately access information, to capture it, to interact with it, and to manage it (Nelson & Palumbo, 1992).

When the environment in which information is presented is loosely structured, the role of instruction in technology mediated learning becomes a critical interplay of student interaction with the learning environment, the emergence of strategies through experience, and expert advice. The process that takes place when using a hypermedia system allows for review, revision, and improvement by an accomplished user. "When structured into learning environments that motivate guided inquiry, hypermedia has the potential to develop more user metacognition than linear media." (Dede, 1992, p. 56)

**Instructional Guidance and Information Construction**

In an attempt to address some of the concerns teachers may have with technology implementation, a study was conducted to explore methods of connecting teachers and students and technology in an easy, yet meaningful way. More specifically, it explored the role of instructional guidance to aid the development of search strategies in a commercially produced, situated, hypermedia environment.

**Methods**

**Students**

This study involved 32 fifth grade language arts students in a third-fifth grade elementary school located in a working class suburb of a major southwestern city. All students were grouped in above average ability groups and were taught by the same language arts teacher. Technology use in the school was limited to computer lab tutorials and computerized library card catalogs. All students have had some experience with basic navigation in hypermedia environments.

**Software**

The software used in this study is a commercially produced title, *The Nile: Passage to Egypt* (Discovery Communications, Inc., 1995). It is a multimedia/hypermedia environment that is rich with still photos, videos, narration, and text about life along the Nile. The user navigates an Egyptian boat down the Nile and can choose direction, areas, and depth of investigation. Clicking on an area of interest allows the user to obtain audio explanation at a broad level, or audio, visual and text at a greater level of detail. Information can also be retrieved directly from the database, if desired. *The Nile* also has a journal in which users can record the information that they find - text, audio, and visual - as well as their own words. *The Nile* includes 30 minutes of video, 351 photographs, 3.5 hours of narrated articles on 300 topics. The user also has access to 17 thematically based guided tours which include video, text, and narration, as well as a glossary of terms.

**Task**

All students were given the same task, which attempted to capitalize on the situated environment (Brown, Collins, & Duguid, 1989; Choi & Hannafin, 1995) provided by *The Nile*. Students were asked to imagine that they were famous explorers who were commissioned by a national magazine to take a trip down the Nile and write an article about an aspect of life there. They were encouraged to use include information in whatever form they found interesting and that would make a good story for the magazine.

**Procedure**

Approximately one week prior to the study, students were asked to create a research report on the life of an animal of their choice, with a similar goal of producing a magazine article. They were required to use at least two text-based sources.

Students were randomly placed in one of three groups, reflecting the amount of instructional guidance they would receive. The free exploration group received no guidance on searching for information or organizing their ideas for their article. The guided search group received instruction on basic strategies that might help organize their search. This instruction took place prior to the task assignment only. Instruction included general strategy ideas, as well as related uses of tools in *The Nile*. Some examples include using the navigation map to determine an area to explore, or index (data base) to determine a topic to explore;
determining a topic sentence (or search question) to guide the search; using information in the media player to help determine subtopics; keeping on track; separating useful information from less important details. These concepts were also summarized on a card that the students were invited to use for reference. Students in the directed search group were given detailed, step-by-step instruction on organizing their searches, and using The Nile tools. This instruction took place prior to task assignment only. The students in this group were also provided with a summary reference card.

The students participated in five, forty minute sessions to produce their manuscript. A brief introduction to the tools used in the program preceded the first session. The first two sessions provided time for free exploration within the software environment. The students who were in either the guided or directed search groups received pertinent instruction prior to their third session. Students used the last three sessions to create their multimedia-based articles.

Analysis
Upon completion of the study, both the written reports on animals and the multimedia writing products were scored holistically by a group of three language arts teachers. The writing sample was scored using a holistic rating scale (Myers, 1980), with special attention to content related elements: organization of writing, accomplishment of task, depth of topic development, and number of topics included. Ratings were given on a scale of 1-4 for both types of products, using a rubric based on the general scoring rubric developed for the Integrated Assessment System, Language Arts Performance Assessment (The Psychological Corporation, 1990). The scoring was accomplished by a panel of three raters, with an initial random scoring activity to establish interrater reliability (Lohr, Ross, & Morrison, 1995). Agreement among raters was 89%. It was decided that two raters would score the samples initially, and discrepancies would be mediated by the third rater. Special attention was paid to scoring the digital writing samples, due to their multimedia content. The text component would be scored using the identical rubric for the preliminary (text-based) samples. Allowance for graphic elements was made by the use of a relevant graphic elements/total number of graphic elements ratio.

After all the writing samples were scored, a two-factor (Treatment by Testing Occasion) ANOVA with repeated measures on one factor (Testing Occasion) with writing sample as the dependent measure was performed.

Results

The 2-factor (Treatment x Testing Occasion) ANOVA with repeated measures on one factor (Testing Occasion) with writing sample as the dependent measure did not show a significant treatment main effect $F (2,29)=132, p =$.8768. There was a significant Treatment x Testing Occasion interaction $F (2,1)=4.653, p =.0394$.

Mean scores for the technology based (post treatment) writing samples were lower than the text-based (pre treatment) writing samples for all three treatments (free exploration/control, guided search, directed search). The greatest decrease from pre to post score mean occurred in the free exploration group, the smallest decrease occurred in the directed search group.

As a part of the scoring activity for the digital writing samples, a tally was kept of number of relevant graphic elements/total number of graphic elements for each student's journal. A relevant graphic element was either a still photo or a video that was directly related to the text, either by topic or by specific mention in the text. The mean percentage of relevant/total graphics ratio is listed in Table 3 below.

This study found that the use of an information-rich situated environment for information gathering has an effect on students’ writing products. However, the effect, as measured by comparing text-based research and writing products to multimedia/hypermedia based was a negative one. Holistic scores on the multimedia writing product were generally lower than those for the preliminary, text-oriented writing product. The difference between means of pre-treatment (text-based) and post-treatment (multimedia-based) writing scores was less for those groups that experienced instructional guidance prior to carrying out the task.

Discussion

A situated hypermedia/multimedia environment can be a very powerful tool. While this study did not provide hard evidence regarding the relationship between instruction, search strategies, and organizing information, examination of other uncontrolled variables provides valuable information for teachers interested in using similar technology-mediated environments to develop information search strategies as part of writing process skills. The use of commercially produced titles may be timely and easy to implement, but teachers must have an awareness of variables that can possibly distract the learner from the primary task.

The ability of the students in this study to create a digital version of a research report within a hypermedia environment was severely hampered by varying levels of keyboarding and/or word processing skills. In hypermedia, cognitive overhead (Conklin, 1987) refers to the extra cognitive effort required to make decisions about which links to follow and which to abandon. This extra effort can distract the user from the primary task. Many participants in this study had the burden of dealing with an overhead of another kind - learning prerequisite technology-based skills while learning to use new software.

The findings of this study illustrate the increasing complexity of the task of searching for information in hypermedia environments that are enriched with pictures, movies, and sound. The multimedia, while providing a rich source of information, may have distracted students from their tasks. It also may have exacerbated the organization of information problems already demonstrated in hypermedia environments. Organizing information for a research-type report was a relatively new task for the fifth grade students. Providing a large amount of information in a relatively unstructured format was a challenge. Enhancing the information with rich graphic elements provided another level to the organizational challenge. These problems point to the need for students’ guidance in methods of limiting their explorations.

Conclusion

Learning environments like The Nile provide a flexible tool that offers teachers and learners the ability to explore new levels of knowledge representation and construction. In the process, learners can develop new cognitive strategies and metacognitive skills. In this study, an act as simple as including a picture or video in the writing product called for students’ reflection on the graphic element’s relevancy as well as the criteria for its inclusion in the final report. Just as multimedia enhances our visual and auditory experiences, it can enhance cognitive efforts. In this study, multimedia-based writing skills required and broadened text-based skills.

Situated hypermedia learning environments encourage engagement of the students. They can be easily implemented in the classroom. Inexpensive, readily available software can be used in new ways. Well-planned activities can capitalize on student development of new information interaction skills. Clearly, there is more for a teacher to consider when using multimedia/hypermedia environments as cognitive tools. The possibility of a much richer process and product as a result of these efforts exists as well.
Finally, teachers need to be aware of the impact of the use of technology on the roles of student and teacher as well as on evaluation of new types of student work.

The educational system is increasingly challenged by the rapid pace of technological innovations. It is often assumed that these technologies can solve problems in traditional education and provide opportunities for new forms of teaching and learning (Smith, 1995). This has given rise to numerous arguments in favour of integrating technologies in teacher education programs. However, disappointing results are often the result of a highly pro-active and technology-driven approach. Media-comparison studies have shown that learning processes are influenced more by the content and the instructional design than by the technology (Clark, 1983). Therefore, more attention should be paid to design aspects, and less to technological aspects.

This does not mean that technologies cannot make any contribution to education. Although no learning benefits are found for media (Clark & Sugrue, 1990), the use of technologies in education may increase the efficiency of learning and instructional processes. Moreover, explorative learning environments create opportunities for discovery learning that would be difficult to realise without computers (Leutner, 1993). The use of computers in education, however, is often inappropriate or even absent. One of the reasons is the lack of knowledge and numerous misconceptions of teachers about instructional design and the potential of computers for education.

In order to contribute to solving this problem and enlarge training opportunities, a hypermedia information system (DigIT) was developed at the University of Leuven about the use, development and evaluation of courseware. This information system supports teachers in making a sensible use of courseware in their teaching and enables them to gain experience with the use of digitalized information systems. Technology is used to educate teachers about the use of technology for student education. First, DigIT itself and the underlying design options are discussed. Next, suggestions are offered for the use of DigIT as one component of teacher education initiatives at various levels (pre-service, induction, in-service).

**DigIT as Part of an Electronic Performance Support System**

DigIT is an information system about the use, development, and evaluation of courseware. As such, DigIT can be conceived as one component of an Electronic Performance Support System (EPSS) (Elen, Hendrickx, & Proost, 1996). EPSS are digitalized, information-based instruments that may help people to execute (part of) their job and/or to develop relevant knowledge and skills. Generally an EPSS consists of a combination of three components (Gery, 1991): a database, training opportunities and tools. These are shown in Figure 1.

![Figure 1. Components of an EPSS.](image)

The database contains task-relevant and well-structured information accessible from multiple perspectives. Training opportunities in an EPSS generally deal with working with the system (e.g. digIT) as well as supporting users to construct a comprehensive and integrated understanding of the tasks supported by the system (e.g. evaluating courseware). EPSS also contribute to improved performance by providing tools that may apply in executing (part of) the task. Such tools may be situated on a dimension from simple to intelligent. Simple tools are to be conceived as an extension of the user. They help him/her to perform better by allowing the user to do something that would be more difficult or even impossible without the tool. A typical example would be a word-processor or, more specifically, tools to create transparencies. At the other end...
of the dimension are intelligent tools. They execute a number of core cognitive tasks which normally would be executed by the users. With respect to teaching, such intelligent tools have already been developed for supporting for instance curriculum development (Nieveen, van den Akker, & Plomp, 1994), design decisions (Elen & Stevens, 1993), and courseware development (Van Marcke, in press). Usually, such tools do not aim at replacing decision-making by the user, but at increasing its quality or efficiency.

Design of DigIT

Underlying every instructional design effort is a theory about learning and instruction. This theory influences the way instructional design and learning is conceptualised as well as what (learner-related and instruction-related design) parameters are taken into account (Elen, 1995). The development of DigIT is based on a mild constructivist viewpoint. Within this conception, “it is acknowledged that learners’ activities are of greater importance for learning results than the activities of instructional agents, but it is equally ascertained that instructional agents may influence the learning activities of the learners” (Elen, 1995, p.81). Support is directed towards enhancing knowledge and skills of learners to process information independently (Lowyck & Elen, 1992).

First, a brief outline is provided of characteristics of meaningful learning within a cognitive conception. Next, learner-related and instruction-related parameters and their relation to the design of DigIT are discussed.

Cognitive Conception of Learning

A cognitive conception of learning highlights the active, constructive, cumulative, self-regulated and goal-oriented nature of learning (Shuell, 1988, 1992). The ‘active’ nature of learning implies that knowledge is the result of an energetic process in which the learner has to engage (Bereiter & Scardamalia, 1989). This activity is a ‘constructive’ one by means of which meaning is attributed to information. New information is selectively perceived and interpreted in a more or less unique manner, based on the learner’s prior knowledge (Osborne & Wittrock, 1983). This refers to the ‘cumulative’ nature of learning. Successful learning implies relating new information to and integrating it in previously acquired knowledge. This, in turn, implies that successful learning results in alterations to both incoming information and prior knowledge of the learner (De Corte, 1989; Wittrock, 1981). This process of successful learning is ‘self-regulated’. This means that the learner executes appropriate cognitive activities and prepares his or her own learning as well as continuously monitors these learning processes and evaluates learning results. Self-regulation is most likely to be successful when the learner is aware of the goal towards which one is working and possesses expectations that are appropriate for attaining the desired outcome (Shuell, 1988).

Learner-Related Parameters

Whether or not teachers will be able to engage in meaningful learning as characterised above, depends on mainly three factors: prior knowledge, cognitive skills, and metacognitive skills. Novice teachers differ from expert teachers with regard to these three characteristics.

Prior knowledge is the knowledge one has about a certain content domain. With regard to DigIT, prior knowledge pertains to knowledge about different types of courseware and tools that support the teacher in student education, instructional design issues and criteria for the evaluation of courseware.

Cognitive skills are mainly information processing skills. In order to learn, one needs to execute cognitive operations (e.g. structuring, relating, memorising, applying, etc.) on the incoming information. Experts differ from novices in both quality and quantity of cognitive skills.

Experts differ from novices also in their ability to adapt their cognitive activities to the learning task (Snow & Lohman, 1984). This ability to adequately apply and monitor cognitive activities, is a metacognitive skill. Metacognitive skills (e.g. goal setting, monitoring the learning process, evaluating learning results, etc.) enable the learner to regulate one’s own learning processes.

Instruction-Related Design Parameters

These individual differences between teachers do not need to be accepted as “given facts.” Support can be offered to enable meaningful learning of all types of teachers. Instruction-related parameters should be manipulated in order to guarantee successful learning of novice and expert teachers.

Within a cognitive viewpoint, mainly two instructional-related design parameters can be identified, namely content and support. Main educational functions are offering meaningful content to the learner and supporting the information-processing in order to reach the learning goals.

Support can be presented implicitly (mainly by means of the structure of the information) or explicitly. Support can also differ in its object and amount. Support can be directed toward all conditions for and/or impediments for learning. The most important difficulties in learning pertain to prior knowledge, cognitive activities and metacognitive activities. These learner-related parameters also determine the amount of support that should be offered. Vermunt (1989) distinguishes between support being absent, capitalising on the skills already acquired by the learner, and cognitive processing taken over by instruction.

Educational Functions

Since the information in DigIT should be useful to teachers, the information elements were selected on the basis of interviews with teachers. Attention was paid both to the object of the information (programmed instruction,
Explicit support is offered in several ways and varies in amount. First, the information can be accessed in three different ways. Each entrance represents a different amount of support and is directed towards users with different knowledge and skills. Novices usually do not have a clear goal and are not able to select relevant information. They may rather want to get a systematic overview of the information, without the danger of being overwhelmed by too much information. For these users, an overview entrance is available. By using this functionality, the user enters the matrix directly and can navigate both horizontally and vertically, one step at a time. Other navigation possibilities are excluded for preventing the user of getting lost in hyperspace. Experts users, on the other hand, do not need this support, since their prior knowledge enables them to ask specific questions. The main problem these users are faced with is to locate and access the information searched for in the database. This problem is solved by an index entrance. The index gives an alphabetic list of all the topics covered by the system. Just clicking on it will provide immediate access to the requested information. Between novices and experts are users with no profound knowledge of the use, development and evaluation of courseware. They do have questions but may get overwhelmed by a high information load. Some pre-structuring is indicated. For these users a third entrance has been created which allows to retrieve all information elements relevant to a particular question.

Disorientation can also be avoided by increasing the transparency of the structure of the database. This will help the user in locating the information in the database. Within DigIT, transparency is guaranteed by always providing an indication of the context of a particular screen. This is done by dividing the screen into three parts: one part indicates the structure of the information, the second part indicates the current location within this structure and the third part shows the information itself. This is indicated in Figure 3.

Figure 3. Screen Print of DigIT.
The limited domain knowledge of novices will restrict the comprehensibility of the (domain-related) information in the system. Therefore, a lexicon, accessible from each cell, was added which contains a simple clarification of technical terms (such as operant conditioning).

The amount of support is left to the control of the user. Support opportunities are offered but it is left to the user to make use of it or not. Besides, whether or not and the way the learner will use the support available to them, is dependent on the way the support is perceived.

Possible Applications of DigIT in Teacher Education

DigIT and EPSS can prove useful in several ways in teacher education. They can be useful for actual teachers, already working in an educational institution as well as for future teachers, during pre-service and induction periods. The main differences between the two groups is that the second group can more easily be reached by explicit, face-to-face training efforts.

In the first group, teachers who are interested in using courseware for education, may use DigIT as a simple information system. These teachers can obtain a systematic overview of types of courseware and concrete examples as well as answers to specific questions. Although this information can already create learning opportunities, more intensive training will often be necessary to enhance the knowledge and information processing and self-regulation skills of these teachers. These training opportunities might be provided in a more elaborated EPSS that also contains tools that teachers may apply in executing (part of) their tasks.

The use of EPSS offers advantages that are especially relevant for lifelong learning of actual teachers. First of all, EPSS allow for continuous and just-in-time learning as they are transportable in time and place and hence can be used by the teacher whenever needed. EPSS also provide training opportunities that can be adapted to the specific learning needs of the learner and can be made available whenever needed. Besides, EPSS offer a suitable context for situated learning since the information can be used in direct relationship with a concrete task. Since the information is available on computer, which can be networked with other computers all over the world, EPSS also support cooperation as they allow for information exchange and communication between different users as well as access to relevant information and experts from all over the world.

Within the context of training programs for future teachers, DigIT can be used in a more structured way for mainly three different purposes. First, it can be used as a digitalized text for the course. This means that DigIT will be used as the main information source for the course. Moreover, DigIT offers an important extension of a written course in the sense that it implies structured access to related information all over the world. Second, DigIT can be used to educate future teachers information processing and self-regulation skills for successfully navigating hypertext-databases and independently selecting and processing relevant information. Third, DigIT can prepare future teachers for evolutions towards the widespread use of Electronic Performance Support Systems in the workplace.

Conclusion

Teachers will increasingly be challenged by using technologies in education. Due to the rapid speed of technological evolutions, important learning efforts will have to be invested by teachers to keep up with these changes. This implies that teachers will have to be able and motivated to select relevant information out of a huge amount of information and to process this information independently. Since educational programs can not keep up with this pace of technological evolutions, educational support should be directed towards “learning teachers to learn”. This means providing the necessary information processing and metacognitive skills to learn independently. One way to provide this support is by means of an EPSS.

The DigIT-project reported here is part of a larger one that aims at consolidating know-how on teaching-related matters and at developing tools and courseware with high relevancy for teachers. The development of DigIT is a first step towards the construction of an Electronic Performance Support System which supports teachers in their educational assignment.

First indications about the value of DigIT for education of teachers will be revealed when the system gets implemented and used by a large group of teachers. Evaluation efforts should direct conditions under which systems such as DigIT and more broadly EPSS may contribute to the learning of teachers. Especially relevant would be research that investigates how user, system and context variables interact and affect the use of such a system. In general, however, the use of such systems depends on two factors: the quality of the system, and the perception of the functionality of that system by the user. The quality of the system is determined by the quality of the information as well as the quality of the support that is offered for processing the information. Decisions with regard to object and amount of support, therefore, should be based on individual characteristics of the user. Perceptions of the functionality of the system also influence whether or not the system will be used. Therefore, when presenting the system to teachers, careful attention should be paid to explaining the functionality of the system for improving the quality of teaching. Hence, introducing teachers to use DigIT may help them to overcome fear and resistance towards integrating technology in their courses.

Anthropologists believe that a major advancement in evolution occurred when early cavemen formed teams to hunt and farm. Our ancestors learned that they could accomplish more together as teams. They could take on different roles, depending on their interests and skills, and could witness group accomplishments and successes. In addition, pooled ideas of a group were generally superior to the ideas of the individual. Over the years, with improved labor laws and new management and production theories, the concept of the individual in the work place has changed. Organizations have found that promoting individual skills is not enough. How individuals work and relate to each other is equally important. Therefore, as organizational and business problems become more complex, organizations have begun to regard teams as an effective way to increase production, performance and job satisfaction, and handle varied types of work.

Teams are also serving useful purposes in K-12 and higher education. Practical applications include staff and professional development, curriculum development, program design, cooperative teaching, educational reform, family interventions, and in-service and pre-service training. Team projects are also a useful classroom technique. This approach forces the individual student to become an active learner and serves as an introduction to project teams and self-directed work groups found in many business processes.

A cross-functional team is a special kind of team and is usually formed to complete a single complex project, or a series of related projects. Members of cross-functional teams bring a variety of individual skills and expertise to the project, hence the name cross-functional. Large multimedia projects are carried out through the use of cross-functional teams. Common multimedia team members' roles are: designer, programmer, audio-video specialist, content writer, and project leader.

In Spring 1996, the Instructional Technology Program in the Department of Curriculum and Instruction, College of Education, University of Houston, offered a graduate level course titled Development of Instructional Packages. This was a new course and the instructor had previous experience working on multimedia project teams. She divided the class into four, five-member multimedia teams and assigned team members roles that are commonly found in multimedia teams: (1) content writer (2) audio/video specialist, (3) multimedia programmer/author, (4) visual designer, and (5) project manager. Each team was responsible for working with a “client” in the College of Education, developing a multimedia project according to that client’s specifications, and completing the project by the end of the semester. The purpose of this approach was to provide introductory, yet realistic, experience in developing multimedia packages.

The following account provides a close-up of the working relationship of one of the multimedia project teams in this class. Team members tell about their experiences and contributions to the overall success of the project; how they came together in understanding their strengths and weaknesses in order to make effective, practical, and creative decisions; and how they think these experiences might be applicable to in-service and pre-service teacher education.

In the Beginning

No doubt, team work can bring together the best skills and efforts of its individual members. However, “synergy” is difficult to achieve — especially in project work assigned to graduate students. This is certainly true at the University of Houston which is a “commuter campus.” For the most part, students drive from the outlying suburbs and communities to attend classes. At the graduate level, most students work full time in addition to attending classes. As a result, team or group projects are very difficult to carry out and most students generally don’t like this type of assignment. Pam, our graphics designer, expresses how most of the class probably felt at the beginning of the semester: “I was not looking forward to this class. I’d just completed a
Nevertheless, working individually in this class was not exactly appealing to me. I usually shy away from group work (especially when dealing with technology) primarily because of my need to experience and be familiar with every aspect of a project. I think I work better by doing all of the work myself. Also, I have worked in groups before where personalities clashed or where there was an imbalance of effort and contribution among members. Nevertheless, working individually in this class was not an option. Gita, our audio/video specialist, was looking forward to taking the course and working with the instructor, but she too expressed reservations about doing team projects. Our team leader, Marilyn; our writer, Larry; and our programmer, Tom; all had previous experience working on teams in their work, but each knew that class project teams could be entirely different from work project teams.

Our instructor, Dr. Sara McNeil, made the team assignments during the third or fourth session and tried to balance the teams by assigning students based on their individual experience. Each of us silently worried about what team we would be on and the role we would be assigned. We all knew that we couldn’t choose our job. Larry, our content writer says: "I thought — no big deal. Based on my previous experience, I would be either project manager or programmer. But I soon found out this was not to be. My previous work experience had also included a lot of technical and proposal writing, but that only partially prepared me. I was now responsible for both the text for the graphic displays and the audio script for the voice-overs." Gita, remembers, “The only apprehension that I had was that I had to measure up to the high standards of our group.” With the exception of Larry, all of the members of the team knew each other from other classes. Marilyn, our project leader, remembers thinking, “Being project leader is going to be a lot of work!”

Our group was assigned to create a multimedia package for a “client,” one of the science education professors in the College of Education. The topic was evolution — earth history — which gave us ample opportunity to explore a variety of graphics, photos, video and audio. Everyone was excited about our topic. As Pam says: “This was a welcome change from the usual practice of creating a project for the sole purpose of receiving a grade. Yes, we would be graded, but we were also fulfilling an educational need to design a multimedia project which would be used in a class.”

One of our first group efforts was to meet with our client to ask questions and to clarify the scope of the project. Once we did this, we began the conceptual design process where we discussed the direction we wanted to take with the project. This proved to be more difficult than we had anticipated … as we would soon find out.

Marilyn comments, “I remember all of us being polite to each other at first. However, we had a lot of creative work to accomplish and ‘polite’ wasn’t exactly what I had in mind from this team. But as soon as we got to know each other, our meetings became more open and lively. Also, when I was a project manager at my work, I had to make so many decisions! I wanted our class project team to make decisions together. So, I made a conscientious effort to get everyone involved. Fortunately, everyone wanted to contribute and stepped up to the task and participated whole-heartedly.”

Gita adds, “I found these discussions, sometimes heated ones, to be thought provoking and interesting. Ideas were put forth, discussed and then tested for consensus. We tossed a lot of ideas back and forth while we were trying to visualize how this product should look and what was needed to make it a reality.”

Pam recalls, “While we did not immediately ‘mesh’, our mutual respect for the opinions and ideas of our teammates made this process very productive. We had to ‘start from scratch’ a few times, but those times were well justified — and were TEAM decisions. It took us about two weeks before we settled on a direction. And we did not make a major change after that point.”

Larry felt that the team was successful making headway because of early decisions regarding decision-making. “As a team we decided to establish some ground rules, especially to operate on the grounds of consensus. When our team used consensus to reach decisions, it was not done by majority rule. Instead, each member of the team decided that even if they did not particularly like a decision, they could live with it. This resulted in every member of the team having bought in and been part of the decision. They could not put up the excuse that they objected, but were overruled by the majority. Each member of the team spoke from their area of responsibility and made their arguments. Even if a member of the team had much experience in another area, they did not represent that area in team discussions. To curtail circular or endless discussions on ideas we insisted that just to say that you did not like an idea was not enough. There had to be a technical reason the idea would not work, or an alternative must be suggested. This eliminated the ‘I don’t like it but have nothing better to offer’ type of fruitless discussion. We also recognized that everyone could not always be at all of the meetings. Various things could arise and prevent someone from attending just as occurs in the real world. To deal with this we agreed that if the team had already met and come to a consensus on ideas, then the team’s decisions must not be allowed to unravel because someone was not there and missed all the discussion. Previous decisions would hold unless a technical reason surfaced that required the decision to be revisited.

After these ground rules were put in place we quickly came to a consensus and decisions were made. Occasionally a technical issue arose that required a change, but that
was discussed in the team and a consensus agreement reached on any necessary change."

Marilyn, a natural ‘worrier,’ had some concerns. “I was worried about how large the project had become and was concerned about our ability to successfully bring all of our ideas to life — by the end of the semester. We had so much to do and some of us were doing new things — I wanted everyone to be sure to ask for help if they needed it. I didn’t want ‘false pride’ to get in the way.”

Tom, our programmer, was able to assist the team in determining what was technologically possible — given the limitations of the software and his coding ability (He was new in his role, too)! Needless to say, putting all of the pieces together became a challenge — a fun challenge.

“When we began to try to work as a team, I was amazed at how dedicated each member was to the success of the project and the team. My initial expectation was that each person would draw upon their own expertise and try to do others’ job. This never happened; we each had enough work on our plates to keep us busy,” recalls Larry.

Everyone contributed to collecting bits and pieces, QuickTime movies, sounds, still images, and graphics from the WWW and every other available source. Digitizing and editing audio, movies, and images became skills that Gita and Pam artfully mastered. Larry developed a detailed script early on which turned out to be the “master plan” that kept us focused throughout the project. We developed a series of tentative frame sketches which became the basis of the prototype. We then worked from Larry’s script to compile a list of all the necessary elements and which stage of development we would need them. We also made a priority list: “nice to have” versus “must have.” We had our set-backs — visual concepts that didn’t work, technology failures, disappearing files, and inadequate time for alpha and beta testing. Even though we couldn’t add hours to the week or days to the semester, we were able to find technical assistance from technology staff and department instructors.

The final project was assembled and programmed in MacroMedia Authorware. Tom, our programmer, had only “casual” knowledge of Authorware. However, he learned how to make our program do what we wanted. Tom recalls, “I guess I was a little frustrated. I didn’t have sufficient time to complete the coding to allow for an alpha and a beta test as had been originally planned. I did the debugging for the final presentation during the final class of the semester. Fortunately, we didn’t find any major bugs and we finished the project on time.”

Our excitement grew as we started to get closer to the finished project. Marilyn recalls, “When I saw the prototype with the placeholders, I thought, well ... it’s OK. However, the next time I saw it ... it had graphics, video, and some sounds. I was amazed ... totally amazed to see how everything was coming together! I was so impressed!”

As Gita recalls, “The reward (for all of our hard work) came when we, as a group, enjoyed watching our final project grow before our eyes.”

At the End

During the course of the semester, there were clear indications that each team was functioning differently — some successfully and some not successfully. As the semester came to a close, we found that we were the only team in the class that was not experiencing major difficulties. Our project was on schedule, our team had no major conflicts, and our client liked the work we were doing. All of the teams had similar challenges, deadlines, and expectations. However, the teams were performing quite differently in terms of project productivity and interpersonal relationships. What caused these differences? Was it because of the difference of individual skills, members’ personalities, team leadership, or the situation at hand? Or, was it just pure chance? What was our secret?

Our team wishes it could answer that question because working on a successful project team is a truly gratifying experience. Social-psychologists, as well as managers and team leaders, are also interested in knowing how to put together effective teams. Why do some teams work and others don’t? Is it a matter of luck and timing? Or, are there other key elements to consider? All of these questions are beyond the scope of this paper but we think it is probably a combination of all of the above mentioned things.

Pam offers an explanation, “... working in a cooperative group allowed me to create great things! Perhaps it was the support and encouragement that we gave each other.” Gita explains, “Our group was a team of talented individuals... who understood their own strengths and weaknesses, and as a result, they were able to come together as a whole.”

Marilyn adds, “Everyone was totally focused ... we all wanted to make it work.” Larry sums it up in saying, “Each and every person carried their weight and did not depend on someone else to do their job. We functioned as a team and not a collection of individuals. Our group rose to the highest definition of a team.”

While we can only speak from our team’s experience, we think that this class activity has provided a unique and positive opportunity to experience and receive the benefits of working with others. As a group, we were able to create something that was beyond the ability of any one of us to accomplish individually. A “traditional” class, complete with textbook and weekly assignments, would not have produced the same type of learning experience. Having an interesting project to work on with dedicated team members, is only a part of what contributes to the success of using project teams in the classroom. A sensitive and encouraging teacher is the remaining piece. Because of her experience working on project teams, our instructor, Sara
McNeil, was able to successfully guide us through the semester. She anticipated and understood the constraints and problems we might have, and planned the semester accordingly.

In 1830, Warren Colburn gave this advice to teachers wishing to teach children arithmetic: "It is necessary rather to furnish occasions for them to exercise their own skill in performing examples, than to give them rules. They should be allowed to pursue their own method first, and then they should be made to observe and explain it, and if it was not the best, some improvement should be suggested ... Examples of any kind upon abstract numbers, are of very little use, until the learner has discovered the principle from practical examples" (Colburn, 1830/1970, p. 15-16).

In 1991, the National Council of Teachers of Mathematics (NCTM) suggested that mathematics teachers be proficient in such things as:

- selecting mathematical tasks to engage students’ interests and intellect;
- providing opportunities to deepen their understanding of the mathematics being studied and its applications;
- orchestrating classroom discourse in ways that promote the investigation and growth of mathematical ideas;
- seeking, and helping students seek, connections to previous and developing knowledge (p. 1).

Surprisingly, these visions of mathematics teaching, although over 160 years apart, display very similar sentiments which emphasize the need for student-centered approaches to learning mathematics. In the majority of schools across the world the reality is quite different. In classrooms, students are seated individually, they are required to listen passively and to observe the teacher demonstrating rules and then they spend extensive time practicing these rules. It is apparent that views about teaching mathematics are resistant to change and require restating generation after generation. The answer may lie in the methods through which new teachers become aware of and develop their pedagogical knowledge, skills and attitudes.

For many teachers of mathematics, knowledge about teaching develops from observing and imitating the way their teachers taught the subject (Ball, 1994; Lampert & Ball, 1990). Knowledge of teaching gained from tertiary institutions plays a secondary role. Here knowledge is often transmitted in the form of abstract theories generally unrelated to the contingencies of real classrooms. Where real experiences in classrooms are encountered through, for example, a teaching practicum, preservice teachers are often faced with the admonitions from their more experienced colleagues to put aside their book-learned theories and adopt traditional approaches more in line with their own school experiences. Being able to observe teachers and students working in situations that reflect the views expressed by Colburn and NCTM was, for some, a lucky encounter. However, with the use of current technologies a wide range of experiences can become a part of all student teachers’ developing knowledge of ways in which mathematics can be taught and learned with understanding.

Multimedia appears to be an environment that supports aspects of observation, discussion and collaborative activity developing teachers’ knowledge. The use of a technology which provides unrestricted access to large amounts of video, graphical, audio and textual material appears to be one way of exposing students to a learning environment. In this environment, students can experience aspects of classroom teaching various perspectives, and view a multitude of important ideas and representations of knowledge.

The purpose of this paper is to provide a description of interactive, self-paced and instructor-supported learning modules that can provide preservice teachers with a more complete range of mathematics teaching and assessment strategies. These modules would provide:

- an understanding of the purpose of each strategy;
- an awareness of the particular strengths and weaknesses of each;
- instances of where each could be usefully employed, and
- an inclination and willingness to employ these strategies in their own classrooms.

The design of the multimedia project was based on a theoretical framework of learning whose focus was on
the notion of apprenticeships and to try to distinguish those
teachers and researchers in education began to investigate
Newman, 1989). In the mid-to-late nineteen eighties,
on the required skills to the apprentice (Collins, Brown, &
knowledge and skill was transferred through apprentice-
Situated Cognition

demanded of teacher education programs.

Until the invention of schools, nearly all formal
knowledge and skill was transferred through apprentices-
ships (Collins, 1988). Agricultural skills, trades, medicine,
law and the arts were all taught by the master who handed
on the required skills to the apprentice (Collins, Brown, &
Newman, 1989). In the mid-to-late nineteen eighties,
teachers and researchers in education began to investigate
the notion of apprenticeships and to try to distinguish those
characteristics which were critical to its success. Their aim
was to begin the process of developing a theoretical
perspective for successful learning based on the apprentice-
ship model, that cognitive science had, to date, not been
able to explain.

Brown, Collins and Duguid (1989) were the first to use
the ideas to produce a proposal for a model of instruction
that has implications for classroom practice. In their model
of situated cognition (or situated learning), Brown et al.
(1989) argue that meaningful learning will only take place
if it is embedded in the social and physical context within
which it will be used. Collins (1988) defines situated
learning as “the notion of learning knowledge and skills in
contexts that reflect the way the knowledge will be useful in
real life” (p. 2). The situated learning model is constantly
evolving and recent contributions of various theorists and
researchers, including the original authors of the model,
have expanded and refined the notion to a much more
comprehensive and far-reaching framework for classroom
application. Many of these authors and theorists believe
that usable knowledge is best gained in learning environ-
ments which feature the following characteristics
(Herrington & Oliver, 1995):

- Authentic context that allows for the natural complexity
  of the real world
- Authentic activities
- Access to expert performances and the modeling of
  processes
- Multiple roles and perspectives
- Collaboration to support the cooperative construction of
  knowledge
- Coaching and scaffolding which provides the skills,
  strategies and links that the students are initially unable
  to provide to complete the task
- Reflection to enable abstractions to be formed
- Articulation to enable tacit knowledge to be made
  explicit
- Integrated assessment of learning within the tasks

Situated learning, as defined in these characteristics,
has implications not only for classroom practice but also for
the design of interactive multimedia. Not all these elements
can be discretely included in a software program, but they
can be provided for in a learning environment by consider-
"ing the ways in which the program will be implemented
and evaluated. These characteristics have been incorpo-
rated into a learning environment designed to provide a
situated learning context in which students can investigate
teaching and assessment strategies in mathematics educa-

Elements of the Multimedia Learning
Environment

Drawing upon the characteristics of a situated learning
environment and the requirements of the content area of
mathematics, each program was designed to comprise two
elements.

1) A CD-ROM on the issues of teaching or assessment
strategies in mathematics education, each incorporating:
- Video clips of teachers using various techniques within
  their classrooms, with original sound;
- Video clips of teachers reflecting and discussing the
  strengths and weaknesses of the approach;
- Video clips of children discussing their feelings and
  thoughts;
- Interviews with experts in the field providing theoretical
  perspectives;
- Text descriptions of each approach;
- Teacher and student work samples;
- A problem-based notebook providing a variety of tasks
  within which to examine the resource.

2) A manual for users and facilitators on how to
implement the resource, which would also provide advice
on the situated learning elements which were not included
in the resource itself (such as collaboration and articula-
tion).

Twenty three categories of assessment and twenty eight
teaching strategies were selected as relevant to K-12
mathematics classrooms. This was done by conducting a
review of the literature on teaching and assessment and
from the reading of current issues in the field. Assistance
was provided by two visiting scholars, one with experience
in multimedia development in mathematics education, the
other knowledgeable in the area of assessment in math-
ematics. Figure 1 shows the interface of the assessment
multimedia program and its constitutive elements.

Videos

By clicking on the video cassette objects under the
television screen, preservice teachers can view a short video
sequence of either the scene in the classroom where the
teacher demonstrates the use of the technique (Scenario),
the teacher’s comments on the use of the technique
(Teacher), or a student’s comment (Student).
Filing Cabinet Resources

Descriptions
By clicking on the top filing cabinet drawer, students can read a description of the strategy which includes advice on how to implement the strategy effectively in the classroom.

Samples
By clicking on the second drawer students can examine samples of school children's work or teachers' records. These samples were collected from the schools at the time of filming the segments and then digitized and imported into the program.

Reflections
The third drawer of the filing cabinet contains advice given by a preservice teacher on his or her experience of using the strategy on professional practice in schools.

Interview
Clicking on the bottom drawer of the filing cabinet gives students access to an expert commentary on the use of the strategy. Apart from providing valuable advice on methods of implementing the strategies in the classroom, the expert's comment is important because it allow students to compare their own level of thinking on the issue with the expert's. This is critical to the kind of reflection students might engage in as they use the program.

Notebook
Clicking the notebook on the table allows students to use the electronic notepad and also gives them access to the authentic activities of the program. The first tab, Notes, enables students to write their own reflections and ideas as they explore the various elements provided, and also to cut and paste text from three of the resources provided in the filing cabinet drawers: the description of the strategy, the preservice teachers' advice and the expert's comment. At the end of a work session, students can save copies of their notes to their own disks, then format them using their regular word-processing program.

The Investigations tab takes students to a series of authentic activities which replicate the kind of task a school teacher might be faced with in real life. The tasks are presented to the student realistically, such as in a memo or letter, rather than simply a list of possible activities, and they include genuine constraints such as deadlines and time allowances. Activities assume that students will be working in pairs or small groups, and require them to examine the resource over an extended period of time, and from a variety of perspectives.
Clicking on the Problem Solving tab gives students access to short problems which are more narrowly focused and require less time to solve. Such problems do not necessarily conform to the situated learning model proposed for the program, but were included to allow lecturers a broader range of approaches and to add versatility to the resource as a marketable item. The problems could be attempted in a single work session rather than the extended period of time recommended for the investigations.

The Manual

The manual provides educators and students with a list of optimum implementation conditions which are all based on the situated learning model used for the development of the program, and acknowledges the position that not all the critical elements of this model can be incorporated into the program itself. Some of necessity must be provided by the educator, and some by the students themselves. This list of optimum conditions is given below:

- The resource is best examined in depth, from a number of different perspectives.
- The resource is best used over a sustained period of 2-3 weeks rather than for a single session.
- The resource is best used by students working in pairs or small groups around each computer, rather than individually.
- The resource is best used when the lecturer is initially present during use to provide 'scaffolding' and support.
- The resource is best used when the lecturer demonstrates the resource by thinking-aloud as an investigation is modeled. Students then choose an investigation from those provided, or their own choice.

The manual also provides educators and students with a description of the theoretical framework on which the program was based, summaries of each of the strategies, and ways in which educators can assess students' use of the resource.

Requirements To Use the Programs

The large amount of multimedia used in the programs necessitated the use of CD-ROM technology as a storage and delivery medium. The resource was developed using Macromind Director, an application well suited to developments of this nature, which also enables cross-platform delivery. The resource has been developed with a mid-range delivery platform in mind. Then programs run on most multimedia compatible computer systems, such as a dual speed CD-ROM with 12Mb RAM, either Windows or Macintosh.

Implementation

Two similar but slightly different methods have been employed to trial the materials with teacher education students. The program on assessment strategies was used with classes of preservice secondary and primary mathematics teachers. In this situation, the lecturer was present and organized all the students to use the computer laboratory at the same time. The other method of no lecturer present (the lecturer-free method) and student nomination of time was used with Graduate Diploma primary and third year Bachelor's of Education students. In this case the lecturer was available on demand after the initial briefing of the workings of the resource and the requirements of the course had been explained.

In both cases students were asked to work in small collaborative groups of three or four members. They were required to select or were given one of the investigations from the program to consider. The activity needed the students to assume the identities of new teachers to a school or the mathematics coordinating committee of a school. They were then given the task to prepare a report on assessment or teaching procedures to be relayed to the rest of the staff (in reality the rest of their class) in a verbal presentation and also in a written form.

Evaluation

Initial evaluation of the resource was done by observation of the classes using the program, by interview with two students who were videotaped during their investigation of the activity and by assessment of the learning shown in the presentation and written report. The interview investigated students' perceptions of the elements of situated learning which had been incorporated into the design of the materials, the design aspects of the interface, the style of working and the quality of their learning.

The response to the interface was positive with students being able to conceptualize the layout of various resources and contents very quickly. They appreciated the classroom context and there was no hint that they felt patronized by the use of pictures in the interface design. One student commented:

It was set up in a fun way, like it was a classroom. You had a video sitting there, you didn't just have the word 'video' and it didn't have the word 'filing cabinet' there. It was all there with pictures and you could relate to it.

Students generally found the interface and navigation system were logical in their layout and very easy to use, even for those students who were 'not very good with computers'. The non-linear nature of the system also found favor with the students as they were able to access the information in the order of their own choosing. Generally students did not recognize they were learning in a complex environment—each package contains over sixty video clips and over eighty documents—as they referred to the simplicity of the program. Of all the features only the television screen for the video clips was disliked as it was deemed by some students to be too small.
The students valued most the context and real-life relevance of the material they were using. Frequently, they drew contrasts between the authentic context presented in the program and the decontextualised approach often used in their teacher education course.

Instead of just showing us the theory, it also showed the scenario inside the classroom so we can do that when we go on prac. It gave practical examples which I think the course is lacking a lot of.

There were, however, minor irritations for some of the students with certain personalities on the video clips for example a student commented negatively on the teaching style of one teacher while another noted the variation in the quality of teacher and child interview responses.

The approach established with the program involved, for many, a change in role and expectation both for themselves and the lecturer. For the student, it involved collaboration and thinking, often in a context of uncertainty. Responsibility for when to learn and what to learn was placed with the group of students. Hogan (1996) noted the crucial nature of this change of emphasis as she reflected on her role as lecturer:

I was struck by the irony that I did an enormous amount of reading and thinking about education in order to prepare my lectures, plan effective workshops and select readings and texts for my students, while the students did relatively little. I was the most active learner in my classes - because I had total responsibility for what was learned and how it was presented for consumption. (p. 79)

The extra flexibility offered in this approach meant that students not only had to decide what the task was, but also decide the steps that would enable them to complete the task. The freedom was a positive feature for some as they could organize their many commitments, domestic, social as well as academic, and find better or more convenient times to work but for others the temptation to procrastinate often resulted in rushed and ill-prepared work.

As was noted earlier, two models of teacher role were used. Both roles attempted to activate the principles of situated learning namely supporting, coaching, clarifying and scaffolding the development of learning. Generally assistance was procedural on both content and software. While the ‘lecturer-free’ method allowed flexibility of time and was established to interact with the student group as the need arose, this was not always possible due to other commitments or the late evening use of the materials. Often, however, scaffolding or clarifying was done by another member of the group.

Collaborative aspects of the material were seen as crucial to higher quality learning of the main issues related to assessment and teaching. In a minority of cases students allocated aspects of the task to individuals who accessed them on their own and then brought this information back to the group for the presentation. This generally resulted in a qualitatively lower standard of presentation where each aspect of assessment or teaching was briefly sketched by the person who researched it. No overall or deeper knowledge of the issue was established; no argument was presented. The majority, however, worked together to clarify the issue or problem and to develop their response through joint planning and collaboration. In these cases the learning was richer and at a deep level. Students saw the value of collaboration as it aided their understanding both as a result of having someone explain aspects to them or, in the reverse of the case, having to justify or clarify their idea. A student noted:

When we were doing our notes, it would be like 'What does that mean?' and you would have to explain exactly what you meant. You'd have to explain and explaining always clarifies no matter what you’re doing.

Students articulated their understanding of assessment or teaching strategies in two ways: the formal reporting to the staff meeting and in their discussions with their partners as they used the program. One student noted that the capacity of the audience (the staff/class) to respond and question the findings of the report meant that the presenter could not merely copy large amounts of text and present that as a report. The possibility exists in this situation that further explanation will be necessary and understanding of the material is therefore essential. This is a very different form of learning for many students who are experienced at learning and repeating the notes of their lecturer. This depth of understanding established through cooperative work on the issue resulted in many students becoming highly knowledgeable in the areas of teaching and assessment.

The multimedia programs described in this paper, provide a different approach to learning, one that recognizes the importance of making connections to real-life situations, in this case real classroom experiences. The motivation to learn from these experiences has resulted in student teachers developing self-directed strategies that have resulted in quality learning. Ongoing research will determine whether such learning nurtures and promotes the kind of classroom practice envisioned by Colburn and NCTM.

Having a basic knowledge of phonetics is indispensable to any person who works with language. Teachers of languages, especially, need both the theoretical and practical knowledge of phonetics to diagnose students’ pronunciation errors, and to devise means to help them correct errors. Students of languages also need the same knowledge to self-monitor their own pronunciation. In order to improve Spanish phonetic instruction, the authors examined the major difficulties that students frequently encountered in the traditional classroom.

To gain a thorough knowledge of phonetics, one should rely upon not only reading literature and studies, but, more importantly, actual practice through capturing the differences between various sounds by listening and manipulating articulators in the vocal tract. Unfortunately, traditional teaching methodology fails to facilitate an effective learning environment that engages students in needed practice. Students taking Spanish phonetics are rarely taught how to contrast sounds through listening or consciously controlling their articulators. Phonetic class focuses mostly on the discussion of the sound system rather than on gaining a practical knowledge and experience about it. Students are often left alone to imagine how a phonetic symbol being described sounds like. They do it either by deducting notes from the lectures or explanations in the textbook, or by associating it with a sound that they are familiar with. Audio cassettes are a major device used in the classroom to demonstrate sounds, and they are made available to students outside the classroom. However, the cassette player, with limited capacity, can lead to a frustrating and time-consuming experience when one tries to locate a specific item by rewinding cassettes back and forth many times. Moreover, it creates an unpleasant interruption to the learning flow. In reality, the demonstration of sounds using a cassette player is usually employed immediately at the end of a lecture. It usually covers a long list of items and several exercises for various purposes. This strategy generally does not produce a good result. As an alternative approach, inviting native speakers for live demonstration has also been adopted by instructors. However, bringing informants to the classroom is not always feasible because locating them and scheduling their visits are not easy tasks. Besides, they are not accessible to students any longer after the class.

In reality, practical and effective tools that meet various students’ needs are desired to attain a very important objective of Spanish phonetic course. That objective is to help students improve their pronunciation through self-monitoring and recognizing common problems demonstrated by American-English speakers. Faced with the obstacles depicted above, the authors evaluated various types of available resources including computer programs as well as traditional audio-visual aids, which are still widely used in the classroom. After a careful examination of all these resources, the authors concluded that current computer hypermedia technologies (with elements of text, audio, video, and animation) should be our choice in an effort to help students acquire needed phonetic skills.

Personal computers have been around for over one and a half decades, and have made great impact on teaching and learning in the K-12 classroom. New computers are faster, more powerful, and easier to use than ever. Thousands of software titles have become available to enrich the content instruction with exciting activities. However, in an effort to find needed electronic resources to enhance the Spanish phonetic instruction, the authors were surprised by the shortage of the existing titles. The authors then concluded that an in-house hypermedia-based Spanish phonetic application should be developed and the first step is to develop a prototype.

**Search for a Suitable Authoring Tool**

Presently, many powerful, and yet easy-to-use programs are available on the market. They have provided a great potential for teachers to develop in-house applications that can contain many exciting elements such as text, graphics, animation, audio, video clips, and hypertext. The authors have evaluated various graphics, authoring, and presenta-
tion packages, such as HyperStudio, Powerbuilder, Visual Basic, PowerPoint, Macromedia Authorware, and Macromedia Director. In order to meet the needs of our project, many factors, such as the program’s power, flexibility, and compatibility and the hardware and software requirements, have to be considered. Finally, Macromedia Authorware was chosen to be the main control of the program and Macromedia Director was chosen for its maximized control over the exact synchronization of sound and animated graphics. In addition, CorelDraw was employed to create graphics that generate animated effects.

Objectives of the Application

To accomplish our curriculum objectives and to match varied needs of a dynamic student population, the objectives of the program are defined. The application is to contain features that address the following needs:

- To encourage students to explore and experiment with their own articulators at the stage of trial and error in a private setting.
- To assist students to visualize the movement of articulators.
- To provide samples of dialectal pronunciation in various phonological contexts.
- To provide a tireless native speaker to repeat items with a click of the mouse button.
- To offer an easy record and play-back device to allow users to compare their pronunciation with the model’s pronunciation.
- To provide a self-paced tool to cater for students with different levels of attainment.
- To provide an easily accessed tool for the overview of the correlation between sounds and their spelling symbols.
- To offer pronunciation models and practices to correct common pronunciation errors made by English speakers.
- To provide an assessment to show learners their progress in learning.
- To support learning with a wide range of information resources.

Description of the Hypermedia Prototype Application

In this prototype, phoneme /s/ is selected to demonstrate the design of the prototype of this project. The corresponding orthography rules are chosen to be the first lessons because they are the basis of Spanish phonetics. Before starting the lessons on a phoneme, students, whether native or non-native speakers, need to have an understanding of the relationship of spelling to the spoken language. Contrary to English, this relationship is almost entirely regular in Spanish.

The objectives of the articulation lessons are to provide a concise explanation of articulation for every allophone of a phoneme, and to help students visualize the physical process of articulation through animation. The animation is to describe and simulate the movement of articulators and is synchronized with narration and sound. It aims to help students who have difficulty visualizing articulation process through ordinary textual explanations.

For each variation of the pronunciation of the phoneme /s/, there is a corresponding lesson on listening practice. The lesson serves to substitute traditional audio tapes to provide samples of dialectal pronunciation in various phonological contexts. Students can replay a recording by clicking the play button to play the entire list or by clicking directly the word or phrase they want to hear. In addition, this lesson offers an easy recording and play-back device to allow users to compare their own pronunciation with the model’s pronunciation.

The lessons on pronunciation aim at pointing out pronunciation errors commonly made by American students, and providing correct model pronunciations. The lessons also offer an easy recording and play-back device to allow users to compare their pronunciation with the model’s pronunciation.

The Quiz gives students an opportunity to check their comprehension of the material covered in the whole course under one phoneme. It consists of three sub-tests. The first test serves as a pre-test evaluating intellectual comprehension of the subject, of which the questions are either textual or concern the movement of articulators demonstrated by animation. The second test is a listening test on sound distinction at the word level. The third test evaluates the sound distinction ability at the sentence level. Both tests allow users to hear the words or sentences being tested as many times as they wish.

Program Structure

To satisfy students’ individual needs, the program offers six different paths under one phoneme. Each path has a course title reflecting its function: Complete Course, Orthography Rules, Articulation, Listening, Pronunciation Practice, and Quiz. Each course can be accessed individually. Therefore, for students who only want to go over the listening exercises on one phoneme, they do not have to go through every lesson in the program.

The Complete Course is a path which allow students to access all the materials covered under one phoneme. It targets at users who wish to preview, review, or reinforce the learning of Spanish phonetics in an individualized way. Although the course follows a predefined path, users have the freedom to move from any point in the system to any other whenever they wish. Thus the path is predetermined from the instructor’s perspective on how lessons can be best learned.
Navigation

The program, from top to bottom, contains two menu screens. When a user enters the program, the first menu s/he encounters is the main menu, where s/he selects a phoneme. Subsequently a sub-menu screen appears, which contains a list of six radio buttons corresponding to the six paths (or courses). As soon as the user clicks on one of the path units from the list, a detailed sub-menu containing a list of the corresponding lesson screens will appear at the right side of the current screen. The user can either click on the start button to start the lesson screens contained within the selected path (or course) in a linear way or the user can click directly on the lesson screen that s/he is interested in from the detailed sub-menu. This makes each lesson screen within a path accessible individually. This means that if a user chooses to abort the program in the middle of a course, s/he can restart right from the point where s/he left off.

Other Features

Narration

Narration is provided in the program whenever applicable since it takes less effort to listen than to read text. However, it is used in congruence with visual display to facilitate processing of information (Hoogeveen, 1995).

Animated Texts Synchronized with Narration

As mentioned in the previous paragraph, one of the hypermedia features included in this program is the synchronization of animated texts and narration to simulate a live lecture. This feature is used when simple texts are needed to exemplify the points in the lecture.

Animated Graphics

Graphics showing the side-view of the vocal tract have been widely used by phonetic books for instructional purposes. In this program, graphics of such nature are adopted and further enhanced. We use animated arrows as well as animated colored shapes on articulators to clarify and emphasize points in the lecture. In addition, movement of articulators within the vocal tract demonstrated by animated graphics along with concurrent pronunciation are used to simulate the process of articulation.

Hypertext

The transcripts of narration are organized into hypertexts. When users click on a linked-text, a pop-up glossary explaining the terminology will appear.

Pilot Study

The prototype program was tested with four students taking Spanish phonetics during the fall semester of 1996. All of them volunteered to participate in the pilot study. Each one used the program for approximately one hour and answered a questionnaire based on her/his experience with using the program.
designer reevaluate the instructional objective and rethink the instructional strategy both in the classroom and with the computer.

One important factor that determines the selection of the authoring tools is the user interface design, which is usually under the constraint of the software capacity. Hence, before selecting tools, the designer should have considered how the interface will look like and what features it contains. It is also important to enumerate the features that the application is to provide before searching for a suitable tool. A right tool can save numerous hours on redesigning the program and hard programming. For example, initially, the design of this project was to use a tree-like interface, as the Microsoft Explorer, to provide easy access to each lesson screen and to show an updated indication of the lessons being accessed. This type of interface structure is more exhaustive and the user does not need to make any provisional jumps in order to decide which further step to take. Unfortunately, Authorware does not provide an easy way of implementation. The authors therefore have to compromise with the selected tool and redesign the interface in order to maintain the navigation efficiency.

Teachers who are interested in designing an in-house application also need as much exposure to different educational and entertainment hypermedia softwares as possible. The more exposure and knowledge mean the more creative and effective the design will be. As many of our students have experience with many different hypermedia softwares, a dull design will be hard to meet their expectation on quality. In addition, programmers usually do not have the same knowledge background on the subject as the designer. Therefore, the application relies heavily on the designer’s vision on how to take advantage of the technology to achieve the instructional goals.

Pilot study is an indispensable task. Through the pilot study, the designer will find out immediately if the design has met the established goals. Additionally, students can give many useful feedbacks on what features they like most, what additional features they want to have, or which parts of the program are confusing to them. Before conducting the study, it is important to direct students to focus on the meaningful aspects of the program instead of looking at errors that can easily be corrected (such as typos). Nevertheless, within the domain of feasibility and practicality, the prototype program for students should contain as less errors as possible because certain errors tend to distract some people’s attention from the focus of the evaluation.

Summary

Spanish phonetics class plays an important role in helping students acquire needed knowledge and skills in differentiating sounds and in correcting pronunciation errors. The new computer hypermedia technology has made it possible for educators to develop appropriate application programs that fulfill students’ needs as well as correct the inadequacy of traditional teaching methodology. This paper has discussed the various phases in planning and developing a hypermedia-assisted application to enhance the traditional teaching methodology. The development of this project suggests that it is feasible to develop an in-house hypermedia application and educators should be encouraged to develop their own applications.

Hypermedia, a non-linear, non-sequential type of authoring package, has become a very popular technological medium among school teachers and corporate trainers. This is because hypermedia allows the teaching and training professionals to create dynamic textual, graphical, audio, or visual information to enhance the effectiveness of the instructional or training content. Among the popular hypermedia authoring packages include HyperCard in Macintosh computers, ToolBook, and LinkWay for PC Windows, and Authorware for both Macintosh and PC Windows (Brader & Dwyer, 1994).

The purpose of this paper is to present the findings of a survey study for revealing the level of academic confidence and motivations (perceived value and usefulness of learning to create hypermedia), as well as learning style preferences of the graduate students, mostly in-service teachers and corporate trainers, while learning to create hypermedia. It is hoped that the results of the study can be insightful to instructors of hypermedia to identify the motivational factors and learning methods that influence working teachers and trainers as they learn to create hypermedia.

The Participants

The participants of this study were twenty-two graduate students, mainly in-service teachers and corporate trainers, from the course titled “The Design, Development, and Evaluation of Computer-Based instruction” (CBI course) offered by the Program of Instructional Systems at the Great Valley Graduate Center of the Pennsylvania State University. Among these students, there were ten students in the CBI course of the Fall I section and twelve students in the Fall II section, both in the 1996 Fall Semester. In the Fall I course, the students were required to create a hypermedia lesson by using ToolBook for Windows, while the students in the Fall II course were using Authorware for Windows to create hypermedia lessons. There were nine male and thirteen female students in these two courses, and their working experience ranged from three to twenty-five years.

The Survey Questions

The questions in the survey were grouped into three major categories: academic confidence and computer experience, value/usefulness of learning to create hypermedia, and learning methods. There were open ended questions and statements to be ranked, and the rankings for the statements ranged from strongly agree, agree, neither agree or disagree, disagree, to strongly disagree.

In the section of Biographical Information, there were three questions inquiring about gender, working experience, and job function of the students. In the next section, Academic Confidence and Computer Experience, questions for the students to answer included:

1. The number of years ago I started using a computer regularly;
2. The total number of hours per week I spend using a computer;
3. The number of hours outside of the classroom that I invested in learning to create hypermedia;
4. I do well in the graduate classes I have taken;
5. I expect to get the following grade in this class: A, B, C, D, E, F.

In the following section, Value and Usefulness of Learning to Create Hypermedia, the questions for the students to rank included:

1. I currently use hypermedia at work;
2. I currently create hypermedia instructional environments;
3. I will be creating hypermedia in the future;
4. The ability to create hypermedia will help me move ahead in my career;
5. I am not sure how creating Hypermedia will fit into my future career;
6. An understanding of the theoretical foundations for the instructional use of hypermedia will help me to succeed as a hypermedia developer.
The two open-ended questions in this section were
1. Which theories were most useful to you, and why?
2. What part of this course is most useful to you, and why?

In the last section, Learning Methods, the questions to be ranked included:
1. The best way for me to learn hypermedia is on my own with the manual;
2. The best way for me to learn hypermedia is on my own with the on-line help;
3. The best way for me to learn hypermedia is on my own with an on-line tutorial;
4. The best way for me to learn hypermedia is on my own with a text book;
5. The best way for me to learn hypermedia is with a personal tutor;
6. The best way for me to learn hypermedia is classroom instruction (lecture style);
7. The best way for me to learn hypermedia is classroom instruction (hands-on participation);
8. The best way for me to learn hypermedia is lab time with an instructor available.

The two open-ended questions in this section were:
1. The best way for me to learn new software is OTHER (Please describe);
2. What part of learning to create hypertext was the most difficult, and why?

The Results
The results of the survey revealed that, while the average years of using a computer of these students was 7.8, with a range of 0 to 16 years, the average computer use hours per week was 19.3, with a range of 1 to 50 hours. The average hours learning to create hypermedia outside the classroom was 2.5 hours, with a range of 0 to 8 hours. With respect to the academic confidence of these students, the results showed that most students either agreed or strongly agreed that they had done well in the graduate classes they had taken up to this point. Among these 22 students, there were only two students indicated that they expected to obtain the B grade from this CBI design course.

Regarding the value and usefulness of learning to create hypermedia, there were only 5 to 7 students who agreed that they were using or creating hypermedia recently. Most of them were hypermedia novices. However, 17 out of 22 students either agreed or strongly agreed that they will be creating hypermedia in the future. In responding to the open-ended questions about which theories were most useful to them, some of the representative responses included:

"The constructivistic information gave me a name for a set of educational practices I used in the classroom."

"The review of the learning theories was helpful because they can be applied to any CBI program. The use of CBI in the future is the most interesting information."

"Integrating instructional systems to the development & design of hypermedia."

"Screen design—user interactivity—establishing CBT program goals"

As for the question: which part of the course was most useful to them, the majority of the students indicated using the computer (the hands-on experience) to create hypermedia was most useful.

With respect to the learning methods, the three top preferred methods were using classroom instruction with hands-on participation, lab time with an instructor available, and a personal tutor. From the responses, it was found that there were 7 students, whose computer experience ranged from 9 to 16 years, ranked using lab time with an instructor available as their top preference of learning method. The rest of the 15 students, whose computer experience ranged from 0 to 8 years, preferred using classroom instruction with hands-on participation as the learning method. Most of the students (nearly 90%) strongly disagreed that, the best way to learn hypermedia was through a manual. A few students also responded to the open-ended question about other learning methods. These responses included:

"Practice—clear direction on paper (the ToolBook handout you gave was very concise and useful)"

"The classroom format with job aids (brief written instructions) worked well for me."

"Self-paced course (CRI) with instructor available"

While responding to the question of what part of learning to create hypermedia was most difficult, and why, the two most representative responses were:

"Variables and coding process"

"There are many aspects and steps to learn in a very limited amount of time."

Discussion and Conclusion
This paper reports the major findings of a survey study for revealing the perceived value and usefulness of learning to create hypermedia of the graduate students, mostly in-service teachers and professional trainers. The findings also revealed the preferences of the learning methods for creating hypermedia among these students.

Primarily, the results showed that most of these students were hypermedia novices. Although they were not using hypermedia recently, they believed that they will
need to create hypermedia in the future. The results also indicated that the constructivistic information and learning and design theories were considered to be very important, while hands-on practice and learning-by doing approach were experienced as the most useful strategies for learning to create hypermedia.

Regarding the learning methods, the students with very limited computer experience preferred using classroom instruction with hands-on participation. In contrast, the students with at least 9 years of computer experience preferred using lab time with an instructor available. However, the majority of the students resented the idea of learning hypermedia through a manual. They indicated that the most difficult part of learning to create hypermedia was the programming and coding process. Few students also suggested that self-pace or job aids should be provided. Based on these findings, it is necessary for the future study to investigate what kind of relationships exist between a student's hypermedia experience, learning styles, preferences, and motivations as it relates to learning to create hypermedia.

Educators must understand that teaching roles in a technologically rich environment differ significantly from their experiences when they were students. Because students today are more technologically literate than their teachers, higher education must respond with the training of preservice teachers. To be prepared for life and work in the 21st century, students need to explore as many aspects and capabilities of technology as resources will permit (Peterson & Orde, 1995).

In an attempt to meet this challenge, educators at the University of Central Florida have discovered a unique and innovative way to develop lesson plans. They are using multi-media authoring software which allows students to integrate text, graphics, video, audio, and digitized images into their lesson plans.

In the past teachers have used lesson plans from written curriculum guides or developed their own written plans. A reoccurring problem was the extreme difficulty visualizing the lesson from the written directions. Conversely, multimedia lessons plans allow teachers to add the visual aspect of the lesson. Now lesson plans can be stored and easily accessed!

Benefits of Multimedia Lesson Plans

The benefit of the multimedia lesson plan is to replace the two-dimensional written word with the three dimensional written, auditory or visual lesson. This is a tremendous benefit in many curriculum areas where an auditory explanation or a visual (picture, illustration, or video) would help with the understanding of the lesson. For example, a multimedia lesson plan can show a short video clip with narration on how to solve a math problem, complete a science lab, or perform a gymnastics skill. Also, a multimedia program captures student interest by providing information through a variety of senses. Multimedia has the potential to enhance, enrich, extend, and ultimately transform the curriculum.

Multimedia Software Selected

The multimedia software selected was HyperStudio which is a entry-level multimedia authoring tool. It can be put together using a basic set of navigation and media control functions, none of which really require scripting. In HyperStudio a series of cards are produced which is called a stack. Buttons can be produced on the individual card which allow you to move from one card to another card or to another stack. Each card created allows the individual to combine text and graphics, link cards, add and control audio, and run QuickTime (AVI) movies. Newer versions provide QuickTime support, easy-to-create buttons, animation, record and playback sound capability, audio CD support, live “real-time” video digitizing, built-in paint tools, group built-in- text editor, and “ready-made” templates.

Developing the Multimedia Lesson Plan

A seminar was held in the technology lab to give preservice teachers an opportunity to become familiar with the software. The multimedia portion had four parts: (a) the written lesson plan; (b) credits to reference any materials or products used for the presentation; (c) an author biography which included a picture and gave brief information about the presenter; and (d) a video (to auditorily and/or visually demonstrate parts of the lesson).

A “main menu” card or a table of contents was developed which included “buttons” that represented the parts of the plan. This made their plan interactive because individuals viewing the plan could “click” on a “button” to view the portion of the plan that they chose. Preservice teachers learned or had assistance in video taping, capturing the video, scanning their picture or using the QuickTake camera, and importing graphics. Some chose to add sound or special effects to their production. In addition to HyperStudio, there are many other excellent software packages available.

Other Ways for Educators to Utilize Multimedia

Preservice teachers realized that multimedia allows the creation of an infinite number of presentations for a variety of purposes with different audiences. Some ideas were: to incorporate multimedia lesson plans into their portfolios; to show to administrators as a sample of their work; to gain support from faculty, staff, and parents by producing a slide show; to highlight students’ yearly activities; to provide...
additional information that students would work on independently; to develop and keep as a resource or to share with other teachers; and to provide lessons for learning centers.

Conclusion

This experience will help preservice teachers be able to adjust to the diverse and rapidly changing hardware and software environments they will encounter. In the Editorial page of Technological Horizons in Education, T.H.E. Journal (1995) it was stated that multimedia seems to be the wave of the future, especially for training. Multimedia can bring about significant time-savings, cost-effectiveness and produce favorable results.

According to Mohnsen (1995), more than 30 research studies have indicated a reduction in average learning time for 50% of students using multimedia instructional programs. There has also been shown an increase of 33% to 70% greater mastery in students using interactive technology as compared to students using more traditional methods. Also noted was that students have greater motivation and learning enjoyment because they are actively involved and their attention is focused.

Teachers who experience many aspects of technology and develop or use multimedia lesson plans will have their own teaching tool to improve the quality of their teaching. By utilizing multimedia they can better capture and maintain their students’ interest and enhance motivation and enjoyment. Used wisely, today’s computer-based multimedia products will make it possible to learn more, in less time, and with far less overhead. Moving ahead educationally with multimedia is all about a collaboration among teachers, students, and technology to make learning more accessible, more meaningful, and more lasting (Dyrli & Kinnaman, 1995)

Additional examples of student multimedia lesson plans may be found on the CD-ROM.

Multimedia integrates the sounds, images, and textures. It can motivate students to learn and write. To meet the needs of the 21st century, students in schools today will be able to take responsible for learning, cope with new technologies, and work cooperatively in a high-performance team environment (D’Ignazio, 1992). Pre-service teachers and in-service teachers are facing the challenge of training students for the 21st century. For improving teaching effectiveness, presenters have designed an instructional module for pre-service and in-service teachers to teach research writing with a multimedia approach. The instructional module consists of six phases, and is designed to be integrated in subject teaching units through out an academic year. In this paper, presenters will introduce the structure of the instructional module, discuss its potential effectiveness of teaching, and provide teachers with suggestions of implementation.

Background
The instructional module of using computer technology to teach research writing is one of the products of Kennesaw State University’s Classroom Technology Initiative (CTI) projects. School of Education at Kennesaw State University initialized ten projects in 1996 and all projects were funded by one of Coca-Cola grants. Fourteen P-12 teachers from six school systems in northwest Georgia and fifteen faculty from Kennesaw State University were involved in the projects. Under the umbrella of CTI, there were ten project teams working on ten different projects. Teaching research writing with a multimedia approach was one of them.

Multimedia is defined as a communication format that integrates several media—text, audio, video, and animation—most commonly implemented with a computer (Grabe and Grabe, 1996). Multimedia approach provides teachers with a variety of tools to facilitate students to create and link information resources, to integrate sounds and images, and to see their learning married to computer technology (Grabe and Grabe, 1996; Thomson Technology Service Group, 1996). Presenters believe that technology has finally given teachers an instrument that can truly enhance the quality of education. If used correctly, computers can be a major asset in the classroom. Using computer as a medium, not only can a teacher teach computer skills, but he or she can also teach many other curriculum related subjects. With the every increasing dependence on computers, a teacher should give students the opportunity to explore all of its possibilities. Teachers need provide students with the chances of use computers to develop computer skills, to learn how to investigate using this instrument. The students also need to learn how to work cooperatively and be responsible for their own learning. Therefore, an instructional module of teaching research writing with a multimedia approach is born.

An Instructional Module
Presenters have participated in Kennesaw State University’s CIT project teams and put the instructional module into practice in an elementary school which is located at northwest Atlanta, Georgia. The instructional module of using computer technology to teach research writing consists of six phases: (a) identifying research topic, (b) generating research plan, (c) collecting and analyzing data, (d) drafting research paper, (e) creating multimedia presentation, and (f) sharing multimedia production. Six phases in the instructional module are not isolated but connected to support each other. They are not exactly linearly structured but can be a circular learning process to be integrated in curriculum. With this instructional module, teachers guide students to learn about computers, facilitate students’ research writings, and bring the multimedia into the classroom. Guided by teachers, students accomplish their writing tasks through out an academic year’s research units .

Phase One: Identifying the Research Topic
In this phase, teachers facilitate students to locate specific research topics. Students are provided with the opportunities of learning about computers, the experience of on-line research, and the exploration of CD-ROM resources.

Guided by teachers, students read related books and encyclopedias, discuss their readings, and identify their research writing topics.
Phase two: Generating the Research Plan.

In this phase after the writing topics are identified, teachers guide students in exploring the use of computers for brainstorming research ideas and diagramming research plans. Assisted by teachers, students use a powerful ideas organizer package, such as Inspiration, to group their research teams, formulate research questions, and map research ideas and tasks. Students work cooperatively to outline research hypotheses, list research procedures, and divide research tasks among team members.

Phase Three: Collecting and Analyzing Data

According to the research plan, each student takes responsibility for collecting and analyzing data. In this phase, teachers help students decide which data is necessary to support or disprove the hypotheses. Students learn how to download appropriate audio and video materials from CD-ROM resources and on-line searches, and to use a scanner or digital camera to get information from printed material.

Phase Four: Drafting the Research Paper

In this phase, teachers supervise students’ discussion of their research data and the process of organizing the research ideas and drafting research papers. Teachers may allow students to control their learning process with their cooperative efforts; however, teachers can schedule group conferences to monitor and facilitate students’ research projects.

Phase Five: Creating a Multimedia Presentation.

In this phase, teachers provide students with necessary multimedia presentation skills. Guided by teachers, students learn about multimedia, and create research papers with multimedia tools. The research papers will not only be presented in a informative texture format, they will also be integrated with related audio and video materials and animation effects.

Phase Six: Sharing Multimedia Production

Finally, instead of reading the hard copy of their research, students present their multimedia production. This opportunity reinforces students’ initiative of reading and writing, and encourages their cooperative learning efforts in class.

Potential Effectiveness

Teaching research writing with a multimedia approach has multiple potential benefits for pre-service and in-service teachers. First, teachers will be able to help students become knowledgeable of computer technology and develop skills in using this technology since the project is computer-based. Guided by teachers, students work at computers to accomplish their research projects. They locate related readings and identify their research topics with computers. They map research ideas and diagram research plans on the computers. They collect and analyze research data through computers. They depend on the computers to create presentations with an integration of texture, sounds, and images. Student research writing is no longer limited to paper format.

Second, using a multimedia approach will allow teachers to make teaching and learning activities more meaningful. In a multimedia instruction environment, teachers allow students to experience the learning with computers; students learn that the computer is more than an instrument to play games or gather information. The computer can also be used to communicate ideas, conduct research, and produce a multimedia presentation. Students, therefore, are motivated to develop not only their technology skills, but also academic research and writing skills. With hands-on research activities, students will learn that the objectives they are being taught are objectives that they will use in their daily life. While creating a multimedia presentation, students generate texture in writing, implement audio effect, and insert related images and animations. Students immediately see their achievements visually, and become proud of their learning.

Third, students become responsible for their own learning and develop cooperative learning skills. In an environment of research writing with a multimedia approach, the majority of communication will be focused on the use computer technology to generate research writings. Students are responsible for coping with new technologies, conducting research, and creating a multimedia presentation. Students work cooperatively while searching for information through the network or from CD-ROM resources. These cooperative activities include assigning research tasks to the group members, outlining research hypotheses and generating research writings together. Their final research papers are the product of the cooperative efforts of the group.

Overall, teaching research writing with a multimedia approach benefits teachers to develop students’ technology skills as well as academic reading and writing skills. More importantly, it facilitates the students’ learning process which makes them become responsible learners for the 21st century.

Suggestions for Implementation

Obviously, the effectiveness of teaching research writing with a multimedia approach depends on a teacher’s initiative. Teachers should take an initiative to implement technology in subject teaching and learning. With a multimedia approach, teachers can offer students more diverse experiences in learning and sharing. However, teachers themselves should first become comfortable and competent in utilizing multimedia mediums while designing instructional plans and delivering lessons in the classroom. The support of administrators and the community are considered equally critical as a teacher’s initiative.
Presenters realize that the effectiveness of adopting multimedia mediums into research writing instruction will be enhanced with appropriate multimedia tools which include both hardware and software. For an effective implementation of multimedia mediums in research writing, it is recommended to have a system of 6100 and above for Macintosh computers and a system of 486 and above for DOS/Windows based computers. Either platforms needs 16 MB of RAM memory, adequate audio and video I/O devices, and other necessary components.

There are currently dozens of multimedia authoring packages in the market. Based on the needs of teaching research writing, teachers should consider three categories of software application packages. These categories include the software used to brainstorm ideas and generate research plans, the software used to collect data and draft research papers, and the software to create the multimedia presentation. Here are some suggestions:

**Inspiration**: Inspiration is one of the products of Inspiration Software Company, and is characterized with its powerful mapping and diagramming functions. It is an ideal package for teachers to guide students to brainstorm and map research topics and plans.

**Microsoft Works or ClarisWorks**: Microsoft Works and ClarisWorks are two common software packages almost available in all schools. These two integrated packages, provide a word processor, spreadsheet, database, and communication tools, and are effective tools for teachers to assist students in collecting and analyzing research data, and drafting research papers.

**HyperStudio or Actions**: HyperStudio and Action are two multimedia authoring packages. Both packages are easy to use and learn. They can motivate students to learn about multimedia, learn with multimedia, and learn from multimedia through the research writing process.

In addition to basic knowledge about multimedia tools, it is also important for a teacher to know how to implement those tools in instruction. For teachers who want to teach research writing with a multimedia approach, here are some of useful tips:

- Identify students' technological and academic needs;
- Start with a demonstration to motivate students to write with a multimedia medium;
- Encourage students to work cooperatively in groups;
- Facilitate students in their research and learning process;
- Use guided instruction strategies to assist students in moving from a simple, linear multimedia format to a sophisticated, free structured multimedia presentation format;
- Let students control their learning pace to make learning more meaningful, but monitor students' learning process closely;
- Take advantages of all available technology and allow students to explore all possible resources;
- Integrate the six-phase teaching module into curriculum units to make the teaching and learning more meaningful;
- Provide students with hands-on activities to learn about technology, learn with technology, and learn from technology;
- Share students' “final” writing products at the end of each teaching unit to assess achievement.

Creating Multimedia: The Difficult Transition for Educators

Ronald M. Stammen
North Dakota State University

This article describes a two-year grant funded by the USWEST Foundation entitled, "Collaboratively Creating Multimedia Modules for Teachers and Professors." The initial developmental procedure was based on the Systematic Curriculum Instructional Development (SCID) process which was utilized to outline the scope of work from conceptual to the pilot phases. This curriculum development involved teams of experts in teaching, computer science and multimedia technology. The primary focus of the project is to teach college professors and K-12 teachers how to use multimedia to enhance their classroom curricula. The second year of the project, underway at the time of this writing, involves pilot-testing in four K-12 schools and at two universities. The author is the primary investigator of the grant. The following reflects on the activities encountered by educators involved with transitions from process to strategies.

The transition from print-based (static) data to electronic-based (dynamic) data is a challenge for faculty who are not accustomed to developing their own text material for students. Most educators are not trained to develop their courseware. Traditionally, they select textbooks, prescribe readings, and use lesson plans and/or lecture notes to follow the sequence of their discipline. The challenge was overwhelming to educators not accustomed to discovering with students a new way of thinking and learning. The adjustments were more profound or overwhelming with professors than with K-12 educators.

Making the Transition

Decisions to utilize instructional technology for coursework has piqued interest in instructional design and other curricula development procedures. The expertise for developing courseware via story boarding procedures to place content in Disney, Sesame Street-like frames, which are backed by formative evaluation to define outcomes, is found lacking among many educators. This is a new phenomena brought about by the convergence of technologies associated with television, telephone, and the computer industry.

Academia activity resulting from this convergence identifies a need to associate with the evolving art and science of creating dynamic educational media with computerized multimedia. Developing a dynamic interactive multimedia production to actively display the essence of the course’s educational objectives incorporates various skills and expertise associated with both pedagogy and technology.

Lessons Learned

Faculty members knowledgeable about instructional design, especially in depth formal processes such as Systematic Curriculum Instructional Development (SCID), have experience preparing content in sequential, print-based media but likely lack expertise to technologically place such data for non-sequential, electronically dynamic interaction. The instructional requirements for each learning task contains specific performance standards which are utilized to determine training approaches for developing learning objectives, performance measures, and aspects of the training program regarding faculty needs, needed equipment, and subsequent support.

Procedures and Strategies Utilized

This systematic procedure establishes the sequence for developing competency profiles, related materials, supportive media, modules and/or learning guides, and field-tested procedures to judge to what extent competency-based (learning) objectives are achieved in the process. This is done according to an array of outcomes and specific recommendations which are part of the Program Evaluation and Improvement Plan. When these competency-based data are ready to be placed in dynamic electronic computer multimedia screens for interactive media display, the data development process is ended and development of strategy commences. The lessons learned at the initial brainstorming phase help to explain the issues, concerns, and successes encountered when the educational data is manipulated electronically to interact from a production perspective. The scope of work included sorting out...
distinct differences among faculties in defining a multimedia project which would enhance the teaching-learning process in the classroom. The individual strategy developed by each instructor took into account the following elements:

1. Establish a system whereby the multimedia modules addressing these learning objectives will adhere to adult learner characteristics such as:
   a. to acquire and sustain attention
   b. to assure the project has relevance to their immediate needs
   c. to instill a sense of confidence and desire to stay involved
   d. to promote satisfaction through participation

2. Establish a system whereby multimedia modules addressing these learning objectives will be updated and kept current with new technological developments.

It was established at the onset that there was not a right or wrong instructional design model to use in the task of developing a learning module. However, the opportunity to brainstorm with a cohort group for three days tended toward uniformity in such design endeavors. This was counterbalanced when different teams were organized to begin developing strategies for utilizing computerized multimedia. A sequence of steps helped these educators to be efficient in terms of time and effort to produce quality results. These steps were presented the first hour of a three day workshop. The participants were asked to use generic instructional models until such time each had appropriate knowledge and skill to develop their own style in accord with the tools, environment, and content needed to accomplish the teaching/learning purpose and objectives of their field of study. Everyone was provided the opportunity to show their individual results and explain their efforts a month later. This helped reinforce the learning process even though most participants had not finalized their multimedia projects.

The first step was to provide a process for each participant to obtain a good mental fix on the educational purpose they had in mind. In other words, they had to answer the question, “Why are you doing multimedia?” Many were focused, but many could not answer this question because they felt they were required to “do multimedia in their classroom.” Consequently, two of the twenty-five participants dropped out during the second day.

Once the educators were satisfied or comfortable describing their purpose for using multimedia in their classrooms, they had no difficulty developing a mental fix on the appropriate competencies expected of their students. They became focused on the multimedia learning module they intended to produce. They were able to describe the competency or performance outcome their efforts would illicit from students. Such competency statements helped them to determine meaning and understanding of the limits that exist regarding their learning objective. Many chose to clarify and update their thinking to develop the competency and/or performance objectives. A performance objective is education’s counterpart of a competency. It describes briefly what you want students to do when they have completed the learning module and are ready to demonstrate the particular competency of the learning module.

This process helped the educators outline what they wanted their students to demonstrate or achieve for each target competency. In essence, they started to research their class content thoroughly to define the appropriate strategies needed to fulfill their teaching assignment. They reread standard sources, located special references, and brainstormed with peers about how to bring new information to their original proposals. In general, these experienced educators were bringing their knowledge up to date before learning about how to use multimedia technology as a teaching tool.

Some chose to develop or refine the performance enablers to further define what they were going to place in storyboard scenarios. Performance enablers are units of study or practice, including activities and experiences, that are designed to help (or “enable”) the student to learn the target skill. They break the learning into a few major elements, making it easier and more efficient for the student to master each part. This helped determine the extent of the cognitive (or knowledge) component of the competency. They completed task analysis by working in pairs to devise or refine performance enablers for the practice component.

The workshop multimedia experts provided a series of demonstrations and hands-on exploratory exercises so these educators could determine which multimedia computer program best fit their needs. A considerable amount of time was spent learning the mechanics or functions of the software. The three day workshop ended with instructions and discussions about how the workshop participants would utilize their mentor (facilitator) or multimedia module instructions to complete the following activities during a five week period after the three day workshop:

- Located media materials that may be included as learning activities
- Previewed media materials carefully for suitability for inclusion in their multimedia module
- Developed learning activities for each performance enabler selected for multimedia interactivity or hypertext activity
- Decided on the specific experiences they wanted students to have during the instruction provided with multimedia modules
- Carefully sequenced all prepared data to analyze it all for any needed special instructions.
The participants produced storyboard scenarios by utilizing existing materials or developing new ones to fill in any gaps they discovered which would enhance any electronic or printed resources available to students. A storyboard is a series of sketches or pictures which visualizes each topic or sequence in instructional media to be produced; generally prepared after the research and before scripting multimedia data on the computer frames (screens). Wherever appropriate the educators would enhance their multimedia modules by doing the following activities:

- Devise project and laboratory exercises if these are appropriate.
- Develop the self-checks. Determine which enablers would benefit from self-checks, select the appropriate form of self-check, and write the items and model answers.
- Construct the knowledge test for the cognitive component of a selected competency if such a test was necessary. Prepare an accurate answer key and choose which would be on the Web, if applicable.
- Develop the final performance test and the performance standards. Some chose to have another professor in their program review and critique the standards.
- Review and check all data for any copyright compliance.

The introductions were written after the multimedia modules were refined and ready to use with students. At this stage the participants knew what points to stress, and how best to interest the student. The last construction steps were as follows:

- Edit and polish the entire module.
- Review the module first for correct format and structure.
- Go through it again for grammar, usage, and style.

Finally, the module was checked once more for correct spelling, punctuation and capitalization. The next stage is a reunion session with the participants in the cohort who participated in the first three day planning and development workshop. The multimedia instructional modules are scheduled to be used in the classroom during the 1997 spring semester.

LearningLinks: A Visual Basic Tool for Developing Hypermedia Learning Experiences

Harold R. Strang
University of Virginia

Zahrl G. Schoeny
University of Virginia

LearningLinks is an easy-to-use and versatile software tool that allows teachers to prepare hypermedia lessons in virtually any content area. It can be used to implement direct instruction outcomes such as learning definitions, spatial orientations, and interrelationships among specific content elements. It can also be used to promote higher level outcomes defined by exploratory and problem-solving learner actions. Its instruction and testing functions center on a student's interaction with a series of frames, each containing several layers of information and cues pertaining to the current instructional focus. LearningLinks' architecture is grounded to powerful learning concepts such as prompting, feedback, reinforcement, and practice—concepts whose instructional utility has been repeatedly demonstrated by research findings gleaned from a series of previously developed teaching simulations (Strang, Badt, & Kauffman, 1987; Strang & Moore, 1994).

This Windows-based tool consists of three Visual Basic program modules: the Authoring Module guides the teacher through content and test development; the Instruction/Testing Module implements instruction and testing; the Feedback Module demonstrates post-instruction and post-testing student feedback.

The Authoring Module

The authoring module allows the teacher to create completely new instructional units or to alter existing units to meet current needs. The following outcomes are achieved via a series of simple button clicks, list selections, text insertions, and sizing maneuvers.

Frame Definition

As many as 10 pictorial and/or text templates can be included in a frame pool. Individual frames function as the stages on which the content is accessed.

Content Definition

As many as 50 instructional terms and their definitions can be included in a content pool that is tapped during instruction and testing.

Hotspot Definition

As many as 12 individual hotspots can be quickly and accurately positioned on each frame. These areas, sensitive to mouse clicks, offer access to additional information during instruction and cues for recall or recognition responses during testing.

Navigation Flexibility

As many as 10 navigation commands can be preset for use during instruction. The active command pattern defines the degree to which the instruction follows a preset series of focused experiences or is controlled by the learner's exploration.

Test Construction

Tests including as many as 25 individual items can be created to assess instructional gains. The test design window illustrated in Figure 1 guides the teacher through the construction of four types of questions.

During test construction, the teacher also determines on an item-by-item basis whether a student, upon answering,

Figure 1. Test Construction Window.

Technology and Teacher Education Annual — 1997
will immediately receive feedback as to the accuracy of that response.

Through simple menu selections individual items can be designed to assess learning defined by spatial recall, item recognition, item recall, and item meaning for any content that has been assigned to any frame. A test may include a series of like items or a mix-and-match of item types.

**The Instruction/Testing Module**

The instruction/testing module allows the student to engage actively via preset navigational selections with each program frame's content. With a lesson offering maximum flexibility (10 command buttons enabled), the student can navigate lesson frames in any sequence, and, as illustrated in figure 2, by a single button click, can activate the following four viewing modes.

*Normal viewing.* The main instructional and sole testing working environments are active during normal viewing. The frame content and the navigation options menu are displayed. During instruction, all content item hotspots are enabled, and, if preset, current content label-definition links and notepad are also accessible.

*Micro viewing.* An enlarged view of the content frame is displayed during micro viewing. This mode is particularly useful in instructional applications that include high graphical content.

*Macro viewing.* The current frame is positioned in a larger spatial context during macro viewing. As with micro viewing, this mode's utility is linked to high graphical applications.

*Multi viewing.* A sequential array of the current lesson's content frames is displayed during multi viewing. Since clicking any frame within this window activates that frame's normal window mode, the student can freely develop individualized lessons. The student can review the instructional content of previous frames or preview the content of new frames.

Under the maximum flexibility setting, the student also controls the display of all picture-text links at all times and can activate a text box control to record and store personal notes on information pertaining to the current frame. Under the minimum flexibility setting, which is automatically evoked during testing, the student's only option is to progress through the frame and response testing chain that has been predefined by the teacher. In the testing mode, the note box control is used for recording answers to test questions.

**The Feedback Module**

Key action and time variables are automatically recorded into a sequential text file as a student engages in either instructional or testing activities. Following the completion of these activities, the teacher can easily access the files for an entire class and then generate up to three feedback printings for individual students. The Navigation Record, the first of two post-instruction feedback instruments, is illustrated in figure 3.

![Figure 2. Four Viewing Modes.](image)

This report offers a complete history of the student's movements through an instructional unit, clearly documenting both decisions and their temporal benchmarks. Students provided with a similar instrument (Strang, 1993, p. 10) have found the contextual nature of its feedback to be particularly helpful during a review of their performance on a teaching simulation. The Learning Pattern Report, the second post-instruction feedback instrument, provides summary information on twenty-three specific variables. These variables are designed to reveal the general patterns that define a student's approach to learning during the instruction phase. Areas addressed by these variables include student persistence, lesson pacing, practice and review, and note taking.

The Test Response Record feedback instrument provides a record of a student's test performance. Accuracy and completion time measures for each item are imbedded in a tabular display which also lists each item's question type and topical focus.

**Field Testing**

A unit defined by a general content file with several accompanying instruction and testing files is currently
being field tested in an audiology course taught at the Curry School of Education. This unit contains a series of macro-sections of the human temporal bone that demonstrate spatial organization of this structure. Participants are graduate students who are familiar with the temporal bone content. An initial series of trials was designed to assess the instruction phase’s ease of use. The three students who completed this phase were encouraged to use the note-taking option to critique the tool’s operating features and also to create a “wish list” of potential future enhancements. Feedback obtained from this preliminary testing resulted in several small program changes.

Figure 3. The Navigation Record

More recently, a second series of trials was implemented to explore student navigation during the instruction phase. A review of fifteen student Navigation Records yielded the following three general patterns:

a. Six students employed a superficial strategy defined by simply moving from frame to frame without accessing either definition information or hotspot locations;

b. five students employed a more sophisticated strategy that included accessing definition information but did not include locating hotspots; and

c. four students employed the most comprehensive strategy that included accessing both definition and hotspot information.

Information in the notes files that students created during their instruction generally complemented the pattern defined by their navigation choices. Beyond these early results, the relationship between navigation patterns and content acquisition and retention must be explored. This exploration includes using both program-designed testing and assessment obtained in the larger context of the course in which LearningLinks is employed. Finally, new content must be developed and included in the field testing process. Content in areas including statistics, technology training, and human development is currently under review.

This section of the proceedings presents papers on preservice teacher preparation regarding technology in education. As in previous editions of the proceedings, you will find papers here on the integration of technology into specific methods courses, the systematic efforts of institutions at technology training for teachers, and video technology education. Also, a fourth traditional theme received greater attention this year than in previous ones: instructional management with technology.

With the emergence of the importance of the Internet, the World-Wide Web, and technology-mediated communications in education another new major trend has emerged for 1997... we call it virtual teacher education. Another, smaller, new trend also developed: technology and paradigm shift. Finally, the section closes with a paper on technology and preservice teacher attitude.

More than in most previous years, the papers in this collection document a continuing improvement in the field. They build upon earlier work to bring us better-developed perspectives on technology in education. We hope that you enjoy and profit from reading them as much as we have.

Specific Methods Course Integration
Dunn (Washington State University) describes how preservice teachers use presentation software to draw and to animate visual models to develop conceptualizations of rational number operations. Gimenez (Universidad de La Rioja, Spain) portrays the integration of technology into the music education curriculum. Johnson (University of Central Arkansas) depicts preservice teachers enrolled in a reading course dialogue electronically (email) with practicing elementary teacher mentors. Knop, Gehring, & Tannehill (Ohio State and Ohio Wesleyan Universities) indicate how email and online resources are integrated into a physical education Medical Aspects of Sports course.

Systematic Preservice Teacher Technology Education
Brush (Auburn University), Ledford & Peel (East Carolina University), and Parmley, Navarrete, Benton, & Nilles (Kansas State University) each offer papers on the development of coordinated college-wide approaches to technology integration across the teacher education curriculum. In the Auburn process, ISTE standards were included in the objective base. Thomerson (Valdosta State University) documents a different direction: extension of the course – development of an intermediate-level applied educational computing course. Ferry & Brown (University of Wollongong, Australia) use student multimedia journals to enhance technology education for preservice teachers. Jackson (St. Mary’s University of Minnesota) and Doty & Hillman (Elmhurst College) each offer papers centering on the evaluation of the use of a student-developed technology portfolio to enhance college-wide integration of technology training for preservice teachers. Lan (University of Alabama at Birmingham) offers lessons to be learned from an analysis of the evolution of computer education and teacher training in Shanghai secondary schools. Powers (Indiana State University) bases technology training on the standards of the Interstate New Teacher Assessment and Support Consortium. Zhang (Concordia College) presents survey-based recommendations for preservice teacher technology training.

Video Technology
Lund (Robert Morris College) describes teaching preservice teachers about the use of television and video production in the secondary school communications curriculum. Stephens, Fabris, Leavell, Buford, & Hill (Southwest Texas State University, University of Houston, and University of Houston – Clear Lake) offer guidelines for the production of random-access (CD/Laserdisc) video-cases that enhance instruction.

Instructional Management with Technology
Matthew (Louisiana Tech University) presents an evaluation of PDA-based classroom anecdotal record-
keeping by preservice teachers using the Newton MessagePad. Wellington (University of Sheffield, UK) explains evaluation of online, hypertext-formatted readings for students enrolled in a postgraduate education certification program. Zhang, Borkowski, & Bao (Universities of Maryland and Shippensberg) characterize the use of LAN-based teaching theaters and lectureware instructional management systems to enhance the teaching performance.

Virtual Teacher Education

Breithaupt (Brigham Young University) depicts collaborative technology education for preservice and inservice teachers. Fryatt & Gregg (Nechako Electronic Busing Program, Canada) design virtual practicums for pre-service teachers. Greene (Appalachian State University) has preservice teachers connect learning theory with concrete practice in an early field experience: the technology-rich Fifth Dimension project. Justice & Espinosa (Texas A&M University – Commerce) tell how classroom supervising teachers and university faculty use cognitive coaching strategies to guide interning preservice teachers in the integration of technology for teaching. Marcovitz (Florida Atlantic University) presents student teachers as technology change agents. LaMaster & Tannehill (San Diego State and The Ohio State Universities) cause preservice teachers to use email to mentor students in the field. McDonald & Stephens (Stephen F. Austin State University) offer online teaching experiences for preservice teachers.

Technology and Paradigm Shift

Allen (University of Central Florida) argues the importance of teaching thinking and problem solving with technology and offers a model for preservice teacher engagement in such. Diem (University of Texas at San Antonio) establishes the importance of attracting technologically-proficient minority candidates who can work collaboratively to the teaching profession and describes of the use of summer institute programs to achieve these ends.

Preservice Teacher Attitude Toward Technology

Knezek, Christensen, & Rice (University of North Texas, Texas Center for Educational Technology, and Lamar University) used a compendium of 14 previously-published instruments to study changes in 32 dimensions of teacher attitude during information technology training.
USING TECHNOLOGY TO CONSTRUCT MATHEMATICAL UNDERSTANDING: DEVELOPING PRESERVICE ELEMENTARY TEACHERS’ CONCEPTUALIZATIONS OF RATIONAL NUMBER OPERATIONS

Thea K. Dunn
Washington State University

Preservice elementary teachers’ use of general-purpose presentation software programs to build dynamic, interactive visual models for operations with rational numbers in a K-8 mathematics methods course was the focus of the present study. Two interrelated issues are addressed in this paper: (a) the preservice teachers’ conceptualizations of multiplication and division of fractions; and (b) their responses to the use of technology to build dynamic imagery for these mathematical concepts. In addition to providing insight into preservice elementary teachers’ responses to technology and their conceptualization of operations with rational numbers, this study was designed to provide some guidance to university faculty seeking to design elementary mathematics methods classes that enhance preservice elementary teachers’ understanding of rational number operations.

Throughout the course, the use of technology, specifically the computer, was encouraged and promoted as an essential component of concept development. Computer-generated, dynamic, interactive, visual models were utilized to enhance concept development by providing a bridge between traditional manipulatives (e.g., fraction bars) and symbolic representations of rational numbers. The preservice teachers worked with two general-purpose presentation programs, PowerPoint and Kid Pix, retrofitted to the educational environment. The software allowed them to draw and animate visual models of rational number operations. Unlike static, inert representations of rational numbers, the technology was dynamic (changing as a function of time and showing continuous transition of intermediate states) and interactive (allowing for the manipulation and modification of the models).

Theoretical Framework

For many preservice teachers, their own experiences learning multiplication and division with rational numbers involved memorizing algorithms, plugging in values, and manipulating symbols. Rather than promoting relational knowledge (conceptual structures that enable the mathematics learner to know what to do and why), these instructional experiences appear to encourage procedural knowledge - “instrumental understanding” and “rules without reasons” (Skemp, 1978). The use of such superficial strategies may encourage an over reliance on direct rather than analytical approaches to problem-solving resulting, ultimately, in limited reasoning and understanding of word problems (Sowder, 1988). Indeed, research that reveals preservice teachers’ misconceptions about the multiplication and division of rational numbers suggests that they may inadvertently pass their misunderstandings onto their own learners (Post, Harel, Behr, & Lesh, 1991; Tirosh & Graeber, 1989).

Multiplication and division of rational numbers are complex operations because, in addition to being difficult to represent with concrete and pictorial analogs, they do not map readily onto whole-number models (Taber, 1993). Technology may facilitate learning by providing physical representations of abstract strategies and concepts, making them tangible for inspection, manipulation, and discussion (Derry & Lajoie, 1993). Current reform efforts concerning the nature of teaching and learning mathematics emphasize the role of the computer in improving mathematics teaching and learning (Kaput, 1992; NCTM, 1989). However, many preservice and inservice teachers lack confidence in using computer technologies for education (Piña & Harris, 1993).

Because research suggests that the effective use of broad-based teaching repertoires fosters higher student achievement (Brown & McIntyre, 1993; Hiebert, 1991), educating elementary teachers in methods of mathematics
instruction that utilize technology may result, ultimately, in both teachers and students in developing broader and deeper understandings of mathematical concepts.

**Methods and Data Sources**

Twenty undergraduate elementary education majors enrolled in a mathematics methods course for preservice elementary teachers participated in the study. The participants were seniors and juniors enrolled in the teacher preparation program at a large, research university. Student demographics revealed that ninety percent of the participants (n=18) were women and ten percent of the participants (n=2) were male. The preservice teachers ranged in age from 20-27 years, with the majority (n=19) of the participants aged 20-23 years. Participants were selected according to the following criteria: (a) elementary education majors, admitted to the teacher certification program, who were in their junior or senior year at the university; and (b) had no social or personal ties to the researcher.

The researcher examined the experiences of the participants in a course designed to help them prepare to teach elementary school mathematics. The mathematics methods course is an integral part of the elementary teacher preparation program at a large, research university. The majority of the preservice teachers in this study had completed at least one mathematics content course prior to enrolling in the methods course. This particular methods course was offered during a six week summer session. The course was taught in an educational computer lab and, throughout the six weeks, the use of technology, specifically the computer, was encouraged and, promoted as an essential learning tool. Technology was utilized to provide a bridge between concrete and abstract models of rational numbers. Unlike printed illustrations, the technology was interactive, enabling the preservice teachers to manipulate and change the models.

In addition to meeting as a whole class, small groups met with the instructor, before, during, and after class. Out-of-class discussions were held with preservice teachers individually and in small groups. The instructor emphasized a constructivist, experiential, collaborative approach to learning mathematical concepts. The preservice teachers were encouraged to work in small groups, collaborate on their assignments, and utilize technology to visually represent mathematical concepts (NCTM, 1989).

This study utilized a qualitative research framework to explore the experiences of the preservice elementary teachers utilizing technology as an integrated approach to learning mathematical concepts. The use of a qualitative research framework illuminated the perspectives of the preservice teachers and enabled the researcher to gain an understanding of the nature of the interactions of the participants with the computer in designing visual models. Data sources included semi-structured open-ended interviews; participant observations of the class; and collection of classroom artifacts, including student assignments, portfolios, and a written final exam. Following completion of the assignments, interviews, each lasting approximately thirty to forty-five minutes, were conducted with five of the participants in order to obtain additional information about their conceptualizations of the multiplication and division of rational numbers and their responses to responses to using technology to create interactive, dynamic, visual models of these mathematical concepts.

Assignments were designed to provide information about the preservice teachers' reasoning strategies and to assess their conceptual understanding of the multiplication and division of rational numbers. Because the researcher sought to ascertain the participants' thinking about operations with rational numbers, rather than simply performing the given operations, the preservice teachers were asked to write both expressions and word problems, design computer-generated models, and reflect on their thinking. Participants were given time to work on the assignments during class. In addition, they were provided access to the instructor and the computers before and after class. Two relatively general-purpose programs, with origins outside of education, PowerPoint and Kid Pix, were retrofitted into the educational environment. The programs could be further modified by the preservice teachers.

Assignments included the following items:

- **Item 1:** Write a number sentence and design a model to illustrate: Rosario has 1 1/2 kg of sugar. She plans to bake pan dulce and each batch requires 1/4 kg of sugar. How many batches of pan dulce can she make? Reflect on your thinking.
- **Item 2:** Write a word problem for the expression: 1/8 x 3/4 Illustrate and solve your word problem using a model - not the algorithm. Reflect on your thinking.
- **Item 3:** Write a number sentence and design a model to illustrate: Teik has 7/8 meter of silk fabric. He uses 1/2 of it to make a sarong. How much silk did he use to make the sarong? Reflect on your thinking.
- **Item 4:** Write a number sentence and design a model to illustrate: Curtis can plow 1/3 of an acre in one hour. On Tuesday, he plowed 3/4 of an acre. How long did it take him? Reflect on your thinking.
- **Item 5:** Write a word problem for the expression: 2/3 + 1/5 Illustrate and solve your word problem using a model - not the algorithm. Reflect on your thinking.

Preservice teachers' responses were categorized across five major variables (Post, Harel, Behr, & Lesh, 1991). The variables included: (a) answer: correct or incorrect; (b) solution strategy: types; (c) explanation: adequacy of logical structure and flow of explanation; (d) procedural vs. conceptual; and (e) reference to model: supportive or nonsupportive.

---

670 — Technology and Teacher Education Annual — 1997
The data indicate that while 35% of the preservice teachers were able to correctly identify Item 1 as a division problem, only 10% were able to provide adequate explanations and demonstrate conceptual knowledge. Similarly, only 10% of the preservice teachers were able to create a model that was both correct and complete. One preservice teacher, whose response was typical of those who were able to provide a correct and complete model, explained her thinking and her model:

This type of problem would have thrown me before - but now that I finally see how it works, it makes more sense - all it's really asking me is 'how many 1/4s are there in 1 1/2?' - so I created a model shows all the 1/4s in 1 1/2 - I took the 1 1/2 and showed it dividing up into 1/4's - then you can see the six 1/4s as they're counted off (Interview, Female, Junior).

In response to Item 2, the data indicate that 70% of the preservice teachers applied the standard multiplication algorithm. Only 10% provided a supportive model that was both complete and correct and only 5% demonstrated evidence of conceptual understanding. Interestingly, while 70% of the teachers attempted to apply the standard algorithm as a solution strategy, because of application of an incorrect algorithm, only 15% were able to arrive at the correct answer. Many of the preservice teachers who created word problems and models for a subtraction, rather than a multiplication expression, relied upon "rule without reason" strategies (Skemp, 1978). One preservice teacher, whose explanation was shared by other participants, elaborated:

I remember that when you multiply and divide fractions you are going to have the opposite effect of when you multiply and divide whole numbers - so, in this case, where I'm multiplying two fractions, I'm looking for a word problem where I end up with less than what I started with. In my model, I wanted to physically show the process of getting smaller (Interview, Female, Senior).

Although the data reveal that 35% of the preservice teachers correctly identified Item 3 as a multiplication problem, an equal percentage of the participants (35%) mistakenly identified the item as a division problem. Additionally, 30% of the preservice teachers mistakenly identified Item 3 as a subtraction problem. The following response is typical of preservice teachers who were able to write appropriate number sentences and models and explain their reasoning:

Has, uses - you're taking something away here - it's obvious we're making smaller because he's using up the silk. So, I know we're talking about multiplication here because when you're making smaller in fractions, it's a multiplication problem. The model was harder to come up with - how do I know it's showing multiplying and not subtracting? I think, take 3/4 of 7/8 - then I can begin - look, try showing 7/8 of a meter, that's the blue - then show 1/2 of it - the yellow - watch it now, the green is 7/16 of it, you can see it, 7/16 of a meter, that's what he used (Interview, Female, Junior).

While nearly all of the preservice teachers (75%), recognized Item 4 as a division problem, the data indicate that only 40% of them were able to write a correct number sentence for the problem. An even smaller percentage, 15%, were able to create supportive models that were both complete and correct. One preservice teacher's articulation of how the models moved her toward a conceptual understanding of the problem was shared by many of the participants:

When I used to see a problem like this I couldn't tell what operation to use - when I was forced to move away from the algorithm I began to see it as division - but I had to see it first - in the model - then I began to see the meaning. The model shows you 3/4 and the number of 3rds in it - that's 3/4 divided by 1/3 (Interview, Female, Senior).

When presented with a number expression for the division of two fractions, the data reveal that 70% of the preservice teachers wrote word problems for the subtraction of fractions. However, 40% attempted to solve the expression using the standard division algorithm. This discrepancy between their word problems and their solutions of the numerical expression suggests a possible reason for their inability to provide adequate explanations or supportive models. The preservice teachers' explanations of their strategies demonstrated a move away from relying on the standard algorithm toward a conceptual understanding of the expression. For example:

I used to look at a problem like this and want to flip the numbers and multiply - now the first thing I think to myself is 'how many 1/5s in 2/3?' Writing a word problem is the easy part - the model takes more thinking - but once you've done it, the model makes the meaning of the problem much clearer (Interview, Female, Junior).

While the preservice teachers had previous experiences performing routine computations with rational numbers, the creation and use of computer-generated, dynamic, interactive, visual models to enhance concept development was unfamiliar to them. In addition, the majority of participants had not been exposed to word problems involving computation with rational numbers. The results of the present study suggest that using technology as an integrated approach to learning computation with rational numbers caused cognitive conflict between the preservice teachers' ability to manipulate symbols, create the models,
and explain the meaning of the operations. Many of the participants shared the feelings of one preservice teacher who reflected:

As I began to start my operations, I thought this would be the easiest part of my assignments. I soon found it to be the most difficult. I feel this is so because of a couple of different reasons. One is that I do not remember doing story problems that involved multiplication and division of fractions. When I was making my problems, I also found trying to visually solve the problem difficult. The second is that I've never been exposed to technology in this way before (Interview, Male, Junior).

Initially, many of the preservice teachers attempted to employ the standard algorithms to solve the problems and then, based upon their results, create the models and word problems. However, these preservice teachers were unable to explain their conceptions once they had created the models. This finding is consistent with the work of Hiebert and Wearne who observed that, once procedural knowledge is acquired, “it is difficult for students to penetrate their own routinized procedures with meaningful information” (Hiebert & Wearne, 1987, p. 397). In addition, several of the participants held the belief that technological proficiency follows, rather than facilitates, mathematical understanding. Many of the participants who attempted to rely solely upon the standard algorithm to work their way through the assignments shared the response of a preservice teacher who expressed his feelings as follows:

One word sums up my experience with these problems: frustration. Multiplication and division with fractions must be one of the most difficult concepts to write word problems and models for. It took me almost an hour to come up with just two word problems and create the models that correspond with them. To be honest, if I've struggled this much, I can't imagine giving this to a fifth-grader who didn't know the math (Interview, Male, Senior).

As the preservice teachers acquired proficiency with the software, they began to develop relational knowledge and construct conceptualizations related to the multiplication and division of fractions. However, their lack of experience with technology posed some initial difficulties. In addition to high levels of frustration, many of the preservice teachers exhibited a need for constant guidance and approval from the instructor. The preservice teachers reflected on their experiences with both the technology and their developing understanding of the underlying mathematical concepts. For example:

My lack of computer experience has been a problem as far as this course is concerned. I think I can understand the models once I've made them but it was difficult and took a lot of explaining and then I'm still not sure if what I've done is right. Part of it is that, before this course, my only computer experience was word processing and part of it is that I rely too heavily on the algorithm (Interview, Female, Junior).

When I was making my models, I found visually trying to solve the problems difficult. After I was shown different ways of creating dynamic models, the visuals began to make more sense to me. I think that now I could accurately portray these meanings to my own students (Interview, Female, Senior).

The high ratio of preservice teachers to computers made it necessary for the participants to work cooperatively, in groups of three or four. It appears that this collaboration, because it encouraged discussions about both the technology and the mathematical concepts may have facilitated the preservice teachers’ construction of understandings. As one preservice teacher explained:

I never thought about having kids work together at computers like this in math - it’s different than what I imagined my own class would look like. But now that I can see how it helped us - working together, talking about it - it could benefit my own students (Interview, Female, Junior).

Conclusions and Significance

This study investigated preservice elementary teachers’ conceptualizations of rational number operations and their responses to using technology to create interactive, dynamic, visual models of these concepts. Interviews with the participants encouraged them to verbalize their understanding of the mathematical operations and explain their conceptualizations of those operations. The data from the present study reveal that, while the preservice teachers are able to manipulate symbols and provide correct answers to problems involving multiplication and division of rational numbers, they initially lacked the relational knowledge to provide explanations for the mathematical relations, concepts, and operations (NCTM, 1989). These results also provide evidence to suggest that the preservice teachers’ knowledge of computations with rational numbers is more procedural than conceptual.

In the present study, the general-purpose software computer environment appears to have played a role in the preservice teachers’ developing relational knowledge of computations with rational numbers. Because of its dynamic and interactive nature, the software appears to have facilitated the preservice teachers’ transitions between the concrete and symbolic representations of rational numbers. However, lack of computer experience initially hindered several of the preservice teachers’ attempts to utilize the technology. Additionally, because of inadequate
subject matter preparation, many of the participants had difficulty understanding the mathematical problems.

As the preservice teachers gained experience with the software, they evinced a progressive construction of concepts related to the multiplication and division of rational numbers. The results of this study suggest that traditional manipulatives and symbolic representations may not be adequate for developing preservice teachers’ conceptualizations of operations with rational numbers. The data that emerged appear to support the usefulness and efficacy of technology to enhance preservice teachers’ understanding of mathematical concepts and, ultimately, improve their preparation for teaching mathematics for understanding.

Technology and Music Education: An Integration into the Music Education Curriculum at the University of La Rioja

Jesus Tejada Gimenez
Universidad de La Rioja -Spain-

Since 1993 music technology has been used as a part of the music teachers' arsenal at the University of La Rioja in Spain. Knowledge of these types of tools is integrated into the curriculum through Armonia Funcional (Functional Harmony), a one semester subject. Also music technologies are used as a didactic resource in other degrees offered by this university. The present article will present both several curriculum aspects and pedagogical reflections related to the use of technology into curricula as well as its incidences in learning processes.

Infrastructures at University of La Rioja

In the academic year 1993-94 Music Lab had five workstations each made up of a MIDI synthesizer, MIDI interface, Macintosh computer, headphones, sequencer soft (Master Tracks), editor score soft (Encore) and a generator of rhythmic-harmonics (Band in a Box). Also Music Lab included a liquid crystal display, a mixing board, a CD-ROM drive, an amplifying system, a deck tape recorder and a postscript laser printer. In 1994-95 four complete workstations were added. LocalTalk net for using common resources such as printer or hard disk drives was installed in 1995-96.

As a complement, other software is available for students' use, i.e. Finale, Cubase or Practica Musica, as well as several musical works in CD-ROM format. In this current academic year we have added three complete workstations, to make a total of twelve. Also, we have purchased a multitrack recorder.

Curricular Aspects

Integration of Music Education and other university degrees is important at the University of La Rioja. We consider that Function al Harmony must be basically practical, as pupils in professional situations will use his/her knowledge of harmonization, arranging and instrumentation in order to release his/her own didactic materials beginning from melodic lines, folk & popular songs or musical works carried out by either groups or individuals. So in this subject it is more important to acquire skills and capabilities in the above mentioned fields rather the conceptual and theoretical elements; these are undoubtedly useful in other situations and studies but in some way they are out of context in this subject which has a low number of academic credits (4.5 or 45 hours).

We also need to consider the evident heterogeneous class groupings due in large part to ingress of people without previous musical experiences into these studies as well the lack of musical skills they arrive with. Because of this, we have considered offering to pupils some extra reinforcements in form of aural training software that helps them in order to consolidate both capabilities and skills. The technology is also a teacher's tool in other university degrees such as Maestro de Educacion Infantil (Early Childhood Educator), Maestro de Lengua Extranjera (Foreign Language Teacher) or Maestro de Educacion Fisica (Physical Education Teacher).

Organization of Subject “Armonia Funcional”

Armonia Funcional is an obligatory subject of the university; in the Spanish educational system this means that each university requires a limited number of subjects, i.e., Armonia Funcional; while, another organization called Consejo de Universidades (University Council) requires other subjects called “troncales” which are also compulsory, in this case to all Spanish universities. These, along with the obligatory optatives and free configuration courses, make up the curriculum of a given university degree. Armonia Funcional is inserted into a Music Education Teacher's curriculum in the second year. Three years are needed to achieve a degree. Armonia Funcional have two different blocks: Foundations of Harmony and Music Technology. In the first, we broach theory directly related with Harmony as an academic discipline such as
voicing chords; we also give notions on composition and arranging in order to deal with scholarly curricular materials of value in his/her future professional life.

In Music Technology we give some technological basics, such as communication between computers and MIDI devices or the use of technological tools which support an active methodology based music education, like Orff, Kodaly, Willems, Martenot or Dalcroze. Also, pupils learn to deal with multitrack recorder. Of course, apart from subject length, pupils can take practical complementary classes as electives.

We will trade materials elaborated by our pupils with others educative centers from USA, Germany, Korea and Italy, via email.

Subject's Program

As mentioned before, in Armonia Funcional practical contents carry more weight than the theoretical (75% vs. 25% of schedule). So the subject is devoted to aural training of chord and harmonic progressions, composition of melodic lines, harmonization, arranging and scoring (popular songs and pupils' melodic lines and harmonizations). These activities are released by means of technology. Contents before mentioned related to composition, arranging and scoring are elements that are not explicit from the subject's program and they make up a hidden part of the curriculum.
The use of interactive telecommunications has tremendous potential for teaching the language arts, especially if teachers are knowledgeable about its use. Electronic dialoguing is a motivational telecommunications technology that allows students to have ongoing discussions via the computer. According to Reutzel and Cooter, Jr. (1996) there are three major advantages of utilizing electronic dialoguing. First, the reason for writing is authentic and motivational because a real person is awaiting a communication and second, planning and scheduling is extremely flexible on the part of both audiences because they may respond at their own convenience. Finally, it offers a real world opportunity to use writing skills with an understanding audience. The purpose of the project I am going to describe was to model how technology can be incorporated into the curriculum of a reading methods course for preservice teachers to facilitate learning as well as provide hands on experiences with computer applications.

Project Description

The following is a description of a project conducted with preservice teachers in a reading methods course in Arkansas using electronic dialoguing. The reading methods course in which this project was conducted is the first of two reading courses preservice teachers are required to enroll before student teaching. One major goal of the course is for preservice teachers to gain a thorough understanding of different reading philosophies, advantages, and disadvantages of each and varying approaches teachers use to teach reading as a result of their philosophy. It is one thing to read about the theory behind different reading philosophies in a textbook and a very different thing to actually observe the approach a teacher uses to teach reading as a result of their personal philosophy.

All students enrolled in education courses at the university are required to participate in a field requisite. Each student is placed in an elementary classroom for a specified number of hours, one day each week throughout the semester, and asked to complete a certain number of requirements outlined by each course the student is enrolled. For example, one field requirement for the reading methods course I teach is to keep a journal documenting the students' observations of reading instruction and the learning environment along with any comments the students may have. After many observations and in collaboration with the teacher, the student is to determine the teacher's reading philosophy. The cooperating classroom teacher is asked to provide time for the student to complete these requirements, observe the student's performance and provide feedback as well as continue daily instruction. Many times the student and the teacher are overwhelmed and as a result have little if any time to discuss the theory behind the methods the student has practiced or observed.

Goodlad (1988) submits two fundamental conditions needed for collaboration to be effective: (1) frequent opportunities to share experiences with other persons in similar roles, and (2) opportunities to reflect upon how theory and research can inform practice. Goodlad states that developing and maintaining a method for ongoing communication between the school district and the university should be given the highest priority if collaboration is to have a chance of succeeding. Therefore, a specific goal of this project was to provide an avenue for the preservice teachers to gain a greater understanding of different philosophies of reading through collaboration with practicing teachers across the country via electronic dialoguing.

At the beginning of the semester, I provided each preservice teacher with an e-mail account through the university. I then assigned each preservice teacher with a mentor "e-pal." All of the e-pals were practicing elementary teachers located in various regions of the US. I solicited participation for the e-pal mentoring project through a request on a listserv. All of the mentors had taught three or more years in a self-contained K-5 elementary classroom.

All of the preservice teachers participated in a training session on how to use e-mail prior to sending their first message to their e-pal. All students had previously taken a required educational technology course (approximately one semester ago), but most stated that they did not remember
how to use e-mail. Following a brief demonstration and subsequent practice session, all students sent their first e-mail message to their e-pal. After this initial group session, all further correspondence was on their own time outside of class. An additional class period was dedicated to showing students how to join listservs and newsgroups and to use Netscape as a resource for information.

Electronic Dialoguing Collaborations

I requested that the preservice teachers begin their collaborations with their mentor e-pals by asking about the approach they use to teach reading. From then on, collaborative topics were determined by the preservice teachers and their mentor e-pals. Initially, I was concerned that the students may need more structure as far as topics for collaboration. I contacted the mentor e-pals and asked for their input. It was obvious from their responses that the informality of the collaborations allowed the students the freedom to ask questions they believed relevant. Topic variations ranged anywhere from assessment to discipline. One mentor e-pal simply stated, "I think it should be easy for the students to ask almost anything of an experienced teacher...especially since I will not be judging their performance. I hope this could be a comfortable learning experience."

There was no requirement as to how many times a student must collaborate with the mentor e-pal. As a result, communications ranged from weekly to a total of once or twice for the entire semester. Overall, the students were very impressed with their mentor e-pals and became very close to them. The mentor e-pals took their roles very seriously and spent hours responding to the students' questions. During class, I would provide many opportunities for the preservice teachers to discuss the messages they received with one another and to spend time in the classroom. The unique aspect of this project is that it capitalized upon the opportunity to expand the teaching role while remaining a classroom teacher.

Outcomes of the Project for Preservice Teachers

The outcomes of incorporating electronic dialing into the reading methods course were three fold. First, students were able to see telecommunications as a multifaceted resource. Students were given the opportunity to experience the power of technology as a tool for communicating, problem solving, brainstorming, and finding information. Additionally, students were involved in a different type of field experience in order to gain a deeper perspective on different philosophies possible. The project provided the students with a broader set of experiences than were available during their field placements by extending the face-to-face collaboration through electronic dialoguing. This ultimately provided a more powerful context for learning. Finally, students collaborated with experienced, technology-using teachers. The mentors were able to share their experiences as classroom teachers as well as encourage students to view technology as a tool to improve their professional lives.

Outcomes of the Project for Mentor Teachers

I was able to ascertain the benefits of this project for the mentor teachers that participated through a survey administered electronically. In general, the mentor teachers gained the satisfaction of being able to transfer skills and knowledge accumulated through extensive professional practice. The questions from the preservice teachers provided opportunities for the mentor teachers to reexamine their own classroom practices and the effects of accepted instructional techniques on the teaching/learning process.

Conclusion

It was obvious by the end of the semester that the preservice teachers had benefited greatly from participating in the electronic dialoguing project. Through hands-on experience, they gained an understanding of how technology can promote collaboration and sharing of ideas, which is one of the most promising areas of telecommunications for teachers in the battle against isolation. Recent advances in microcomputers and telecommunications have produced low-cost computer-based networks that can allow us to extend field experiences throughout the teacher preparation process. Through the use of telecommunications, teacher educators can provide an electronic educational community in which preservice teachers can learn through interactions with mentor teachers. This helps to establish stronger links between teacher education programs and classroom teaching practice. As one student stated, "It is amazing to me that you can get on a little screen and a little keyboard and talk to people clear across the world. That just shows that we really are a global community."

Mentoring benefits everyone involved: the mentor, the student, the university and the school system. The combination of real life application and effective instructional practice increase the likelihood that these preservice teachers will incorporate the use of technology into their teaching in the future. The positive outcomes of this project indicate that those of us involved with the preparation of teachers must engage in providing students with opportunities to apply technology skills so that effective teaching is modeled.

Preservice Teacher Education — 677
Technology infusion into classroom coursework has been demonstrated to enhance student learning (Tosteson, 1996; Padron & Waxman, 1996). The value added comes from the increased potential for student communication (Smith, 1996) and increased access to current information from multiple sources, particularly via the World Wide Web (Land, 1996). With this in mind, technology was infused into an upper level physical education course at a private college in central Ohio. The project was not an empirical study, but instead, an attempt by an instructor to make her class more meaningful to students. This paper will discuss the infusion process and report the results from the instructor’s and students’ viewpoint.

Background
I became involved in this project while helping a physical education instructor at a small Ohio liberal arts University develop instruction that infused technology into a college level foundations course. The instructor was in her second year teaching at this institution and second year of teaching this particular class. She had five years of teaching experience at the college level behind her and was strongly based in the course content. From previous experience teaching this class, she recognized that a different instructional strategy was needed. Students were coming to the class with varied backgrounds, experiences, and interests requiring instruction to be more responsive to the learning goals of all students. Beyond that she was interested in finding ways for students to increase their professional interactions among peers and with practicing professionals in their career areas.

This instructor was avidly interested in exploring instructional and learning possibilities using varied technology sources. She knew of multiple technological resources and their availability on campus. Further, she was ready and willing to take some risks in her classroom, provided they lead to an increased potential for greater present and future student learning. In a sense she was like the famous space traveler, Buzz Lightyear, the affable astronaut from Disney’s movie *Toy Story*, whose motto “To Infinity and Beyond”, seemed to characterize her continued search for new and better ways to understand what we do and how we do it. Buzz’s existence in *Toy Story* was framed by his continual exploration of known limits as he tried to be the first to break through those barriers and help create a new reality. The teacher in this project ascribed to a similar philosophy, trying new methods and media that might extend options for student learning, discovery, and problem solving.

The Course
The class, Medical Aspects of Sports, was an upper level physical education required class. It was intended to be taken after students mastered prerequisite study of anatomy and physiology. The class was designed for physical education majors, potential coaches, and students preparing for graduate school particularly in science related physical education subdisciplines and other health related fields.

This particular semester 21 students were enrolled, 14 from physical education and 7 non-majors from either zoology or microbiology. One instructor did all the teaching although she enlisted the cooperation of several librarians to facilitate the on-line library search process. All students had access to computers, the University communication system (VAX), and E-mail accounts at the student computer lab. The course objectives were to:
1. Study the causes of a variety of athletically related injuries and to examine prevention measures for these injuries;
2. Study the affect of certain variables on sport performance. These were specific variables like present fitness level, present and past nutrition, and present and past injuries;
3. Study the affect that special conditions, like asthma, exercise induced asthma, environmental conditions, or ergogenic aids has on sport performance, and perform an all encompassing personal fitness assessment and use this information to design a training and nutritional program.
Given these objectives, technology infusion was intended to supplement reading, lecture, and lab materials with several additional, and hopefully user friendly, information and problem solving resources. Increasing inter-student communication was a further purpose. We hoped to use E-mail to break the mostly one-way teacher to student interactions into multiple way conversations where students were encouraged to value peers’ ideas. Additionally, we wanted to create incentives for student initiated and sustained interactions with professionals in their field. Another purpose of the infusion process involved introducing students to several methods of problem solving allowing them to choose the most appropriate one for their content and problem. Finally, and perhaps most importantly, we hoped to make the class more fun. We thought that learning might be more fun when available through multiple media resources. Since students vary in what they think is fun, options using different technologies allowed students to choose the medium they enjoyed most.

Delivering the instructional sequences in this context where technological skill was not the primary content focus required some special arrangements. First, three hour long class sessions were devoted to introducing technological skills. These were the first, third, and fifth Friday classes of the semester. These classes met in the student computer lab where all students had access to a computer. These class sessions were supported with extensive documentation. The intent of each session was to walk students through the process steps using the documentation to support progress. Those who mastered the process moved on to their content related task using that medium. After guiding students through the process, the instructor offered remediation during that session and via E-mail after the session. The technology options incorporated into the instruction were:

1. On-line library searches where students learned how to conduct a search and what kinds of things they had access to beyond University holdings;
2. E-mail, which would become the primary communication system for inter-student and student-instructor interactions;
3. Internet newsgroups which were introduced to allow students access to “conversations” among professional and lay individuals with common interest in specific sport content;
4. Gopher, an internet search tool, which was introduced as a way of searching for topic specific information at a multitude of sites, and;
5. World Wide Web, which was introduced as a bonus. Half way through the quarter, the University gained access to the Web at their public computing sites. The instructor was able to shuffle her instruction enough to introduce and provide support for students using it.

Given the course objective, it was important to determine the level of technological skill students had prior to entering the class. From this assessment, instruction could be developed to support and facilitate student learning of the basic technological skills necessary to access each medium. The assessment was a simple questionaire used to determine students’ prior experience. It included seven questions asking students the degree to which they had experienced E-mail, Gopher, and the World Wide Web. Of the 21 entering students, three quarters had at least limited experience accessing and using the E-mail system. Less than half had at least limited experience accessing and using the E-mail system while less than one third had ever used a Gopher. Very few students, in fact 2, had ever accessed World Wide Web and none had ever downloaded information from a site.

The Projects

Assessment supporting the infusion process took the form of a technology project which culminated in student demonstration of skills necessary to use the media effectively to find content related material. Since the purpose of infusing technology was to increase opportunities for learning and problem solving, the five technological instructional steps were each linked to a content based task. For instance, E-mail supported inter-student and instructor-student communication. The introduction to Newsgroups culminated in each student sharing an article and related search process with their fellow students via E-mail. The intent was to provide each student with sport specific articles documenting injuries, conditions, and prevention issues.

The Weather Project was a problem solving task with the objective of demonstrating the varied uses and breadth of information that can be found using the Gopher system. Relative to course content, this project focused on students applying knowledge of how environmental factors, like temperature, elevation, and humidity might affect performance in two physiologically different sporting events. Each student was assigned a “pick” city, a specific competition date, and given the Gopher address serving that region. After accessing Gopher, students’ searched for sites that might contain information they would need, like Weather Service or the Geographical Service. They determined what questions were relevant to ask and where to find the answers. They, then summarized the impact this environment had on the following 2 activities: one, requiring maximal endurance lasting 30-45 minutes and the other a repetetive anaerobic event.

World Wide Web exploration supported the final research presentation and involved accessing, navigating, and locating information sources specific to their research topic. These findinges were incorparated into their research topic presentation, including a printed copy of the sport specific menu to share with the class. Finally, the technology project was the opportunity for students to thoroughly investigate a specific question. Each student, using multiple
media resources prepared a written summary of findings and presented this and the specifics search process to the class. An example of this process documented by one student is as follows: the topic generally search was “tennis elbow”. The student’s question generated from earlier search processes was “What are some ways of alleviating the pain of tennis elbow, including prevention or form changes”. This student found most of the information by reading and interacting on newsgroups under FAQ (frequently asked questions) of rec.sport.tennis.

The students investigated a variety of interests as indicated by the breadth of a selected list of topics and questions they searched. For instance, one student was interested in facts about cholesterol and trends for healthy living. Her search process included using Gopher and World Wide Web under general headings of health and nutrition. A student trainer in class interested in the best rehabilitation after knee surgery, searched both World Wide Web under general health, injury, and knee exercises and a Gopher site at the University of Illinois under the same headings. A student interested in caffeine and its effects on athletes used World Wide Web to access the US Food and Drug Administration to find information. A basketball player interested in injury rehabilitation wondered what the difference was between cardiorespiratory responses to exercise performed on land versus in water. She searched World Wide Web and Gopher generally under health and specifically under the headings hydrotherapy and rehabilitation. Another student, planning a diving trip to the Caribbean, asked the question of how to prevent decompression sickness in diving. He found information under a scuba listserve and in various World Wide Web sites, one of which was a NASA site.

**What Did We Learn?**

Several methods were used to evaluate the success of embedding technology into the Medical Aspects of Sports class. First, the quality of student projects provided a demonstration of the extent of learning at each of the five technological infusion instructional stages. Problems were discovered and attempts made to remediate after each project stage. Student logbooks were checked periodically for evidence of student understanding and application of knowledge. Additionally, at the end of the semester, students were encouraged to evaluate the course and give feedback. However questions guiding the evaluation were specific to the course in general, and did not elicit student response to the technology infused in the course. After the quarter, the instructor also was asked to evaluate the success of the technology infusion in her class. In addition, the instructor kept a journal of her perceptions of successes and failures throughout the semester.

A number of problems specific to the way technology was infused into the course arose throughout the semester. For instance, we learned that technology itself can create dynamic problems. For example, during the weather project, the Michigan underground weather access “went out”. This technological glitch added to the student and instructor frustration. Back-up plans would have been very appropriate in this situation, but instead it took the student time to figure out it was not a student error but a technological failure that caused the problem. When the student informed the instructor of the problem, it took the instructor time to generate a new site and Gopher. It worked out, but at a time loss and frustration cost for both the instructor and student.

We also learned that the final project may have been too big and that given the instructional time frame and size of the project, instructor expectations may have been too high. Perhaps more importantly we learned that extensive advanced preparation and planning are necessary to “carry off” a redesigned class including technological infusion. On the other hand, the technology mediums did seem to increase inter-student communication and sharing of ideas. World Wide Web was fun, easy to access, and rewarding for students who worked with it. The instructor found that more material could be covered in the class in less time. Students were doing more problem solving and searching for content driven by related, but interest specific questions, instead of instructor guided inquiry generated in the lecture/lab. Additionally, E-mail supplemented the instructor’s teaching resources allowing her to be more accessible to student questions, beyond office hours and phone calls.

**Recommendations**

In conclusion, after this first attempt at infusing technology in the Medical Aspects of Sports class, several changes to the present instruction seem prudent. First, much has been learned from the first attempt. Many of the materials can be used again with small changes. However, time does need to be spent to create alternative plans for responding to technological failures and student failures using technology. Second, the class needs to be structured to allow more time in lab settings for both content and technological learning. This may include decreasing the amount of material covered or increasing the time spent at each activity. This may also include peer mentored activities or cooperative group activities so the instructor could take advantage of the competencies and experiences students have when they enter the class. Finally, the culminating technology project needs to be subdivided into smaller parts allowing students to get feedback and earlier remediation from the instructor. The breakdown of the final project into subparts, each worth a portion of the final grade and due in a sequential manner, would give added incentive for students to complete the task in a timely manner and with more guidance.
The take home message hopefully delivered by this demonstration is that infusing technology into physical education foundations coursework can create more opportunities and methods for students to learn and more choice in how they learn. Physical education instructional delivery decisions that infuse technology are risky, both from the instructor and student's viewpoint. The risk arises in the potential for frustration simply from learning how to use the media, even though it is that learning that can drive future student inquiry. At the risk of over-simplification, "To Infinity and Beyond" implies instructional delivery decisions that can empower students to explore their knowledge limits. The beauty of infused technology is that, once some basic skill in using each medium have been acquired, there are few right or wrong ways to find information. This is important to promote problem solving and inquiry minded questioning.

There is little argument among leaders in the field of educational technology that teacher training institutions are not adequately preparing undergraduate teacher education students to effectively integrate technology into their teaching. Although technology is becoming more and more prevalent in today's schools (Ely (1995) has noted that the student/computer ratio in U.S. schools has dropped from 1/75 in 1984 to under 1/12 today), research continues to show that teachers feel that they are not prepared to effectively use technology in their classrooms (Bosch & Cardinale, 1993; Office of Technology Assessment, 1995; Topp, Mortensen, & Grandgenett, 1995). Because teachers still feel uncomfortable truly integrating technology into their instructional activities, they continue to use computers for low-level, supplemental tasks such as drill and practice activities, word processing, educational games, and computer-based tutorials (Ely, 1995; Hunt & Bohlin, 1995; Lazio & Castro, 1995; Office of Technology Assessment, 1995). Some researchers have even gone so far as to state that “...few teachers routinely use computer-based technologies for instructional purposes” (Abdal-Haqq, 1995, p. 1). Thus, our education students are graduating with little knowledge as to the instructional applications of one of the most revolutionary sets of instructional tools of the past two decades. As the use of technology tools increases in the K-12 environment, schools will be looking to university teacher preparation programs to provide them with staff members who are not only trained to use technology, but have the ability to provide other staff members with models and examples of how to effectively use technology in their classrooms.

While most researchers agree that more technology training is needed for teachers, numerous suggestions exist in the literature regarding the content of the training and the methods for delivering the training. In terms of content, suggestions for topics to be covered in preservice or inservice teacher education courses include multimedia, problem-solving applications, networking, the internet, curriculum integration, software evaluation, telecommunications, use of applications and tools, hypermedia, and a host of other areas (Abdal-Haqq, 1995; Baron & Goldman, 1994; Taylor & Wiebe, 1994; Walters, 1992). In terms of the most effective methods for providing teachers with technology skills and experiences, many researchers believe that technology skills should be integrated with graduate and undergraduate methods courses, thus providing students with specific skills and concepts for using technology in their specific content areas (Wiebe, 1995). Others believe that well-designed instruction which provides teacher education students with technology skills and experiences in a variety of content domains and gives students opportunities to apply technology in those domains is the most appropriate training methodology (Abdal-Haqq, 1995). However, nearly all researchers agree that teacher education programs should focus on training prospective teachers to integrate technology in their teaching and learning activities, as opposed to providing a “survey” of computers and instructional technology. As West (1994, p. 104) states, “Do not require [teachers] to sit through a survey of computing history or a course in computer programming.”

This paper will describe the revisions and enhancements made to an undergraduate teacher education course focusing on the use of technology across the curriculum. Prior to its redesign, this course focused on introducing students to issues and research in educational technology, with an emphasis on the history of educational technology, identification of different computers, programming languages, and basic technology skills for classroom management purposes. Through redesign of the content, materials, and evaluation criteria, this course now emphasizes pedagogical uses of technology and provides students with opportunities to develop, apply, and evaluate technology-based instructional materials for classroom use. A project-based learning environment was created within the class, in which students complete activities directly related to the use of technology in their specific content areas.
Through the completion of these activities, students not only acquired knowledge regarding the

Course Development Process

The development process for this new course took place in several phases. First, information was collected for teacher education faculty in order to determine the necessary skills and experiences pre-service teachers need to effectively integrate technology into their content area, and were compared with national standards and benchmarks for technology skills for practicing teachers. Once these data were collected, the overall objectives for the course were developed using this information, and activities were constructed and sequenced to guide students towards meeting those objectives. Materials were developed to assist students with completing the activities, and these materials were provided to the students in multiple formats. Finally, students were asked to evaluate each course topic and class activity so that the course could be improved upon each successive quarter. Each of these processes are described in detail below.

Data Collection

The first step in redesigning this course was to open a dialogue with the teacher education faculty at Auburn in order to receive their views regarding important skills and experiences pre-service teachers needed in the area of technology, particularly skills related to teaching in their content areas. Faculty in math and science education were consulted first due to faculty members’ extensive knowledge of instructional technology. Faculty in early childhood, social studies, language arts, and art education will be consulted as the development process continues. The math and science faculty members initially consulted provided an extensive list of technology skills they felt prospective teachers would need. These skills were condensed and categorized into the following areas:

- using technology for productivity. This included such areas as basic word processing, database, and spreadsheet skills, electronic search skills, and electronic mail (e-mail) and world-wide-web (www) teaching resources.
- using technology for teaching. This included presentation hardware and software, multimedia and hypermedia, interactive video, telecommunications, e-mail and the www, instructional software evaluation and integration, and using productivity tools in the curriculum.
- using technology for organization and administration. This included electronic testbanks, electronic gradebooks/attendance software, lesson plan designers and other electronic curriculum aids, and organizational tools such as inventory software and seating charts.

The faculty interviewed also emphasized the need to inform students of both the possibilities and limitations of instructional technology. They felt that students needed to exit the teacher education program with knowledge that would eliminate their fear of technology and enhance their skills in integrating technology into their classroom activities.

One area that teacher education faculty did not address was technical skills such as hardware troubleshooting and programming. In terms of hardware, they felt that schools needed to provide personnel to assist teachers with technical problems and hardware troubleshooting. In addition, they felt that programming skills such as BASIC or Pascal were best left out of the undergraduate instructional technology courses. Once again, they felt that emphasis needed to be placed on the use of available technology tools in the curriculum as opposed to teacher-created tools.

After these data had been gathered from the teacher education faculty, they were compared with national standards developed by the International Society for Technology in Education (ISTE, 1996; Thomas, 1994). ISTE, in conjunction with the National Council for Accreditation of Teacher Education (NCATE) have developed a series of technology skills which should be used as guidelines for state endorsements in instructional technology teacher education. The first set of skills serve as foundations and prerequisite preparation for a technology endorsement. These skills were used as a benchmark for comparing how information gleaned from interviews with teacher education faculty compare with national standards developed by ISTE. A comparison is provided in Table 1.

While many of the areas (particularly those dealing with integrating technology into teaching) were identified in both the teacher education faculty interviews and the ISTE technology standards, there are several areas which were not addressed by both sources. For example, many of the basic technology skills identified in the ISTE standards were not deemed important by the teacher education faculty. Similarly, many of the administrative/organizational skills and experiences discussed by the teacher education faculty were not included in the basic ISTE standards. Based on these inconsistencies, it was decided to use both data sources as guides for determining the overall objectives and activities for the revised pre-service instructional technology course.

Development of Objectives and Activities

Using the data described above, objectives were developed to address each area identified as an important technology skill/experience for pre-service teachers. The objectives were categorized as either skill (S) objectives or knowledge (K) objectives. Skill objectives required the student to perform some operation or develop some product using a technology tool. Knowledge objectives required the
student to develop classroom policies, synthesize current research, or describe potential uses of different technologies in various settings. These objectives are summarized in Table 2.

Table 1.
Comparison between technology skills identified by teacher education faculty and ISTE technology standards.

Table 2.
Objectives for EM370 course.

Technology Skill Area EM370 Course Objectives
Basic Technology Concepts (ISTE)
S.1. Students will demonstrate the operation of a multimedia computer and CD-ROM software.
S.2. Students will demonstrate the use of a peripheral device designed to import multimedia into a computer. K.5. Students will identify adaptive devices which can be used to provide access to computers for students with special needs. K.6. Students will describe educational uses of distance technology such as instructional television and telecommunications. K.7. Students will identify how technology is used in various business and industry settings.

Personal/Professional Use of Technology (ISTE)
S.3. Students will use a database program for data collection purposes.
S.4. Students will use presentation software and hardware for information communication purposes.
S.5. Students will use a world-wide-web browser for data collection purposes.
K.3. Students will describe their ethical and legal responsibilities regarding personal and professional use of technology.

Application of Technology in Instruction (ISTE)
S.6. Students will use a hypermedia authoring tool to develop an instructional activity.
S.7. Students will use word processing, spreadsheet, and graphics software to design classroom learning activities.
S.8. Students will use world-wide-web resources to design classroom learning activities.
S.9. Students will use off-the-shelf instructional software to design classroom learning activities.
K.1. Students will read and synthesize current research in the field of instructional technology.
K.2. Students will demonstrate knowledge of software evaluation methods and techniques.
K.4. Students will describe methods for teaching ethical and legal issues regarding technology.

Using Technology for Productivity (Teacher Education Faculty)
S.3. Students will use a database program for data collection purposes.
S.8. Students will use a world-wide-web browser for data collection purposes.

Using Technology for Teaching (Teacher Education Faculty)
S.4. Students will use presentation software and hardware for information communication purposes.
S.6. Students will use a hypermedia authoring tool to develop an instructional activity.
S.7. Students will use word processing, spreadsheet, and graphics software to design classroom learning activities.
S.8. Students will use world-wide-web resources to design classroom learning activities.
S.9. Students will use off-the-shelf instructional software to design classroom learning activities.
S.10. Students will use video-based information to design a classroom learning activity.
K.2. Students will demonstrate knowledge of software evaluation methods and techniques.

Using Technology for Organization/Administration (Teacher Education Faculty)
S.11. Students will use test generation software to develop a classroom assessment device.
S.12. Students will use the computer to develop either an electronic gradebook or an electronic portfolio assessment device.

The activities for the course were designed to integrate as many of the objectives into each activity, thus allowing students to demonstrate mastery of several objectives through the completion of each activity. Activities were developed in five areas: data collection and analysis, classroom integration of technology, classroom organiza-
tion, multimedia development, and information synthesis. Each of these activities are described below.

Data collection and analysis. This consisted of two electronic database projects. The first project required students to read, summarize, and critique nine journal articles dealing with current issues in instructional technology (course objectives S.1 and S.3). Each article was selected by the instructor and disseminated to the students at the beginning of each week. Students would read the articles and enter their critiques into a class-developed database. The second database project required students to select and evaluate five pieces of instructional software using evaluation criteria discussed in class (course objectives K.2 and S.3). An evaluation template was constructed by each student using database software, and the evaluations were entered into their databases.

Classroom integration of technology. This involved the development of four instructional lessons. Each lesson was required to utilize a specific technology tool or product (course objectives S.1, S.5, S.7, S.8, S.9, and S.10). These included a spreadsheet application, an instructional video program, videotape, or videodisc, a piece of instructional software, and an internet source. Students were required to develop a lesson plan (including target subject/grade level, objectives, materials, lesson description, and evaluation methodology) using each technology tool/resource. In this way, students were integrating a variety of instructional technology tools and information sources into classroom instructional activities.

Classroom organization. These projects were designed to introduce students to software which could assist them with tasks dealing with classroom management and assessment. Students were required to use computer software to develop a classroom assessment device and develop a strategy for recording assessment information (course objectives S.11 and S.12). Teacher productivity tools such as test generators, electronic gradebooks, and electronic portfolio development packages were demonstrated in class and provided to the students in order to complete these projects.

Multimedia development. This involved requiring student groups to design, develop, and demonstrate a multimedia project dealing with their instructional content area. Using Hyperstudio, a simple multimedia authoring tool, student groups designed and created projects dealing with a topic relevant to their content area. Students were required to incorporate sound and graphics into their projects. Once the projects were completed, each student group demonstrated their projects to other class members using electronic presentation hardware and software (course objectives S.2, S.4, and S.6).

Information synthesis. These activities were designed to assess student knowledge and understanding of important instructional technology issues in education (course objectives K.3, K.4, K.5, K.6, and K.7). Issues dealing with computer ethics, adapting the classroom environment based on student needs, internet access in schools, and future trends in instructional technology were discussed in class using a variety of techniques. These discussions were used as a basis for two take-home assignments. Each assignment required students to use the information discussed in class to develop a solution to a problem they may encounter in the classroom. Examples of the "problems" students were asked to solve included: "Develop a plan to teach your students about the benefits and problems with information available on the internet.", "Design a class activity to inform students of the ethical and legal issues involved in accessing inappropriate information via a computer.", "What are some steps you would take to help your school plan for future uses of technology?" and "What are some actions you should consider if you are going to have a student with special needs placed in your classroom?"

Through these scenarios, students were able to demonstrate their understanding of important instructional technology concepts discussed in class.

Material Development and Dissemination

In order to assist students with the completion of the activities required for the course, numerous materials were developed. In addition, information resources (both electronic and other) were identified and needed to be disseminated to students in an organized and timely fashion. Thus, an electronic database of course materials and information resources was developed for the class and posted on the world-wide-web (the location is www.auburn.edu/~brushtalem370.html).

The course database is divided into five areas. The Instructor and Course Information section includes information regarding instructor contact information, office hours, the course syllabus, meeting times and dates, and student information (only if students allow this information to be posted). The Course Topics section includes a list of weekly topics covered in the course, along with objectives and class activities associated with each topic. This area is also linked to information and www sites which can assist students with preparing for class discussions. The Course Materials section includes lesson plan and database templates, an overview of the required text, a list of required and supplemental readings, and a list of administrative, instructional, and productivity software available to the students. This software list is linked to descriptions of the software and the publishers' internet sites, if available. The Supporting Links and Information section includes a list of links to internet sites related to topics discussed in class. Finally, the EM370 Forum section is an area where students in EM370 can participate in electronic conversations, leave electronic messages for the instructor, and communicate with other members of the class during non-class hours. The structure of this area is similar to other...
electronic forums, where students enter information on the screen and it is posted to a common “text box” that everyone viewing the page at that time can see.

Evaluation of Course Topics and Materials

This is the first quarter we have offered this course in its new format. Thus, continuous formative evaluation is crucial in order to determine areas of the course that need revisions and improvement. We are currently in the data collection phase of the evaluation. We have developed and disseminated course evaluations to all participating students, and are in the process of analyzing the data to determine revisions which need to be addressed prior to the delivery of the course in the winter and spring quarters.

Summary

This paper has provided a rationale and design for a pre-service teacher education course dealing with the integration of technology into classroom activities. While evaluative data is limited, preliminary results show positive student reaction to this course. However, this is only the first step in the development process. Results of formative evaluations will assist with making the course more relevant to the needs of future teachers. Also, with rapid changes in instructional technology, this course will need to be continually revised and updated in order to provide pre-service teachers with the skills and experiences they will need to effectively use technology in their future professional placements.

With continued collaboration between faculty in instructional technology and teacher education faculty, it is hoped that eventually many (if not all) of the topics covered in this course will be introduced in teacher education courses. In this way, instructional technology faculty can work with teacher education faculty to provide technology training to pre-service teachers while they are in the process of learning their craft. Until then, however, instructional technology faculty need to work hand-in-hand with teacher education faculty to continue to provide pre-service teachers with relevant technology skills and experiences in their classes.

PREPARING PRESERVICE ELEMENTARY TEACHERS TO USE TECHNOLOGY

Carolyn C. Ledford  
East Carolina University  

Betty B. Peel  
East Carolina University

North Carolina (1995) has established basic technology competencies that all students must pass by the beginning of the second semester of the senior year. These standards address a broad range of competencies related to computer applications. The competencies are to ensure that all educators can use information technologies to improve student learning, support effective teaching, and enhance overall teacher productivity.

Karen Sheingold of Educational Testing Service captured the scope of the problem when she asked:  
How do we help teachers teach in ways they were not taught, to create classrooms unlike the ones they studied in, and to develop confidence that they are doing the right thing for their students? (Sheingold, 1995, p.2).

The challenge for teacher educators is to prepare preservice teachers to use technology as a tool as well as meet the technology competencies. In response to this challenge, an interdisciplinary study team was established to plan a developmental framework for integrating technology into the current elementary education curriculum. Preservice teachers were required to use various computer applications throughout their classes. The framework includes use of technology as well as modeling by teacher educators of computer use integrated into the curriculum. The preservice teachers are tested in Senior II semester to determine their level of proficiency.

While all courses previously required the use of some technology, the model provides a view of the entire elementary program and coordinates computer applications in a sequential manner to develop technology skills and applications. The model includes 1) the development of a framework to ensure competencies are met, 2) modeling of technology use by teacher educators, and 3) experiences to utilize what is presented in theory through practice in field based practicum accompanied by university faculty in public schools.

Faculty in the Elementary and Middle Grades Education Department at East Carolina University were interviewed to determine the level of technology used in course delivery and in student course requirements. The study team developed the matrix of developmental tasks for the students to demonstrate proficiencies by the end of Senior I with course assignments that could be placed in their portfolio.

Technology Uses in the Elementary Curriculum

Sophomore I  
ELEM 2123: Early Experience for the Prospective Teacher  
• Apply for User-ID  
• find and retrieve a lesson plan from the Internet.  
• Evaluate an interactive curriculum software program.  
• Word process student reflections of the standards.

Junior I  
ELEM 3235/3236: Curriculum and Instruction in the Elementary School  
• Select resources from the WWW.  
• Introduce and use adaptive technology laboratory for use with unit.  
• Evaluate educational software.  
• Download public domain software off the Internet to use in the practicum.  
• Create and word process a letter to parents about the unit.

ELEM 3250: Language Arts in the Early Childhood and Elementary School  
• Word processing/introductory desktop publishing including line spacing, check spelling, grammar, word usage.

Junior II  
ELEM 4525/4526 Classroom Organization and Management in the Early Childhood and Elementary School  
• Use of basic computer operation skills  
• Use of word processing and desktop publishing skills  
• Use of telecommunications to communicate on-line between students and faculty.
teachers. Our survey indicated that like the K-12 population, computer use is not achieved fully by the plurality of students. Investigations into computer use for K-12 schools and classrooms have discovered that not all technology is being used to its greatest potential. Obstacles for this included lack of knowledge of applications.

For preservice teachers to have appropriate modeling of technology use in the university classroom, faculty must have adequate skills. Faculty in the Department of Elementary and Middle Grades Education were surveyed using the Technology Awareness and Use Survey developed by the Educator Technology Group of North Carolina. Since the survey was developed specifically for the North Carolina Competencies, it addressed the level of proficiency for each competence area we are currently addressing with our preservice teachers. The survey addressed five areas: personal use of a computer, instructional technology, the ubiquitous computer, access to computers, and access to telecommunication resources. As would be expected, the area of use with greatest frequency was personal use of a computer. However, the majority of the faculty used the word processing software primarily for typing for personal and professional use. The areas of greatest weakness were use of telecommunications, spreadsheets, multimedia, and databases.

As a result of the surveys several departmental professional development opportunities were provided with the use of telecommunications. In addition professional development workshops were offered by the Education Technology Specialist for the School of Education to provide the skills needed for faculty. These workshops addressed specific topics needed by the faculty but were not mandatory. Additional workshops were available for faculty in the summer and fall. In the most recent workshops, only one faculty member registered to participate.

A more comprehensive survey was administered in the fall. The Basic Technology Competencies for Educators Survey is a self-assessment tool developed by the Educator Technology Group of North Carolina. Findings again indicated faculty knowledge and skills of multimedia, telecommunications, spreadsheets, and databases were not sufficient to model for their classes. The subsets addressed each area of technology from the previous survey. In addition each skill and subskill had four levels of response: do not know, know, but need additional help, know and use, and able to teach. The most glaring finding was that although many faculty felt comfortable using their knowledge and skills, they did not feel comfortable in teaching the skill.

For our preservice teachers to have the level of proficiency needed, university faculty also were not using technology to its greatest potential. Obstacles for this included lack of knowledge of applications.

The Office of Technology Assessment (1995) estimated that the number of computers in K-12 schools would reach 5.8 million during 1995, one for every nine students. Notwithstanding this growth, investigations into computer use for K-12 schools and classrooms have discovered that computer use is not achieved fully by the plurality of teachers. Our survey indicated that like the K-12 population, our university faculty also were not using technology to its greatest potential. Obstacles for this included lack of knowledge of applications.
of faculty to develop presentations and assignments incorporating technology should be encouraged. Professors who are supportive of technology use in the classroom will need to participate in the “selling” of technology if changes are to occur.

DEVELOPING AND TEACHING AN INTERMEDIATE-LEVEL APPLIED EDUCATIONAL COMPUTING COURSE

J. D. Thomerson
Valdosta State University

The College of Education at Valdosta State University (VSU), Valdosta, GA, has for over ten years required all education majors to take an entry-level computer course entitled, “Introduction to Educational Computing.” Unlike many institutions, the introductory computer course is taught by the College of Education rather than the College of Business. This allows the focus of the course to be geared towards the type of computer applications most frequently encountered by teachers.

While attempting to address the needs of future teachers, this 50-hour, entry-level course covers word processing, spreadsheet, database, presentation, Internet, electronic mail, and operating system software as well as basic computer concepts. The results of this course have been an overwhelming success. Students consistently rate the course very high on course evaluations and in-service teachers state that entry-level teachers graduating from VSU are very computer literate. The course is so popular that it is required by many non-education degree programs such as nursing, psychology, and sports medicine.

For many years, students who have taken this entry-level educational computing course have often been more computer literate than many of their professors in the College of Education. Thanks to a strong emphasis on faculty development workshops and funding for up-to-date computer lab facilities, this situation is quickly changing. Faculty in the College of Education are now beginning to incorporate computer technology into their courses as well as requiring students to use the computer skills learned in their entry-level educational computing course to complete class projects.

Due to the ever-increasing emphasis placed on educational computing applications by faculty in the College of Education and the popularity of the required entry-level computer course, students have started asking about appropriate follow-up computer application courses in which to enroll. Although this is wonderful news, it has created a problem. Although the College of Education does offer many upper-level computer courses, each upper-level course generally focuses in-depth on one particular piece of software. In addition, these courses are usually designed for business education majors exclusively and are not as well suited for many other education majors. Also, most education majors have very few electives and can take only perhaps one upper-level computer elective. The need arose to offer a follow-up intermediate-level educational computing course that covers a wide range of software and topics that was appropriate for all education majors.

Planning the New Course—Applied Educational Computing

From the initial days of planning this new intermediate-level educational computing course, the desire to make it a project-based course was of top priority. Because such a wide mix of software is taught in such a short period of time in the entry-level course, instructors only have time to teach the basics of each software package. Unfortunately, most of the time is spent learning the software and working practice problems in class—little time is left for putting what has been learned to practice in any type of meaningful way. This is frustrating to students because by the time they begin to understand how to use a particular software package, it is usually time to move on to the next software package about which they know little or nothing. The entry-level course has taught the student the minimum skills needed to use the computer in an educational environment but has not allowed the student to put his or her skills to practice. Too often, the skills learned in the introductory computer course are never put to use in any meaningful way after completion of the course. Even though it appeared that students had learned the skills needed to complete computer application projects assigned to them by College of Education faculty in other courses, the students often seemed at a loss as to how to get started on a project all by themselves. The need for a course that allowed students to be creative and complete practical, instructional-based projects in the students’ own subject areas was of top priority. Based upon this emphasis, the
new course was given the name “Applied Educational Computing.”

What Should be Taught

Since only the basics of each software package (wordprocessing, spreadsheet, database, presentation, Internet, and e-mail) are taught in the 50-hour introductory level course, tremendous amounts of information are left that could be covered in the new follow-up course. However, if attempts were made to try to master all concepts of each package, the end result would be very similar to the problem encountered at the end of the introductory level course. Students would have learned a great many new skills but would not be able to put them into practice.

Before deciding upon which additional topics should be taught in the new course, a study was made to determine what types of computer application projects are most frequently being used by classroom teachers. For example, it was found that teachers, in addition to typing letters and tests, often use word processing software packages to create programs, brochures, newsletters, tables, and signs. Creating mailing labels and form letters by utilizing mail merges with either word processing or database software packages was also found to be very useful. Teachers use spreadsheets to calculate grades, prepare budgets, keep track of fund raisers, and create charts and graphs to be used as overhead transparencies. Database packages were used to keep track of student records and also to display educational content arranged by subject and category. Presentation software packages were used to present class lectures, prepare class handouts, and create self-paced learning modules that students can work through at their own pace. The Internet was used not only to acquire research information needed by the teacher and students but also to create HTML homepages that can be used by students as a base to explore the Internet. These are just a few examples, but it was decided that the skills needed to complete these types of projects were the skills that would be taught in the new “Applied Educational Computing” course.

Additional Topics

It is very probable that the students electing to take this new “Applied Educational Computing” course will be the future leaders in regard to computer technology in their respective schools. With this in mind, the students must be up to date on relevant issues when purchasing and evaluating computer hardware and software to be used in an educational environment. It was also determined that students must be knowledgeable about topics such as adaptive hardware and software devices available to special populations. They must also be able to demonstrate knowledge and skill in detecting, diagnosing, and repairing computer hardware and software malfunctions. Valdosta State University is predominately a Windows-based computer campus. However, many school labs in the South Georgia region are equipped with Macintosh platform computers. It was decided that students should be taken to one of the Macintosh labs on campus to learn basic Macintosh platform operations. These are just a few of the additional topics that were included in the content to be covered in the “Applied Educational Computing” course.

Course Structure

The first Applied Educational Computing course was taught Spring Quarter, 1996. It met twice a week for 2 1/2 hours each day for ten weeks. The first week was mainly spent reviewing old information learned in the introductory course. Handouts and notes were used extensively due to the fact that a textbook was not required or used in the course. In order to learn the new skills, the students and teacher completed example problems together using the aid of a projection device. Students were then required to complete class exercises assigned to them by the instructor in much the same way they did in the entry-level computer course. Next, students had to be creative and create a couple of their own exercises and problems similar to the class exercises that the teacher had assigned. Once the new concepts had been successfully learned, the individual student projects were assigned (see Appendix A and B). These projects required the students to be creative and complete practical, instructional-based materials suitable for use in the students’ own subject area.

Course Evaluation

Two examinations over course content accounted for 30% of the overall course grade. The two exams, one given at midterm and the other on the final exam date, were mainly composed of hands-on computer exercises but also contained objective questions dealt with during the quarter. Classwork/homework assignments assigned by the instructor accounted for 30% of the course grade. The two projects combined to count for 30% of the overall course grade. The remaining 10% of the course grade was accounted for by two oral presentations. One oral presentation was a short mini-lesson which the student was required to complete in his/her future teaching area, using Microsoft PowerPoint. The other oral presentation was required to be on using adaptive hardware and software with special populations.

Results and Conclusions

The results of the first “Applied Educational Computing” course were very encouraging. The students who took the course were highly motivated and did outstanding work. The most encouraging part of the course was the outstanding job the students did on their individual projects. The creativity and professionalism shown on these projects proved that the course was a success. Students
were very positive on the course evaluations and stated that they would recommend the course to their friends.

Appendix A

APPLIED EDUCATIONAL COMPUTING — PROJECT #1

General Guidelines:

Be creative. Pick a topic in your teaching area or major area. Since you will be required to create tables and graphs, make sure the topic area you choose has a certain amount of numeric or statistical content. The topic area might be a unit of study for a particular course you might one day teach. Perhaps you are planning a big event at your school or business and you want to promote and educate the public. These are just a couple of examples—you decide. The more creative you are the better!

Requirements:

Listed below are the minimum requirements that must be included in your project. All of the exercises you create should relate to the same topic area you are presenting or promoting.

PowerPoint: A 12 slide presentation. The presentation must include at least one graph. Use transitions and builds as you see fit. Save your work on your disk and print handouts — 3 slides per page.

Quattro Pro: Create and print on paper three original graphs of any kind that you could use as transparencies to present information on your topic.

Create a spreadsheet that could be used to help keep track of information, budgets, finances, data, related to your selected topic.

WordPerfect: Create at least two tables that could be used as handout information to your targeted audience.

Create a newsletter with columns and graphics—the newsletter must fill up at least two pages. An example might be a monthly or quarterly newsletter updating parents or others about what is going on in your classroom, school, or business. It could be a weekly reader full of information you want your students to read and study.

Create a program like the one you worked in class. Plan a banquet, meeting, or occasion where a program is needed. It could be a PTO meeting or a promotional dinner for something. It could be an outline of events that will take place at your school or business during the day, week, or month you present your topic. It should be printed on front and back of a sheet of paper.

Appendix B

APPLIED EDUCATIONAL COMPUTING — PROJECT #2

1. Create WordPerfect Form Letters for a minimum of six records that illustrate how you might use this word processing feature in your subject area. Also, print mailing envelopes for each of these six letters.

2. Create a Paradox database table that contains educational content that can be browsed and studied by individuals trying to learn about the topic you choose. The table must contain at least ten records and seven fields including one memo field. Create an attractive Form for the information and create and Print a Form Report that displays all records and fields.

3. Create a Paradox database table that contains mailing address information as well as some other meaningful data for at least six records. Create a form letter dealing with a topic in your subject area that utilizes all of the fields in your table. Print a copy of the form letter for each record in your table.

4. Create an original HTML Home Page that contains educational information about a particular topic in your subject area. The page must include at least two links to other related sites. Use the example we created together in class as a guide.

NOTE: Please turn in your diskette containing all project files as well as a sheet of paper listing filenames used for each part of the project.

This paper reports on the use of a multimedia journal to enhance a subject in technology education. The multimedia journal was used to assist in the delivery of the subject and to record the progress made by students. It is argued that multimedia used in this manner complements and extends upon the teaching program and becomes an integral part of the learning process. This study discusses the development and evaluation of a new subject in technology education, and demonstrates how a multimedia journal can be used to assist preservice teachers to further their understanding of the design and make process.

The movement toward national curricula in the United Kingdom and Australia revitalized interest in improving science and technology-related primary school education (D.E.S., 1985; Australian Academy of Science, 1991; Curriculum Corporation, 1994). However, as educational planners produce new primary school science and technology curricula, they are also morally obligated to provide teachers with support documentation and professional development courses (Renner, 1990). Past practices such as providing one-off inservice given to a fraction of teachers have been strongly criticized by Ingvarson (1987) who argues that more consideration needs to be given to other ways of providing inservice and preservice training of teachers. Teachers need relevant preservice experience with technology education and this paper outlines an approach that employed multimedia to complement and extend the technology education of preservice teachers.

Technology Education in Australian Primary (elementary) Schools

A study conducted in New South Wales, Australia (Ferry, 1993) showed that only 50% of primary teachers had taught technology-based units, and 80% needed assistance in planning, implementing and evaluating such units. Interview data from this study showed that teachers were reluctant to teach technology education because they had little or no experience with the processes involved. Yet in 1991 the Australian Academy of Science and the Australian Science Teachers Association recommended that technology become an integral part of primary school experience for all Australian children (Australian Academy of Science, 1991).

Current research associated with technology education suggests that there is a lack of opportunity for primary teachers to train in the processes involved in technology education (Layton, 1993). Therefore technology education is unlikely to receive sufficient attention in many Australian primary schools.

Preservice Teacher Experience in Technology Education

Technology education in primary schools it is expected to developed through integrated, interdisciplinary investigational topic work. It follows that a technology subject that introduces preservice teachers to the strands of technology education should also use an integrated, interdisciplinary investigational approach so that preservice teachers have first-hand experience with the processes that their pupils would experience. The subject also has to empower trainee teachers in the design and make process (Bonollo, 1993) and develop trainee teacher competence, confidence and enthusiasm. A certain amount of judgment is required in order to match the challenge to the persons and this requires a negotiation and mentoring process in which lecturers and preservice teachers are fully aware of the outcomes of the subject (Lewis & Bonollo, 1994; Ramsden, 1990).

Restructuring of the four year Bachelor of Education degree for primary teachers at the University of Wollongong provided an opportunity to offer a fourth year elective subject related to technology education in primary schools. Two lecturers shared the responsibility for this subject. It was also important to us to develop a resource that could be used in the future by preservice and classroom teachers. Two parallel processes were put in place to meet these needs: one concentrated upon the delivery of the subject to the students and the other concentrated upon the task of developing a multimedia “class journal” that would become a resource for preservice and classroom teachers. While both lecturers involved in the subject had expertise...
in multimedia and technology education, it was convenient to divide the responsibilities and to collaborate on a "need to know" basis. Therefore the more experienced lecturer in pedagogy took overall responsibility for the delivery of the subject and the more experienced one in multimedia took overall responsibility for the development of the multimedia "journal".

**Subject Organisation**

The subject was allocated three hours of face to face teaching for one semester. Care was taken to present the technology/design process as recursive and non-linear, and Figure 1 shows the model that was presented in lectures. Lectures and tutorials were scheduled to support the stages in the technology/design processes that the trainee teachers could be expected to experience as they developed their prototypes. They were required to keep a reflective journal that contained their responses to the different stages of the technology/design process. Tuman (1992) claims that reflective journals represent a new form of "engineering literacy" and they have a legitimate place in the design and make process. Journal writing helps the student to construct knowledge and various researchers argue that there is a need for engineers to write their own knowledge (Winsor, 1990; Johnson, Lee & McGregor 1994). The reflective journals provided a mechanism for students to integrate and make use of ideas, and to test them (Boysen, 1994; Lawson, 1980).

When we were planning the subject we were concerned that anxiety associated with assessment and the perception that engineering was a “male” subject could adversely affect the outcomes. Initially most students were very worried about how they would be assessed, and discussion centred around product assessment versus process assessment. It was agreed to give equal weight to both product and process. Other researchers (Boysen, 1994; Boyapati, Inglis & Phillips, 1994) also support this approach.

Another factor reported in the literature was a student perception that subjects associated with processes such as construction, design and engineering were more suited to males (Nandy, 1979; Georg, 1993; Wiley, 1992). As the majority of students were female and were prepared to enrol in what was perceived to be a high risk subject it was important that both lecturers provided support and acted as mentors. In an attempt to address the dual issues of anxiety and perceived gender bias we allowed students to consult with the lecturer of their choice.

**The Electronic Journal**

The electronic journal was in HyperCard form and entries were gathered during the session. Each entry contained a photograph (taken with a Canon ion camera) of the preservice teacher, a title for their prototype (Winsor, 1990; Johnson, Lee & McGregor 1994). The reflective journals provided a mechanism for students to integrate and make use of ideas, and to test them (Boysen, 1994; Lawson, 1980).

When we were planning the subject we were concerned that anxiety associated with assessment and the perception that engineering was a “male” subject could adversely affect the outcomes. Initially most students were very worried about how they would be assessed, and discussion centred around product assessment versus process assessment. It was agreed to give equal weight to both product and process. Other researchers (Boysen, 1994; Boyapati, Inglis & Phillips, 1994) also support this approach.

Another factor reported in the literature was a student perception that subjects associated with processes such as construction, design and engineering were more suited to males (Nandy, 1979; Georg, 1993; Wiley, 1992). As the majority of students were female and were prepared to enrol in what was perceived to be a high risk subject it was important that both lecturers provided support and acted as mentors. In an attempt to address the dual issues of anxiety and perceived gender bias we allowed students to consult with the lecturer of their choice.

**The Electronic Journal**

The electronic journal was in HyperCard form and entries were gathered during the session. Each entry contained a photograph (taken with a Canon ion camera) of the preservice teacher plus a title for their prototype. Buttons allowed the browser access to selected sound files chosen from interview tapes, photographs of various stages in the development of the prototype, and selected entries from the reflective journals. Sketch diagrams of the initial prototypes of the projects completed were scanned and included in the electronic journal.

**Figure 1. A Model of the Processes Involved in Technology as it Responds to a Human Purpose (from Fensham, 1990, p. 17)**

---
Results and Discussion

The subject was evaluated by the university centre for staff development. The instrument uses a five point Likert scale to rate the various questionnaire items. The highest score is five and the lowest one, and a mean of 3.4 (S.D. 0.5) is regarded as standard for most subjects. The mean for this subject was 4.75 (S.D. 0.4), higher than most subjects. Therefore the subject appears to have been well regarded by the students Table 1 summarise the student responses to relevant question from the survey.

Table 1.
Preservice Teacher Responses to Survey Questions, n=68

</tbody>
</table>

It can be seen that the outcomes of enthusiasm for the subject and confidence in teaching designing and making appear to have been realised. The other sources used for this study were the reflective journal entries and the transcripts from the interviews. Whilst both sources of data support the view that the outcomes of competence, confidence and enthusiasm were achieved, it needs to be acknowledged that the factors that led to the success of this subject may not transfer to a different context.

The following quote selected from the reflective journals represents some reactions of participants. Fiona, a female trainee teacher aged in her mid twenties. Her chosen task was to design a removable parcel shelf for hatchback cars. "It is important to make use of other people to listen to your ideas and discover whether or not what you want to do and what you say you will do are the same thing...the experience has been extremely rewarding, especially in the sense that I have solved my own problem."

Two important themes emerged from the interviews transcripts and from the journals. One theme was the importance of collaboration with a wide range of people; many of whom were not “experts” but sympathetic listeners (mentioned by 74% of subjects). These people acted as a non-threatening audience with whom the learner could "sound out" ideas. A study by Tibbitts, Collits and Lucas (1994) supports these findings. They report that it is important for students to share and discuss projects in a non-threatening situation.

The other theme was the satisfaction gained from solving a problem that was different to anything attempted.
teachers had developed their competence and confidence in the journal as the sample is small and no control group was better projects. It cannot be claimed this effect was due to preservice teachers were: delivered. Features of the journal that appealed to the completed during the first session that the subject was process and such research will involve tracking learners as they use the electronic journal.

As the first version of the electronic journal was completed during the first session that the subject was delivered. Features of the journal that appealed to the preservice teachers were:

- access to the pictures, printed text and sound. They could browse and select the features that were relevant to their interests. For example some were contented to browse at the pictures of projects, while others wanted to read the related text or listen to relevant interviews.
- access to the ideas of others. They often used the pictures of students in the previous cohort to find students with whom they could discuss their ideas.

Those that chose to use the journal tended to produce better projects. It cannot be claimed this effect was due to the journal as the sample is small and no control group was organised. It may just be that the more conscientious students used the journal.

Conclusion

The data supports the interpretation that the preservice teachers had developed their competence and confidence in designing and making skills. Triangulation from multiple data sources suggests that the findings are reliable for this group of preservice teachers, but no claim is made about transferring the findings to a different context.

The way in which the subject was delivered challenged preservice teachers to become independent learners and to develop their technological literacy, technological awareness, technological capability and to use information technology. It also allowed them to be actively involved in the process of design and make rather than just focusing upon the final product. We felt that the multimedia journal added another dimension to the learning process and presented students with a holistic view of their participation in the design and make process. In particular, the use of excerpts from recorded interviews from students, the inclusion of text from journals and photographs of projects focused student attention and encouraged them to reflect on their role at critical stages in the process. We also feel that the multi-media journal was a popular and effective innovation, but it was not a panacea and should not replace "real life" experience with the design and make process.

Nevertheless some important principles have emerged:

1. when equal emphasis is placed upon the process and the product preservice teachers tend to respond positively to an approach to designing and making that emphasises integrated, interdisciplinary and investigational work.
2. the product-focused assessment procedures often "imposed" by university administrators can have an adverse effect upon learners enrolled in a subject that challenges them to develop a whole range of new skills which cannot always be identified in advance.
3. the benefits of "learning by doing" cannot be underestimated. The majority of trainee teachers enrolled in this subject now appreciate the processes that their students will experience as they undertake a design and make project.
4. it also important that preservice teachers reflect upon what they are doing and we feel that the multimedia journal can be an effective tool for reflection.
5. the traditional lecture/tutorial means of subject delivery was not always appropriate in the context of this study.
6. a subject that is perceived to favour one gender group over another can generate anxiety in enrolled students. Lecturers need to be aware of this situation and to develop strategies that help to dispel such perceptions.
7. "show and tell" sessions provide a good forum for swapping ideas and also help to boost the confidence of the more anxious members of the class.

In future years we intend to create web pages as a means of conveying this information to a wider audience.

The development of portfolios by preservice teachers can provide a wonderful opportunity for students to reflect upon their strengths and weaknesses prior to entering the profession. Now, with the advent of new technologies that have become common place in our schools, the opportunity for preservice teachers to develop their own computer portfolios provides them with many significant benefits including a greater understanding of technology.

At St. Mary’s University of Minnesota, preservice teachers upon leaving the teacher education program are developing their own menu driven computer portfolios. Included in these computer portfolios are such items as text casts of philosophical beliefs, voice casts of effective teaching strategies, and digitized videos of actual teaching performance. This capstone project allowed preservice teachers an opportunity to both self reflect and assess their recent student teaching experiences. This project was not without some challenges. Some of the most problematic technical issues that students had to overcomes were; dealing with limited disk storage capacity, finding a balance between quality of video output and file size constraints, producing a usable end product for a job search, and creating CD-ROM versions of portfolios.

The process of preservice teachers developing their own computer portfolio however had many positive outcomes. First, these preservice teachers benefited by reflecting upon their student teaching experience as they compiled their own effective teaching characteristics. Second, the end product became a very valuable instrument in the student’s job search. Third, the opportunity to author their own computer portfolio provided students with an increase capacity to infuse technology later in their classrooms.

The development of a computer portfolios through the use of Macromedia Director was an extremely valuable learning opportunity for our preservice teachers. Many of the preservice teachers spoke of their intent to take their new found knowledge of technology and apply it directly to their classrooms. In the end, both future teachers and their students will benefit directly from this process.

**Value of Portfolios**

My observations of students striving to put in place their most exemplar pieces of work along with writing and rewriting their most current philosophical foundations revealed a sense of value portfolios have upon my student teachers as they prepare to enter the profession. Their portfolio in the end represented, in essence, a capstone to their preservice teacher education. The pride of their accomplishments are now exhibited through their portfolio.

Furthermore, the reflection needed to successfully complete their portfolios provides a springboard to future development. They came away from this experience knowing that while they have made great strides in becoming solid young teachers, they still have much to experience and work towards in becoming outstanding teachers.

The value of creating a portfolio that will be shared with others makes the nature of this portfolio not only an individual possession but also a public document. This development of a publicly shared portfolio requires people to be active, socially responsive, and willing to transform his or her teaching from a private to a public experience (Schram, Mills, and Leach, 1995, p.71). By having students preparing a portfolio with one of the intended outcomes being its use in their job search, the portfolio becomes extremely public with regards to the quality of their personal teaching experiences.

The value of having students develop a portfolio for use in a job search makes this experience not only a exercise in reflective teaching, but also a very meaningful exercise tied to improving their opportunities for a job. This added component of producing a portfolio not only for their and our programs sake, but for others, resulted in preservice students placing even more emphasis upon the quality of their portfolios.

**Determining the Portfolio’s Content**

There are undoubtedly a multitude of items that could be included in a preservice teacher’s portfolio. Thomasena Adams (1995, p. 569) referred to the items that were to be collected to rest solely on the assessment information that is needed to respond to specific and general questions about preservice teachers. In a somewhat similar way, I approached this question of what students needed to include in their portfolios by setting...
forth a set of standards that students should be able to
demonstrate through evidence collected in their electronic
portfolios. The major emphasis of our students' portfolios
were to but forth their highest quality work which demon-
strated the standards of knowledge, organization, and
teacher effectiveness.

Because of constraints in data storage, students were
restricted to selecting only the best pieces of evidence to be
included in their electronic portfolios. They also were
expected to maintain a more traditional portfolio which
would contain additional evidence of meeting these
standards of teacher effectiveness. Perhaps one of the most
important factors I discovered in having students complete
a computer generated portfolio was to allow them to
determine how they were going to demonstrate their
mastery of effective teaching. When preservice teachers
are given the responsibility to demonstrate the standards
based upon their analysis, synthesis, and evaluation of their
evidence, it forces them to reflect upon the quality of
teaching and learning taking place in their classroom.

**Developing the Portfolios with Multimedia Director**

The utilization of Multimedia Director as the software
foundation for our students’ portfolios was based upon the
belief that it will better prepare our students to be more
effective in infusing technology into their own classrooms.
Perhaps one of the most beneficial uses of Multimedia
Director is its value in producing a diverse set of multime-
dia applications for use in the classroom. Teachers who
are well versed in Director can take advantage of this
software with their students to teach them how to produce
their own multimedia presentations.

The interactive capabilities of Multimedia Director
script language allows for students to develop menu driven
programs that are very user friendly. While this does
require time for teaching students how to effective utilize
the powerful tools Director has to offer, the benefits of this
knowledge far exceeds the time requirement. With this
project however, I choose to assist the students by providing
them with a template which included the scripting
needed to complete their portfolio projects. This was done
to meet a time requirement that didn’t allow for the
necessary teaching of scripting versus time needed to
develop their portfolios.

Students had access to a PowerMac lab (Mac 7500/100
with video input capabilities). To digitize their teaching
videos, they utilized Apple Media Conferencing by
recording into the self view window video clips from their
teaching experiences. Since digitized video clips require
large amounts of data storage, students who were planning
on sending their electronic portfolios on 1.3MB disks with
their resumes, choose to record their videos at one frame
per second and set their sound preferences at a six to one
compression. Videos were saved as quick time video files
which were easily imported into a Director cast member for
later use.

Students also scanned in images with the use of
Photoshop. They then added any enhancements to those
images and saved them as PICT files which Director
utilizes. Students with images saved in a variety of other
formats, utilized a graphics conversion program to place all
images into PICT files before loading them into Director
cast members.

Text cast members were either copied over to Director
or composed right in the text cast page. Students were
encouraged to compose utilizing a word processor before
copying them over to Director because of the access to spell
checkers in most word processing programs.

**Positive Outcomes of the Project**

I found three very distinct benefits from having students
complete their own computer generated portfolios. First,
these preservice teachers benefited by reflecting upon their
student teaching experience as they compiled their own
effective teaching characteristics. Second, the end product
became a very valuable instrument in the student’s job
search. Third, the opportunity to author their own com-
puter portfolio provide students with an increased capacity
to infuse technology later into their classrooms.

By engaging the students in developing their own
portfolios, it required them to analyze what they had
accomplished during their student teaching experience.
They came away from this process with a clear understand-
ing of how they were effective in the classroom and
teaching areas they needed to refine in the years ahead.
The work they did in developing their philosophy state-
ments/beliefs further defined their understanding of what
makes them effective in the classroom. Without spending
considerable time reflecting upon these areas, the portfolio
would have simply become a series of video clips and
meaningless documents for others to view. The importance
of communicating clear philosophical beliefs and following
those beliefs up with documented evidence makes a truly
significant difference in the quality of the portfolio.

I have little doubt that the technological expertise the
students demonstrated with their computer generated
portfolios had a very positive impact upon their securing
job offers. While I did not conduct follow up interviews
with school administrators who hired these students,
several students returned from interviews with comments
directly related to how impressed the interviewers were
with their computer generated portfolios. In many ways,
the use of computer generated portfolios sends a subtle, but
powerful message that the educator who is applying for this
job is computer literate. A knowledge base that many
districts are seeking candidates with.

Included in this exercise were two teachers who had
returned from their first year of teaching to complete the
masters degree program. On several occasions, they made
repeated comments about how they intended to incorporate Multimedia Director into their curriculum when they return to school. They were coming up with specific examples of how they could involve their students in a multimedia project and their beliefs that multimedia presentations are an important skill for students to master.

**Traditional versus. Computer Generated Portfolios**

Both types of portfolios have benefits and drawbacks. The strength of the traditional portfolio is that one is often looking at original documentation with an unlimited supply of materials. While the materials may be cumbersome to page through, and at times locate, access is generally available.

With a computer generated portfolio, the ease at accessing video clips with a click of the button is truly user friendly. Making duplicates of the portfolio is very easy and can be done at a minimal cost. However, it does require that the user has access to compatible equipment. The other drawback is the data storage limitation that a computer generated portfolio presents. Students wishing to utilize a 1.3 MB disk will only be able to record approximately one minute of video at one frame per minute to be include in their portfolio, those utilizing a CD-ROM disk will be able to record over 600 MB onto their disk. While the CD appears to be the answer to the storage demands of digitized videos and images, producing one for every application is both expense and time consuming.

One case study dealing with evaluating electronic portfolios found it to be clearly superior to paper portfolios because the ease of accessing the information (Bushweller, 1995, p. 19). The majority of computer generated portfolios developed by our students took between five and ten minutes to review. A time frame that should work well for school administrators reviewing teacher applications. These computer generated portfolios were produced for either Apple or PC's and required no special software for most computers before running.

**Summary**

Our students experience with building computer generated portfolios resulted in a very meaningful end product which allowed self reflection, a very user friendly product, and improved knowledge base in technology. As technology becomes more prevalent in our classrooms, the need to take advantage of utilizing computers for portfolio development is even more valuable. The limitations of data storage capacities faced by students today is quickly diminishing as access to larger storage devices become more available. In the future, the questions educators will be asking themselves isn't if they should utilize electronic portfolios, but how they should utilize them.

An Analysis of the Evolution of Computer Education in Shanghai Secondary Schools: Relevant to American Schools?

Jiang (JoAnn) Lan
University of Alabama at Birmingham

In America and throughout much of the world, hi-tech industry has become the locomotive of economic growth and development. Viewed globally, growth resulting from technological applications is driving both old and new economies. New enterprises in cellular and digital personal communications will create in the United States more than a million new jobs by soon after the turn of the century (Mike Mills column for the Washington Post). Computer systems for the control of manufacturing processes are being installed not only at GM and most other North American corporations, but also in China and central and south America. China’s next great leap forward will be computer-assisted manufacturing. Japan is already state-of-the-art in manufacturing, and South Korea, Taiwan, and Singapore are not far behind.

Asia is the world’s fastest growing technology market. Latin America is second, first in the rate of growth of PC acquisitions. The good news for North America is that, most this technology must be imported into these developing counties. As hardware sales increase, so must software sales as well as sophisticated support systems — instruction, consulting, installation, and maintenance. South Florida has become a kind of a HMO for Latin America’s technology health (David Poppe, Miami Herald, 12/3/96).

Reform and more open-policies have brought thriving hopes to China. As the largest city in China and an international metropolis, Shanghai has been the spearhead in setting up and running a system for the projected market economy. The rapid economic development has created urgent needs to train a workforce who can function well in hi-tech environment.

In Shanghai, education has been quick to respond to this need. Computer education in Shanghai secondary schools (grade 7-12) started in 1978. Today, Shanghai has built a group of trained computer teachers and educators who are actively exploring innovative teaching methods, publishing teaching materials, and establishing exam systems for computer education. This paper presents an analysis of the evolution of computer education in Shanghai secondary schools and the relevance of that experience to the schools of America.

Curriculum
The Shanghai schools make computer education a part of the core curriculum at eighth and tenth grades. The stated purpose of computer education is to prepare students for the “future of modernization.” Students learn to understand the concept of the computer, improve their overall knowledge of science and technology, and become computer literate. The curriculum of computer education includes five basic categories:
1. Computer basics,
2. Computer operation and application,
3. Introduction to commonly used software,
4. Programming, and

In the eighth grade, the focus of computer education is on operational skills. For example, keyboarding, Chinese language processing, and disk operation. Very little time is spent on operational principles of the computer or on programming languages. In the tenth grade, computer education aims at introducing students to basic computer knowledge, disk operating systems such as DOS, WIN-DOWS, as well as databases, programing languages, application programs, and computer impact on modern society. Students are taught to see their futures in terms of technologies’ impact on China’s future.

After school programs are available in many secondary schools and at the Youth Science Activity Center in each city district. According to the interest of the individual, a student can choose to study Pascal, C, BASIC, program design, and software/hardware concepts. Some offer more specialized programs such as multimedia and computer-assisted instructional software development.
Equipment

Hardware upgrades have been continuous and costly. Starting with Apple and 286 platforms, upgrades were soon made to 386, and today, most computers are above 386 level. All schools with grade level 7 through 12 have more than 25 workstations, some have more than 50. Some schools have their own local area network (LAN); some LANs are connected to Shanghai Institute of Education's central information system, making possible "the dream of resource sharing." Some schools have established multimedia PC networks through the sponsorship and collaboration of Shanghai businesses. Multimedia will soon be introduced into the classrooms in a number of Shanghai secondary schools in the near future.

Computer-Assisted Instruction (CAI)

CAI is an important part of computer education. Some schools started to develop CAI software soon after Apple computers were available in schools. Some examples of instructional software include: The Structure of the Heart, Cell Split, The Formation of Mountains, Mineral Distribution, The Second World War, etc. Software development on old Apple computers were very much confined by the limited storage space, low speed and display resolution. More recent instructional software were developed on 386, 486, and Pentium machines by most schools. Some examples include: Typing (Chinese) Practice, Little Musician, Test Your Intelligence, Miao Miao Can Draw, etc. Test bank software for secondary school computer education, computer operating systems, and secondary school entrance examinations are also available to students.

Today, some software companies are working with experienced teachers in the field to develop multimedia instructional software that will operate in WINDOWS environment. These software cover the topics of foreign language, mathematics, physics, biology, etc. Educators in Shanghai recognize that good software development must be a joint effort with specialists in psychology, education, computer-assisted instructional design, and computer programing.

Teacher Training

In 1984, when computers first appeared in Shanghai schools in large numbers, schools were facing a severe shortage of computer teachers. At that time, most secondary schools in Shanghai had only one or two computer education teachers; more than 90% of them were trained in math or physics; their rank and promotion were decided in the discipline where they had received training and so was their teaching evaluation. Some teachers, mostly those who were trained in physics or mathematics, taught themselves how to operate the computer. These teachers became the first computer educators in Shanghai secondary schools. It was a small pool of excellent teachers, but not adequate for student classroom demands.

It quickly became imperative to train other teachers to teach computers. In order to enhance the knowledge-base in computer education and improve the stability and reward system for this group, Shanghai Institute of Education as well as some district institutes of education, the former Office of Computer Education Research of Shanghai Education Bureau, and the China Center for Computer Education in Primary and Secondary Schools jointly launched a series of training programs to prepare teachers for the field and to provide in-service training.

Prior to assignment in the field, perspective computer teachers were required to go through an education program which focused on:

- The purpose of computer education,
- Instructional objectives and requirements,
- Teaching contents,
- Basic knowledge and operational skills of the computer,
- Curriculum development
- Computer text analysis, and
- Teaching method study.

For those teachers who had already started teaching computer subjects, training was provided at an advanced level. Examples include:

- Hardware/software knowledge,
- Discipline-specific knowledge,
- Latest development in computational statistics and measurement,
- PASCAL and C languages,
- CAI software development and software engineering,
- PC maintenance and repair,
- Computer education research in primary and secondary education,
- Computer graphics,
- Network and multimedia technology,
- Operating systems such as WINDOWS and UNIX, and
- Computer English.

Today, the number of trained computer education teachers in Shanghai secondary schools has greatly increased. According to the statistics provided by Shanghai Institute of Education, by fall 1996, there are about 358 trained computer teachers, whereas before 1991, all computer teachers were trained in another field. Since 1991, 95 graduates from four-year computer sciences programs and 148 from two-year computer science programs have been assigned to secondary schools in the city. This greatly strengthened the computer education program in Shanghai secondary schools. The table below summarizes this change.
when teacher technology training needs are addressed, it is 

use, "teachersperhaps the most critical part of the 

hardware and software for the students in the schools to 

Technology Assessment, in the process of acquiring 

According to a report by the Congressional Office of 

The first is computer training for teacher in the America. 

experience which have relevance to the practice in the U.S. 

bring technology into the curriculum. 

Willingness of teachers to learn enough computer technol-

able to mobilize from limited resources to train teachers to 

how rapidly Chinese education administrators have been 

teach new technologies, there remains a large percentage of 

educational to American teachers and teacher educators. 

The training focuses on the utilization of the most recent 

texts and software in computer education, and on the 

hands-on practice. By providing secondary schools with 

competent computer education teachers, a ripple effect will 

reach students as well as impact other teachers. 

The Relevance of the Shanghai Experience to 

Schools in the U.S. 

In the U.S., while leading edge users of cyberspace are 

adjusting from a PC-centric environment to a network-

centric and digital environment, at the school level, many 

are still introducing word processing or sometimes nothing 

at all. Despite the recognized need for teachers to use and 

Teach new technologies, there remains a large percentage of 

teachers unprepared to cope with technology in classrooms. 

While China started and remains somewhat behind most 

American schools in access to technology, it is impressive 

how rapidly Chinese education administrators have been 

able to mobilize from limited resources to train teachers to 

bring technology into the curriculum. Similarly, the 

willingness of teachers to learn enough computer technol-

gy to make effective use of it in the classroom may be 

instructional to American teachers and teacher educators. 

Several observations can be made from the Shanghai 

experience which have relevance to the practice in the U.S. 

The first is computer training for teacher in the America. 

According to a report by the Congressional Office of 

Technology Assessment, in the process of acquiring 

hardware and software for the students in the schools to 

use, "teachers—perhaps the most critical part of the 

educational equation—often have been overlooked. Even 

when teacher technology training needs are addressed, it is 

often in the form of short-term, one-shot arrangements." 

Although the intention of such training is to familiarize 
teachers with a specific application or provide general 

computer literacy, in reality, it is difficult for most com-

puter-illiterate teachers to learn enough to be able to apply 

what they have learned in short-term courses. The skills 

are then forgotten or become obsolete, or even worse, 
teachers become more frustrated because the lack of 

proficiency and support. In short-term training, teachers 

often learn isolated computer knowledge and skills and 
don't relate applications to curriculum integration, which is 

essential if technology is to become a truly effective 

instructional resource. A more comprehensive teacher 

training curriculum, such as the one introduced the 

Shanghai approach, may provide an alternative to get 
teachers comfortable with technology, or at least over the 

feelings of "inadequately trained to use technology sources, 
especially computer-based technologies." (OTA Report 

Summary, p3) 

Second, the Shanghai experience features centralized 
in-service teacher training at both city and district levels. 
The institutes of education system provides a natural 

network for this task. Since the system is already in place, 

computer education training just adds another piece of 
curriculum. In the U.S., the federal government and 

private sectors have tended to focus more on technology 

assistance and funding to K-12 schools than to colleges of 

education. While this approach may address the current 

needs, it does not greatly influence the improvement of in-

servce teachers’ technology skills, nor teacher preparation or 

quality control of teacher education over the long term. 

Finally, the top-down planning system and the pressing 

need to share relatively scarce resources at the government 

levels, and the sense of urgency to be able to function in a 

hi-tech society at the individual level, have created the best 

extrinsic and intrinsic motivations for teachers to partici-
pate in computer training. But in order for teachers in the 

U.S. to reach that level of enthusiasm, instead of merely 

staying in the constant loop of "good intentions, moderate 

action, and lack of impact", accessibility of hardware/

software and availability of occasional and uneven training 

and support are not enough. Educational policy must be 

designed to move teachers through the stages of intention 

and action, and to the confidence and ability levels 
necessary to make an impact on student learning through 

the use of technology. 

Reengineering pedagogy represents a profound 

paradigm shift which is well underway in the U.S. 

economy and culture. But too many school teachers and 

not a few teacher educators remain well behind the power 

curve. To avoid crashing the system, we must apply the 
increased energy and forward motion to accelerate 

progress. That means that teachers must learn enough 

about the relevant technologies to apply them in their

professional lives, and to translate them to their students as part of the integrated learning of the subject matter.

Instructional technologies are an issue that continue to haunt teacher education programs. The issue of how to introduce pre-service teachers to technologies and encourage their use in the classroom setting has yet to be resolved one way or the other. A recent survey of Indiana teacher education programs conducted for the North Central Regional Educational Laboratory (Powers, 1996) found that of the schools responding to the survey, the majority required their students to take a stand-alone technology course. Furthermore, technology did not appear again in other teacher education courses. When the technology was integrated into existing courses, it was done only on a course-by-course basis and not curriculum-wide. One teacher education program reported that it had no technology component in its program.

Technology in teacher education is only one movement which has been affecting education. Simultaneously, many states are moving towards standards-based education, not only in the K-12 schools, but also for the accreditation and licensure of teachers. One such set of standards was developed by the Interstate New Teacher Assessment and Support Consortium (INTASC) and released in 1992. This consortium is composed of state education agencies, higher education institutions, and national educational organizations. These standards are built upon and compatible with those developed by the National Board for Professional Teaching Standards and represent those principles which should be present in all teaching regardless of subject matter or grade (CCSSO, 1996a). The ten principles/standards (see Table 1) incorporate knowledge, dispositions, and performance (CCSSO, 1996b). At present, sixteen states have adopted the INTASC principles for use or for adaptation in the development of their own standards.

Integrating Technology Through INTASC

To truly integrate instructional technologies into the teacher education curriculum, there are two levels in which technology could be found: Instruction and Assessment. The following section will examine both of these levels and provide a handful of suggestions and recommendations for how technologies can be integrated and employed. The suggestions offered here are by no means all-inclusive. Individual programs might present opportunities not considered in this paper.

Instruction

In order to address all of the INTASC principles and the accompanying knowledge, dispositions and performances within a teacher education curriculum, instruction can not occur as per usual. An analysis of the principles reveals that there are no subject matters that stand alone. For example, subject matter cannot be addressed without regard to instructional strategies or knowledge about the general community. In other words, teacher education faculty will need to adopt new paradigms and new instructional strategies to adequately address and model the principles.

Stand-Alone Technology Courses. The model of the stand-alone technology course is one facet which would need to change. In order for students to be able to fully understand how technology relates within all ten principles, instructional technology needs to be used in courses that ultimately expound upon all ten principles. Although this may mean that some of the control that can be exercised by technology faculty may be lost, the power of the number of additional faculty which will needed to teach
and use these technologies and therefore be exposed and cognizant of instructional technologies is overwhelming.

Table 1.
Ten INTASC Principles

Principle 1: The teacher understands the central concepts, tools of inquiry, and the structure of the discipline(s) he or she teaches and can create learning experiences that make these aspects of subject matter meaningful for students.

Principle 2: The teacher understands how children learn and develop, and can provide learning opportunities that support their intellectual, social and personal development.

Principle 3: The teacher understands how students differ in their approaches to learning and creates instructional opportunities that are adapted to diverse learners.

Principle 4: The teacher understands and uses a variety of instructional strategies to encourage students’ development of critical thinking, problem solving, and performance skills.

Principle 5: The teacher uses an understanding of individual and group motivation and behavior to create a learning environment that encourages positive social interaction, active engagement in learning and self-motivation.

Principle 6: The teacher uses knowledge of effective verbal, nonverbal, and media communication techniques to foster active inquiry, collaboration, and supportive interaction in the classroom.

Principle 7: The teacher plans instruction based upon knowledge of subject matter, the community, and the curriculum goals.

Principle 8: The teacher understands and uses formal and informal assessment strategies to evaluate and ensure the continuous intellectual, social and physical development of the learner.

Principle 9: The teacher is a reflective practitioner who continually evaluates the effects of his/her choices and actions on others (students, parents, and other professionals in the learning community) and who actively seeks out opportunities to grow professionally.

Principle 10: The teacher fosters relationships with school colleagues, parents, and agencies in the larger community to support students’ learning and well being.

This model does not imply that traditional technology faculty have given up the opportunity to work with teacher education students in favor of integrating technology into methods or instruction courses. Rather, technology faculty can collaborate and team-teach with other teacher educators, thereby also modeling Principle 10, to ensure that certain skills are learned and then integrated into an ultimate student performance.

Field Work. Due to the emphasis on performance, there is an apparent need to have pre-service teachers out in the field with K-12 students to a greater degree than ever before. The possibility of conducting entire university/college courses in the field is not outside the realm of possibility. The field work provides two distinct advantages to the inclusion of instructional technology.

First, when confronted with technology requirements in the teacher education program, students are often not able to make the connection between what they do in class, and what they ultimately might be able to do in their own future classroom. By offering the teacher education class, with inclusive technology, in the field setting, students not only integrate technology into their teaching and assessing performances, but are doing so on equipment that is hopefully representative of what K-12 schools offer (the disadvantage could be working with a field school that does not have adequate equipment). At the same time, given careful field placements, students can also observe their field teachers using technologies for personal productivity, teaching, and assessment.

Second, teacher education faculty, and technology faculty in particular, may not spend a great deal of time out in the field. They may not have an accurate assessment of what equipment is available in the local school systems. Some colleges/universities may have a plethora of equipment that far exceeds the capabilities and cost constraints of local schools. Conversely, many K-12 schools may be better equipped, or at least have a different variety of equipment, than can be found in the teacher education institution. By conducting classes in the field, technology faculty can better communicate with students as far as what is practical and possible in the teaching situation. Faculty can also point out real-life examples of teachers who are effectively using technology in their classrooms. None of the above is to the exclusion of courses taught on-campus, but are a viable alternative and possibility for meeting the INTASC principles.

Assessment

Very few components of the INTASC standards can be assessed through traditional assessment. The emphasis with these standards is on performance. In order for a pre-service teacher’s final performance to be judged as adequate, there must likewise be developmental performance assessment, both in the university classroom and in the field, throughout the teacher education program. All of this assessment points to a definite need and opportunity for the inclusion of instructional technologies. Some of these technologies include videography, telecommunications, electronic portfolios, and distance learning.

Videography. When discussing the assessment of performance, the need for video-taped evidence is never far from consideration. In a perfect world, small teams of teacher educators would be able to observe every teacher education student at multiple times in order to arrive at defensible evaluations of performance. However, given the more realistic constraints of time, faculty load, and limited...
faculty resources, other methods must be employed to provide documentation and evidence of performance.

The idea of videotaping instruction for review is not at all new, it is just not often employed. To be done effectively, students must rely on other students to do a good job of videotaping their performance, this might involve some storyboarding. Then, to make effective use of evaluation time and portfolios, students should also be able to carefully edit and present videotapes to faculty. All of these are teachable skills, but may not have been emphasized in the past in teacher education programs. With the new demands of performance assessment, it becomes critical.

Telecommunications. Many performances can be assessed out in the field and documented through videotape. Knowledge can be assessed perhaps through traditional testing procedures. However, some of the performances such as reflective practitioner (Principle 9) and the dispositions are not as easily addressed and documented. These are often factors which faculty have informally assessed over the past perhaps by talking about a student’s attitude, or level of professionalism. Yet, the faculty member was only called upon to provide documentation for these instances in cases of extreme behavior and circumstances.

The use of electronic communication can provide the basis for some of the documentation and assessment. One method would be through the use of e-mail. Students can e-mail instructors personal journals which include reflections on performance. Journals can also be accomplished through the use of notebooks, but maintaining the notebook documentation for a student’s pre-service career could become a storage nightmare. Additionally, only one person could hold the documentation. With the use of electronic mail, the student, as well as the assessment team, can maintain copies of all communication.

More public reflections can also be captured through electronic class discussions (Dutt, Powers & Personett, 1996). Again, the documentation can be collected electronically, and captured in a way that would be difficult to document with in-class discussion. Students become more accountable for their thoughts and actions and must learn to defend their positions, which incorporates a number of the principles. With electronic discussions such as listservs or newsgroups, students are also given the opportunity and time to reflect. In-class discussions must move along quickly due to time constraints. Students may have difficulty formulating their thoughts, or may be too overwhelmed by other class members to speak. The electronic option gives students the opportunity to formulate their thoughts, as well as reflect back on the thoughts and performances of their peers.

Electronic discussions can also provide insight into many of the dispositions that the ten principles expect. For example, the second disposition for Principle #1 states:

"The teacher appreciates multiple perspectives and conveys to learners how knowledge is developed from the vantage point of the knower" (CCSSO, 1996b). When controversial issues are being discussed on something like a listserv, the tolerance of an individual to the perspectives of others, as well as their ability to convey their viewpoint and the substantiation of that viewpoint is apparent. The same argument could be made for traditional in-class discussion on controversial issues, but the documentation is not as readily available.

Electronic Portfolios. Performance does not need to occur only in the field. The type of work a student produces for developmental assessment can demonstrate many of the principles, along with the accompanying knowledge, dispositions and performances. Portfolio assessment is increasingly used both in the K-12 schools, as in teacher education programs. The INTASC Standards will bring a greater push for portfolio assessment as pre-service teachers seek to document their ability to plan multidimensional lessons, provide assessment and feedback, and work with the community.

However, if developmental assessment of performance is to take place, these portfolios need to become a part of the student’s overall, maintained record. States and accrediting bodies will judge the effectiveness of schools and colleges of education by the performances of their graduates. When you consider the potential bulk of these portfolios, which will include video documentation, paper documentation, and electronic documentation, another storage nightmare comes to mind. How much better it might be to have students develop ongoing, living electronic portfolios.

The use of electronic portfolios would also tie back to the instruction issue of inclusive technology use. Students would need to learn a variety of computing skills in order to effectively develop an electronic portfolio. These skills become immediately useful when put to use in the development of a portfolio which will continue with them over their pre-service teaching career, and beyond (INTASC also covers professional development for teachers).

Distance Learning. Earlier, the need for offering courses in the field was described. In that discussion, it was also assumed that the instructor would be available in the field. Realistically, that may not always be possible, particularly if a faculty team is working with a cohort of students. Distance technologies, including Internet, interactive video, one-way video, and audio could be used to bring faculty from the campus in touch with students in the field. By no means could distance learning substitute for the need for faculty to also be in the field with their students, but given the demands of faculty, distance learning technologies could relieve some roadblocks.

Distance learning can also considered to work both ways. Pre-service teachers will not always be able to be in
the field, and a small community might place some prohibitions on how many students are in the field at one time. The same distance technologies that could bring the college/university classroom to the K-12 classroom, could also bring the K-12 classroom to the university/college classroom. How powerful it could be to observe a master teacher working with his/her students and provide critique real-time while sitting on campus. A debriefing session would not need to take place days later with the observing students, and if time permits, the master teacher could even join the debriefing session in order to provide further explanations.

Conclusion

There are a large number of stumbling blocks ahead for institutions which must incorporate the new standards into their curriculum, many of which are not curriculum-related. However, what almost must be considered is the vast potential that the standards also bring with them. Specifically, the Ten INTASC Principles present new opportunities for the inclusion of and need for instructional technology in a way never before presented. Although it might be at first easier for a teacher education program to sweep aside technology considerations because they aren't elaborated upon in the principles or accompanying knowledge, dispositions, and performances, these programs will soon struggle under the weight of providing instruction and assessment under the guidelines of the standards. This weight can be lessened through the effective and inclusive use of instructional technologies.

How to Better Prepare Preservice Teachers with Modern Technology

Yuehua Zhang
Concordia College

Nationwide there is a growing consensus among educators and the public that we need to seriously examine our curriculum in teacher education. The question most often asked is, “Are we preparing our education majors for tomorrow’s changing world, and how should we accomplish this?” Among all of the proposed changes, teaching with technology is one of the major components we should consider. The information explosion has changed the nature of knowing from the ability to recall information to the ability to define problems, to retrieve information selectively and to solve problems flexibly, which therefore changes the nature of learning from the need to master topics in class to the need to learn autonomously. Learners need to learn how to revise their ideas and select information, and to synthesize it from the vast pools of resources.

The traditional “educational technologies,” such as paper and pencil, chalkboards, printed textbooks, manipulative and flash cards and other resources used to help students develop their basic skills, concepts and generalizations have been partially replaced and augmented by a variety of technologies available to assist learners in the gaining of knowledge and skills. Many technologies can support research analysis, problem-solving and communication effectively (Means and Olson, 1993). One of the most dramatic changes in the last twenty years has been the profound advance in technology, which has gradually found its way into classroom instruction through the increased availability of computer and computer-related technologies (Goodlad, J. I., 1984). As the special needs arise for all preservice teachers to be prepared to play a major role in implementing instructional technology in teaching and learning, we as teacher educators must continue to play a vanguard role in helping these new teachers find effective and meaningful ways to continue to introduce the new technologies into the classroom setting. Exactly how this is to be done continues to be a subject of intense discussion.

The NCATE (National Council for Accreditation of Teacher Education) has promulgated a list of recommendations for candidates seeking initial teacher certification or additional endorsements; these can be summarized as receiving the necessary foundations to operate a modest computer system in order to successfully utilize software and explore, evaluate, use and apply current instructional principles, research, and appropriate assessment practices to the use of computers and related technologies.

A variety of publications have discussed the increasingly important role that technology plays in teacher education. In turn, today’s inservice teachers are becoming increasingly aware of the benefits derived from computer-aided teaching at all levels: from grade school education through higher education.

In attempt to address these issues and to rethink the current curriculum (Shanker, A. 1990), and to search for a clearer picture of what the trends are in the area of preservice teacher training with technology, a short survey was conducted among 11 instructors currently teaching technology courses in different colleges and universities where preservice teachers are trained, in order to find common features in the curriculum and to examine the necessary of restructuring the current curriculum in the related area.

Summary of the Survey Results

In all, 11 surveys were mailed out to education division in 10 Concordia colleges and universities within CUS (Concordia University System) and one state university. Eight were returned, representing a return rate of 73%.

Only one of the respondents indicated that there is not a special course offered on their campus, but that they are redesigning an education 300 course (Audio Visual Methods, which has been determined to be out of date.) and are planning to integrate technology into a variety of the classes that education majors are required to take.

All the schools except one represented in the survey that do offer a course specially designed in instructional technology have made this course a required course for their education majors. The length of the time that such a
course has been offered varies from as many as 21 years to two years, with an average of 7.4 years. While the basic reason for the course's existence is because of recently enacted state requirements for accreditation, however, most schools have required their students to take the course from the time of its inception. It is a 2 or 3 credit hour course. 63% of the schools surveyed in his pool do not require the purchase of any textbook; where textbooks are used, the books Computer Essentials in Education Using computer in the Classroom, Multimedia Literacy and Computers in Education were cited.

The majority of schools responded that only one platform was taught in the classroom, either Macintosh or IBM, the decision of which platform to use largely determined by factors such as limited facilities, and limited personnel. Another school indicated that facilities permitted the introduction to both platforms, but that the instructor would decide at the outset with platform he/she would cover in the course, and then cover only this platform. Only two colleges indicated that both platforms were covered in the relevant course.

Almost all the schools treat this course as a production course despite some of the traditional aspects of lecture and class discussion. One respondent indicated still searching for a better way to design and deliver the course. The determining factor for most schools is that students spend most of their class time learning the necessary skills to produce something assigned to them as projects.

The basic skills expected of the students when they complete the course also vary from the very rudimentary to using multimedia author ware to create a presentation or a teaching tool for classroom use. Particular skills mentioned among the respondents included the use of email, word processors, spreadsheets, databases, Web searches and HTML authoring, graphic programs (including LOGO), and some BASIC computer language programming.

Grading systems varied among the schools, with some assigning percentage grades for individual projects, while others graded the students' work more holistically. In the latter case, it was typical for students who did satisfactory work on assigned projects to receive "B" grades, while "A" grades were reserved for students whose projects involved more complexity than what was actually called for in the individual assignments.

As far as the technology component of the curriculum was concerned, I found no decisive similarities. In fact, the survey results showed a variety of approaches and content, as well as profound differences among objectives from each school. Thus questions are raised, such as, "What should we do to better prepare our future teachers?" and "What is the best way to prepare our future teachers to meet the demand of the rapidly developing technology?" Or, "Should any standardized requirements of technical skills be developed statewide or even nationwide?" On the other hand, the survey results do give valuable information, on the basis of which we can examine the existing curriculum involving training in the use of computers and related technologies in education programs with an eye toward seeking improvement. Most educators would contend that we need to seriously rethink the current education programs because of the many aforementioned advances in instructional technology in order to prepare our preservice teacher for their respective futures.

Concerns

The major concerns raised from the data above are:

1. Students' attitude toward learning to use technology;
2. Appropriate textbooks to use to aid the process of theory building and understanding of teaching with technology and learn how to design the curriculum with the use of technology;
3. Basic skills as prerequisites;
4. Basic skills as required when completing the course;
5. Designing a course with limited facilities and personnel;
6. Setting the course time constrains; Exposing the student to both major platforms (Mac and IBM);
7. Software and hardware selection.
8. Information from interview

Five students who are currently taking the Media for the Classroom at one of the Concordia Colleges were interviewed with a major focus on the discussion about two commonly used platforms. All of the five students agree that an exposure to both two platforms is of great benefit. On the basis of this exposure, many students concluded that they now had a clear basis on which to select personal computers for use in their future classrooms. All agreed that, perhaps even more importantly, they are likely to find themselves employed where a computer system is already in place, and an exposure to both platforms will greatly facilitate the ease with which they can become familiar with the established system. In addition, the students responded that the well-rounded education gained through the study of both platforms will allow them to more quickly assist their future colleagues in important decisions concerning their future schools' computer systems, both in terms of general enhancement, as well as in terms of assessing software and hardware issues of the systems.

Suggestions

1. Micro as well as macro plans are required for the restructuring of instructional technology curricula (Newby, T.J.; Stepich, D.A.; Lehman, J.D. and Russell, J.D., 1996);
2. More faculty and staff members should be involved.
3. Serious consideration of the course hours should be given, possibly resulting in increasing the number of hours per week from two hours to three hours;
4. Develop standards for course prerequisites and course content;
5. Encourage exchange of ideas among colleges of education;
6. Encourage collective decisions on selection of hardware and software; avoiding extreme personal preference;
7. Develop a more holistic evaluation system.

Conclusion
The industrial age has been replaced by the information age. The teacher’s role is to assist students to find and put information together in unique and different ways, to critically analyze it and to relate the information to their existing knowledge and skills. As teacher education professionals, we should keep in mind that we have to restructure the approach to teaching with technology (Niess, M.L. 1991) so as to address the needs of today’s learners and realize that technological skills combined with research based theory will eventually translate into improved classroom teaching of tomorrow’s inservice teachers.

Preservice Teacher Education — 711
TEACHING TELEVISION AND VIDEO PRODUCTION IN THE SECONDARY SCHOOL

Donna Lund
Robert Morris College

To meet requirements for teacher certification in communications in the state of Pennsylvania, candidates must demonstrate the ability to teach typical language arts subjects, such as literature, composition, and grammar, and they must also have expertise in teaching at least one form of non-print media. The media specialty at my college is television and video production; therefore, our student teachers divide their time between high school English classes and electives in media. Our methods courses for these communications certification students must include, along with language arts, strategies for teaching both the technical and intellectual skills required to carry out the various steps in the video production process.

Incorporating Video Production into the High School Curriculum

Many high schools and middle schools in Western Pennsylvania now offer some form of instruction or experience in video production. Schools with Channel One equipment use the system to broadcast morning announcements into every classroom. Some of these schools reach a high degree of professionalism, using news roll-ins, computerized weather reports, and an array of on-camera student talent.

In elective courses or as after-school club activities, high school students plan and shoot public service announcements, cover sports and other school activities, and create documentaries, instructional videos, and imaginative projects ranging from music videos to children’s puppet shows, story hours, cooking shows, soap operas, talk shows, and man-in-the-hall interviews.

Even though television (studio) or video (non-studio) classes are elective courses, many schools do assign letter grades, and school boards will not willingly spend large amounts to furnish cameras and equipment unless real educational goals are being met. Therefore, a high school television/video course must have formal objectives, planned activities, and evaluation instruments comparable to more traditional courses.

Preparing Pre-service Teachers for Video Production Classes

To prepare our communications majors to teach video production in high school, we require college classes in studio and non-studio production, post-production (editing), and media management. But a person who knows how to plan a production, operate a camera, create effective sound and lighting, and carry out editing and graphic enhancement may still not be able to teach these skills to others, particularly high school students.

Therefore we have built into our program a variety of opportunities for pre-service teachers to gain hands-on experience in teaching video technology to students of varying motivation and previous knowledge. During our methods course, we invite groups of high school and middle school students to the campus for half-day sessions in our television studio.

Working together, the pre-service teachers create lessons that take the high school students through the process of learning the camera functions, scripting, storyboarding, shooting and lighting techniques, in-camera editing and graphics enhancement. During the summer, pre-service teachers can participate in the video camp we offer for high school students. At other times in the school year, we have arranged mini-courses for various groups of interested secondary students.

Through trial and error, success and failure, the students (both high school and college) learn together that it takes hours and hours of work to produce even a three to five minute television or video program, and that good ideas and pre-planning are more important than the glitz of the technology.

Challenges of Teaching the Video Production Process

Until they take a formal class, many students perceive television as a form of entertainment rather than a tool for education. The hours spent watching MTV, sports, and soaps far outweigh any brief exposure they may have had to serious documentaries or news. Therefore the teacher must
often direct students towards projects that are acceptable in the school environment and do-able in terms of the time, equipment, and expertise available.

In one of the off-campus, after-school, mini-courses our pre-service teachers conducted, the high school students were broken into small groups or production companies to produce several five-minute segments for a video magazine. To give the students a sense of "ownership" of the project, the pre-service teachers gave them absolute freedom of subject matter. Time had to spent convincing one group that "gang violence" was too broad, that an erotic murder mystery would not be appropriate, and that we lacked the technical expertise to create a fantasy creature somewhat like "Gumby."

The pre-service teachers came to the video production workshop with notebooks full of paper for each student in the class, expecting them to keep journals of all phases of the project. What they found was that students did not want to write anything. They just wanted to have fun with the camera, starting immediately. To get the high school students to discuss and decide on a clear purpose, identify an audience, and sketch a story board or write an elementary script took two complete three hour sessions.

During these same sessions, the pre-service teachers had lesson plans for demonstrating the parts of a camcorder, basic shots, lighting, and sound principles. But the high school students did not want to be told how to do anything; they just wanted to do it themselves. Finally the pre-service teachers asked each group to plan and shoot an interview of another student in the class. When they re-assembled to show the footage to the entire class, their own disappointment and embarrassment at the poor results helped the pre-service teachers establish the need to know and the need to plan. The pre-service teachers determined that learners need an awareness of the many small steps that must be taken on the way to acquiring skill with a complex new technology.

The three groups eventually created enough footage for three five-minute segments of a video magazine program they planned to share with parents and friends. Having invested at least twenty-five hours into these brief programs, they came to realize that television may be easy and relaxing to watch, but it is extremely difficult to create.

Teaching Strategies for the Video Production Class

Teaching a video production class requires careful planning of when and how to introduce technical information. Some teachers treat the subject like a science course, requiring students to know optics, physics, and mechanics, while others stress aesthetics and creativity. At the very least, teachers must be able to provide knowledge and experience in basic videographic techniques: composition, shot sequence and variety, clean entrances and exits, purposeful transitions, sufficient lighting, avoiding unnecessary zooms, and using a tripod or other means to steady the camera. The teacher must plan a combination of lecture and hands-on experience that will give students what they need for each step of the process. Using other student products and professional models, the teacher can demonstrate what works and what doesn't, and then let the students try to create their own effects.

Until recently, few textbooks have been available for use in high school television and video classes (some recent publications are listed at the end of this article). In many cases, the person teaching the class has no preparation other than experience with home video. We have all heard complaints of schools that buy a room full of computers but refuse to hire a trained teacher or secure training for current staff. Similarly, teachers assigned to television and video classes need and deserve training and support to put the technology to work for the good of the students.

Educational Outcomes of Video Production Classes

For the past five years, I have taught methods courses and observed student teachers in English and in video classes. As a traditional English major, I experienced some of the same fear of machinery as other liberal arts majors—I did not want to submit my classes to the whimsy of a machine. While I am still an imperfect videographer, I have learned and observed enough to appreciate the power of video technology to enhance language arts skills of secondary school students in many ways.

1. Writing Activities: purpose statement; description of intended audience; script (words that will accompany visual images); production log (record of what was accomplished on each shoot); written evaluation of professional and student video work; self-evaluation and reflection on what was learned during the video production process.

2. Speaking Activities: interview skills (planning and asking good questions); on-camera presence requiring professional language and demeanor; ability to speak within groups to negotiate differences.

3. Research Skills: using print and electronic data bases to gather information for documentaries, news, and interviews.

4. Group Skills: accepting responsibility for carrying our various crew positions; investing time and effort for the sake of a good group product; surrendering personal agendas to the goal of the group.

5. Problem-Solving: using creativity and imagination to solve production problems, such as talent (actors) not showing up, props, mikes, and lights disappearing, batteries going dead, and interview subjects having nothing to say.
6. Self-esteem: gains in confidence as a result of acquiring a useful technical skill that can open up job opportunities or enhance college opportunities.

Summary

More and more secondary schools are offering video production classes or opportunities for experiences in video clubs. New schools or schools undergoing renovation are often blessed with fully-equipped television studios. This technology offers many ways to achieve a variety of educational goals, providing teachers have the requisite training. In my observations of pre-service teachers giving mini-courses and student teachers working in high school settings, I have observed many positive results. In addition to achieving technical goals of learning to handle video equipment, students improved their language skills, enhanced their self-esteem and ability to work responsibly in groups, and had the satisfaction of producing a creative product they could share with parents, friends, and possible employers or college admissions officers.

E-mail: lund@robert-morris.edu
To prepare preservice teachers for their role in the classroom, colleges and universities have traditionally provided students an opportunity to observe K-12 classrooms before they enter field placement and/or student teach. This practice has obvious benefits for teachers-in-training, however, it may limit observers’ attempts to critically analyze what they have seen. Students usually observe different classrooms alone or with a partner. Therefore, when whole class discussions are conducted, the conversation is limited to verbal descriptions of the unique and unrelated events recollected by each of the participants. In addition, the events observed cannot be replayed in order to carefully and critically analyze interactions. Certainly being in a classroom and observing the interactions first hand is a valuable practice. However, providing students an opportunity to collectively view and carefully critique videocases of various classroom activities can enrich their learning.

Commercial videotapes, which are often 20-40 minutes in length, can provide edited videocases of classroom practice. Despite the growing quantity and improving quality of these tapes, the videotape format makes them inefficient tools because they limit exploration to a linear viewing of video-cases. Video minicasess are short vignettes selected as examples of teaching practice. When they are engraved on a laserdisc or CD-ROM, they can be superior to both long-laying or short-playing videocases on videotape because the laserdisc and CD-ROM offer quick and random access to minicases.

Research on videocase methodology used in laser disc and CD-ROM programs suggests that when students view video minicases, they are able to examine the dynamics of K-12 classroom from multiple perspectives (Abate & Hannah, 1994; Fabris, 1996; Risko, 1991; Spiro, Feltovich, Jacobson, & Coulson, 1992; Stephens, 1995). They are able to compare their interpretations with those of others viewing the same case, and they are able to replay the events in order to look at the multiple layers of interactions as they unfold.

With the increasing availability of multimedia authoring programs and with increasingly affordable video editing/digitizing technology, videocase instruction will likely be used more commonly for preservice teacher education. Multiple video minicases can be recorded on CD-ROM and laserdiscs.

In order to make video minicases powerful instructional tools, several matters must be considered. The most important of these is the purpose and format of the product. Additional considerations are the time to be invested, selection of a delivery mode, cost of production, copyright and other legal issues, and the evaluation process.

This paper will discuss these considerations and the decisions made when four videocase-based instructional programs were designed and produced by the presenters using laserdisc and CD-ROM.

Four Sample Video-case Based Programs

The four video-case based instructional programs produced are described briefly: Literacy Education: Application and Practice (LEAP) (Stephens, 1995); Integrating Technology into the Elementary Curriculum: A Hypermedia (I-TECH) Learning Environment for Preservice Teachers (Fabris, 1996); Delivering Instruction with Video Images of Reading (DIVIR); and Putting the Pieces Together: Educating Students with Behavior Disorders (PPT).

Literacy Education: Application and Practice (LEAP)

The design and development of LEAP reflects the notion of cognitive flexibility theory (Spiro & Jeung, 1996) and includes video minicases a laserdisc, software that controls the laserdisc player, and a collection of books on the program’s topic, the reading/writing workshop approach (see Atwell, 1987, and Rief, 1992 for a detailed description of the approach). The minicases are naturalistic.
portrayals of middle school teachers and can be randomly accessed, explored, and interpreted from a variety of perspectives.

**Integrating Technology into the Elementary Curriculum: A Hypermedia (I-TECH) Learning Environment for Preservice Teachers**

This is exploratory study that profits from the flexibility and power of hypertext learning environments (Spiro et al., 1992) to create an information-rich context for examination, discussion, and evaluation of actual technology-enhanced classroom practice. This multimedia package of resources for methods instructors and teachers-in-training includes two major components: (a) a prototype CD-ROM containing video-based minicases that illustrate the multiple new roles the students, the teacher, and the technology play in a technology-rich elementary classroom and (b) a software support system that facilitates the manipulation and critical analysis of the classroom video minicases.

**Delivering Instruction with Video Images of Reading (DIVIR)**

Like LEAP, this program frames video minicases in an interactive, software guided environment. In the minicases, advanced teachers-in-training can observe instructing young readers on the use of cognitive strategies that will help with vocabulary development, word identification, and comprehension. DIVIR also includes a section on how to administer a structured informal reading inventory. The user is guided through the video images on three levels: surface (a holistic analysis of the strategies demonstrated), intermediary (a guided analysis of series of sequences within a video minicase), and deep (an critical analysis of the strategies from varying theoretical perspectives.)

**Putting the Pieces Together: Teaching Students with Behavior Disorders (PPT)**

PPT is an interactive multimedia CD-ROM project that is designed for the preparation of pre-service and novice general and special education teachers. It introduces best and least restrictive practices for instruction of K-12 students with behavior disorders through text and video scenarios. PPT is intended to provide initial information, therefore, the video minicases are activity-based.

**Determining a Purpose and Format**

Before the design and development can take shape, the creator of a video-case based program must clearly articulate a purpose for the product. The discussion that follows this section of the paper will make increasingly clear the reasons why this stage is so important. Much time, effort, and money will be spent. Keeping focus of the goal will insure that the path to completion is efficient and the final product is well-structured.

The following questions can elicit a statement of purpose and guide the design and development process:

1. What is the content to be delivered?
2. How is the content to be delivered?
3. What theoretical model or models frame the program?
4. What assumptions are made about the potential user of the program?
5. How will the program be evaluated and assessed?
6. How will the creator of the program know that what occurred when the product was used resembles the intended outcome?

LEAP, I-TECH, DIVIR, and PPT each had different and definite purposes. LEAP's content is the reading/writing workshop, a nontraditional approach used to teach literacy in K-12 schools. Twenty-three short minicases of three middle school teachers who use the approach can be viewed on a laserdisc. I-TECH's content is the use of multimedia technology in the elementary diverse classroom. It contains over 50 minicases culled from the 40 hours of naturalistic episodes captured on videotape and burned on a CD-ROM.

Both programs are framed in cognitive flexibility theory (Spiro et al., 1992) and can be described as constructivist methods of delivering instruction. Capturing interactions that were neither rehearsed nor scripted for the video was of primary concern to the creators of these programs so that they provide a "window" through which the user could examine and analyze the complexity of a real context from a number of perspectives. The creators assumed that students using LEAP and I-TECH would bring prior knowledge, either from experience or readings, to their viewing of the minicases. In a collaborative setting, LEAP and I-TECH would facilitate dialogue and encourage critical analyses of a multitude of issues embedded in the minicases. This would then lead to social construction of notions about teacher-student interactions in the classroom.

The content of DIVIR is diagnostic and prescriptive reading instruction. The content of PPT is best teaching practices for students with behavior disorders. The purpose of both programs is to guide advanced teachers-in-training through demonstrations of prescribed strategies used in classroom settings. In the case of DIVIR, the intended users are students preparing for, or enrolled in, a practicum course, the capstone course in the series of reading teacher preparation courses. The practicum entails one-on-one tutoring of an at-risk child in a clinical setting. PPT's intended users are enrolled in a core course designed to provide general teachers for inclusive classrooms and to provide special education teachers with an introduction to general concepts related to special education.

Unlike LEAP and I-TECH, where cases are naturalistic and users are encouraged to become critical observers as they view the layers within a minicase, DIVIR and PPT captured more structured, pre-planned and deliberate interactions and users are encouraged to imitate the particular strategies being demonstrated. Creators, thus,
framed the programs within a more cognitive-behavioral theoretical model. However, components of these programs do support more critical analyses and socially constructed interpretations that can occur in a collaborative setting.

**Scheduling Time for Design and Development**

Time is a critical factor when planning and producing a video-case based program. Besides investing time in the conceptualization and planning of the program, the creators must invest time in all of the facets of videotaping, editing, and evaluating. The time involved in formative and summative evaluation will be discussed elsewhere.

Unless a media support group is available, the creator must be prepared to allot considerable amounts of time to taping, and particularly, to editing. In order to capture enough minicases to represent naturalistic classroom interactions or enough minicases from which to select the best demonstrations of a particular strategy, many hours of tape must be used. Twenty-two hours of tape were reduced to one hour in the production of LEAP. The many hours of tape were reduced to 54 short digitized segments for I-TECH, and some 7 hours of tape were reduced to 20 minutes of QuickTime movies in DIVIR.

To determine how much videotaping needs to be done, the creators should, after determining the purpose, examine potential settings and models. Is there more than one classroom that should be video-taped? How long are classes? How many days should camera-persons be in the classroom before the students become accustomed to the camera and therefore perform naturally? (That occurred after 3-4 days in the LEAP videotapiings.) How many models should be video-taped in order to select a good representation of a given strategy? How long will each strategy take?

Schedules are important and require much coordination. If a classroom is being taped, permissions must be secured from the district office, principal’s office, teachers, and parents of the students in the classroom. That process often may take days or even months. Once this process is accomplished, camera-persons and teachers must be coordinated so that the appropriate classes are being taped on selected days.

When raw tapes arrive at the editing suite, time once again becomes critical because all processes The developer begins by logging the raw video. This process of tape logging is again time-consuming. However, a detailed tape logging eventually saves time and avoids frustration when the program assembly process begin. The result is a library of organized video footage that later facilitates the viewing of video segments and can be copied directly into an edit decision list (EDL).

To produce visually effective minicases, two cameras should be used—one to follow the key player in the interaction—most likely the teacher—and one to follow the secondary player(s)—usually the student(s). When using insert editing techniques, a minicase will show not only the teacher’s performance but also the students’ response/reaction to that performance. Selecting the “A-roll” section on which the “B-roll” clips will be dropped, and then dropping those short clips of “B-roll” in precisely the right location on the “A-roll” section can become a tedious and protracted process, particularly for the novice editor.

If nonlinear editing is selected—as in the case of I-TECH—the next step is to digitize the analog video signal of tape into computer data. This require specialized hardware and software. After the video capture comes the task of editing for length and appropriateness, adding titles, rendering all transitions, and making the movies. This step also requires special video-editing software such as Adobe Premiere. The resulting video clips or QuickTime movies can be exported to a variety of formats.

In the making of PPT, one camera was used so the issue of insert editing was avoided.

Finally, how much time is entailed in the designing and developing process will also be greatly influenced by the selected mode of delivery.

**Selecting a Mode of Delivery**

CD-ROM? Laserdisc? These are the two more desirable modes of delivery because the user is allowed to access video-cases quickly and randomly. It is an efficient tool particularly when it is used to support group dialogue and user-computer interaction.

Laserdiscs indulge the viewer with a large, exceptionally crisp image and stereo sound. If the purpose of the video-case instructional tool is to explore layers of interactions, nuances, facial expressions, etc. as in LEAP, then a laserdisc may be the most effective medium. However, it may not be the most convenient. To use a computer-controlled laserdisc, three pieces of equipment and a variety of cables are required: the computer system, laserdisc player, and TV monitor. This can become particularly cumbersome, if not prohibitive, if individuals or small groups are to use a laserdisc at the same time. For large group viewing and discussion, however, the laserdisc played on a large TV monitor, is an ideal way to view the cases.

CD-ROM is a convenient, effective mode for interactive video-case exploration. Video-cases are produced as QuickTime movies and imported into the software that can be created in a number of authoring programs such as HyperStudio, SuperCard, HyperCard, MacroMedia Authorware, and Macromind Director.

As with laserdiscs, CD-ROM has a disadvantage: video images are not as clear as they are on laserdisc, and when projected from a computer screen to a large size, the image is less clear and bright. Also, to avoid a jerky image during playback, QuickTime movies are usually no longer than two minutes. Sections of a single episode that is longer.
than that time frame must then be “patched,” or played back to back in order to view the entire episode. In DIVIR, for example, there are three sections of the informal reading inventory, a process that normally takes about 45 minutes and that was edited to approximately 5 minutes. The viewer must click to watch the first part, then click again to watch the subsequent parts.

While longer videos are potentially more powerful in terms of leading the audience down a particular path, incorporating shorter clip segments in a supporting role adds clarity to a message. Further, using the QuickTime controls, the user can manipulate the movie playback and audio volume.

Examining Cost of Production and Replication

The cost of producing a laserdisc and of producing a CD-ROM is difficult to estimate because several factors must be considered. For example, in both cases, videographic equipment is needed: cameras, videotapes, tape decks, microphones, cables, and possible lights and light umbrellas. Super VHS cameras, tape decks, and tapes are recommended because they are relatively affordable and can provide a high quality, pseudo-professional quality video. Cameras range between $800 and $14,000 and tapes are approximately $12 for 60 minutes. Telescopic or “zoom” microphones, which can capture otherwise garbled sound from across an average classroom when aimed at the speaker, range from $100 to $300. Pressure zone or “pancake” microphones give the object to which they are attached the qualities of a microphone and cost approximately $150-300. Playback decks are $800-2400.

The cost of an editing suite can range from $6,000 to an unlimited price depending on the sophistication of the system and the desired quality of the end product. Many universities do provide editing service, however, for a range of fees.

Engraving a laserdisc or a CD-ROM will also vary greatly in costs. Engraving one side of a laserdisc (30 minutes of video) costs approximately $300. A blank CD-ROM can be purchased for approximately $9, and a CD-ROM maker can cost from $800 to more than $2,000. And finally, authoring software ranges in price as well—from a low $100 for HyperStudio to $2,989 for the full version of Macromind Director.

In light of the price tags of the essential tools needed to create video-case instructional programs, it is wise to seek existing university/college media services or to write a grant to fund the production. LEAP, DIVIR, and PPT were subsidized by grants. I-TECH was the effort of a single individual.

Investigating Copyright and Other Legal Issues

Researchers are aware of the legal ramifications of using human subjects. Researchers and developers who use video images of school children must be aware that they may be entering an incredibly puzzling legal lair because laws regarding videotape are diverse and changeable. It is good practice to investigate the laws protecting video of students by visiting with legal representatives, either in private practice or through the university/college's administrative offices. Release forms must be secured from all persons whose images or whose children's images will appear in video-cases. In the production of LEAP and I-TECH, for example, all children and the three teachers videotaped received a form explaining that the sole purpose for the programs was to improve the education of preschool teachers. Some parents refused to allow their children to be videotaped, and those children were seated behind the cameras during the taping sessions.

Evaluating the Product

What might have been envisioned to occur when a prototype of a video-case program is used may be far different from the reality. Responsive formative evaluations conducted with stakeholders, experts in the content field, and potential users can help to insure that the purpose and goals set for the product are achieved. For example, stakeholders, the professors who would be using LEAP, were interviewed at the start and asked to critique the prototype of the product on two occasions during the development process. Experts on the reading/writing approach were asked to rate a number of potential minicases using a Likert-type scale. And two groups of students (potential users) were asked to comment on the raw footage, and later, on the prototype. The final prototype was field-tested and modified after data collected through observations, interviews, and a survey conducted were analyzed. The prototype components of I-TECH were also continuously revised and evaluated experts, potential users, and individuals not familiar with the topic or content. Revisions and improvements suggested by stakeholders were incorporated into the product.

Certainly, not all video minicase based programs need to be rigorously tested; however, creators of such programs will design a more valuable instructional tool if time is reserved for carefully thinking through and reflecting on their purpose, goals, intentions, and assumptions at the start, during, and after the program is developed.

Final Remarks

Of the four products described in this paper, one—LEAP—has been field-tested. I-TECH's creator conducted a series of formative evaluations during all stages of design and development, and DIVIR and PPT are still in production. Results of the field test of LEAP show evidence of a
shift in philosophy among the users—from a teacher-centered orientation to a student-centered perspective. The most valuable gain, however, was that the teachers-in-training had an opportunity to collectively explore their future professional world and to share their interpretations of it in a safe, encouraging environment. Although some aspects of designing, developing, and evaluating a video-case based instructional tool may seem daunting (cost and legal issues, for example), benefits as these are too notable to discount.

The cover story of the March/April 1996 issue of *Electronic Learning* was “New Teachers: Unplugged - Why schools of education are still sending you staff you’ll have to train in technology” (Barksdale, 1996). One of the reasons for this is that schools of education do not have the latest technology to use for teaching their students. To provide education students with the opportunity to use one example of the latest technology, the funds from a summer research grant were used to help purchase a Newton MessagePad 130.

**Review of the Literature**

An Apple Newton MessagePad is one type of handheld, battery-operated, personal digital assistant (PDA) that organizes, transmits, and retrieves data. PDAs contain a mixture of personal-information-management tools for people on the go (Zilber, 1996). These miniature computers were first introduced in 1992, and if PDAs follow the course of PCs, by the year 1999 everyone will have to own one (Malloy, 1996). The first Newtons were plagued with poor handwriting recognition ability. This was disastrous because many people purchased them specifically for their ability transform hand written notes into text. The Newton MessagePad 120 and 130 with the 2.0 operating system have excellent handwriting recognition. Additionally, improved battery life, improved communication capabilities, and an increase in the number of third-party applications make the Newtons contenders in the PDA war (Zilber).

The Newton MessagePad 130 ships with cables for computer connections and backup software for both Windows and Macintosh platforms. By connecting the MessagePad to a printer, handwritten notes can be printed. With the addition of a software program, such as X-Port, hand written notes can be downloaded to a personal computer and opened up in a word processing program. These once hand written notes are converted to text to be formatted and printed as a word processed document. X-Port also exports information from either a Windows or Macintosh computer to the Newton.

Software programs such as Learner Profile and Grady Profile Companion for the Newton MessagePad combined with Grady Profile - Portfolio Assessment enable teachers to use the Newton to facilitate alternative assessments of student learning. These programs provide rubrics and matrices for teachers to check off as they observe students working in their classrooms. Teachers can customize the programs to suit their needs and record anecdotal comments. The portability of the Newton makes it easy for teachers to carry with them throughout the school and on field trips. Records and information gathered on the Newton can then be downloaded to student records stored on a computer, and then used to print out student records of progress.

Johnston (1992) contends “The most powerful assessment for student learning occurs in the classroom moment-to-moment among teachers and students” (p. 60). Teachers’ assess students’ learning as they teach. Based on these assessments, teachers modify how and what they are teaching. Teachers intuitively assess student learning in a narrative rather than numerical manner during personal interactions with students (Johnston). A hand-held message pad allows teachers to immediately record and store their anecdotal observations for later reflection on students’ learning. These anecdotal records provide a broad range of assessment data gathered over time, rather than the snapshot assessment of tests.

The purpose of this study was to provide education students with access to a Newton MessagePad 130 and to provide data on the feasibility of using a Newton in a classroom for anecdotal record keeping. Whereas the ideal situation would have been to have the students use the Newton MessagePad 130 in their own classes, the constraints of two-three week summer courses required them to use the Newton to keep anecdotal records of their university classroom activities.

**Methodology**

A pretest-posttest design was used in this study as well as an analysis of anecdotal records kept by the students.

**Participants**

The participants were thirteen students who were enrolled in two of the courses required for computer literacy endorsement in the summer of 1996 at Louisiana Tech University. Seventeen students were enrolled in the first course. Since three students did not enroll in the second course, their responses were not included in the data.
analysis. One student did not attend the last day of class when the posttest was given, hence data was collected for only thirteen students. Two participants were male and eleven were female. Eight of the participants took the course for graduate credit and were practicing K - 12 teachers. Two participants were graduate students with limited prior teaching experience, one of whom planned to begin teaching in the fall. The other three participants graduated in May, had not been admitted to graduate school, and planned to begin teaching in the fall.

**Instruments**

Instruments used in this study were researcher designed pre- and posttests consisting of open-ended questions. The pretest contained the following three questions about the Newton: 1) What is a Newton MessagePad 130?, 2) What can you do with a Newton MessagePad 130?, and 3) How can a Newton MessagePad 130 be used in a classroom? The pretest questions about anecdotal records were: 1) Have you used anecdotal records before? If yes, when and where?, 2) What are anecdotal records?, 3) How can anecdotal records be used in a classroom?, 4) What are some of the benefits of anecdotal records to a classroom teacher?, and 5) What problems might you encounter when using anecdotal records in a classroom?

The posttest contained the same three questions about the Newton with four additional questions. These questions were: 1) How could a Newton MessagePad 130 benefit a teacher in the classroom?, 2) What problems might you encounter when using a Newton MessagePad 130 in the classroom?, 3) If a Newton MessagePad 130 was available to you, would you as a classroom teachers use it in your classroom? Why or why not?, and 4) If you answered “yes” to the previous question, how would you use it in your classroom? Please be as specific as possible.

**Procedure**

Prior to data collection students were given a pretest consisting of three open-ended questions to assess their knowledge of the Newton and five open-ended questions to assess their knowledge of anecdotal records.

Students were provided with information on taking anecdotal records. They were advised to describe rather than interpret the behavior they observed using positive descriptions (Wright, 1967). Students were instructed to record the entire situation including detailed, accurate descriptions of the actions and setting using adjectives and adverbs to enhance the description (Cohen & Stern, 1967).

A brief introduction was given to the students on how to use and care for the Newton. They were given the opportunity to explore the Newton and had an opportunity to examine demo programs of Grady Profile on both the Newton and a Macintosh.

Over a six week period students were required to spend two thirty minute sessions using the Newton to record classroom observations. Some students enjoyed using the Newton and worked with it for longer periods of time. Students were advised not to write down their classmates names as they recorded their observations. Since most of the class time was spent in working in groups, students simply gave each group they observed a number.

As students finished their observations, they connected the Newton to a printer and printed their observations to turn in as part of a classwork assignment. At the end of the six weeks, students took a posttest. This consisted of the original three open-ended questions about the Newton with four additional open-ended questions about potential benefits, problems and uses associated with having a Newton in the classroom. The portion of the posttest regarding anecdotal records contained the same five open-ended questions as the pretest.

**Results**

This section includes an analysis of pretest responses, posttest responses, and students’ anecdotal records.

**Pretest**

Pretest responses to questions about the Newton ranged from “I don’t know” to a rather informed “record credit card transactions & keep running balances; record important dates.” Students’ pretest responses to “What is a Newton MessagePad 130?” indicated that 2 students had no idea what it was. Eleven students responded that it was used to record messages. Six of these respondents also stated that it was plugged into a computer, or was a computer. For question two, “What can you do with a Newton MessagePad 130?, eight respondents wrote that it was used for messages. One respondent replied draw pictures, and one guessed that it could be implemented in the classroom. Another respondent wrote “record credit card transactions & keep running balances; record important dates.” The other two respondents did not know what to do with a Newton. Question three asked, “How can a Newton MessagePad 130 be used in a classroom?” Seven replied that they did not know how to use it in a classroom with one student adding the comment “can’t wait to find out.” Two students commented on using it to take notes with one clarifying that by saying “to record what the children are doing.” Three indicated that students could write notes on the Newton. One student wrote “I guess it could be used with different projects.”

Pretest responses to the five questions regarding anecdotal records ranged from “I don’t know” to more in-depth knowledge of them. Question one about having used anecdotal records before indicated that six students had used them before and seven had not. Students reported using them several years ago, during student teaching, and while supervising student teachers. All six had used them in a classroom. Question two asked “What are anecdotal records?” Six students responded that they did not know. The remaining seven responses pertained to taking notes.
about what students were doing or saying. Only one of these respondents commented that anecdotal records were gathered to obtain a total picture and analyzed.

The remaining three questions focused on using anecdotal records in the classroom. The six students who responded that they did not know what anecdotal records were did not answer the last three questions. Question three asked, “How can anecdotal records be used in a classroom?” Students responses included comments such as recording behavior, recording events as a measure of progress, to compile thoughts, and for portfolio assessment. In response to question four about the benefits of anecdotal records students had an array of answers relating to helping keep accurate records, providing more information than grades, and adjusting for individual differences. Problems with using anecdotal records were queried in question five. Here students frequently commented on the problem of finding the time to record, organize, and analyze them.

**Posttest**

Posttest responses to “What is a Newton MessagePad 130?” were more detailed than pretest responses with most referring to it as a computer or an electronic device used for note taking. One student referred to it as “a highly specialized computer,” while another student wrote “It is a small device (I cannot call it a computer)…” The second question about what can you do with a Newton elicited a variety of responses. They included: take notes, print out, calculate, draw, import and export information, keep records, handwriting conversion, calculate loan repayments, calculate interest rates, store information, play phone numbers, calendar, and store addresses. Classroom uses of the Newton evoked ten different ideas with one student commenting that it would be a waste to use in the classroom. Students would use one in a classroom for: anecdotal records, lesson planning, making records, checklists, field trip observations, storing grades, scheduling, a clipboard, notes for student evaluations, and for children to take notes for students who are absent.

Students comments about the benefits of using a Newton in classroom were favorable except for one student who wrote “waste of money in an educational setting.” Students remarked that they could use it to take notes in class, record and evaluate student progress, and record observations. Responses also indicated that the students had developed an appreciation for the convenience of the Newton and had thought about other ways to use it in a classroom as well as for their personal use. They commented that the Newton could be used to take notes during class, to write reminders, to jot down ideas for assignments, for short dictation, to write lesson plans, to schedule events, and to print out ideas for children. Some respondents included student uses such as, recording observations on a field trip and having students use it to take notes for absent students. They had ideas for using the calculator, address book, and calendar on the Newton. Students commented that it could be used to place phone calls, calculate loan payments, draw, and “store all sorts of information.” Comments included that it was “easier to use than writing on paper, handy to operate in a classroom, goes from place to place to record data, and could be taken home.”

When asked about potential problems involved in using a Newton in the classroom, 9 students or 69%, commented on problems with getting it to recognize their handwriting. This can be attributed to the fact that the students used the Newton in “guest user” mode; hence, it was not individually configured for each students’ handwriting. Two students were concerned about the Newton being stolen in a classroom setting. One teacher remarked that it would be difficult to take notes on the Newton in a classroom of young children. Problems with upkeep and maintenance were also mentioned. This is probably related to the fact that many school districts in the area lack technology support personnel. Students also commented on the Newton’s slowness in converting handwriting to text. One respondent expressed concern about “all of the students not being able to use it at the same time.” This response is similar to teachers’ concerns about one computer in a classroom. Another respondent felt that given the opportunity to become more familiar with the Newton, it would be more beneficial.

Overall, students had very favorable comments about using a Newton in their classrooms. They were asked, “If a Newton MessagePad 130 was available to you, would you, as a classroom teacher, use it in your classroom?” Ten respondents or 77% circled “yes,” while three respondents circled “no.” They viewed it as a personal tool to “keep track of ideas to focus on later, reminders to self, print out notes, and easily accessible information.” Three respondents, who indicated they would not use one if available, indicated why they would not use it. One respondent stated that it would not be practical for a physical education teacher who worked outside with students. Another respondent felt that “a sheet of paper and pen would work just as well.” The third respondent commented “I can take notes faster by hand than on the Newton MessagePad.” However, the respondent further commented, “Possibly, if I had more experience on the Newton, I would like it a little more.”

When asked to be as specific as possible about ways to use the Newton in their classroom, student reiterated previously mentioned ideas. These included answers such as: keeping anecdotal records, writing lesson plans, student addresses, keeping track of ideas to focus on later, check lists, writing quick notes to print out, sharing with students, and preparing class assignments.

Two participants did not respond to any of the posttest questions on anecdotal records, therefore, responses for only eleven responses were analyzed for this portion of the
posttest. Students described anecdotal records as “factual notes of student behavior or class activity” and “short brief notes.” Responses to the use of anecdotal records in the classroom included: recording inappropriate behaviors, identifying students in need of remediation, documentation, notes to use during parent conferences, and to record observations of student teachers. For the benefits of anecdotal records in the classroom, students wrote: reminder of students’ past behavior, provide a great deal of information, to keep up with student progress, documentation of student behavior, and reflection on instruction and student performance. Regarding potential problems with anecdotal records, students noted: recording of opinion rather than facts, time consuming, not being able to write everything down, and having the time to work on and read the records.

**Students Anecdotal Records**

Students anecdotal records captured the classroom atmosphere of periods of intense work and periods of laughter. One student wrote: “Students are not discussing very much, rather they’re concentrating heavily on the projects at hand. Hesitant students are asking for help from the teacher. The atmosphere in the room continues to be quiet with students consciously keyboarding.” Another one wrote “In a nutshell, the class is working very hard to complete their assignment.” Humorous times were also noted: “A lot of laughter can be heard in the lab this morning” and “Group 4 - Three students are working in HyperLogo. One student humorously requests to be in another group.”

The frustration of creating multimedia projects was evidenced by “Two students worked on the laser disc player. They had trouble getting the picture to show up on the screen.” One student’s notes contained this grim statement, “Their complete program just crashed and they must begin again.” Problems with Internet searches were also sources of frustration as noted in the following record: “Some students are showing signs of great frustrations due to their searches not giving the desired information needed to complete their projects.”

Students recorded observations about the group work being done in the class such as group of 4.

The members of the group seem to enjoy what they are doing but they need to work on sharing the mouse. One student has been using the mouse for 30 minutes. A second student in the group has acted as the leader to long. The last two members in the group have not spoke in 10 minutes. The last two members do seem to understand the material being covered. The group consults on all the choices to be made about the project.

Along with the frustrations encountered with technology and problems with group members, students noted the fun and excitement of learning with technology. Students’ observations included statements such as, “... this is starting to be fun,” “We are having fun,” and “Group 4 is using the QuickCam. They are having a blast.” And one statement that sums up the experience, “Now that I actually know what I’m doing, I may take (EDUC) 447 and (EDUC) 448 again just for fun.”

**Discussion**

Students’ posttest responses indicated that they had learned a great deal about the Newton MessagePad. However, one student was still uncertain as to what it was and hesitated to call it a computer. They discovered a variety of uses for the Newton as both a personal productivity tool and as a tool to use in their classrooms. Problems encountered with handwriting recognition could be overcome if they had each had their own. In actual usage only two students had a great deal of difficulty getting the Newton to recognize their handwriting and this was overcome with practice. One student, a keyboarding teacher, preferred to use the pop-up keyboard on the Newton screen. She would have benefited from the Newton’s optional keyboard.

Posttest responses to questions about anecdotal records indicated that providing practice in taking anecdotal records facilitated their understanding of the uses of these valuable records. Experiencing taking anecdotal records provided students with opportunities to discover how time consuming it is to record observations. However, judging by their observations of the benefits of anecdotal records, students find them valuable records to document student activities, behavior, and progress.

An analysis of the anecdotal records students wrote during class indicated that they understood the importance of describing rather than interpreting the behavior they observed. They described the setting in which the events were occurring. Students did not, however, use many adjectives or adverbs to enhance their descriptions. Their observations provided an intimate glimpse of classroom activities including the mood of the class, the frustrations, learning, and excitement taking place.

Students appreciated the fact that they had hands-on opportunities to use this new technology and enjoyed using the Newton. If made available to them, the majority of the students would incorporate it into their classrooms. The responses recorded to the open-ended questions on the posttest indicated that students would find a wide array of uses for the Newton in their class rooms. They were able to find personal uses for the Newton as well as classroom applications. This is important because teachers who use technology for their personal benefit are more likely to use technology with their students.

The short time frame of this study and the small sample size limits the generalizability of these results. However, the favorable responses to using the Newton indicate that additional research should be done in this area. Additionally, as the prices drop on these products and new PDAs
are introduced, it is likely that they will be available in classrooms in the future.

This research was supported in part by a Faculty Summer Research Grant provided by Louisiana Tech University.

These days, word processing, e-mail, and the World Wide Web have changed the way businesses operate and people communicate, yet how students learn in the classroom seems to have been overlooked by this onslaught of new technology. The traditional teaching method of a professor lecturing to students using limited visuals such as chalkboards and overhead projectors is till the norm. But things are changing. University of Maryland's Teaching Theaters is the first step in extending technology to the lecture environment. The three Theaters - the AT&T Teaching Theater, the IBM-TQ Teaching Theater, and the AT&T Foreign Language Classroom, are unique classroom environments that provide integrated computer networks, customized presentation equipment, as well as an assortment of locally developed "Lectureware" (software specifically designed for the lecture environment).

Teaching Theaters
The University of Maryland at College Park, with the financial support of AT&T and IBM, has designed, constructed, and is using classrooms which spotlight technology to transform lectures and learning. A network of computers, highly integrated with a broad array of audio/visual equipment, is available in an effective setting to support instruction and research. The room, The AT&T Teaching Theater, is the first step in extending to the lecture environment the benefits of technology that are revolutionizing other aspects of the teaching/learning process.

The AT&T Teaching Theater is located in room 3140 of the Engineering Classroom Building. It is also available for a single class, short session, or meeting. Staff are available to assist in preparing for and running these sessions. For maximum benefit, faculty or staff are encouraged to schedule at least one month in advance of the planned dates for the class, short session or meeting. Demonstration sessions are also available. The computers in all Teaching Theaters run under Microsoft Windows on a Novell Network.

The Teaching Theaters are run by the Academic Information Technology Services at the University of Maryland. The use of them is, therefore, not restricted to any particular discipline. Previous users include instructors from Anthropology, Art History, Business, Chinese, Civil Engineering, Computer Science, Electrical Engineering, English, Government and Politics, History, Housing and Design, Library & Information Services, Math, Mechanical Engineering, Physics, Psychology, Spanish and Speech Communications. The courses range from the undergraduate to the graduate levels.

Lectureware
Lectureware is software application specifically designed for the lecture environment. Some Lectureware are designed specifically for instructor to use while some are designed for student, or for the interaction of both student and instructor. The following Lectureware applications have been developed by the Teaching Technologies staff to provide tools to enhance the collaborative learning environment available in the Teaching Theaters.

Caprina
Caprina makes high-quality color images easily accessible on many computers at the University of Maryland at College Park. Currently, access is limited to IBM and IBM-compatible computers with adequate quality video capability, running Windows, and having the Caprina access software installed. Fortunately, this includes many of the computers in public labs.

Caprina currently provides two ways of accessing images: MultiSlide and QuizSlide. In MultiSlide you are presented with a list of the images in the order in which they will appear in your course. You can view several images at one time for ease of comparison. QuizSlide is a iflashcardi study tool to help you learn to recognize images. It presents you with images, one at time, chosen at random from a certain collection. After you have completed your identification, you can easily have it confirmed. (Kozintsev, Stenchikova, Chang & Gilbert 1996; Chang & Gilbert, 1992)
Class Directory

The Class Directory combines each student's picture, name, and a personal biographical sketch into a format searchable by picture or by name. It is particularly useful during the first few weeks of class to aid students as they get to know each other. It is also useful to the instructor for learning the names and backgrounds of the students. The instructor is also included in the directory. (Stenchikova, Chang & Gilbert, 1992)

Feedback Meter

The Feedback Meter is a simple tool which enables the instructor to get feedback from the students as to whether they need clarification during a lecture. Students can simply click on one of two buttons on their program window: "I've got it," or "Please clarify." (Figure 1) The instructor receives immediate feedback as to the number of students who need clarification. (Figure 2) It is also used for simple Yes/No class polling. (Taylor, Chang & Gilbert, 1992)

MultiChat

Multichat is an interactive communication package which allows students to "chat" with each other in small groups. While this will not replace conventional small-group work, it provides some useful enhancements. Multichat creates a permanent record of student transactions which enables the class to analyze student group processes as well as outcomes. Additionally, students can use the Switch Group function, which allows them to go from one small group to another. Once they enter the new group, they can read all the group transactions before participating. In addition, students do not need to enter a group at the same time. Students can participate in groups which continue all semester, synchronously. (Chu, Gilbert & Stenchikova, 1993)

These are the features of this program:

- Users have to specify the group they want to join.
- Send Identified/SendAnonymous: Users can send their messages with their name or not.
- Messages Released/Hold: Users can browse the old messages without being interrupted by new incoming messages.
- Switch Group: Users can switch groups at any time they want.
- Delete Group: (for FACULTY only) Users can delete a group.

One Minute Paper

The concept behind the One Minute Paper has been in education for some time: ask students to take out a piece of paper, but not to put their name on it. They should take one minute to answer a simple question such as:

What is the most important thing they've learned today? or What should be covered next class?

The One Minute Paper program allows the instructor to ask these questions electronically. In addition, by collecting this type of information quickly, electronically and anonymously, it is possible to use this technique in various ways. In the teaching theaters, for example, the instructor has the option to look at the data alone, or to project it to the class for analysis. The One Minute Paper could be used as a kick-off for class, asking a question about the previous homework assignment. (Yoo et al, 1994)

Random Number Generator

The Random Number Generator is another simple tool which will pick a random number. The user starts the numbers counting (in random order) and then clicks on stop to pick a number. (Elvove & Chang, 1994)
WinQuiz

WinQuiz is a program that allows the instructor to create a quiz on-line and the students to take the quiz on-line. The instructor has the ability to create the following types of questions:

Multiple Choice, True/False, Short Answer, Essay. When the student is taking the quiz, they are allowed to move back and forth between questions and change their answers. However, once they have submitted a quiz, they are not allowed to submit the quiz a second time. The instructor is able to view all the students' answers together in a table for quick grading and individual student answers may be viewed for further examination. (Olien, Chu, Chang & Gilbert, 1994)

WinSeat

WinSeat provides the instructor with the current seating chart for the Teaching Theater. The layout of the screen is identical to the physical layout of the Teaching Theater. The login id of the student who is currently logged in at each station is displayed. The instructor has the ability to print the list of students logged in. (Dan, Chang & Borkowski, 1995)

WinTimer

WinTimer is a simple application that allows the instructor to enter a set amount of time and to start the clock. The timer counts down the entered time. The user can pause the clock if desired. (Wu, Do & Chang, 1994)

Implications for Teacher Education

The desire to enhance the classroom experience with new and changing technology is growing among campus faculty; the demand for resources and support is also mushrooming. However, with the proliferation of networks, computing platforms and software, authoring systems, and experimental teaching environments, the kinds of instructional support needed is changing dramatically. The goal then is to offer a powerful, interactive educational environment in which it is actually easier to teach than it is in the traditional classroom. The design, implementation and operation of the Teaching Theaters...
and Lectureware are successful examples of incorporating information technology into teacher education.

One of the great challenges facing today's education system is the computer revolution in education. The same technological advances schools are supposed to prepare students to use are not being utilized in the classrooms. Former U.S. Secretary of Education Terrel H. Bell (Bell & Elmquist, 1992) points out that U.S. teaching practices are outdated and that students and teachers need to be provided access to the same technological tools which have revolutionized American industry. He draws the analogy that "technologically, American education is wobbling down Electronic Avenue in an oxcart" (p. 22). However, merely providing access to computer technology is not sufficient. Efforts to place high powered hardware and software in schools will do little to increase computer support of curriculum in the classroom without a concomitant effort at inservice and preservice computer education.

A lack of preservice education on the integration of computers in the curriculum is one of the most common obstacles new teachers face when beginning their careers. Several researchers have stressed the need for preservice education programs which emphasize integration of computer use in subject content areas and individual curriculum units (Dugdale, 1994; see also Robinson, 1993; Novak & Berger, 1991; Nuccio, 1990; Diem, 1989). The primary need is to structure computer education so student teachers will be enabled to use computers to support their curriculum most effectively.

Though preservice education on the integration of computers into curriculum is lacking, productive inservice education on this topic is practically non-existent (Main & Roberts, 1990). Main & Roberts go on to say that computer education for experienced teachers is most often limited to short seminars the week before school begins or perhaps on Career Ladder Day. Other efforts by experienced teachers at computer integration into curriculum must be undertaken by the individual teacher, usually on their own time.

While computers have become more accessible to the teacher in the classroom and computer capabilities have increased dramatically, efforts to provide more effective computer education for student teachers have not kept pace. Early efforts to meet the need focused on either creation of stand alone core curriculum courses in computer use or addition of computer instruction modules in teaching methods courses for all student teachers. Many of these programs encountered problems in that every student received the same instruction and completed the same assignments. These assignments, however, were not necessarily related to the individual student's curricular interests or teaching disciplines (Dugdale, 1994; Robinson, 1993).

The next generation of preservice education is exemplified at the University of California (UC) at Davis (Dugdale, 1994). UC Davis discontinued the computer core course in favor of a classroom-based experience. Student teachers in both the elementary and secondary education programs were assigned to complete a computer project which was used to support classroom lessons. These projects were prepared and presented by the student teachers and were supervised by the mentor teacher at the school and the supervising professor at the college of education.

Dugdale (1994) reports that student teachers participating in the computer instruction program were enthusiastic about using computers to support their curriculum. Student teachers reported feeling confident that they would be able to use computers effectively and were eager to continue working with computers in their classrooms. Additionally, the mentor teachers in the schools were supportive of the student teacher's work and saw the assignment as an opportunity to broaden their own expertise.

Foundations for Collaborative Computer Education

Collaborative computer education expands the work of Dugdale (1994) at UC Davis and builds upon previous efforts at technology integration in the teacher education program of a large private university. During the 1994-1995 academic year, a computer-based instructional module was developed and integrated into selected sections of the course Teaching Methods in Secondary Education.
(Secondary Education 375R) (see Wentworth & Breithaupt, 1995; Breithaupt & Wentworth, 1996). This module was centered around a computerized tutorial program that demonstrated several computer-based instructional techniques. Students were taught to program with the HyperStudio authoring system and completed the activities contained in the computer demonstration program. The heart of these assignments required students to write a computer program which would support one of the lesson plans they prepared as part of their term curriculum project. The lesson plans and supporting computer programs were collaborative efforts by interdisciplinary groups of students. The computer programming assignment was made discipline-specific by requiring student groups to incorporate elements of each student’s specific teaching discipline.

By retaining the core computer courses, students are given a background in basic computer programming and software selection. Additional computer instruction which is discipline-specific for each student to the teaching methods course provides each student the basic background needed to use computers to support their own secondary education curriculum. The results of research on the effects of this computer instruction module show that the core computer courses have minimal effect on whether the students do or do not use computers to support their curriculum. However, students who received discipline-specific computer integration instruction in their Teaching Methods in Secondary Education course are significantly more likely to integrate computers into their curriculum than those who did not receive the computer integration module (Breithaupt, 1996).

Collaborative computer education extends preservice computer integration education into actual classrooms. It is designed to simultaneously teach student and mentor teachers to support their curriculum with computer technology. The student and mentor teacher team identifies problem areas in their curriculum which might be resolved by integrating computer technology into that part of the course. To assist the student-mentor teacher team, a support team is organized consisting of a teacher educator, an arts and sciences faculty member, and an instructional designer from the university. Also included in the support team is the media specialist from the student-mentor teacher team’s school. The support team is available to collaborate as needed in the revision of existing curriculum or development of new curriculum based upon the latest pedagogy, instructional technology, and teaching discipline content.

Method

Participants

Student teachers participating in collaborative computer education have already received background knowledge and experience in software selection and evaluation, as well as having participated in a computer programming project to support lesson plans they have made in their own teaching discipline. The mentor teacher will not necessarily have a strong background or education in computer use, only an interest in learning to develop computer support for his or her curriculum. The mentor teachers have the primary responsibility for the curriculum taught in their classrooms. They direct the curriculum development effort and approve all revisions. Mentor teachers have final approval on the curriculum development effort, and will decide whether or not the new or revised curriculum is actually presented to their students.

Support team members fill a variety of roles based upon the requests of the student and mentor teaching team. The support teams are made up of the following members: (a) teacher educators, who are supervising professors from the Department of Teacher Education assigned to supervise the student teachers; (b) arts and science faculty members from the university departments which teach the preservice education courses in the student teachers’ various disciplines; (c) instructional designers, professors and graduate students in instructional design and technology; and (d) media specialists, media/computer lab supervisors from the mentor teacher’s school or district.

The student and mentor teachers will, of necessity, be in the same teaching discipline. Likewise, the teacher educators and arts and sciences faculty members participating in collaborative computer education will be in the same teaching disciplines as the student-mentor teaching teams.

Procedure

During the student teacher’s teaching practicum, student-mentor teaching teams are asked to develop computer support for at least one lesson plan in their regular curriculum. The computer-based instruction may be either presented to their students in the classroom or assigned as homework. This computer support may be selected from appropriate commercially available software, or prepared by the teachers using any authoring system or programming language available. The teachers are given wide latitude in the format and methodology used. This is a collaborative development effort: the teaching teams have access to all members of the support team listed above. The support teams provide guidance, ideas, suggestions, and editorial and formative evaluation services. At the teacher team’s request, the development effort may be made available to an instructional design graduate student as an internship or project. In all cases, the collaborative effort is to be under the control of the mentor teacher. It is this teacher’s curriculum that is being developed or revised, and his or her students who will receive the computer supported curriculum. This teacher is the individual responsible for the outcome of the collaborative curriculum development effort.
Discussion

Collaborative computer education is currently undergoing pilot testing and revision. The primary contribution of collaborative computer education is to extend teacher education and professional development beyond the bounds of colleges of education to include members of the arts and sciences faculty from throughout the university. This extension connects teachers to university resources in addition to that currently available from colleges of education.

Collaborative computer education also combines development of computer supported curriculum with teacher education and professional development. Previous efforts have separated the education of student teachers and professional development of experienced teachers. Often, both efforts have yielded marginal results. Simultaneous teacher education and professional development streamlines the process and should yield improved results.

However, the real contribution of this work may not be realized until the participants have participated in collaborative computer education for a period of time. This suggests that a longitudinal study of the participants in collaborative computer education covering the next two or three years may yield additional useful data. Further study may also help strengthen curriculum and improve instructional delivery throughout the educational system.

DESIGNING VIRTUAL PRACTICUMS FOR PRE-SERVICE TEACHERS: THREE PROJECT ITERATIONS

A. Margaret Fryatt  
Nechako Electronic Busing Pgm.

David A. Gregg  
Nechako Elec. Busing Program

This paper reviews the development of three Virtual Practicums for pre-service teachers over a 12 month period. The first iteration of the project involved matching more than 20 pre-service teachers at Massey University (Palmerston North, New Zealand) with 40 students drawn from the Nechako Electronic Busing Program and Sinkutview Elementary School (Vanderhoof, B.C.). This electronic project was delivered over a period of six weeks. A second pilot project explored the potential of Virtual Practicums connecting pre-service teachers from the University of Calgary with On-line Teachers from the Nechako Electronic Busing Program for a six week on-line teaching /learning experience with E-Bus families. Recommendations arising from this experience were incorporated into a full practicum project offered during the 1997 winter term, connecting student teachers at the University of Calgary with On-Line teachers from the Nechako Electronic Busing Program.

Literature Review

While there is a growing research base that supports the notion of providing technology training for pre-service teachers [Levin, (1995), Duckett (1995), McClintock (1994), Maddux, Johnson, and Harlow (1994), Kester and Beacham (1994)], and also a growing body of research that describes some of the necessary features of on-line learning environments [Hiltz (1995)], there is almost no research that describes how pre-service teachers might acquire the skills necessary to create, foster and evaluate on-line learning activities for direct use with students.

Levin, Waugh, Clift and Brown's (1995) Teleapprenticeship Model developed at University of Illinois, looks at support systems for pre-service and beginning teachers. His model does not look at using technology to develop on-line teaching skills or to assist in the design, delivery and support of computer mediated learning activities.

The models developed by Makurat, (1994), Gunn, (1994) Kester and Beacham, (1994) look at teaching pre-service teachers how to use electronic mail and then try to extend these skills into collaborative learning activities. These models and projects do not explore the skills, knowledge and attitudes important in preparing teachers to use telecommunication technologies to actually teach distant students. This project is an attempt to gather that information.

Project One: Massey University Students

The purpose of the project was to explore the skills needed to develop, deliver and support educational activities electronically to elementary students and to provide opportunities to integrate technical skills in teaching practice. The student teacher pairs created 3-6 learning activities to achieve stated learning outcomes supported by Internet resources and delivered these via electronic mail over a 3-4 week period. Learning how to use electronic mail and Internet tool skills were vital.

Data. Messages between all parties were collected and archived. Transcripts totaled approximately 135 pages. Student teachers were also asked to record comments, observations, and insights weekly in a reflective electronic journal. Message and journal texts were examined for the emergence of factors and themes significant to participants.

Identified Themes and Discussion

1. Significant Organizational Factors included:
   - Roles and responsibilities
   - Clarifying expectations
   - Establishing timelines
   - Assumptions/cultural backgrounds and differences.

   Future projects could be improved by sharing class schedules, assignment dates, and holiday times. Clarifying expectations about the amount of electronic communication necessary during the start-up period between student teacher pairs and the facilitator would also be helpful.

   Creating an archive of projects to which new student teacher pairs can refer will be extremely useful in future efforts.
2. Management Factors included:
- Managing volume of communications
- Updates - keeping all parties in the picture
- Adjusting to change; making modifications.

In retrospect, handling ten groups of communicating partners amounted to more traffic than should have been attempted in an exploratory project. Reducing the number of groups or sharing the mentorship task would reduce this load. Involving classroom teachers in providing feedback directly to student teachers in the planning stage would be very helpful.

3. Project Factors: Planning, Preparation, Delivering, Supporting and Evaluating:
- Partner selection and group process
- Topic selection
- Identifying resources
- Setting goals/learning outcomes
- Background knowledge
- Time
- Instructions and referencing resources
- Expectations for students and student work
- Feedback.

Project activities need to be blended into an integrated series of steps towards a specific goal; these steps need to reflect more clearly the important aspects of good pedagogy.

The provision of superior Internet resources to support projects is very important. Unfortunately groups who provided an insufficient number of supporting resources, or used inappropriate resources for the specific task had real problems with the completion rate of tasks or lessons. The task of locating resources cannot be passed on to the students unless adequate guided practice is provided first.

Formatting of messages needs to become much more important. Being able to draw the student's attention to important information within a text based medium is an art form. The biggest formatting error was to include too much text in each message. Students need instructions broken into manageable chunks — perhaps outlining what can be accomplished in one 30 minute session. Consistency in referring to activities as lessons, or tasks was also helpful, but a feature that many groups overlooked. Preservice teachers with a higher degree of Internet literacy might be able to take advantage of posting materials on the Internet.

Feedback and how it is provided to students is also important. Personal messages from both partners making specific references to earlier communications were valued by the participating students and their parents. Both students and parents requested that answers be provided so that self checking could occur. Evaluation of student work requires further exploration.

4. Communication Factors:
- Learning to use electronic mail / e-mail etiquette
- Security
- Frustration at amount of feedback provided by students.

This collaboration hinged on the ability of the student teacher pairs to use electronic mail as their fundamental communication tool. Quick and effective communication was particularly crucial at the beginning of the project when the greatest number of concerns arose.

The early pattern of once a week communication was not sufficient to support the kind of collaboration required to get all of the groups off to a productive start. The initial lag on message turnaround was a significant factor in successful completion. As the project progressed, the number of contacts per group per week increased and this allowed for more efficient feedback and problem solving.

It was very important that expectations surrounding the frequency, and the format for messages be established early in the process. More time needed to be devoted to the less formal exchanges of information that occurred at the beginning when curiosity was high. The immediacy of communication between parties was what excited and captured the interest of elementary students. Teaching all parties to check their mail regularly and to respond to each new messages was an extremely important task.

Many of the elementary students had minimal keyboarding skills, thus responding to information requests took time away from completing the “job”. Students tended to respond with generalities instead of specific information, and time lags between receiving the request and answering it varied according to other pressures in the classroom. If students come to expect new “mail” each time they check, then they will quickly learn that checking is important. If they receive quick answers to their questions, then asking for clarification via e-mail becomes an option for them. When no communication occurs the parties involved assumed that no work was being done. This was often incorrect. Students were so busy “working” they didn't have time for e-mail (which was not seen as part of the work). Student teacher pairs should communicate in future directly with classroom teachers who can provide valuable feedback that the children are unable to articulate.

Student teacher partners working with students from elementary classrooms, experienced different problems than those working with students from the Electronic Busing Program. Students in classroom settings operated in a largely independent context where there were competing demands on their time and energy, assistance was not always readily available, and access to computer networks and Internet resources needed to be shared. Students from the E-Bus program had more guidance and supervision from parents at all times, and were able to concentrate their energies on completing the task at hand.

736 Preservice Teacher Education — 733
This project was a very time consuming undertaking requiring many more hours of preparation than the average classroom lesson. Student teachers simply ran out of time. Students who could tolerate high levels of ambiguity, decided to proceed with a course and action that could be modified as needed. Others, faced with indecision, had difficulty completing the project. It is important to recognize that in addition to this undertaking, Massey University students were involved in many other class activities that demanded their time and attention.

5. Technical
   - Hardware/software
   - Access to lab facilities
   - Basic computer literacy
   - Learning/applying skills simultaneously.

   If this kind of project is used as a vehicle for teaching pre-service teachers how to use electronic mail and Internet tools in educational practice, two distinct phases should occur. In the first phase, student teachers acquire and practice the skills needed; in the second phase, they can concentrate on applying the skills to the task of creating, delivering and supporting on-line activities. If additional access to lab facilities cannot be provided, then groups will need to organize themselves to make sure that regular e-mail contact is maintained with students, and with the facilitator.

Recommendations

1. Require that participating student teachers have basic skills in using electronic mail and Internet tools OR develop the project in two stages.
   - Stage One would focus on learning how to use e-mail and Internet tools,
   - Stage Two would explore how these can be used to support electronic learning activities and collaborative exchanges between partners.

2. Share complete time table information in advance so that timelines are more appropriate.

3. Create a complete archive of papers, and projects from this year’s participating student teachers to be provided to the next group of student teachers.

4. Limit the number of groups participating in the project, or share mentorship tasks.

5. Involve classroom teachers and parents in the planning of projects and in providing feedback and mentoring.

6. Emphasize the connections between good pedagogical practice in a classroom and good pedagogical practice in preparing learning activities for electronic delivery.

7. Pay special attention to resources provided to support activities, and to how activities are formatted for use with elementary students.

8. Increase the volume, frequency and quick response of communications between participants at all levels.

9. Concentrate on creating an electronic communication “process” which articulates the expectations with students. Invest time in the initial stages of the project establishing with students what good electronic communications look like and what kinds of information must be shared.

Project 2: Calgary Students

Two student teachers from the University of Calgary were paired with teachers from the Nechako Electronic Busing Program in May, 1996. The first tasks of these students were to set up the computer, become familiar with the software, arrange for Internet connections, and to prepare an electronic letter of introduction to forward to all clientele. These letters were then electronically circulated to parents. At the same time, e-mail correspondences were begun between the student teachers and the cooperating teachers to establish a rapport and a common understanding of the practicum.

Several tasks were required of the student teachers over this short, six week practicum. Initially, Internet searches were conducted to identify resources that could be utilized in a variety of instructional settings. The student teachers then constructed discrete units of study that employed some of the strengths of electronic communication. These units evolved through several iterations in order to have them not resemble correspondence courses with a directive teacher approach.

The intent at this point was to have volunteer E-Bus families work with the student teachers to implement the unit and then offer feedback on its effectiveness. Due to time limitations and the fact that many families were winding up their academic activities for the year, the student teachers did not have an opportunity to completely implement their work. Evaluations of the process proved to be quite positive. student teacher or parents? Initial responsive journal entries focused on the paradigm shift required for on-line work, and later moved to a more comprehensive discussion of the trials and benefits of the process.

Project Three: University of Calgary Students

Another Virtual Practicum Project was proposed for the winter 1997 semester at the University of Calgary that followed the model of delivering curricular support online. Student teacher tasks would include clarification of BC Learning Outcomes Identify for parents, identifying Internet resources to meet learning outcomes, writing tutorials of pedagogical techniques, the development of online projects for specific groups of students and expansion of the e-bus.com web page.
Student teachers will also explore the Internet as a source of on-line professional development to challenge their own thinking about teaching and to encourage them to develop new ideas and skills. Other responsibilities will also include communicating and negotiating with parents on when, what and how to assess student growth and report this information.

Drawing on the experiences of the previous virtual practicums several prerequisite skills were identified as well as the development of a profile of a student teacher who would benefit from such an experience.

Prerequisites skills tended to focus on tools skills, electronic resource and communication skills and pedagogical skills. Tool skills included a basic computer literacy and comfort with at least one operating system and a knowledge of basic applications such as word processing. Electronic communication prerequisite skills that would benefit a student teacher in a virtual practicum include a knowledge of e-mail and the ability to search the world wide web. Students with a wide range of teaching and subject experience will find the practicum experience more rewarding and gratifying considering the diversified nature of the clientele; specialists might not get the opportunity to draw upon their particular area of expertise.

Further, successful participants in previous virtual practicums include a willingness to be a problem solver, the ability to tolerate change and ambiguity, a degree of creativity and flexibility and the willingness to relinquish instructional control to parents and value them as full partners.

A number of ongoing expectations for student teachers participating in the Winter 1997 virtual practicum were articulated:

- weekly scheduled meetings online
- entries in a reflective journal
- participation in an educational listserv.
- correspondence between student and a number of volunteer E-Bus families
- connection of student teacher with a classroom teacher for development of a specific classroom-based project.

A number of specific projects were to be completed over the 13 week practicum:

- develop a simple web page and resource page
- work with a specific web resources and develop several ways to integrate the resource into curriculum (learning outcomes) through multilevel learning activities
- collect Internet resources to support a specific theme, topic or cluster of learning outcomes with very general descriptions of how they might be used
- develop an e-mail based project such as a writing or editing activity, letter exchange, or data exchange

- develop an integrated thematic unit equal to about 5 hours of student time. This would involve the student teacher in planning, delivering, managing, and assessing student learning for the project they design.

Conclusion

The format for the Winter 1997 practicum and the Virtual Practicum Project in general has enormous potential as a vehicle for accomplishing a series of diverse aims within any teacher preparation program. It provides a meaningful reason for learning Internet skills and offers an application of these skills into classroom settings. Student teachers are also encouraged to integrate curriculum across traditional subject and age boundaries as they integrate technology into practice. Opportunities to connect pre-service teachers with experienced classroom teachers for a mutually beneficial experience are presented. Such collaborations have enormous potential not only to further our knowledge of the processes and skills involved in online teaching, but also in providing an application of technology skills into teaching practice that require a high degree of integration.

Preservice teachers have the opportunity to mesh theory with practice in an introductory course linked to the Fifth Dimension Project. This paper reveals the theoretical underpinnings of an early field experience as well as its value to a future educator. The Fifth Dimension Project is an international distributed literacy consortium located in after school programs under the auspices of Boys and Girls Clubs, YMCA/YWCA’s, recreation centers and public schools. This project includes a cultural system with rules, artifacts, and a division of labor that combines play, education, and peer interaction (Cole, 1995). At Appalachian State University preservice teachers enrolled in an introduction to teaching course have an opportunity to participate in The Fifth Dimension during their laboratory experience. This project provides an opportunity for undergraduates to connect theory with practice while providing a rich technological context for children to acquire knowledge and literacies mediating cognitive and social development.

The goals for the introduction to teaching course include developing an understanding of the teaching and learning process, identifying the various tasks and responsibilities of a teacher, becoming knowledgeable of the diversity in today’s classroom, gaining experience with technology, using reflection as a tool for professional development, and making decisions about teaching as a career. Initially, students complete a preassessment instrument which surveys current definitions of teaching, learning, technology, etc. Course readings provide theoretical knowledge of teaching, learning, and schools. Classes are held twice weekly on the university campus and a two-hour lab is scheduled on alternating days in a technology lab in a public school. Students are engaged in conversations and reflections throughout the semester during class meeting dates, along with notes conferencing and electronic field notes written immediately after each lab experience. A post-assessment instrument gathers personal reactions to the class and field components with regard to the cultural and intellectual development of each individual participating in the Fifth Dimension community.

Purpose of the Study

The purpose of this study was to determine if undergraduates could connect the theoretical underpinnings of cultural-historical activity theory (CHAT) with cultural practices in the Fifth Dimension laboratory experience. Findings from two semesters of class discussions, field notes, assessment instruments, and course evaluations were analyzed. There were 35 university students involved in the study. Each one was a prospective teacher and was an applicant for admission into the College of Education.

Approximately 70% of the students were pursuing a degree in elementary education and the remaining students were seeking degrees in either secondary education or a K-12 program such as special education, speech pathology, or physical education. These students were enrolled for either the spring or fall semester of 1996. The majority of the students were sophomore, female, and Anglo-American.

Merging Theory with Practice

Former psychology and foundations courses provide a schema for educational theories for the preservice teacher. Prior knowledge of Piaget, Skinner, Vygotsky, etc. is discussed and elaborated upon to create a base for extending theory into practice. One activity assigned to students is to describe how an activity such as learning to tie a shoe would occur according to one’s theoretical orientation. The responses give insight into students’ understanding of behaviorist, cognitivist, and social constructivists views of learning. Although most students have had previous experiences with these theories, they lack concrete examples of the principles guiding theories such as CHAT. Insight is gained on all theories while the lab experiences target furthering the learner’s knowledge base for CHAT. Within the context of the Fifth Dimension, practice does not mean action to be repeated to a level of automaticity. Students are not practicing a teaching skill to achieve perfection. Rather, students are actively engaged in technological activities such as computer games and electronic mail, and practice is viewed as a social activity.
Preservice teachers learn about technology, teaching, and learning simultaneously. Throughout the semester, conversations bridging field experiences with pedagogy are encouraged.

**Roles of Preservice Teachers**

Defining the role of the preservice teacher in the Fifth Dimension setting is problematic initially as a result of the influence of their prior and multiple experiences as pupils in school. The confusion is theoretical in nature and comments such as “I don’t see what I’m learning about teaching here” were made by preservice teachers early in the practicum. Most defined teaching as information giving or guiding. Therefore, when children were teaching them or when play occurred, their traditional role of teacher was questioned. With increased understanding of the theoretical underpinnings of Fifth Dimension, students began to accept their role in the community and gained more confidence when they were not always the information giver in the lab. This shift in how one defines teaching and learning is a major thrust in their preservice training. When the preservice teachers ceased to worry about being the authority on games and activities, reflections regarding the quality of their relationships and affiliations with the students increased. Students began to see themselves as partners in learning and also began to take a different direction with assigned children in the lab. Possible roles played by preservice teachers were expanded. A peership evolved in some situations where the university student felt a need to explain the special characteristics and needs of his partner as topics of diversity arose in the university classroom.

At the present time, some children enrolled in the Fifth Dimension program have reached the expert level in technology - referred to as Young Golem Assistant. When preservice teachers are linked with an expert child, it quickly becomes clear that the “teacher authority” role does not work. The child knows much more about the program of games than his partner and therefore assumes the role of the more knowledgeable member of the community. It is here that the concept of the zone of proximal development becomes clear. Each member of the community brings a level of performance and understanding to the setting. What is easily comprehended by one member may be a high level of frustration to another. Socialization occurs as the more knowledgeable one attempts to share what is known. Evidence that learning is a social activity before it is a cognitive one is affirmed. Preservice teachers observe firsthand how one’s thinking develops through language mediated social interactions.

**Results of the Study**

When interns begin to draw conclusions about the validity of the theory which drives practice in the Fifth Dimension experience, other dilemmas arise. Interns soon see themselves as active participants in a classroom rather than former passive recipients of teacher directed learning. They express a sense of accomplishment from total immersion into a practice that was driven by a theoretical base. Future learning was projected to be influenced by the conclusion that a community setting can be of tremendous value - especially when the more accomplished members strive to bring group members from a level of frustration to one of understanding and independence. In many instances, teaching and learning are redefined in the post assessment instruments. Interns are no longer operating under the assumption that they are solely responsible for all the learning that should occur in a classroom. Each member can assume some responsibility.

**Future Projections**

University students pursuing a career in teaching are well served by a practicum with the Fifth Dimension. It offers an opportunity to have an early clinical experience with children, to merge theory with practice, to learn about technology, and to make important career decisions. Follow-up studies of these preservice teachers to determine paradigm shifts about teaching, confidence with technology, and attitudes towards children would be beneficial. Insight could be given into the validity of meshing theory and practice during the pivotal years of teacher training. These studies could also assist in reshaping how teaching and learning are defined inside and outside school.

PARADIGMS FOR PRESERVICE TEACHERS: EMPHASIS ON TECHNOLOGICAL INTEGRATION

Richard A. Diem
The University of Texas at San Antonio

The continuous advances in technology over the past two decades have radically altered our access to information, facilitating prospects for a truly world-wide community of learners. The growing number of computers in the schools and rapid proliferation of instructional software, coupled with the rich educational content being added to the Internet daily, have the potential to provide an effective and exciting environment for teachers and students alike - one where technology can help teachers to teach, and in helping students to learn. Unfortunately, all too often we must think of these opportunities in terms of potential, not reality. We are still at a point where we can only imagine a world in which the successes of our students are eloquent testimony to the ways in which we have employed technology in the classroom. We know, through a myriad of research done over the past twenty years, that the wise use of technology can lead to improved student achievement, motivation, self concept, attendance, and enhanced instruction. The question still facing all of us in education is how transform our schools so that they will reflect this knowledge. One way is through recruiting and training preservice teacher who might be predisposed to this philosophy, even before they begin formal teacher training.

Collaborative Training Paradigm

In 1992, a collaborative effort began in San Antonio, Texas involving all the teacher education programs from throughout the metropolitan area. Representatives from these entities, several independent school districts, the community college district, and the local business community came together to draft a mission statement and set of goals for a collaborative organization that would have far-reaching impacts on a variety of educational environments in San Antonio. As a result of these meetings, a proposal was sent to the Texas Education Agency that led to an initial grant award of almost two million dollars for the 1992-1993 school year for the establishment of a Center for Professional Development and Technology (CPDT). One of the original eight Professional Development Centers funded across the State of Texas, the San Antonio Center for Education Development and Excellence / Centro Educacional para el Desarrollo y Excelencia, or CEDE, was the only award recipient from a major metropolitan area during the first year of CPDT funding.

The CEDE signatories included five universities; six independent school districts; three private schools; a community college; an education service center and representatives from the local business community. Through its first four years, CEDE partnerships have expanded to include twenty five (25) Professional Development School Sites.

CEDE’s ongoing mission was, and is, that of a collaborative community that can serve as a center of inquiry dedicated to the continuous life-long development of teachers as learners in a culturally diverse, technologically enriched environment. It was dedicated to serving the teachers of the greater San Antonio and South Central Texas areas with innovative teacher education programs that would be field based and technology oriented. Two unique features of CEDE were that it represented an unparalleled collaboration among local educational and community institutions and that it was designed to cultivate classroom teachers, school administrators and teacher educators who could meet the educational needs of the multicultural populations in South Texas’ schools.

Developmental Background - Training

As the collaborative began to take form, its partners recognized that one of the greatest challenges facing their teacher education programs was how to adequately prepare potential teachers to respond appropriately to the linguistically and culturally diverse student populations found in the professional development settings they were forming, while developing a technologically rich environment. Research noted that the problem the collaborative was facing was of one of the factors that caused disproportionately high failure rates among minority students; namely, a failure of the learning setting to accommodate cultural diversity (Marshall, 1993).
The collaborative partners felt that one possible answer to the problem of the lack of the cultural responsiveness in educational environments might be to increase the number of minority teachers who knew how to use and integrate technology in those schools. To meet this challenge CEDE's teacher preparation programs needed to find a way to increase the number of minority education students participating in their programs.

The CEDE collaborative understood that recognizing this need and doing providing a solution for it would be difficult, at best. Indeed studies reveal that 92% of all preservice education students are white and have minimal exposure to technology (Goodlad, 1990). Based on this data, increasing the number of technologically oriented minority students going into the teaching profession would also require dramatic changes and increased minority recruitment projects designed by the CEDE teacher education programs.

Addressing the problems of minority recruitment in teacher preparation programs had also become one of the most important educational issues in the State of Texas during the time period. A policy research report produced by the Texas Education Agency (T.E.A.), related that the Texas teaching force was far from matching the diversity of its student body. For example, in 1992-93, 52% of Texas students were minorities while 77% of the teaching force was white (Texas Education Agency, May, 1994).

This discrepancy prompted T.E.A. to suggest that teacher education programs throughout Texas develop minority recruitment projects in teacher preparation programs through a model of professional, school, and community partnerships which would link colleges of education, schools, and perspective teacher education students. As Arthur Greenberg (1992) has noted, a significant push towards this an interest in collaboration in these efforts is an awareness that recruitment of minorities to become professional educators will require a community wide effort in which institutions of higher education will be asked to play a much larger role than was previously reserved for them. These partnerships will serve to prepare preservice teachers, induct novice teachers, and support experienced teachers as well as to experiment with new ideas and conduct research in the study of teaching (McIntyre, 1994).

From its inception, CEDE partners recognized that, in addition to providing professional development opportunities for preservice and continuing professional educators, they also had a responsibility to recruit prospective teachers. With San Antonio's distinctive multicultural mix, especially its Mexican American population which constitutes over half of the community, one of the specific objectives of CEDE was to recruit and increase substantially the number of minority teachers in San Antonio area schools (San Antonio Center for Educational Development and Excellence, 1992). This goal is congruent with nation wide developmental efforts that call for imaginative recruitment programs developed through private and public resources to attract minority students to professional education programs (Donnelly, 1988).

As part of CEDE's commitment to enlisting new teacher educators, especially from minority populations, two summer institutes for prospective educational professionals were developed. These institutes, for students who might choose teaching as a career, were designed for different age groups. One institute was for high school students, who had completed at least the ninth grade, and the other was for college students who had completed their freshman or sophomore years. As per CEDE's overall goals, both institutes actively sought minority participants.

The High School Institute

The first CEDE High School Summer Institute was held in the summer of 1993. The program's focus, then and now, was to recruit primarily minority students who had expressed an interest in the teaching profession and to further their pursuit of teaching by providing a variety of educational professional and technological experiences that would expose them to a variety of occupational endeavors available to them as professional educators.

Students were actively recruited from seventeen Bexar County (San Antonio) Independent School Districts and private schools. Interested participants were required to submit an application with two letters of reference, current G.P.A. standings and a letter of purpose. In its three years, one hundred and eighty five (185) students have applied for admission to this program. Of these, one hundred and fifteen (115) high school students have participated in this Institute. Sixty two percent (62%) of these youngsters have been minorities; of whom ninety two percent (92%) were female.

A significant focus of each of the institutes has been the discussion, demonstration and use of educational technology. Efforts were made to incorporate current and future technological advances in the curriculum. Students have produced their own newspapers and evaluation portfolios using the most up to date computer laboratories. They have visited university computer centers, have been instructed in the use of interactive television and had opportunities for hands-on application of a variety of other interactive technologies. They have also been trained on the use and function of the Internet.

Students also visited innovative PDS sites at the early childhood, elementary, middle, and secondary levels, that incorporated technology into their learning environments. Sea World Education Center, the Fiesta Texas Education Center, the Southwest Research Institute, and a visit to one of the CEDE business partners have also been on the agenda.

740 — Technology and Teacher Education Annual — 1997
The two most enthusiastically received trips have been to the YO Ranch near Kerrville, Texas and to the Children's Association for Maximum Potential (Camp CAMP). The YO Ranch adventure consisted of a ropes challenge course and a team-building experiences course. Camp CAMP is a summer program for children who are so medically, emotionally or physically challenged that they would be unable to attend other camp programs. The CEDE students were particularly drawn to this population and were encouraged to have hands-on experiences with the campers while there. CEDE students have taken this challenge and as a result in the summer of 1994, for example, six CEDE high school student volunteered their time at camp after the completion of the CEDE program.

In addition to the “field trips,” seminars were held to provide information on financial aid, college admission procedures, SAT and ACT review procedures. Sessions on innovative classroom technology, programs for the future in a “fair” format, and a discussion on gangs and violence in the schools sponsored by the Bexar County Probation’s Department have also been held.

The College Institute

As with the High School Institute, the College Institute has been held since 1993. College and university students apply for the CEDE college program through their own respective schools. They are given a scholarship to attend and three hours of credit through each college and university participating in the program.

The agenda is primarily the same for both the university and high school cohorts; however, the university format deletes college information and provides instead teacher certification information. Additionally, students have an opportunity to meet with a panel of teachers representing various grade levels and areas of specialization. This panel of teachers provides the college students with insights into the challenges of a teaching career.

In addition to preparing and editing a newspaper of their experiences, as the high school group does, the collegiate cohort must also develop an individual portfolio. The portfolio includes a daily journal, a review of at least five current education articles, a resume and a personal, autobiographical, section. These portfolios are presented orally to the entire group on the final day of the program and then given to respective professors from each of the universities for further evaluation.

As with the high school institute, one of the primary goals of the college institute is to recruit minority groups into teacher education programs. Over the its first three years, the CEDE College Institute has attracted 40 college students, of whom seventy (70%) percent were minority; ninety five percent (92%) of whom were female.

Evaluation

In an effort to evaluate the Summer Institute program a ten item questionnaire that focused on programmatic and affective queries was mailed to all of the students who had enrolled in either the CEDE High School or College Institute in 1993, 1994, or 1995. One hundred and twenty (120), of one hundred and fifty (155) participants current addresses were available. Of the 120, twenty five were returned as undeliverable. Thirty one (31) questionnaires (40%) were returned in completed form. Of the thirty one, 25 had attended the High School Institute and six had attended the College Institute. Since the numbers were small, responses were analyzed in aggregate form and were not broken out by High School or College responses. Completed forms from minorities constituted 82%. Over 90% of the respondents were female.

Twenty nine of the respondents indicated that they still intended to pursue a career in education. Fifteen of this group indicated that the CEDE Summer Institute influenced or strengthened their decision to go into teaching.

The students noted that “CEDE helped me to confirm my decision to teach and remove any doubts I had.” Another stated that “I’ve always known that I wanted to teach but wasn’t sure I had “what it takes.” CEDE showed me that there isn’t just one way to define a teacher and that YES I do have “what it takes.”

The participants indicated that the most meaningful parts of the institute were related to: (1). interaction and visits with teachers and students in school site settings that used technology; here a student noted that “it was the actual times we went to schools and interacted with children that affected me the most.” (2). working with children; especially during CAMP Camp trip; a youngster stated that “these visits encouraged my decision to teach.” (3). bonding activities including the ropes course at the YO Ranch; commentary here noted that “The most meaningful part of the program was the bond, the oneness, the unity we all had as aspiring potential teachers. We all shared a belief. Strangers became friends.” and (4). use of technology in educational oriented activities; “CEDE taught me that there is more than one way to teach and that education doesn’t always occur in a school.”

Commentary

The CEDE Summer Institute experience has been a success from its inception. The goal to encourage minority students to enter the teaching profession has been met and constantly reinforced through the institutes determination to attract a full spectrum of students to become professional educators.

The use of school sites as teaching laboratories has helped strengthen CEDE’s ties to the teaching community and made the program as realistic as possible. The notion that one can learn best through actual observation and
interaction rather than from mere abstractions is a constant part of these efforts.

Further, CEDE has helped students understand their particular academic and interpersonal skills that can contribute to the teaching profession. It has done this through activities that bring students together showing them that they have the ability to work with groups and as individuals in problem solving situations. These are the very skills that all classroom teachers need if they are to be successful.

The call for reform in public education and teacher education has been directed toward both public education and teacher education programs (Commeyras, Rienking, Heuback, Pangucco, 1993; Dixon, and Ishler, 1992; Goodlad; 1984, Holmes Group, 1986, 1990). The Holmes Group (1986, p. 56) advocated that a design for improvement in tomorrow's schools is found in the structure of the professional school, as a collaboration between universities and public schools. These professional schools would bring practicing teachers and administrators together with university faculty in a partnership to improve teaching and learning by students at both institutions. Various approaches, both traditional and innovative, have been used to support this venture, in a search to find the most effective and efficient way to provide educational experiences for all involved. This paper describes how one university and its surrounding public schools have addressed this issue by joining forces to enhance the learning of both the public school students and the university's preservice teachers. The team has joined together to use a combination of technology and both new and traditional teaching methods to improve the skills and abilities of preservice teachers. One approach to this issue combines the concept of cognitive coaching with the infusion of technology into both the professional teacher education courses and the public school classrooms into which these preservice teachers have been placed.

Using technology as a widely recognized and necessary tool and cognitive coaching as a valuable technique, the collaborative team received greater insight into what an ideal teacher education program should contain and offer its preservice teachers. Technology and cognitive coaching added a new dimension to the professional course sequence and the students' field experiences, supporting the instructional decision-making processes of preservice teachers.

Cognitive Coaching

Cognitive coaching, one of the new buzz words in education, is a supervisory/peer coaching model that supports informed teacher decision-making. It is a nonjudgemental process that is built around a planning conference, observation, and a reflecting conference. Anyone in the educational setting can become a cognitive coach—teacher, administrator, department chair, or support personnel. In this program, though, it is the student teacher supervisor who becomes the coach who propels the preservice teacher into making decisions about teaching.

Cognitive coaching is organized around three major goals:

1. establishing and maintaining trust, an assured reliance on the character, ability, or strength of someone or something;
2. facilitating mutual learning, which is the engagement and transformation of mental processes and perceptions; and
3. enhancing growth toward holonomy, which is defined in two parts: individuals acting autonomously while simultaneously acting interdependently with the group.

These three goals help to develop and maintain a fundamental trust which creates a safe environment for learning and change in a preservice teacher. This learning by the preservice teacher and the coaches (both the university supervisor and the public school faculty) encourages all partners to move beyond their present capacities into new behaviors and skills. The entire process is based on incorporating the following:

...[the basic principles of knowledge construction by Jerome Bruner, Jean Piaget, and Hilda Taba; the adult learning theories of Malcolm Knowles; human development sequences based upon the work of Jean Piaget, Lawrence Kohlberg, Frances Fuller, and Eric Erickson; the neurolinguistic studies of]
When the preservice teacher becomes an autonomous individual the person becomes self-asserting, self-perpetuating, and self-modifying. Then the preservice teacher becomes a member of the school community and begins to function interdependently, recognizing the capacity to both self-regulate and be regulated by the norms, values, and concerns of the larger system. The preservice teacher begins to realize the capacity that influences the values, norms, and practices of the entire system. (Costa and Garmston, 1994).

**Integrating Technology and Cognitive Coaching**

Technology is a tool that assists preservice teachers in becoming self-assertive, self-perpetuating, and self-modifying. In the year-long program, preservice teachers participate in an internship during the first semester, and are residents during the second semester. Fifty to sixty secondary and all-level preservice teachers begin the program by becoming familiar with basic computer skills before or during the internship semester. The students move to advanced computer skills in the resident semester. Students start with discovering why they should learn to use the computer and what it has to offer, and then move through assignments that include sending messages by e-mail, doing research on the internet, and making slide presentations for their classes—as well as the traditional word processing database and spreadsheet educational applications. By the end of the year many are amazed at what they have accomplished and how valuable the knowledge and skills they have gained will be used in their classrooms.

At the same time, in their seminars they are introduced to cognitive coaching and its purpose. Students work with the same mentor teachers for both semesters, which gives an air of continuity to their year in the field, allowing them to explore and then move through assignments that include sending messages by e-mail, doing research on the internet, and making slide presentations for their classes—as well as the traditional word processing database and spreadsheet educational applications. By the end of the year many are amazed at what they have accomplished and how valuable the knowledge and skills they have gained will be used in their classrooms.

By the end of the year many are amazed at what they have accomplished and how valuable the knowledge and skills they have gained will be used in their classrooms.

**Goal One: Student Achievement**

The entire procedure of cognitive coaching is coupled with the use of technology to enhance performance. In accomplishing the first goal, the area of student achievement, preservice teachers develop a database to keep student records, and actually chart and graph student progress. The preservice teachers also show these charts to their students so that the students, themselves, can monitor their own progress as they prepare for the future. For example, one preservice teacher charted the progress of her students in a weightlifting program. By the end of the teacher's term, the students, for the first time, could see that they were making progress and they continued the program instead of becoming discouraged and transferring out of the program.

**Goal Two: Cognitive Development**

For the second goal, the area of cognitive development, preservice teachers find instructional strategies that support their specific subject areas, and materials that will help them improve their skills in classroom organization and management. They modify their instruction in the classroom as they begin to visit different Web sites that show sample lesson plans. For the example, they use search engines to find and then visit sites relevant to their teaching fields, and explore the links found at these sites. Two favorite sites have been the Armadillo WWW server (http://chico.rice.edu/armadillo) and SEARCH—the Cisco Educational Archive (http://sunsite.unc.edu/cisco/schoolhouse.html). The preservice service teachers are coached into integrating what they find into their daily lessons. For example one preservice teacher shared how he had asked his students about fish and their sleeping habits. He did not know the answer to his questions himself, but because he had learned how to get online to get up-to-date information about the science questions, he was able to retrieve his information and start his class the next day with the answer and photos he found online. Another example comes from an art class. A preservice teacher had downloaded, with the help of his mentor teacher, artwork that refined a lesson on drawing lines in a particular way to develop a picture. Students watched as the mentor teacher and the preservice teacher team taught the lesson from the monitor. Students in both of these instances enjoyed and learned the latest information from the Web.

Preservice teachers visit their university supervisor's web page (http://www.tamu-commerce.edu/coe/shed/justice) to look at multicultural lessons and to visit other sites that help them understand and work with special students. In addition to visiting these sites, preservice service teachers are encouraged to produce their own activities that can be added to some of the sites or share what they have done by sending responses to certain home pages. These activities give preservice teachers a chance to...
really think and evaluate what they see others do and what they actually do in their classrooms.

Goal Three: Professional Growth

For the final goal, professional growth, the teachers visit premiere educational organizational sites, and also look at job opportunities on TENET, the Texas Educational NETwork. From the TENET web site (http://www.tenet.edu), preservice teachers are able to access information about each district in the state. They get a chance to decide upon the district in which they would like to teach and began to learn about the districts before they interview with prospective personnel directors at the job fair that is held each year on the university campus. Students are also able to look at the professional organizations in the state and begin to decide on which ones will be an asset to them.

Online Communication

After the initial development of their goals, the preservice teachers communicate with the supervising teacher through e-mail. Coaching takes place online and in person. They share their experiences based on the three goals and evaluate their teaching experiences by sending journal reflections to the coaches (university faculty, public school teacher, and peers). Some of these personal reflections have included asking for advice when conferencing with parents; asking questions about seminar assignments and student classroom behavior; and discussing the ups and downs of their experiences. In addition, they communicate with their peers online to get support about some of their ideas, and they share and ask for advice about what they have learned. The computer facilitates this sharing and coaching.

Students also communicate with other professionals who teach in their subject area. This helps them understand the process of what other professionals go through when they are planning lessons. These professionals (other teachers) give them tips that assist them in organizing their classroom and in the how-to-skill of applying instructional strategies and management techniques. Since textbooks cannot be replaced every year, the information that is given by these professionals is more up-to-date material than they are apt to find in their schools. This online contact has richly added to the improvement of their lessons, especially when they are also able to get tips on student motivation, learning styles, multicultural materials, government documents, biographies of scientist or authors, and news magazine articles. Preservice teachers have included some of this information in the presentations that they have made in their classes. These preservice teachers have discovered that the Web has actually added personality, depth, and breath to their original information. A favorite site for these types of information is the Classroom Connect web site, at http://www.classroom.net/.

The Portfolio

The preservice teacher ends the semester with a portfolio that demonstrates personal and professional growth. The portfolio is an appropriate vehicle for metacognitive awareness. All of the coaches can see a term's work through the goals performed and reflected upon through the use of technology. The goals that are included grow out of interactive experiences and are not imposed from the outside. The specifics are important to the author because of the reflective change that could not be foreseen in the area of both personal and professional growth.

The portfolios contain students' vita, philosophy of teaching, and the three goals that they have achieved throughout the semester. This portfolio can assist them in seeking employment, but most of all, it helps them measure their students' growth under their supervision and their own growth and development as a teacher. In addition, they are able to move on to advanced technological skills that include building their own web pages, using other technology in the classroom, and helping their students communicate with other students electronically.

Summary

Research indicates that teaching is a complex intellectual activity and that preservice teachers who think at a higher level produce students who are higher achieving, more cooperative, and better problem solvers. Using technology enables preservice teachers to arrange their environment not only to enhance intellectual capacities but also to modify themselves.

If teaching is an art, the selection and identification of creative talents and abilities may be at the core of changing the kind of students that are training to become teachers; however if teaching is a science, then tested and verifiable training experience may be the answer. If, as Gage (1972) states, teaching is an instrumental art, then one may need a combined approach to producing good teachers. The cognitive coaching model used in conjunction with a variety of technologies, assist pre-service teachers in cognitive development that promotes a deep understanding that may not be present in programs that do not combine a theoretical frame for developing and interpreting practice. Combining cognitive coaching with the use of technology is one such innovative approach, and anyone who is involved with it can understand that it is definitely producing a new breed of teachers.

Technology and Change in Schools: The Roles of Student Teachers

David M. Marcovitz
Florida Atlantic University

I think it’s energizing to have a student teacher. I think they keep you current. I was very impressed. Jackie knew her word processor very well. She had the Powerbook since the very beginning. She was very comfortable with email. She was very comfortable with using any of the programs. It didn’t scare her to go in, pop in a program, and to play around with it. That, from a technological standpoint, I think is a real breakthrough. As compared to last year, while I had a terrific student teacher, technology was not a real strong suit. She just hadn’t been exposed to it. And the year before that even less.... The young people always keep me really thinking, “Am I doing what I need to be doing?” (Sarah, interview, May 5, 1994)

We do not often think of student teachers as change agents. Their role is that of apprentice and student, learning to be good teachers. Change agents come into situations as experts ready to transform a situation.

The nature of school is such that it is slow to change. From an organizational standpoint, it is almost a closed system with few avenues of input from the outside. Student teachers can be one of the few sources of input and new ideas for a school. This exaggerates their role as change agents and places them in the conflicting position of students and change agents at the same time.

Because of this conflict, student teachers can have a wide range of functions in supporting technology and change in the schools. Sometimes they initiate change and bring in new ideas; sometimes they directly support the efforts of teachers to change their classrooms with technology; and sometimes they indirectly support teachers’ change efforts.

I spent several months at Burnham Elementary School (this and all other names in this paper are pseudonyms to protect the anonymity of the participants) as part of a qualitative study of support for technology and innovation. In this paper, I discuss a continuum on which student teachers live: from student to teacher, and I discuss the kinds of things I observed student teachers doing to support technology and how these things fit on the continuum. I tie student teacher support into a theoretical context of organizational theory, situated-evaluation, and a theory of support for innovation.

Research Methodology: Ethnography, Case Study and Situated-Evaluation

This study combines methods of ethnography, case study, and situated-evaluation. I combine my experience and my interpretations of the experiences of the participants to build an understanding of what I observed and how it relates to support for innovation.

In parts of the 1992-93 and 1993-94 school years, I spent several hours each week at Burnham Elementary School observing classes, talking informally to teachers, interviewing teachers, and attending school and district Technology Committee meetings.

Situated-Evaluation and Support for Technology

Situated-evaluation is an important theoretical basis for my approach to this research. Bruce (1993) contrasts traditional views of an innovation as the chief actor in a situation with the situated-evaluation view:

In reality, the innovation is but one small addition to a complex social system. Instead of seeing it as the primary instrument of change, it is better to see it as a tool that is incorporated into ongoing processes of change.

We are thus led to a different model for implementation of innovations. In this model, the active agents are not innovations, but the participants in the setting in which the innovation is placed. Participants interpret the innovation and then re-create it as they adapt it to fit with institutional and physical constraints, and with their own goals and practices. (p. 17)
In this view of innovation:
1. The participants in the setting are the chief actors.
2. The innovation is an idealization that will be achieved more or less when brought into the real situation.
3. This idealization is interpreted and recreated by the participants in the setting to adapt it to fit the context and constraints of the setting.
4. Every situation is different, so the innovation-in-context will be different for every context.

Situated-evaluation is an important way to look at support because it helps us understand why support does not always meet its objectives. A situated-evaluation approach might find that the support was inadequate because the designers of the support did not account for the contexts and constraints of the situation, or it might bring about a better understanding of how the situation and the support interact to provide different, not necessarily better or worse, support than what was originally intended.

Research Procedures
In this ethnographic study (Marcovitz, 1996), I developed new models for support and innovation by looking closely at support for technology and the use of technology in three 3rd and 4th grade classes at Burnham Elementary School. I spent most of my time with these three classes and their teachers: Sarah, Jennifer, and Cindy. I also looked more broadly at the 3rd/4th grade of Burnham Elementary School, the school in general, and the district.

I began my study by looking at the impact of changes in the school, especially the change in principal and the change in computer coordinator. Those changes were rich sources of information and comparison data, but they were not the primary focus of the study. Even the three teachers who were the primary participants in the study became the context of the study, rather than the primary focus. By the end, the study focused on models of support and innovation as they applied to the situations in the three classes and at the school and district more generally.

The Roles of Student Teachers
Student Teaching Programs
Burnham Elementary School is near a major university that provides most of the student teachers. The university has three student teaching programs: the junior practicum, the standard semester-long placement, and the Full Year Program.

The junior practicum provides juniors with a limited exposure, a few hours per week for a few weeks, to a classroom.

The standard semester-long placement is a one semester assignment in one classroom that culminates at the end of the semester in a three week take-over period during which time the student teacher is almost completely in charge of the class.

The Full Year Program is a two semester assignment in which the student teacher spends time in three different classrooms. The Full Year students are loaned Powerbook Macintosh computers for the year to facilitate communication among the students and their university supervisors.

The Student to Teacher Continuum
Student teachers’ primary function is to learn. They are students. They are not in schools to act as direct or indirect supporters of change.

First of all, that is not a criteria that they are for support. That is not at all. In fact, people who say, “I want a student teacher because I’m going to have an extra pair of hands in the room,” is one of the first indicators that you don’t want a student teacher for the right reasons, the reasons that you can model and teach a student. So I really disagree with that. They can be support. Daniel [Cindy’s student teacher in the spring] was support, but there are many student teachers out there that are of no support; they’re more work for a teacher. (Cindy, interview, May 16, 1994)

Student teachers never completely escape their student role; their function is to learn to teach and practice being teachers. But at times, they are teachers. The roles of student and teacher form the ends of a continuum of roles. At Burnham, I observed four somewhat distinct roles for student teachers that lie along the continuum: student; adult; adult plus; teacher.

These roles are not completely distinct in two ways. First, any given action can be interpreted in different ways and be interpreted, for example, as more or less like the action of a teacher. Second, the student teacher is usually acting in multiple ways, and at any one time could be in several different roles.

Student Role. In the student role, the purpose of the student’s actions is to learn about teaching. This can take the form of observing and talking to the teacher. In some cases, it can interfere:

Cindy told a story about a student teacher who used to constantly take notes. She found the practice a little disturbing, especially at a parent-teacher conference. She said that parents are already uncomfortable about having a student teacher at a conference, and it was inappropriate for him to be taking notes. (fieldnotes, informal conversation with Cindy, September 30, 1993)

Adult Role. In the adult role, the student teacher is acting like any adult volunteer would in the classroom. The student teacher’s role does not require any special training or status.
Sarah [the teacher] decided that Ken [3rd grade student] should write down the directions for what he did so he could remember. Sarah got Ken to tell Anne [the student teacher] what he did so she could write it down. (fieldnotes, Sarah's after-school program, October 26, 1993)

In this example, Anne is doing something that any adult volunteer could have done.

**Adult Plus Role.** In the adult plus role, the student teacher is doing something special that most adult volunteers would not do. Volunteers might perform these tasks, but the tasks would generally require some training or status. The adult plus role includes disciplining students for misbehavior, spending time alone with the class (a privilege reserved exclusively for certified teachers, substitutes, and student teachers), working on special projects with students, and providing special expertise. Jennifer had a difficult class, and she spoke about how someone, such as a student teacher, could be very helpful to her.

Jennifer said that her class is unmanageable. She can’t spend time with one student because if she turns her back, the rest of the students will be out of control. She said that if she had a student teacher or someone else who could be involved with the rest of the students, she could work with one student on the computer to show them some of the advanced features of ClarisWorks. While she is by herself, she can’t work with one or a few students on the computer. (fieldnotes, interview with Jennifer, December 16, 1993)

**Teacher Role.** In the teacher role, the student teacher does things that are generally done by teachers. This is most evident during take-over when the student teacher has primary responsibility for the class. This also can be seen when student teachers give instructions and permission to students.

Renee and Terri finished. Connie [the student teacher] showed them how to save and told them they could go around and help others. (fieldnotes, Cindy's class at the university computer lab, October 5, 1993)

The four levels on the continuum are merely marking places, not absolutes. In most cases, student teachers are working in multiple roles, and any given role falls somewhere between the marking places listed here.

**Support for Technology**

Student teachers support the use of technology in different ways, some of which provide direct support to the teacher’s use of technology, and others indirect support.

I observed nine functions of student teachers that support the use of technology in the classroom, and that can be classified along the student to teacher continuum. These functions and their categories are:

1. take-over, teacher
2. teamwork, teacher
3. projects, teacher
4. future, teacher
5. alone with class, teacher or adult plus
6. university resources, adult plus
7. discipline, adult plus
8. expertise, adult plus
9. general help, adult

**Take-Over.** During take-over student teachers provide indirect support for technology. The purpose of take-over is to provide student teachers with a practice teaching experience. But if take-over goes well, the student teacher is in charge of the class for three weeks, giving the teacher a three-week period to spend time away from the classroom or working on special projects, including technology projects, with a few students at a time.

Sarah had several computer applications she wanted to teach her students during the school year. She said she plans to concentrate on Hypercard, Hyperstudio, Lego Logo, and ClarisWorks-in-the-Classroom.... She said she is going to pull students out to work on these things while the student teacher is in take-over. (fieldnotes, interview with Sarah, March 10, 1994)

While the three-week take-over period did not provide Sarah enough time to do everything she wanted to do with technology, it did serve as a time to take steps toward her goal of integrating technology throughout her curriculum.

**Teamwork.** “What's nice about having them [student teachers] is the teamwork. You feel like there is a lot of brainstorming that goes on when you're creating units” (Sarah, interview, May 5, 1994). Sarah reported a sense of teamwork from her student teachers that allows her and her student teacher to bounce new ideas off of each other and exposes her to new ideas. Cindy warned that some student teachers never reach a point where they are helpful, but others are “naturals:”

It works out lovely if you do [have a good student teacher], and many of us have very good teachers. These are the naturals, that I call them, so we didn’t have to spend as much time training them, but we were able to immediately draw them into co-teaching with us, this teacher associate idea. (Cindy, interview, May 16, 1994)

Graham (1993) discusses the potential for conflict and uncertainty as well as the potential for teamwork and growth:

But this shared situation also creates an opportunity for genuine collaboration—a dynamic which
engages and alters both teacher and student teacher as they explore each other's intentions and reflect upon their shared work and teaching context. Faced with such a task, their relationship has the potential to become "joint work," the kind of collaboration most likely to lead to sustained professional growth and change. (pp. 213-214)

Projects. Cindy's class participated in the TeleOlympics, a project in which students compete in athletic competitions and email the results to other schools to be tabulated. As part of the TeleOlympics project, Daniel (Cindy's student teacher) organized the results in a spreadsheet. Cindy would have had difficulty doing this without Daniel. He offered computer expertise: while Cindy was comfortable with word processing, her experience with spreadsheets was limited. He offered an extra helper: this was a labor intensive project because the students could not do most of the computer work themselves—they had not learned spreadsheets, and the email was set up so that Daniel had to send the messages for the students—so Cindy would not have been able to spend the time on this project without her student teacher.

Future. With networking technology, schools across the country and around the world have more of an opportunity than in the past to communicate with one another and participate in joint projects. One implication for this is that student teachers can maintain a relationship with their cooperating teachers once they move to their own classrooms in other schools. For example, Daniel expressed an interest in continuing his contact with Cindy, "Daniel wants to get involved in TeleOlympics and do email with my class wherever he is."

Alone With Class. At Burnham Elementary School, only certified teachers are allowed to spend time alone with the class. The exception to this is student teachers. This issue was most prominent in Jennifer's class because she had an aide who was not certified, and Jennifer could not leave the class alone with her for extended periods of time. In take-over, student teachers provide long periods of time that the teacher is free to leave the room. At other times, when the student teacher is ready, the teacher can leave the class alone with the student teacher in order to attend meetings or prepare for the class.

University Resources. As part of the Full Year Program, the student teachers are provided with Powerbook Macintosches. Cindy suggested that the student teachers be encouraged to bring their Powerbooks to the classroom to use as an extra computer. Both Daniel (Cindy's student teacher) and Jackie (Sarah's student teacher) brought their Powerbooks into the classroom regularly. "It was great, as far as the technology goes, to have these people because they were specifically trained [with technology]" (Cindy, interview, May 16, 1994).

The Powerbooks were brought into existing situations: classrooms that are trying to use computers and finding that they could use more. The support was being altered in two ways. First, the teachers were asking the students to bring their Powerbooks into the classroom to use as an extra computer. Second, some teachers were asking if they could use the Powerbooks outside of school. What started as support for student teachers was altered to become support for teachers and classrooms.

Discipline. In my observations, parent volunteers rarely disciplined students for misbehaving, but student teachers did regularly. This provided indirect support for technology by allowing teachers to work with small groups of students while student teachers maintained order in the rest of the class.

Expertise. Some student teachers, especially those in the Full Year Program had training and expertise with technology. This allowed them to work on additional projects and offer support for the teacher's projects. For example, when Cindy was showing her class some of the basics of Microsoft Word, Connie (her student teacher) helped her with some of the things she was not sure about.

In Connie's case, Cindy was fairly new to word processing, and Connie was more advanced, so she was able to help Cindy with some of the basics of the word processor. In Daniel's case, he was fairly proficient with several aspects of the computer, such as email and word processing, so he was able to do computer projects with the class.

General Help. Although the purpose of student teachers is not to provide an extra pair of hands for the teacher, they often serve this purpose. For technology, this was especially evident when the teacher took classes to the university computer laboratory. In this lab, the students worked on computers to learn educational games and computer applications. As the students played the games, or worked on the word processing activities, they asked many questions, including: asking permission to go to the bathroom; asking basic technical questions such as "Where is the delete key?" asking questions about the assignment; asking for help. When student teachers or other adults were present, they answered these questions. In many cases the questions were simple enough that any adult could answer them, but this helped relieve the burden for the teacher.

Discussion

Student Teachers and the Organization of Schools

Scott (1987) discusses organizations in terms of open systems. The way an organization interacts with its environment can have a major impact on the organization—the more open the organization, the more significant the role of the environment.
Structurally, schools’ organizations are set up in such a way that contact with the environment is limited. Other than contact with their students and students’ parents, teachers get a great deal of information filtered down to them through principals. This limitation on the interaction outside limits the information which teachers can receive.

Teachers do have contacts with the environment. One of the significant contacts can be through student teachers. As Sarah said, “The young people always keep me really, ‘Am I doing what I need to be doing?’” (Sarah, interview, May 5, 1994). Firestone (1989) suggests that district-level policies filtering down to the schools are the main influence on school change. But he also discusses support: “Sometimes a school lacks the knowledge or skills to do what is required to use reform. Sometimes it lacks the personnel, time, and materials” (p. 161). While Firestone (1989) discusses what the district should do to target support to the needs of the school, in some cases, support exists from factors in the environment, such as student teachers.

**Rising Credibility and Rising Proximity**

Marcovitz (1996) extends models of innovation and support (e.g., Hall & Hord, 1987; Strudler, 1991) by creating a model of support for technology in which the goals of support are support-received and inspiration. These goals are influenced by credibility of the supporter, proximity of the support, and relevance of the support.

In addition to support teachers receive from student teachers, student teachers provide inspiration. Sarah spoke about the student teacher as “energizing,” giving her the opportunity to discuss ideas and reflect on her practice. In a way, the student teacher provides the opportunity for the teacher to inspire herself by reflecting on her practice, validating some of her old ideas and challenging others.

In terms of support-received, student teachers have high proximity: they are in the classroom on a daily basis. Credibility and relevance vary based on the student teacher’s different roles.

In the adult role, credibility and relevance are not an issue because the student teacher is generally being directed by the teacher to what the teacher feels is relevant. However, both credibility and relevance can be a factor based on the teacher’s trust in the student teacher (credibility) and the student teacher’s abilities. Anyone can monitor students at the computer, but the teacher might not rely on someone with no computer background to be of any assistance.

As credibility and relevance increase, the teacher can place the student teacher into more of an adult plus role, relying on the student teacher for expertise and discipline.

With enough credibility and relevance, the student teacher can take the teacher role. All student teachers are placed in the teacher role for the take-over period, but the amount of support that is to the teacher varies based on relevance and credibility. The class remains the responsibility of the teacher, who must feel comfortable leaving the student teacher alone with the class to go work on other projects.

The amount of support-received from the student teacher varies as the teacher can use the student teacher in roles of increasing responsibility along the student to teacher continuum. This generally follows how relevant the ideas of the student teacher are perceived to be and how much credibility the student teacher has.

**Summary**

Although student teachers are not placed in classrooms to provide support to the teachers, they often do provide support at various levels in roles ranging from student to teacher.

Technologically knowledgeable student teachers can provide direct support by being technical consultants, working on projects with students, and bringing teachers up-to-date information about the use of technology in classrooms.

Student teachers can provide indirect support for technology by taking care of students (teaching large or small segments of the class, disciplining students, providing an extra pair of adult hands), allowing the teacher to do technology projects with the whole class, small groups, or individuals.

Student teachers can bring new ideas to teachers, energize teachers, and provide a sense of teamwork for teachers.

Regardless of the intention of student teacher programs, student teachers can provide support to teachers. For at least a short time, student teachers are part of the classroom, not isolated from the teachers, and in some cases, are able to help implement projects on a day-to-day basis. Due to a need for day-to-day help with technology, some teachers have partially recreated the role of the student teacher to be an integral part of support for technology.

PRESERVICE TEACHERS AS MENTORS DURING AN EARLY FIELD EXPERIENCE THROUGH ELECTRONIC COMMUNICATION (E-MAIL)

Kathryn LaMaster
San Diego State University
Deborah Tannehill
The Ohio State University

In 1989, Paese wrote, "The field experience component has always been a vital part of teacher education programs" (Paese, 1989, p. 18). With a national emphasis on educational reform both The Holmes Group (1986) and The Carnegie Task Force (1986) agree that field experiences should be an integral part of teacher education programs. Because field experiences function as a critical link between formal teacher training and apprenticeships researchers should study what happens to students in the field (Dodds, 1989). These early field experiences provide information to students so they can determine their suitability for the teaching profession, orient preservice teachers to schools, and begin the socialization process for potential teachers (Dueck, Altmann, Haslett, & Latimer, 1984).

Mentoring might be one way to develop more effective field experiences for preservice teachers. Bey (1990) noted that mentoring in education has developed along with the growth of support programs for preservice and inservice teachers. Mentoring traditionally refers to a relationship where experienced teachers work with new teachers to strengthen their teaching skills and assist them in the ongoing process of becoming a teacher.

Encouraging peer support during teacher training has been investigated (Dodds, 1975; Verabioff, 1983). A peer assessment model became a viable way for preservice teachers to support one another in the student teaching environment. Peer tutoring is another strategy designed to allow a student to teach another student of approximately the same age and skill level (Cooke, Heron, & Heward, 1983). While providing useful information these investigations have focused on traditional methods of conducting preservice teaching field experiences or traditional mentoring relationships. Future investigations should include other innovative training methods as well as examining the role of technology and electronic communication in the process of educating preservice teachers.

Telecommunications, and specifically electronic mail (e-mail) systems are available on most academic campuses. These systems transmit messages in seconds and it has been suggested that they could become the arena for teachers to share ideas, teaching plans, and problems without having to leave the classroom (Bull, Harris, Lloyd, & Short, 1989; D'Souza, 1992; Eiser, 1990). E-mail has been studied to determine its function and usefulness (Durham & Sunal, 1991), its role as a supplement to classroom communications (D'Souza, 1991; Poling, 1994; Schrum, 1988, 1991), and its usefulness in facilitating collaborative opportunities (Buchanan, Rush, Krockover, & Lehman, 1993; Rush, 1993).

"Every day hundreds of thousands of people are communicating through the Internet" allowing individuals to become friends without ever having met (LaQuey, 1993, p. 41). "Handicaps and disabilities make no difference" when people are communicating through e-mail and online communication (LaQuey, 1993, p. 41). E-mail "eliminates barriers" and prevents communicators from "making judgments" about those with whom they are communicating based on appearance or voice (LaQuey, 1993, p. 41). The advantages of e-mail are several. It is a cheaper way of communicating especially if the communication requires long distance phone charges. Messages can be delivered in seconds without waiting for a written message to be delivered to colleagues in another country (Kent, 1994). Since the connection is asynchronous (not at the same time) e-mail is also convenient to use. Users can send and exchange messages at their own convenience rather than having to worry about time zones or opportunities to connect through telephone (Kent, 1994; LaQuey, 1993). E-mail does have some limitations. Messages are in text form and cannot contain special formatting such as italics or underlining as is used in word processing. A limitation for many is the lack of interpersonal face to face communication. E-mail is a form of conversation, but it is less formal than written letters and lacks inflections found in verbal conversations (Kent, 1994). While there are some ways to communicate emotions using e-mail (symbols) messages can also be misinterpreted more easily due to the casual form of this communication (LaQuey, 1993). Aside from these limitations, "electronic mail is the most popular..."
application in use on the Internet today” (LaQuey, 1993, p. 42).

Teacher preparation programs have utilized e-mail as a way to establish and maintain communication between new teachers, experienced teachers, and university professors (Eskridge & Langer, 1992, 1993), and as support for student teachers (Casey & Vogt, 1994; Hoover, 1994; Lowe, 1993; Thompson & Hamilton, 1991). The potential impact of telecommunications on communication during preservice teachers’ field experiences and other aspects of teacher education requires further investigation. Establishing a communication link between cohort groups of preservice teachers would seem to be a valuable part of their preservice educational process (Eskridge & Langer, 1992; 1993). As yet, there are no studies that have looked at the use of e-mail in a physical education preservice teacher training program.

**Purpose**

The purposes of this study were to determine if field experience students’ could provide one another with support, guidance, and pedagogical feedback concerning classroom issues using e-mail, and to gain the students’ perspective on the use of electronic communication in the field experience process.

**Subjects**

Subjects were 23 juniors in the methods year of a Physical Education Teacher Education program. Selection of this population was determined by the following criteria: access to computers and electronic mail (e-mail) accounts, basic computer knowledge, involvement in a teaching experience, and researcher access. All subjects were enrolled in a secondary teaching methods course and had previously been taught introductory managerial techniques and teaching strategies. These preservice teachers had taken a basic computer skills course prior to the study and utilized e-mail in another course. These subjects were members of a teacher education physical education cohort group and had been in classes together for a period of two and a half years. They had a well established social system and were considered both a social and academic group. Technologically, these subjects were novices with no established communication network, academically or socially. These characteristics were specific to these subjects.

**Data Collection**

E-mail reflector lists, were established for subject use during this project and were monitored by the researcher. Messages posted to reflector lists were sent to subjects on the list for their access and reading.

Six major sources of data were collected for five weeks and included subject participation in e-mail tasks such as posting teaching questions, responding to peers’ questions, and maintaining weekly journals. Subjects also completed pretest and posttest surveys, one week e-mail logs, and participated in group interviews.

Subjects were asked to reflect upon their teaching and utilized their e-mail accounts to post queries to their peers on the reflector list. In addition to posting a query, subjects were asked to react to at least two other posted queries. Peer reactions took the form of ideas, suggestions, and other pedagogical feedback to their peers concerning their queries. Both queries and peer reactions went to all reflector list participants and the researcher.

Weekly journals were also submitted and followed an established question format intended to probe and encourage subject responses concerning this study. During the five week data collection a one week e-mail log was also completed by the subjects. E-mail logs were used to determine types and frequency of messages sent by participants.

A small group interview was conducted with each of the three reflector list groups at the end of the five weeks. All interviews utilized a semi-structured format which included questions concerning positive aspects of e-mail communication, drawbacks to e-mail, comparison of identified benefits and drawbacks, and hypothetical future situations in which the subjects would use e-mail for communication.

Upon completion of the field experience subjects were administered the Delcourt and Kinzie (1993) Attitudes Toward Computer Technologies and modified Self-Efficacy for Computer Technology survey for preservice teacher educators. This survey was administered in a pretest and posttest methodology.

**Data Analysis**

Queries were read and reread until primary foci emerged (Patton, 1990). Focus categories were inductively derived and included five categories; instruction, management, student behavior, and other. All queries were coded into one of the categories.

Peer responses were read in the same manner and categories emerged. These categories were determined by their agreement or disagreement with the query and whether they provided alternative suggestions or strategies. This categorization was confirmed by a colleague who read all of the subjects’ peer responses and categorized them in the same manner as the researcher. The categories included agreement, agreement plus strategy, strategy only, disagreement plus strategy, disagreement.

Journals were read to ascertain subjects’ perceptions of whether or not their field experience peers could provide assistance concerning classroom issues using e-mail communication. They were also examined for subjects’ perceptions of the usefulness of peer feedback, ideas, or alternative strategies provided in peer responses. Since
journals followed a question format, each question was analyzed individually by the researcher.

Analysis of questionnaires was conducted through a comparison between changes in individual item mean scores and shifts in individual item responses (Gravetter & Wallnau, 1992). A simple t-test was utilized to further evaluate the surveys. A t-test is "used to test for significant differences between statistical measures of two samples" (Burns & Grove, 1995).

E-mail logs were examined to determine types of messages sent and possible changes in e-mail use by participants. Data were used to determine the number of connections, average connection time per use, and the preferred day of the week to use e-mail for all participants.

Three small group interviews were used to determine subjects’ perceptions and attitudes concerning this project and the use of e-mail. Participants were asked to identify benefits and disadvantages of e-mail communication as well as their perceptions on future potential uses in their careers and lives. Each question had an individual categorization of patterns or themes depending on the question focus and the types of responses received.

Queries, peer responses, journal responses, and group interview categories were confirmed by a colleague who read all of the entries and categorized them in the same manner as the researcher with 100% agreement.

**Results**

After reflecting upon their teaching these subjects were able to describe their lessons and pose questions to their peers using e-mail. The lesson descriptions were detailed enough so that their teaching colleagues who had not observed the lesson were able to interpret what had occurred and develop ideas and strategies concerning the lesson. In addition to merely posing questions, subjects sought the advice of their peers in their postings.

Preservice teachers focused on instructional aspects of teaching most often in their queries. These subjects were able to read their peers’ questions, interpret them, and respond by posting feedback using e-mail. Additionally, they were able to be positive in their responses. While a few subjects were able to provide some criticism to their peers concerning their teaching, the negative comments were always accompanied by strategies. Journals provided the subjects’ perceptions concerning the use of e-mail and this mentoring study. Information from the journals indicates that subjects were able to read their peers’ responses and interpret the pedagogical feedback that was given. Also, they were able to determine if this feedback could be useful if applied to future teaching episodes and if it was supportive in nature. Subjects reported feeling more confident in their teaching as a result of peer feedback. As a result of being able to understand the feedback many subjects indicated that changes in their upcoming lesson plans would occur.

E-mail logs revealed that most of the messages sent were a requirement of the study. While there was a small percent of messages sent concerning other academic issues, e-mail clearly was not something these subjects used to accomplish communication with professors or instructors. Requiring the e-mail messages from the subjects was viewed as a motivating factor for those who had difficulty with the e-mail system during the study.

There was no significant change in subjects attitudes toward computer technology during this study. Subjects did have a significant change toward increased self-efficacy in this study.

Subjects were able to verbalize their thoughts and perceptions concerning e-mail during the interviews. Answers to the questions posed were similar among all participants during the group interviews. These subjects seemed to value the use of e-mail, specifically noting the ease of communication. The subjects also liked the aspect of being able to send messages and communicate without the other individual necessarily being at home. The greatest complaint that these subjects had revolved around the issue of difficulty with access. Typically the subjects who had e-mail access at home were more positive about using this type of communication. Overall the subjects did believe that the benefits of e-mail outweighed the drawbacks they identified.

The world of education is caught in a bittersweet dilemma. On one hand, we are very excited about the innovations of the modern technological age and the promise technology holds for the field of education. On the other hand, we are perplexed as to how to utilize these technologies to their fullest potential. Many schools are coming online with their own direct connections to the Internet; yet, their teachers are sometimes ill-equipped with good ideas of how to integrate these new technologies into the curriculum (Bernauer, 1996).

This paper focuses on how the Internet is being used to connect students in two small school districts, Central Heights Independent School District (CHISD) and Arp Independent School District (AISD) with preservice teachers at Stephen F. Austin State University (SFASU). Through the Partners for Success project, students in grades 6-12 are gaining a resource to help them academically, while the preservice teachers are gaining telecommunications and teaching experience as “Online Tutors”.

Over the past four years, teacher preparation programs in Texas have placed a major emphasis on field-basing their education programs. Stephen F. Austin State University has participated in this effort of putting preservice teachers into the school setting early in their programs. This effort has yielded outstanding results in both teacher preparation and student achievement.

The Partners for Success project took advantage of telecommunications to bring the preservice teachers and secondary students together sooner in the preservice preparation program than ever before. Many of the preservice teachers participating in the project were in their first semester of professional development coursework. Each was assigned as an “Online Tutor” to a student in a secondary school. This gave them an authentic teaching experience at the very beginning of their teacher preparation program. This project was the first implementation of a project of this type at this university.

Project Concept and Objectives
This project consisted of electronic tutoring activities between one hundred twenty (120) preservice Secondary Education preservice teachers at SFASU in Nacogdoches, Texas and one hundred twenty (120) Junior High and High School students at CHISD, in Central Heights, Texas. Both of these institutions have direct Internet connections which they used to facilitate the project. A small number of students from AISD also participated via dial-up connections. University students in the preservice program were paired one-to-one with secondary students (grades 6-12) in an online guiding/tutoring relationship. The project took place over an eight week period during the Fall 1996 semester.

The objectives of the project were:
1. To introduce preservice teachers to the experience of teaching.
2. To provide Junior and Senior High School students an opportunity to interact with a college student.
3. To provide academic help to students in areas of need.
4. To create in the student a greater interest in attending college.
5. To improve the telecommunications skills of participants at all levels.

Project Details and Definitions
Through weekly electronic mail interactions, preservice teachers worked as online tutors to provide assistance in an academic area to their assigned student. The online tutors and the students were each assigned their own individual email addresses and were given the opportunity to check their email and write messages every few days during the project. Each student identified an academic area in which they wanted to improve. The online tutor provided resources which they thought might be of help to the student. These resources included the tutor’s own knowledge, references to library materials or textbooks, references to Internet sites, Web pages, hints on study techniques, etc. The students were expected to attempt to use any of the suggestions that seemed appropriate and give feedback to the tutor. In addition, the tutors created World Wide Web pages which acted as a collection of resources for their students or any other student studying similar topics. In addition, another group of preservice teachers who interned on the school campus through the University’s field based program were also involved. Their role was to work with the students to help them utilize any instructions or resources received from the online tutor.
Project Results

At the end of the eight week period, the project concluded with the sending of a final message from the online tutor to the student, stating that they had enjoyed working with them and wishing them continued success in school. An informal survey of students, teachers, and online tutors who participated in the project was conducted. The responses from each group of participants are reported below.

Student Responses
1. The CHISS student’s telecommunication skills improved from having participated in this project. Sixty-three (63) percent of the students indicated that their telecommunication skills improved somewhat; whereas, twenty-one (21) percent of the students reported experiencing great improvement.
2. The majority of students (80 percent) responded that teachers allowed them to check their email about once per week; however, seventeen (17) percent checked their email every two weeks and two (2) percent check their email less that once every two weeks.
3. Thirty-eight (38) percent of the students indicated that their online tutor was of no help to them; however, thirty-four (34) percent responded that their online tutor was of some help, and twenty-seven (27) showed that their online tutor was a lot of help by providing information for their project or subject area, providing them with Web page addresses, and helping with their telecommunications skills and in other ways.
4. Thirty-two (32) percent indicated that the project positively affected their interest in attending college in that after having corresponded with a college student they are were more interested in attending college that then were when the project began.
5. Eighty-six (86) percent of the students responded that they would participate in this type of project again. Only thirteen (13) percent indicated that they would not participate in this type of project again.

Teacher Responses
Responses from the teachers indicated that students benefited from participating in the program by improving their technology skills and gaining additional knowledge in the academic areas they had identified. Reflections from teachers involved in the project revealed the need for more effective communication among all participants. It should be noted that this project was planned and implemented totally through the use email. In coming semester, face to face visits between the university and school personnel both during the planning and implementation of the project.

Online Tutors’ Responses
Ninety-six (96) percent of the SFA online tutors indicated that their telecommunication skills improved as a result of participating in this project however fifty-seven (57) percent of the tutors felt that they were of little or no help to their students. Thirty-nine (39) percent reported that they were of help to their student primarily by providing information for their students to use in a class project and by providing references to web pages that were of interest to the students. Reasons given by those who felt that they were of no help to their online students included that their students never wrote them or wrote them rarely, and that longer periods of time were needed to interact with their students. Online tutors should expect different levels of success in actually being able to help their student in a given area through such a project (O’Neill, Wagner, and Gomez, 1996).

When asked if they felt that future preservice teachers should be required to participate in a project like this, the ninety-one (91) percent of the online tutors said “yes.” They went on to say that the experience gives them an opportunity to interact with students and to discover how technology can be used to supplement instruction.

Also, when preservice teachers were asked “What did they learn about being a teacher from having participated in this project?”, the responses included the following: Teaching is a two-way process, teachers must be knowledgeable about the nature of the learner, they must possess effective organizational skills, they must have self confidence and patience because they will not have all the answers, and I can help a student more that I thought.

Play It Again

Plans are underway to repeat the project in the Spring semester of 1997. Specific action items have been targeted for improvement of the project during its second implementation. Instead of trying to make all arrangements online, face to face meetings between the university project coordinator and all participating teachers will be held at the beginning, middle, and end of the project. Steps will be taken to monitor the writing activities of both preservice teachers and their online students more closely to insure prompt and meaningful responses to message received. Duration of the project will extended from eight weeks to ten weeks in order to give more time for groups to utilize limited facilities. Teaching interns will play an increased role in helping students to identify their academic area in need of improvement and in the utilization of messages from their online tutor.

Conclusions

Many preservice teachers enter their programs never having experienced the opportunity to teach a child. Although at the beginning of their program they may be unprepared for the classroom experience, modern telecommunications technology makes possible for preservice teachers the experience of interacting with students in remote schools without ever having to leave the university campus.
Online projects require considerable time and effort of all involved. Planning is crucial to prevent any delays in communication. Everyone involved in the project including the project coordinator, university professors, school administrators and teachers, university students, and school students must not only have the technological support and resources for such a project but also have a clear understanding of the project guidelines and an enthusiastic determination to see the project succeed. When these are in place, all participants will benefit.

The need to teach students to think is not a new idea in American education. Early in this century Dewey (1910) along with other educators called for making the teaching of thinking a goal of formal education. In 1982, the Education Commission of the States concluded that higher order thinking processes should be the “basics” of education (Education Commission of the States, 1982). Robert Sternberg, a leading educator, has asserted that the teaching of thinking should be “the first order of business for school” (Quimby, 1985, p. 53).

Thinking Skills and Strategies
When we discuss the need for schools to teach thinking some people respond that this has always been done. Of course thinking has occurred in schools, however, the quality of thinking has been questionable. Schools have emphasized rote memorization and the accumulation of basic knowledge while putting little emphasis on processes such as problem solving and decision making. Students often make such comments as “Outside school I have to figure things out, but in school I don’t have to really think. I just have to remember what the teacher or the textbook said.” Because of a concern about the life-long relevancy of much of school learning, the teaching of thinking has become a major focus in education. Information may become outdated. Thinking skills and strategies don’t become outdated. They remain constant and useful across content, context, and time (Allen, Hutchinson & Wood, 1995). As Sternberg suggested, the ability to engage in skillful thinking is an important survival skill for society and individuals (Sternberg, 1984).

Thinking can be defined as a search for meaning and at some level is a natural human process. However, quality reflective thinking, like other skills we develop, takes guidance and much practice. Effective skillful thinking does not seem to occur naturally for most people. David Perkins, a Harvard researcher in education, asserts that everyday thinking is as natural as walking. It happens without any formal training. However, to become a skillful effective thinker able to deal with the complicated reality of today requires specialized and specific training. Perkins believes that good thinking is, in fact, often contrary to natural thinking. For example, he states that while we know that good decision making requires that we look at all sides of an issue, this is not a naturally occurring process (Perkins, 1985).

Like the learning of other skills, the process of becoming a good thinker is very much an individual experience. All of the principles of learning and development apply to the learning of thinking. For example, students learn in a variety of ways. What works with one student won’t necessarily work with another. Students learn at their own individual pace; they don’t all learn at the same rate. However, there is evidence that students at all levels can benefit from strategy training (Allen, 1990).

There are numerous variables which contribute to the swelling tide of educators who believe that the teaching of thinking must become the focal point of education. It is not within the scope of this writing to address all of these variables. However, I will mention briefly three major variables. These include research related to learning and instruction, information issues, and the inability of students to engage in effective higher order thinking processes.

Research
Communications research, the development of technology, and the theoretical approach of the information processing framework have all contributed to a new understanding of instruction and learning. We now know more about how the brain functions, how people process information, and better ways to facilitate learning. Specifically, there is research on which to base the teaching of thinking skills and strategies.

Information Issues
In the past, the role of school was thought to be the dispenser of information. This role is being challenged for at least two reasons. First, the amount of information is increasing at an unbelievable rate. Second, there is a serious lack of agreement on what “information” should be taught in school. Information and knowing are important. However, what is known is constantly changing and therefore information becomes outdated. Thinking skills never become outdated (Sternberg, 1984).

School Learning
The inability of American students to engage in the processes associated with higher order thinking and problem solving has been cited as a major concern...
research based approach to problem solving. Also, the lack of transfer of school learning to "real life" has been observed by students, educators, and employers.

According to Beyer (1987), there is more emphasis on improving the thinking of American students today than ever before. This message should be loudly resounding through the halls of the Colleges of Education because unless teacher education programs focus on this approach to teaching, students will be unprepared for the reality of this kind of classroom.

**Technology**

Another critical aspect of education today relates to the rapid changes occurring in the world. These changes, especially those related to technology, have created challenges which must be addressed in our teacher education programs.

Computers are already in the homes of about one third of the American population and in middle class neighborhoods, up to 75% of families own computers. The prediction is that 80% of all families will have home computers by the year 2000 (Debeham & Smith, 1994; Friedman, 1994). Therefore, it is essential that teachers be at the forefront of those in our society who have access to, and proficiency with technology. And in this regard, teacher education programs should be leaders, not laggards.

Once we have addressed the need for teachers to be aware of and prepared to integrate technology into their classes, the next issue becomes ways in which the technological explosion can be used. In "Automating the Past or the Future", Van Horn (1994) states that "...many of today's applications of technology simply automate the past" (p.336). He elaborates on the topic and suggests that the basic skills of the past are not the basic skills of the future. The basic skills of the future are the use of powerful technologies. One primary use of these powerful technologies is to engage in effective thinking and problem solving.

The traditional textbook can no longer keep a breath of the rapidly changing world conditions and the knowledge explosion that is a part of our daily experiences. The traditional teacher-directed classroom is no longer an effective delivery system to prepare students for the realities they face.

Pre-service teachers must be prepared to do things differently than most of them encountered in their schooling experiences. As teacher educators, we have a responsibility to provide the tools and experiences that will prepare them for using technology to do research and solve problems.

This paper will focus on a model for having pre-service teachers engage in the activities of reflective, critical, and creative thinking. The model uses technology to provide a research based approach to problem solving.

The **Process**

The first step of the process involves introducing students to on-line work and providing them with the vocabulary that will facilitate their searching. This is accomplished through modeling and hands-on practice. The students observe while the teacher demonstrates the process. During the demonstration, the teacher is engaging in a "think aloud" protocol The process is:
- Identifying an area of interest for research
- Developing a problem statement
- Analyzing the problem statement to identify key concepts for on-line searches.
- Identifying appropriate search resources
- Engaging in the search
- Critiquing the outcomes
- Using critical thinking skills to review the findings
- Weighing the evidence related to the problem statement
- Making a decision related to the problem statement
- Sharing the decision making process with other class members

After the demonstration, there is a discussion of the process, the internet, and related concepts. At this point, the preservice teachers engage in a series of simulations to reinforce their understanding of the vocabulary and computer functions associated with using the internet. During this phase of the procedure, the more technologically experienced and confident students become teachers for their peers.

Students then spend some time reflecting on areas of interest they would like to research. They identify a partner based on mutual areas of interest. The students are provided a worksheet, that when completed will aid in the pursuit of the information needed. At this point, the partners begin the process by developing a problem statement. In analyzing the problem statement, creative thinking strategies such as brainstorming are suggested to assist in their elaborating on the key concepts and related synonyms.

At this point, students work with their partners in a technology lab. The goal is both to familiarize them with the search process and locate sources which will provide a basis for addressing the problem statement. An important part of this process is to have them experience the vast amount of information and engage in appropriate "narrowing" strategies or deductive thinking. This means that while the students are gathering information and afterward, they are encouraged to engage in a critical thinking process that questions the validity of the information, including the source. This is crucial part of the operation, particularly when working with material gathered from the internet.

When the information has been gathered, critiqued, and sorted, the problem statement is again addressed. At this point, students present their findings to a group of peers.
They share their best judgment and provide justification for their position.

Having pre-service teachers engage in a research based approach to problem solving provides them both tools and experience for guiding their future students into an exciting and realistic approach to learning. Technology learned in isolation becomes pointless. Technology that is nothing more than automation for the past lacks creativity and wisdom. When teacher educators provide the opportunity for pre-service teachers to practice meaningful integration of technology while gaining the insights necessary for effective thinking and problem solving, we have made a giant leap toward better schools for the future.

A compendium of 14 previously-published instruments for assessing teachers' attitudes toward information technology was used to measure pre-post changes among nine groups of K-12 educators completing six weekly training sessions in a southern Texas public school district during 1995-96. Teachers were introduced to the significance of information technology in society and instructed in Macintosh computer applications focusing primarily on teacher productivity. One-hundred eighteen educators completed both pretest and post test questionnaires. This paper contains a description of the attitudinal changes that occurred in teachers during their technology training sessions.

Description of Trainees
Each of the schools in the district was given the opportunity to send teachers with little or no background in information technology to receive training. Each school could send one teacher for a morning session and a second teacher for the afternoon session. 1995-96 was the third year of training, and by this time, several schools sent teachers who had not necessarily volunteered to receive the training. Some of the trainees were very adept at using the keyboard, while others had little or no keyboarding skills. While the majority of the trainees were predominantly elementary school teachers, there was representation of secondary school teachers along with a few secretaries, librarians, and classroom aides.

Description of Training
The training consisted of 2 1/2 hour sessions each held over a period of six weeks for up to 20 trainees at one time. When the trainees came to the media center training room on the first day, they were introduced to the world of technology and the changes that were currently taking place. They were told that the school district had made a commitment to their educational personnel to train them personally as individuals, and that they were under no obligation to have to use any of this for their teaching. This approach was used to take the pressure off the teachers so that they did not feel they were being forced to learn something that was not going to benefit them directly. During this first session they were also introduced to the Macintosh computers (660 A-Vs) and were taught to navigate using the mouse, change desktop patterns, use the calculator, change time, and eventually to play music CDs.

Sessions 2-4 were devoted to learning word processing skills. Session 5 was devoted to learning how to set up a database and print labels, and now to merge a database into a word processing document. The final session focused on setting up a gradebook using the spreadsheet.

Trainees were advised to try to use the computers at their schools or at home to review the skills that they were learning so that they would not forget skills learned each session. While some had immediate access to computers, the majority of the participants rarely practiced their skills prior to the following sessions.

Instrumentation
The Teachers Attitudes Toward Computers Questionnaire (TAC) was used to assess attitudinal change among the teachers participating in the training sessions. A total of 284 items falling on 32 Likert and Semantic Differential subscales were included from the following 14 sources (Christensen & Knezek, 1996a):
1. Computer Attitude Scale (CAS) (Gressard and Loyd, 1986)
   - confidence (CASC), liking (CASL), anxiety (CASA), and usefulness (CASU)
2. The Computer Use Questionnaire (CUQ) (Griswold, 1983)
   - awareness
3. Attitudes Toward Computers Scale (ATCS) (Reece & Gable, 1982)
   - general attitudes toward computers
4. The Computer Survey Scale (CSS) (Stevens, 1982)
   - efficacy and anxiety
5. Computer Anxiety Rating Scale (CARS) (Heinssen, et al., 1987)
Reliability of the TAC for Inservice Trainees

Table 1 contains a listing of the data analysis classification labels for each of the 32 Likert and Semantic Differential subscales, along with the internal consistency reliability for each subscale based on the data gathered from the teachers. The distribution of the internal consistency reliabilities for the 32 subscales was:

- .90 and above ———————————————————— 8
- .80-.89 ———————————————————— 13
- .70-.79 ———————————————————— 6
- .60-.69 ———————————————————— 2
- .50-.59 ———————————————————— 1
- .40-.49 ———————————————————— 2
- Below .40 ———————————————————— 0

According to the guidelines provided by DeVellis (1991, p.5), 27 of the 32 are at least “respectable” ($r >= .70$), and 21 of the 32 are “very good” ($r >= .80$). Only 3 of the subscales are “unacceptable” ($r <= .60$). A more detailed description of the indices and how their 1995-96 measurement accuracies compare with comparable indices from the times of the subscales’ origins, is provided in a companion paper in this issue (see Christensen and Knezek, 1996b).

Major Areas Measured

A cluster analysis and factor analysis (SPSS, 1984) were carried out on the data in an attempt to group the subscales into larger categories. Summed indices for each of the 32 subscales were used as variables in the analyses. Four major areas were identified (Christensen and Knezek, 1996a). As shown in Table 2, 14 subscales appeared to be most closely associated with the Perceived Utility of Computers, while 11 were mainly concerned with various kinds of Computer Anxieties. Five subscales seemed to be measuring Accommodating Outlook, and 2 were associated with the broader Perception of E-mail and other Information Technologies for activities other than professional productivity, such as classroom learning.

Results

Results are based on returns from 118 teachers (approximately 75%) who: a) were participants for the entire six-week training session in which they were enrolled, b) completed both pretest and post test questionnaires, and c) provided sufficient identifying information to match pretest with post test responses. As shown in Table 2 and illustrated in Figure 1, indices for 20 of the 32 subscales drawn from previously published instruments changed in a positive direction ($p < .025$) over the course of technology training.
recognized as a necessary condition for effective use of technology (especially Email) for classroom learning.

Among the teachers completing six-week technology training sessions at a southern Texas school district in 1995-96, reduced anxiety, increased enjoyment, and increased recognition that

Note: n = 118

Groupings resulting from a factor analysis of the 32 subscales indicated that the teachers involved in these training activities changed primarily in the areas of reducing their anxieties about computers (Factor 2) and increasing their estimation of the usefulness of information technology (especially Email) for classroom learning (Factor 4). Several measures related to enjoyment or liking became more positive as well, as is indicated by significant changes in several of the indices listed in the latter half of Factor 1.

### Discussion

Positive teacher attitudes toward computers are widely recognized as a necessary condition for effective use of information technology in the classroom (Woodrow, 1992). Among the teachers completing six-week technology training sessions at a southern Texas school district in 1995-96, reduced anxiety, increased enjoyment, and increased recognition that

Email and related information technologies can help in classroom learning, can be viewed as positive outcomes. The latter is especially encouraging since the teachers did not receive explicit training in the use of information technology to promote classroom learning. On the other hand, the lack of any apparent change in the area of Accommodating Outlook, combined with sparse evidence of any movement toward perceived usefulness of information technology for teacher productivity, would seem to indicate that these teachers, who came to the training sessions often as the last from their schools to sign up, did not drastically alter their views on how willing they were to embrace new information technologies. Perhaps, as much of the literature in this area indicates, anxiety reduction and recognition of potential usefulness are just beginning points. True acceptance may take longer than just six weeks (15 contact hours) of exposure, or perhaps an incubation period is needed after the initial training, to enable the ambivalent trainee to accommodate this new perspective.

Using Hypertext to Enrich an Initial Teacher Education Course

Jerry Wellington
University of Sheffield

Initial teacher education in the UK has become increasingly school-based. Less and less time is now available in college or University to cover content or ‘theory’ in the space of a 36 week postgraduate certificate in education (PGCE) course. As a result of this trend, a decision was made in 1994 to support the coursework of our quota of 50 PGCE science students at the University of Sheffield by providing a range of material on science education in a form known as “hypertext”.

The history of hypertext is long and winding but the coining of the term is usually attributed to Vannevar Bush in 1945 whose paper ‘As We may think’ (Bush, 1945) is seen as the starting point. Fifty years later the term still eludes a concise definition but like the proverbial elephant people can recognise hypertext when they see it. It involves putting text (and other media such as photos, drawings, sound and video in the more general version called “hypermedia”) into an information system so that students can learn, read view or listen as they wish. Thus they learn at their own pace, in their own order and in their own style. Terms associated with hypertext include non-sequential or non-linear reading, which are fairly accurate but more fanciful ideas of the reader as an ‘explorer’, a navigator on an unguided tour also abound. Accounts of hypertext talk in terms of readers not only “traversing established links to pre-existing nodes but also venturing forth into uncharted realms” (but see Nielsen, 1990, for a more sober description). Similarly, in the small number of evaluations of hypertext in teacher education (Lacey and Merseth, 1993; Higham and Morris, 1993) there has perhaps been some research through a rose-coloured lens, as so often happens with new technology. Thus Lacey and Merseth (1993, p. 545) report in their study of hypermedia in teacher education that “students can gain access to data immediately their questions emerge: therefore, their intellectual curiosity guides the use of the technology, not the other way around”. My reaction on reading this: it may have happened in Harvard but can it happen here?

Developing the Project/System

Hence the aim of my own project was two-fold: to produce and develop course material for initial teacher education students (which might also be of value to school-based mentors in the partnership scheme); and secondly to evaluate the use of the system with an open, critical mind but some healthy scepticism. To include details of the hypertext material would not be appropriate here but it is relevant to say that the eight “modules” are all generally central to most UK PGCE courses covering topics such as Planning and Managing Learning, Scientific Investigation, The National Curriculum, Language in Science Teaching, Practical Work and the Use of IT in Teaching and Learning. These areas were presented as modules on the screen, each containing text, figures and tables, and all giving lists of references and further reading at the end. It can be seen that the material was concerned more with what is now commonly termed pedagogical and curricular knowledge rather than subject knowledge (Shulman, 1986).

The text, table and figures were all mine, hence there were no copyright problems in putting the material into hypertext as there can be with other courseware in this form on a computer system (the material itself has since been developed, added to and published as a book: Wellington, 1994). Technical problems were eased for me thanks to a grant from the National Council For Educational Technology (NCET) who supported the project and paid for technical assistance in transferring the material from Word for Windows files into a hypertext form on the University network using a system called Guide. I was also assisted in the design of the screen, the format, the colours and the ways of moving around the system - the “user-interface” was designed so that everything could be done by moving and clicking a mouse i.e. moving from one page to another, turning the pages, moving from one book or module to another, looking at references and so on. We were also able to provide two extra facilities: an easy way of calling up the library catalogue so that students could see if books referred to were actually there; and an icon which students could click on to get them straight into electronic mail and send messages and feedback to me.
The hypertext system used was chosen mainly for three reasons: first, its availability on the University campus network, free of charge; second, its ease of use, although many other hypertext/hypercard systems are also easy for the learner; thirdly, its ability to handle large amounts of text which was an essential requirement in this case with about 40,000 words involved.

**Evaluation of the Project**

There seems to be a paucity of useful frameworks for evaluating multimedia in general and hypertext in particular. My own reading led me to perhaps two lists, or frameworks if they can be so called, of value in this context. The first is in the form of a list provide by Nielsen (1990) who suggested five points that should be met by a hypertext system:

1. Easy to learn: the user can quickly get some work done with the system.
2. Efficient to use: once the user has learnt the system, a high level of productivity is possible.
3. Easy to remember: the casual user is able to return to using the system after some period of not having used it, without having to learn everything again.
4. Few errors: users do not make many errors during the use of the system, or if they do make errors they can easily recover from them. Also, no catastrophic errors must occur.
5. Pleasant to use: users are subjectively satisfied by using the system: they like it.

These helped to guide my own evaluation and I would add a sixth point essential in any course involving students and finite resources: ease of access.

A much less simple but probably more valuable framework was discussed at length by Barker and King (1993) who put forward a whole methodology for evaluating “multimedia courseware” and included a useful checklist for evaluators.

Both lists or frameworks proved useful for my own evaluation and, I would suggest, can be of value in studying the use of IT in teacher education generally. They helped to shape my own interviewing and questionnaire design. A decision was made to personally interview a 20% random sample of each year of students (a total of 10) and then to ask all other students to complete a questionnaire based on the evaluation frameworks above and on points emerging from the interviews. Each interview lasted about half an hour and was taped and transcribed. The interview was semi-structured but plenty of time and space was allowed for open comment, judgement and personal remarks! One of the aims of the interview (and to a lesser extent the questionnaire) was to encourage students to reflect upon their own learning using this medium, in order to add a meta-cognitive aspect to their use of hypertext in the course i.e. to promote their own reflection and self-evaluation on the learning process.

**Results Emerging from the Evaluation**

The system has now been used with 2 cohorts of students and is in progress with a third group. The results from the interview tapes and questionnaires cannot be presented in full here so the summary below represents a distillation of the main points emerging. Responses from the interviews were many and varied and also the questionnaire provided some fairly open-ended questions which brought a range of answers. For the sake of brevity, I have summarised the main findings using just the three headings below:

1. **Quality of the user interface, engagement and interactivity**

   Generally, students did find hypertext easy to use with comments like “simple and convenient to use” and “not very much text on each page”, “easily readable”. Some found it an interesting, novel and attractive way of reading and studying, illustrated by the following comments:

   "I found it a much more accessible way of reading."

   "I liked it a lot better than reading a book...because I don’t have to hold it...I found it less effort...and maybe because of the novelty value. And also because there’s not very much on each page. I did find it easier to read."

   A clear majority however were critical of the idea of reading from a screen especially in the environment of a computer room. A few short quotes from the tapes suffice to make this point:

   "I just don’t feel comfortable reading from a screen.”

   "I can’t concentrate with other people around.”

   "Reading from a screen is very tiresome...I mean you could only do an hour at a time (sic!). I needed several sessions just to go through one module.”

   There were mixed feelings about other aspects of the user interface, such as the diagrams and tables:

   "I don’t like flicking from a table to text and back again.”

   On the other hand some students found the break from text useful, for example:

   “The tables and figures in it help to break it up.”

   On the issue of access and availability views were again split:

   “It’s not always possible to get on to a terminal - I’ve been up there with spare time and not been able to get on it.”
“It’s the fact that it’s just on the University system that’s the problem - if we could have it on disc to take home...that’s when it could be really valuable.”

“The only times it was difficult in getting to the hypertext immediately was when deadlines were approaching for assignments - other than that, if you chose your times, it was all right...late afternoons or early morning...”

I speculate that the view on access to systems such as this depends on the circumstances, working patterns and other commitments e.g. family, of the particular student involved.

2. Learning Styles and ‘Collaborative Reading’

Did the system allow for a variety of learning styles, collaborative use and links to other ways of learning? Styles seemed to vary, from the habitual “serialist notetaker” to the students (a clear majority judging from the questionnaire) who used the system as a “primer”:

“As a starting point, then I’d go off to the library...so I’d used it to get some ideas and some references and then go and follow them up. A lot of the hypertext stuff pointed me in the right direction and gave me a start...which was a great help.”

However, the main factor determining learning style appeared to be the limitation of reading and studying from a screen:

“I didn’t read it in chunks of longer than about 20 minutes because I got a headache. It’s probably the lights in the room more than the computer.”

As for collaborative reading with hypertext, the attitude of many was “perish the thought”. A small selection of comments make the point clearly:

“I can’t imagine why people should want to read together.”

“People read at different speeds don’t they...and then you’d start talking about the football. I’d soon get distracted.”

“When I’m reading I’m oblivious to anything that’s going on round me...so my partner might find it very irritating. I like flicking backwards and forwards too.”

“I think my partner would be bored waiting for me because I’m a slow reader. They’d be wanting to flick to the next screen and I’d still be reading.”

Some students had obviously thought about the possibility of consenting adults reading together from a screen but even these showed (in the interviews) an air of incredulity:

“There probably are reasons why people might want to read together - but I can’t think what they are...I suppose you’re bound to be more critical about what you’re reading if there’s someone else there - you’re bound to question it more aren’t you?”

“It would be easier to read off a screen together than to try and read a book together - partly because the pages are shorter, and partly because you can both look at a screen together.”

3. Fitting Into The Curriculum And The Course

A vital part of the evaluation of any use of new media is the context, the course and more generally the curriculum in which the innovation is situated. This aspect featured in both the interviews and questionnaires. There were many positive comments as well as some very salutary, pragmatic reminders from students who are nothing if not realistic.

“I found them excellent overviews of the topics and a good source of reference, a good back-up to course sessions”.

“If a topic is appropriate for an assignment it saves you having to get books out which aren’t always available. It’s always in.”

But many positive comments were tempered with a general feeling that use of this type of material is a very “seasonal” activity:

“I used it a lot when it was first mentioned...and then on and off for assignments during the course, for a quick look at references and things....not so much recently though”. (the last term of this one year course)

“Right at the beginning of the course a lot of people went and used it because we weren’t quite sure what to do...but what we needed during the course were weekly reminders, especially on the day a week when we were back in the department.” (during the first long school experience)

“After Christmas it would be better to read about more theoretical things on the hypertext, you can appreciate it then after you’ve been in the classroom - it becomes more relevant. The course should be more practically based in the first term and gradually more theoretical after that. I don’t think the theoretical stuff’s relevant to you until you’ve actually been in the classroom.”

In a course which is largely school-based, students cannot use a system such as this is during their periods of extended school experience. Many of the students felt that this is a time when access to a hypertext system of this kind would be especially valuable, not just for them but for the
teacher mentors working with them in our partnership scheme. I should point out that the comments on mentors below were spontaneous and not prompted during the interview:

“The hypertext would be a great system for schools that are networked, so you could access it then while you’re out at school - which is a lot of the time.”

“Teachers who have been out of education for a time...it would do them an awful lot of good just to sit down...because they’re very readable, just a couple of pages on each topic. I think they would benefit greatly from having it in schools. They could sit down, with nobody else there and use it without being seen...especially the older teachers.”

“A lot of them ask what we’ve been doing in the University - this would give them a chance to see...a lot of them are quite open to new ideas.”

“It would be an interesting, accessible way for teachers to keep up to date”...

The Use of New Technology In Teacher Education

The summary above gives a flavour of the main points emerging from this on-going evaluation, whilst not including a large part of the data. Some clear lessons were learnt in the formative evaluation which helped to improve each version in time for the next cohort of students.

However, there is an inherent difficulty in any innovation and on-going evaluation of this kind: a “measurement” or assessment of the impact or effect of any educational intervention, not least one involving IT, is extremely problematic. How can we know with any certainty what the “added-value” of an innovation has been? How can we be sure that any “gain” was unique to this innovation i.e. not achievable by other means; or that the very presence and novelty of a project did not in itself create added interest motivation etc.? (A version of the Hawthorne effect). How can we generalise from our own context to others?

Some studies feel confident enough to assert that their own innovation did bring about a gain or added-value. Thus, in Goldman and Baron’s (1990) hypermedia project with primary teachers they assert that:

“We feel that these technologies, when integrated into courses that have as goals the development of pedagogical content knowledge (Shulman, 1986), can make a major contribution to the reform of teacher education.”

In concluding their article they even suggest that new technology of this kind can bring about a shift in approach in teacher education:

“We believe that hypermedia technology has the potential for creating a new type of teacher education program - one that moves traditional college and university courses away from a teacher-directed lecture format and into a problem-solving/analytical mode.”

I would not feel confident enough, on the basis of the project outlined above, to support either of these assertions. I cannot believe that new technology alone can bring about “a reform of teacher education”, for better or for worse. There are other, far more powerful, forces at work in the current maelstrom.

What light can my own small evaluation shed on possible ways in which new technology might play a part in teacher education? (Bright and Waxman, 1993). Firstly, there is some evidence from my experience that it can enrich teacher education courses, not least by introducing students (as learners) to the technology they are likely to meet as teachers. This will be enhanced by encouraging them to reflect on their own learning in a critical way. However, this will only happen if the new technology is built into the course. My evaluation showed me that students need constant reminding about it, especially if it involves going to another room or even another building to use it. The material needs to be built into the course structure, the lectures and workshops themselves and the assignments. Careful attention also needs to be paid to the rhythm of the course and the evolving needs of students through it.

Finally, how does new technology of this kind relate to the debate over school-based versus higher education based courses? I cannot do justice to this huge and complex debate on the two poles and positions between, but I am prepared to assert that the increased use of IT in teacher education could never compensate for the weaknesses in a totally school-based course. The role of the higher education institution will still be essential for three reasons: in providing a base for the technology, including the staffing required to monitor it, to up-date it and to support it; in providing a forum for students and tutors to share critically the use of the new technology, and to encourage the kind of meta-learning and reflection referred to above; and in monitoring and up-dating the content of the material. My evaluation showed one thing clearly and I would hazard a guess that it can be generalised from: students do not trust their school mentors to keep up-to-date on new developments and new approaches, hence their suggestion in the interviews that mentors themselves should use the hypertext.

There may be ways of dispensing with the higher education institution in teacher education (though I seriously doubt this) - but the introduction of more and newer educational technology is not one of them.

Jerry Wellington, University of Sheffield, Sheffield S10 2 JA, UK. E-mail: j.wellington@sheffield.ac.uk
During the mid 1980’s, Kansas State University’s College of Education developed a common core of professional education experiences required for all students who sought certification at the secondary or middle school levels through the Secondary Education Preservice Program. Although the next several years saw a variety of adjustments in the composition of this required core, significant changes occurred in the Fall Semester of 1993. In response to feedback from students, we took advantage of emerging technological opportunities and significantly altered the learning environment and increased the depth and breadth of the preservice experience. This effort involved the first sequence of professional education courses known as Block One. The major features of the Block include: 1) collaborating on integration of three courses into one experience, 2) integrating and restructuring the content of the three courses into a series of thematic units, 3) structuring students into cooperative teams, and 4) integrating selected computer technologies throughout the experience.

Soon after the original implementation of the required Secondary Education Preservice Core, faculty began receiving complaints about duplication of content among various courses. The initial response to such concerns included a philosophical belief that a certain amount of repetition added emphasis and was beneficial for students. However as students continued to voice concerns, it became increasingly evident that an analysis of these concerns needed to be conducted. As the Fall Semester of 1993 began, faculty from Secondary Education, Special Education, and Educational Psychology met to examine possible overlap in content among the three courses in Block One. The results of this analysis provided concrete evidence that excessive overlap existed among the courses and that additional depth and breadth could be developed through scheduling an extended block of time and through collaborative planning and team teaching.

During this same time period, the College of Education made the move from an Apple IIe and Apple IIgs environment to an all Macintosh environment. The first steps in this transition were taken in 1990 as each faculty office and a student laboratory were equipped with Macintosh computers. Each computer was then connected to an AppleTalk network and subsequently to the University’s Ethernet network. The stage was now set for faculty and students to explore opportunities beyond traditional instruction and learning.

Although the authors would like to report rapid and extensive progress from faculty and students, applications of technology to enhance student learning opportunities has been slow. The College moved quickly to identify and train a Technology Support Group. At that point the trouble shooting and service needs of the College were adequately addressed. In contrast, the development of visions related to using technology to enhance student learning experiences and significant changes in the delivery of instructional programming progressed more slowly.

**Integration of Content**

The three courses involved in Block One include, Educational Psychology from the Department of Counseling and Educational Psychology, Core Teaching Skills from the Department of Secondary Education, and The Exceptional Student in Secondary Schools from the Department of Special Education. Each department is relatively large with undergraduate and graduate programming at the master’s and doctoral levels. With the departments heavily involved in programming at all levels and the Block One instructors involved in teaching undergraduate and graduate courses, time for collaborative planning as well as team teaching was scarce. However, with encouragement from the administrator of each
department, each instructor was able to establish a calendar which included Block One activities as a major focus.

As the first plans to integrate the content from the three courses were developed, each instructor expressed concern about having to give up significant portions of content. However, as the semester unfolded, all instructors reported significant efficiency in the amount of content addressed as well as substantial increases in the depth of student experiences. Implementation of the integrated Block initiated the use of one syllabus with five integrated thematic units as a replacement for individual syllabi for each of the three collaborating courses.

The nature of the teaching and learning experiences also changed significantly. Rather than a traditional “stand and deliver” teaching model or a “sit and listen” learning model, the integration of content, the extended time periods, and the establishment of collaborative student teams led the Block instructors to implement a substantial number of problem solving projects. These projects required students to make use of traditional and technological research methods.

Student reliance on traditional searching within the main campus archives became more challenging during the past two years as an extensive library renovation project moved forward. As interactions in the library became more challenging, students exhibited growing interest in the Internet and World Wide Web. Thus, the curriculum integration and technology integration efforts received sizable encouragement from an unplanned source.

**Integration of Technology**

During the early planning phases which led to the development of the integrated Block, the elimination of needless repetition in content was the overriding focus. As content contributions from each course were refined, the need for different teaching and learning models became readily apparent. The movement away from “stand and deliver” teaching models, implementation of extended time periods, and evolution of problem based projects led to the development of collaborative teams. Each team was composed of four to six students representing different teaching fields.

After the first two semesters, the development of the Block reached a point where the integration of technology became more systematic with more uniform experiences provided for all students.

Although much of the enhanced learning climate could have been achieved without the use of technology, teacher and student uses of technology clearly speeded progress as well as acceptance among students. The technologies selected for integration into Block One included: electronic mail or e-mail, teacher presentation and student interpretation technologies or interactive multimedia, electronic research, and network or Web technologies.

**Electronic Mail**

The use of e-mail was the first technology integrated into the newly configured Block. The climate for successful integration of e-mail was firmly established as all faculty in the College of Education and the student lab were connected to an internal network as well as the world-wide electronic communication system when the Macintosh equipment was installed. The faculty and many students have been using e-mail to enhance communications for several years. Based upon these successful experiences, we required all students to obtain e-mail addresses. Subsequently, students have been able to engage in follow-up conversations with instructors, conduct team planning from on and off-campus sites, and behave in a more professional manner.

**Interactive Multimedia**

As previously mentioned, the nature of learning experiences has undergone significant changes. The presence of collaborative teams has facilitated opportunities for larger projects which are more strongly connected to emerging practices in middle schools and high schools. Students have opportunities to construct multimedia course wear to support class experiences as well as lessons which they direct in the Micro-Teaching Laboratory.

Even though the College of Education is an all Macintosh unit, the selection of multimedia development software has focused attention on products which have PC as well as Macintosh versions. With the initial selection of multimedia development software accomplished, the instructional team began engaging in a variety of activities to enhance their technology talents. Once the faculty reached an initial level of comfort in developing and using multimedia, students began incorporating multimedia applications into their individual and team orchestrated lessons.

Subsequently, problems arose because enrollments in the Block averaged 50 to 60 students who competed with students from other courses to access the 25 computers in the Student Lab. Potential solutions included sequencing projects to provide additional work time, providing computer stations in the classroom, and facilitating student access to computers in other areas of the campus.

A proposal for a technology enhanced classroom with movable, networked computer stations to support the activities of each collaborative team is currently under consideration.

**Electronic Research and World Wide Web**

The classroom in which the three-and-a-half hour sessions of Block One are conducted on Tuesdays and Thursdays, was connected to the internal and external networks through Ethernet during the early developmental stages of the Block. With one and then two Ethernet connections, additional opportunities emerged for faculty
and students to access resources across the World Wide Web, and for faculty and students to develop multimedia presentations and to move such learning materials from any location they could access.

A recent addition to the technology integration agenda provided an opportunity for student teams to extend their understanding and use of the World Wide Web. During Fall Semester 1996, student teams were required to design and develop a Web page which described an integrated thematic unit developed for the Block’s Teaching and Learning Unit. The Web page established and described links to Web sites which supported the various content strands incorporated into their project. It also established and described links to Web sites that addressed effective uses of strategies similar to those utilized to orchestrate student involvement in the team project and/or effective uses of technology in classrooms in general. The results of efforts by these student teams may be located at http://www.educ.ksu.edu/Faculty/ParmleyJohn/Block%20One%20Web%20Project%20F96/ProjectOverview.html

During the implementation of the Web page project, faculty and students encountered obstacles which were the same or very similar to those encountered during development of multimedia applications. The solutions were also very similar to those associated with efforts to develop multimedia as faculty provided access to additional computers in various locations across the College.

Technological accommodations for students with special needs

Students also have had the opportunities to explore technological accommodations for students with special needs. The presence of technology throughout the Block One experience has created an environment in which the impact of such technological accommodations is accepted with serious thoughts toward possible application in students’ future classrooms rather than as technological toys intended for someone else’s classroom.

The faculty involved with the development of the integrated Block have placed a consistent focus on developing students’ decision making abilities and talents related to orchestrating learning experiences for all students. The role of technology has been to facilitate and enhance this focus or mission. Basis for Integrating Technology?

Each of the faculty members involved in development and growth of Block One has reported this as their first experience with such an extensive effort to collaborate on curriculum development and orchestration of instruction. Based upon this relative lack of experience as well as the desire to provide the highest quality experiences for students, faculty invested substantial time reflecting upon proposed changes.

When decisions about selection and integration of technology were being made, faculty examined such works as Sivin-Kachala and Bialo (1994-95) who wrote:

"Technology makes a difference when the teacher has a clear vision of what students are to learn and how technology can help. Success also requires that the teacher include in his or her instructional plan ways to give students guidance in the processes and thinking strategies that make up the skill. Finally, the teacher needs to be actively involved in a variety of roles—sometimes a lecturer, sometimes a coach; one day a consultant, the next day an editor.

What role should the technology play? Research suggests that technology works best as a supporting tool—making complex processes or creative experiences either possible or easier to accomplish. Technology offers new ways to provide meaningful, real-life contexts for learning. And telecommunications technology allows students to collaborate with peers and experts across the country and around the world. (http://glef.org/glhttp/newsletter/2/2/research.html, October 10, 1996)

Maloy’s (1993) Toward a New Science of Instruction provided a significant contribution as the Block instructors developed a conceptual frame for making decisions related to organization and instruction. In this work she states,

To meet the challenges of an increasingly complex world and workplace, students must become what NRCSL (National Research Center on Student Learning) Director Robert Glaser calls “mindful architects of their own knowledge”—thinkers who know a great deal and continually adapt, refine, and use their knowledge. The basic skills of an earlier time—a fundamental competency in reading, arithmetic, and the tasks of citizenship—are no longer enough by themselves. Success today requires new basics: the ability to reason, analyze, plan, and act effectively in a climate of pervasive change.

In order to engage in such fluid knowledge “architecture,” learners must eventually attain intellectual independence. Once they have become full-fledged workers, citizens, and consumers, most will have little access to direct instruction. (http://www.ed.gov/pubs/lnstScience/index.html, October 16, 1996)

The work of Singh and Means (1995) provided additional insight as the conceptual frame was reviewed. These authors wrote:

There are many different kinds of technology, technology applications, and technology uses. Our classification scheme encompasses tutorial, exploratory, tool, and communications uses of technology.

We reason that tutorial uses of technologies (e.g., drill and practice programs, tutoring systems, satellite transmission of lectures) may be useful but are unlikely to transform...
education. These uses in essence use technology to do the same things that schools have traditionally done for more students—albeit perhaps more systematically and efficiently.

Exploratory programs can be exciting adjuncts to an instructional program, but rarely carry a major part of the core curriculum....

If our goal is really to provide students with a different kind of education—structured around the provision of challenging tasks that can prepare them for a technology-laden world—the most relevant uses of technology are as tools and communication channels. Giving students experiences in selecting appropriate technology tools and in applying technologies such as word processors, spreadsheets, hypermedia, and network search tools to their work supports the performance of complex, authentic tasks and provides experiences that prepare students for the world outside of school.

The concept of preservice teachers and developing professionals as mindful architects of their own knowledge is consistent with the College's mission to develop "knowledgeable, ethical, caring decision makers" who direct learning experiences in tomorrow's schools.

The faculty also considered the work of Means, Blando, Olson, and Middleton (1993) who stated:

"The primary motivation for using technologies in education is the belief that they will support superior forms of learning. For this reason, theory and research in learning provide an extremely important source of ideas. Advances in cognitive psychology have sharpened our understanding of the nature of skilled intellectual performance and provide a basis for designing environments conducive to learning. There is now a widespread agreement among educators and psychologists...that advanced skills of comprehension, reasoning, composition, and experimentation are acquired not through the transmission of facts but through the learner's interaction with content. This constructivist view of learning, with its call for teaching basic skills within authentic contexts (hence more complex problems), for modeling expert thought processes, and for providing for collaboration and external supports to permit students to achieve intellectual accomplishments they could not do on their own, provides the wellspring of ideas for many of this decade's curriculum and instruction reform efforts.

In an effort to help students view instructional strategies from a teacher's perspective, the faculty shared the work of such scholars as Knapp and Glenn (1996) who reported:

Teachers teaching with technology say they:

- Can meet the needs of individual students better
- Can be more student-centered in their teaching
- Are more open to multiple perspectives on problems
- Are more willing to experiment
- Feel more professional because, among other things, they spend less time dispensing information and more time helping students learn (p. 17)

The integration of technology along with integration of the content has had a profound effect on the learning environment experienced by K-State's Secondary Education students. Students are constantly involved in activities which enhance skills in comprehension, reasoning, composition, and experimentation. Their projects and other assessment activities reflect greater creativity, they are more enthusiastic about collaborating with other professionals, they exhibit a greater commitment to teaching students rather than totally focusing on content, and they exhibit a greater degree of confidence and professionalism. Faculty and students who are involved with Block One are enthusiastic about the present and excited about the future.

Beginning teachers are often ill prepared for the varied applications of technology in their classroom. The Teacher Technology Portfolio Program is a unique preservice program that combines the infusion of technology throughout the curriculum with the development of a reflective portfolio on technology in education. The program was initially tested with student teachers. Subsequently, every student in the department was required to begin a portfolio to be completed by the end of their student teaching semester. Based on initial evaluation results, a long range plan for continued revision and implementation of the project, training and support for faculty, and acquisition of necessary materials was developed.

It is apparent in the field of education that the preparation of teachers to effectively use and apply technology is lacking. Many local, state and national agencies have indicated a need for teachers, both at the preservice and inservice levels, who are better prepared in the area of technology (Lee, 1996; Northrup & Little, 1996; U.S. Congress, 1995). This viewpoint has been supported by accrediting agencies such as the National Council for the Accreditation of Teacher Education (NCATE) which has implemented new guidelines for teacher preparation including standards for technology (Thomas, 1994). There is continued discussion in the field on the best method for preparing teachers, such as using stand alone courses on technology versus the integration of technology into education courses, using a constructivist perspective versus a behaviorist perspective, or incorporating experiences in student teaching or clinical settings (Bosch & Cardinale, 1993; Thurston, Secaras, & Levin, 1996; White, 1995; Willis & Mehlinger, 1996). The Teacher Technology Portfolio Program was developed in response to these issues raised by cooperating satellite school districts, department graduates, students, and the field of education about teacher preparation and competence with technology.

Elmhurst College is a small, 4-year liberal arts college in the Chicago land area. The Department of Education includes programs in Early Childhood Education, Elementary Education, Secondary Education and Special Education. The Teacher Technology Portfolio Program integrates instruction on technology and modeling of instruction with technology throughout the course work in each of the teacher training programs. Preservice teachers begin their portfolios in their introductory courses or their first education course in the department with opportunities in methods courses to build technological competence; investigate curriculum and technology connections; and develop and implement activities that integrate technology. The Teacher Technology Portfolios are finalized during the professional, student teaching semester.

Development of the Program

Initially, faculty in the Department of Education determined the need for a method of infusing instruction on technology throughout the major courses. The idea of using a portfolio approach that would reflect a student's growth in knowledge and application of technology was proposed and approved. A three person departmental committee was formed to develop and monitor initial implementation of a portfolio approach.

Input requested from several departmental advisory councils, composed of administrators and teachers from surrounding local districts, indicated a strong need for new teachers, as well as veteran teachers, to have both basic and advanced technological competence and the ability to apply that competence in the classroom. Based on this input, the technology committee decided to survey students, assess their current knowledge, and then plan a course of action.

Using the text, Instructional Media Technologies for Learning (Heinich, Molenda, & Russell, 1989), the technology committee formulated a survey which was administered to both those students just entering the department's sequence of courses and those students about to student teach. (That text has since been revised and a 5th edition, 1996, is available). Students were asked to rate their skill proficiency in each of a number of areas by indicating previous acquisition of the task, ability to learn the task in the current clinical setting, or the need for an opportunity to learn the task on campus. The survey was strictly competency based and did not ask the students to
assess their ability to integrate their technological competence into the curriculum.

At this time, guidelines for the portfolio were developed. Portfolio requirements included the development of a reflective statement regarding technology and education, the development and implementation of lesson and unit plans with artifacts integrating technology, and the documentation of mastery of basic and advanced competencies with a variety of instructional technologies. Using the results of the survey a list of basic and advanced competencies, as well as forms for documenting the acquisition of the competencies, were formulated and included. Also at this time, an advisory council specific to the Teacher Technology Portfolio Program was formed with the specific function of providing evaluative feedback and advice for the continued implementation of the program. The council is comprised of members of the college community, department alumni, students, and practitioners.

Time lines were also developed for an initial pilot test of the program in the spring of 1996 with students entering their professional student teaching semester. A series of on campus workshops were planned using the data from the survey to support the student teachers in their attempts to build competencies and complete the portfolio. Workshops were planned primarily in areas relating to computer use, telecommunications, and multimedia. Faculty were asked at this time to begin including technology activities within their course syllabi and to list the Heinich text as an optional text for students to purchase. In order to begin supporting faculty members in their endeavors, the technology committee proposed and received a small mini-grant to provide a series of full and half day workshops for full time and adjunct faculty with a focus on integrating technology into the curriculum.

Implementation of the program for all students in the Department of Education was scheduled for Fall, 1996. Plans for the fall included continued workshops supporting those students entering their professional student teaching semester and expected to complete a portfolio. A series of mini-courses was developed and offered to both student teachers and all other students. Education faculty were required to include the Teacher Technology Portfolio in their syllabus with opportunities for students to build competencies, to develop and field test activities with technology integration, and to reflect upon their experiences.

Evaluation, Revision, and Future Plans

During the pilot test of the program in the Spring of 1996, the student teachers were asked to complete seminar/ workshop evaluations and a survey at the end of the semester about the portfolio process. Completed portfolios were assessed for number of competencies attained, number of lessons utilizing technology with artifacts, and the completion of a reflective statement on technology and education. Overall, the student teachers indicated a sense of the importance of learning to use and apply technology in the classroom. Although a variety of workshops at beginning and advanced levels were offered during student teaching seminars, many of the student teachers felt a lack of preparation to complete the portfolio satisfactorily. As well, a number of the students commented on the lack of technology in their field placements and therefore, the inability to implement the required lesson or unit plans.

Also during the spring, steps for preparing faculty to begin integrating technology into course work and supporting documentation of the student portfolios were begun. Results from a needs assessment, attitude survey, and the all-day workshop evaluation were compiled and indicated the same sense as the students regarding the importance of using technology as well as an equal need by the faculty for more adequate training on a variety of issues in order to be better prepared to infuse technology into their courses.

Based on the results from the pilot test and faculty evaluations, several revisions were made in preparation for the implementation of the program with all students in the fall, 1996. The portfolio guidelines were the first to be revised. Despite the fact that the student teachers were submitting technology portfolios, many completed portfolios were handwritten or typewritten. Specific instructions (with the requirement that all items must be completed on a word processor) and sample elements were developed. A bibliography of available library resources, procedures for documenting competencies from previous clinical or work experiences, and an evaluation checklist for the students to complete prior to final submission were also developed and included. Next, the supporting workshops for student teachers were revised to include a more specific focus on integrating technology into the curriculum, more hands-on, and some sessions for those students who were still fearful of technology. Additional stand alone mini-courses were developed and offered on basic instructional technology and using ClarisWorks for teacher productivity. Finally, plans were made for follow-up training for the faculty at the end of the semester and in the spring, 1997; improving the system for access and use of existing instructional software; and the printing of the portfolio guidelines and placement of them in the campus bookstore for purchase by the students.

Despite the fact that the faculty in the department have indicated the importance of and supported the need for this initiative, many still feel lacking in their preparation to actually implement technology in their courses. Others have expressed the desire to have the program more focused with clearer direction on what competencies and activities are expected in what courses. Stepping back and evaluating what has been completed so far, the realization that perhaps the program has attempted too much too soon...
seems clear. A long range plan with phases of implementation has been developed with start up in the fall, 1997. The phases of implementation in the plan build upon a growing level of expertise in varying areas of technology by the faculty (and subsequently the students) with opportunities for training and the acquisition of necessary resources, materials and hardware to support the phase. Each phase focuses on a specific area of technology, such as productivity software, telecommunications, or presentation software, and includes objectives and competencies synthesized from several sources (ISTE, 1996; Northrup & Little, 1996; Todd, 1993).

Conclusion

The Teacher Technology Portfolio program represents a major initiative with the Department of Education at Elmhurst College to infuse technology throughout the course work of the preservice teacher and to provide an opportunity for continued reflection about the integration and application of technology into the curriculum. The program is designed to produce teachers who can use the technology available in the schools and effectively integrate that technology into their units, lessons, and activities. The program is attempting to achieve the goal of preparing new teachers to effectively use technology. "Technology is the catalyst, but the chemical starters for such fundamental changes are teachers highly skilled in technology, with a deep understanding of curriculum and a knowledge of how children learn" (Lee, 1996, p.12).

We enthusiastically read a dozen papers from professors and graduate students throughout the United States who have incorporated technology into literacy classes. As more and more of our preservice and inservice teachers are challenged by a variety of changes in literacy education, it is exciting that technology continues to play a critical role in the evolution of reading, language arts, and literature in elementary, secondary, and college classrooms. The papers in this section range from theory to practice, and from ways technology can assist teachers to work with elementary students, to ways college professors can use telecommunications to better meet the changing needs of university teaching.

Crawford highlights the advantages of multimedia hypertext software for reading/language arts instruction. Multimedia enables teachers to individualize instruction as they address each student's preferred learning style. She discusses two instructional systems design models that developers of multimedia hypertext software can use to guide the development of multimedia software.

Caron cautions about the potential misuse of technology as literacy experts continue to debate critical issues in reading, and offers suggestions for improving dialog in the literacy classroom community through technology. Through his experiences teaching "audio" classes at his university, we are provided with options for distance learning at our universities. Baines also discusses the success of technology in his English methods course. Through the establishment of a Web-site, students and professor were able to share course information and communicate their responses. He describes student response to reading and writing through this medium and offers solutions to some of the difficulties.

Zibikowski and Pan explore the unlimited possibilities for reading and writing on the Internet. They investigate the resources available on the Internet for research, the possibilities afforded by e-mail for communications across the globe, and the Internet as a means of publishing student work. Practical suggestions for teachers and a checklist for planning reading and writing activities on the Internet provide useful ideas for teachers as they embark on Internet explorations.

Using computers to enhance writing was the topic of several papers. Radar draws upon her own victories using the Language Experience Approach (LEA) when she was a classroom teacher and incorporates the concept into her college classroom. An updated version which includes theories from the process approach to writing and computer technology was a successful and authentic context for both preservice and inservice teachers. Ferris, Rogers, and Skolinkoff reflect on their experiences integrating technology into the writing process in a graduate level writing course. The excitement, motivation, and frustrations of using technology to enhance the writing process are described. Sometimes this medium can be so motivating that the objective of improving writing can be dwarfed by the computer itself. Smith-Gratto and Blackburn describe ways to prevent students from becoming so involved in the options of a writing program that they forget about writing while experimenting with a wide variety of graphics and sounds.

The issue of using technology to motivate and remediate the reluctant readers was the topic of two papers. Reehm and Long illustrate their work with teaching reading specialists during a summer reading and writing program. Through a variety of software programs, both the elementary students and teachers gained information about computers and software. The elementary students also improved in reading and writing. In a similar study, Gipe and Lamare also describe the implementation of technology in a corrective reading summer class for preservice teachers. They also report student responses to the incorporation of technology.

Williams, Tyson, Hilton, Kimbell-Lopez, and Granger write about their experiences of including technology in a field-based literacy course. Each section of the class had different technological outcomes based upon the availability of computers and software at the various elementary schools, and the technological experiences and comfort levels of the preservice teachers.
Two papers focus on ways that teachers of English as a Second Language (ESL) can also incorporate technology into methods courses for preservice and inservice teachers. Henrichsen’s study recounts her experiences using the Internet with her ESL methods students. She discusses the trial and tribulations of both students and professor as they explored the Web and learned to use it with competence and confidence. Zhang and Feng report on software they have developed to help ESL/EFL teachers teach and access the reading strategies used by their students. A copy of their program is on the CD version of the annual.

We hope that you enjoy reading these articles as much as we did and that they motivate you to continue using technology within your educational milieu. We believe, that as literacy educators, it is essential that we allow our teacher preparation programs to evolve to better meet the literacy needs of our children. Technology must be a part!

Developing a Multimedia Program for Reading/Language Arts Instruction

Caroline M. Crawford
University of Houston

The world of Reading/Language Arts is a domain in which the beauty of the written word has the ability to create new, imaginary realms for its readers. The development of multimedia has introduced the educational environment to a vast expanse of intriguing, useful environments through which learners can fully develop a critical understanding of literary masterpieces through multiple learning styles. Through multimedia technology, the blending of visual, textual and auditory information enhances the environment for the learner and aids in the understanding of information and as stated by Elliot Eisner, “in so doing to help provide our children with a balanced educational program that does justice to the capacities of their minds, and that helps them access meanings that transcend the limits of the literal” (Getty Center for Education in the Arts, 1996, p. 10).

“As teachers are given the appropriate tools to incorporate these media into classroom practice they will be using these tools to structure information into a format that allow it to become, for the student, knowledge” (Buck, 1995, p. 12). One way of integrating Reading/Language Arts is the use of hypertext within a multimedia program that integrates the strengths of each student’s learning style within a classroom situation.

Teaching towards the strengths of each student’s learning style, whether it is visual, auditory or kinesthetic, has traditionally been problematic. It is difficult to offer a classroom of students each of these learning situations within a short time each day. However, with the arrival of multimedia technology, the education of each student is personalized to emphasize the learning style strengths, while also offering a variety of learning situations on the same topic (Toh, 1996). The term multimedia describes computer assisted instruction (CAI) which is computer controlled access to multiple medias, including text, sound, animation, pictures and video within an interactive environment while, at the same time, integrating the slides, overhead transparencies and lectures of the instructor in the traditional classroom (Helms and Helms, 1992; Barker, 1996). Multimedia technology can incorporate separate learning styles within the identical learning situation. The integration of hypertext, the examination of linear versus non-linear structural software arrangement, the aesthetic experience of the user, the creation of a multimedia product and the inclusion of instructional principles in multimedia software packages is integral to the development of a sound multimedia hypertext software program.

Multimedia has multiple meanings within the instructional environment. A multimedia program “can be anything from an electronic book to an interactive course, from an interactive slide presentation to a multimedia newspaper or an orientation tool, from an interactive auto manual to a clinical record.” (Makedon, Rebelsky, Cheyney, Owen & Gloor, 1994, p. 38) The incorporation of the multimedia elements into traditional instruction enriches the experience of the user (Toh, 1996) and has the ability to aide in the rejuvenation of even the most staid of curriculums by rebuilding the classroom environment into one of excitement and cooperative, open learning (D’Ignazio, 1993). Kommers and Lanzing state, “Learning is mediated by thinking (mental processes). Thinking is activated by learning and activities, and learning activities are mediated by instructional inventions, including those mediated by technologies” (1996, p. 156). Technology invites the instructional environment to develop useful multimedia hypertext software programs that formulate a creative, effective learning atmosphere for the user.

One aspect of multimedia, which is considered to be the strength behind multimedia, is hypertext. Hypertext is the ability to move in a non-linear fashion throughout subject matter content. It is seen as a positive tool through which a user can develop connections within a body of text, commonly described as context (Paul, 1996). This significant aspect invites the user to develop and thoroughly organize the knowledge being attained in a thorough manner (Murray, 1996). This organizational development helps the user to structure the knowledge into
a personalized, workable model that will aide in knowledge retention and information gain.

The internal structural arrangement of a multimedia hypertext software program is of primary importance to the users' comprehension. An understandable navigational system must be in place for the users so that they will focus upon the knowledge to be gained from the software program, rather than the structural arrangement of the multimedia hypertext software program. Multimedia can be used to develop software that follows a linear arrangement such as Grandma and Me by Brøderbund Software (1994), meaning that the only choice of the users is to move from one frame to the next in a book's page-turning fashion. Multimedia also offers the ability to move in a non-linear (or hypertext) arrangement, which describes the ability to follow multiple paths and allows the user to make choices within the software program. However, disorientation may occur when using non-linear software due to the large structure through which the users must navigate. Disorientation may occur when the users cannot decipher:

1. where they are within the navigational structure,
2. how to move forward within the software program,
3. how to return to their previous point within the software program,
4. what information is available to them from a point within the navigational structure (Conklin, 1987; Rivlin, Botafogo & Shneiderman, 1994; Nemetz et al., 1996).

Due to the problems of disorientation, it is important for the users to understand the structure of the software program (Nemetz et al., 1996). As noted by Kommers and Lanzing, "The advantage of carefully arranged dyads in an early stage of the design process is that several matching criteria like prior knowledge, actual interest, cognitive style or problem approach, can be obeyed" (1996, p. 155). Therefore, although software structured in a linear manner may be easily followed by the users, a well-structured internal navigational system within a multimedia hypertext software program may be advantageous in a non-linear fashion.

Not only is the structure of the software program important, the aesthetic experience presented to the user is also important. The aesthetic experience is the subjective perceivable of the software by its audience. The aesthetics of a software program have "increased learner attention, content relevancy, student assurance, and program satisfaction" (Ent, 1996, p. 764). Ent continues by describing the four areas of aesthetic importance that software designers should consider when developing a software program: a continuous artistic theme should be developed, high-quality moving video and sound files, the aesthetic experience should parallel the informational content of the program, the use of aesthetics to parallel the emotive as well as cognitive responses of the user. The aesthetic experience presented to the user must be of primary consideration to the multimedia hypertext software program developer.

The creation of a multimedia hypertext software program is a rigorous journey through which the developers must proceed. To create a multimedia product, there are several inherent components that occur and this development process is described as the instructional systems design (ISD) model. The ISD model defines the formative structure and order required by a developer to produce a final instructional product. Two well-known models are Dick and Carey's Systems Approach Model, which is so named since the model "is made up of interacting components, each having its own input and output, which together produce predetermined products" (Dick and Carey, 1978, p. 11), and Thiagarajan, Semmel and Semmel's Four-D Model (1974) which is a linear model, also described as a behavioral model, that was originally developed for use as an ISD model for special education modules. The Four-D Model was developed and named due to the four stages of development: define, design, develop, and disseminate. The Systems Approach Model as well as the Four-D Model are two well-known ISD models within the developmental arena; however, numerous other models are available to developers.

Another instructional systems design (ISD) model is Makedon, Rebelsky, Cheyney, Owen and Gloor (1994) which delineates several inherent components that occur to create a multimedia product. The following is a graphic explanation of the previous textual description of the inherent components involved in multimedia software development:

![Figure 1. Components of Multimedia Software Development as Described by Makedon, Rebelsky, Cheyney, Owen and Gloor (1994).](image-url)
The five stated inherent components to multimedia software development are vital to the successful completion and usage of the multimedia software package. Although stage five is not of primary importance to the development of the software package, it is essentially associated with the final, existing end product. Once the multimedia software package is complete its next step, stage five, is dissemination. Dissemination may attract many different areas within the consumer market, such as individual, corporate or educational usage.

The classroom environment takes on a life of its own within each learning situation. Once multimedia software is added to the environment, the instructional principles of the multimedia hypertext software program may become uncertain, if the developer is unaccustomed to the integration of instructional principles with technological aspects. Suprise and Mitchell (1994) articulate instructional principles to guide the user of multimedia software within a classroom environment. Six relevant aspects of instructional principles are stated that, although prevalent within the traditional classroom environment, may be lacking in a multimedia software package:

1. prepare the learner, 
2. attract and direct the learner’s attention, 
3. guide the learner through successive steps of complexity, 
4. present the material repeatedly in a variety of contexts, 
5. provide a vehicle for practice with immediate feedback, and 
6. make connections between new information and old information, showing how it fits into the ‘big picture.’ (Suprise & Mitchell, 1994, p. 532)

Although these are common instructional principles used within a classroom environment, these six principles may be lacking within a multimedia software package, perhaps due to lack of forethought or theoretical background on the part of the multimedia development team.

Teaching towards each student’s learning style and strengths has traditionally been problematic within what is considered to be an established classroom situation. Although these learning styles prefer individual, or perhaps a combination, of instructional situations, the short time allotted for classroom instruction makes teaching towards each distinct student’s learning style unfeasible. However, the advent of multimedia technology has presented the educational community with the ability to seamlessly integrate the visual, auditory and kinaesthetic learning styles into a multimedia hypertext software program, which was previously inaccessible to the instructional situation. This style of software can integrate multiple medias, including text, sound, animation, pictures and video within an interactive environment while also integrating the slides, overhead transparencies and lectures of the traditional classroom instructor (Barker, 1996). The integration of the multiplicity of multimedia hypertext software programs strengthens the instructional classroom situation of the user, due to the ability of the multimedia hypertext software program to meet the learning style needs of each user.

Although the use of multimedia hypertext technology is quite original and unique, the Reading/Language Arts community cannot disregard that, “...as every instructional designer knows, the power of an instructional approach lies in the science and art of instruction - not in the technological components which comprise a hardware system” (Schwier & Misanchuk, 1993, p. 3). Through development of a multimedia program for Reading/Language Arts, the blending of visual, textual and auditory information enhances the environment for the learner and aids in the understanding of information. Therefore, the integration of hypertext, the examination of linear versus non-linear structural software arrangement, the aesthetic experience of the user, the creation of a multimedia product and the inclusion of instructional principles in the design of multimedia software packages is integral to the development of a sound multimedia hypertext software program within Reading/Language Arts. The new, imaginary realms that can be created using multimedia hypertext technology within the world of Reading/Language Arts have the power to move beyond the written word to embrace each learner’s needs as well as strengths. Perhaps the most enticing aspect of this new technology is the realization that it is only a page turn away.

OPTIMIZE LITERACY LEARNING WITH COMPUTER & VIDEO TECHNOLOGY

Tom Caron
West Virginia Graduate College

Technological advances are appearing faster than we can easily integrate them into our educational contexts and settings. Businesses quickly buy up the latest “fully loaded” multi-media computers with all the business software anyone could need. School boards and individual schools jump on the same band wagon, sometimes before deciding what is needed and for what purpose. Educators, administrators, and parents may be easily swept away by promises of optimal learning environments, easy progress tracking and relative low cost for a powerful return on investment. We need to be cautious, however, in thinking about technology in education, remembering always to put relevant technology to use in the achievement of our educational goals, not defining goals according to the latest technological innovation.

All of us who work in teaching and learning recognize the potentially immeasurable benefits that can arise from the uses of technology in our daily work. Some would even suggest that the ways in which children learn shall change through interaction with technology (Pappert, 1987). Others remind us these changes are not to be enjoyed without complications in the transition to new forms of teaching and learning (Selfe & Hilligoss, 1994). This paper will describe how uses of technology have supported an enhanced environment for teaching and learning in Graduate Reading Education.

Computer technology has led recently to possible answers to questions in the field of reading education. The “great debate” in the reading field has been driving discussions in reading education for decades. Frank Smith (1978), following (1967), described the process as primarily one of searching for meaning, driven by a reader’s thoughts and understanding based on a sampling of text. Jeanne Chall (1983) on the other had describes the process of reading on the basis of specific skills and letters and words in isolation. Roger Schank (1982) wrote a computer program to “read”. It soon became evident that decoding is not as valuable as reading for meaning first using prediction on the basis of understanding as a guide. Constanzo (1989) outlines these ideas in The Electronic Text.

Children’s interactions with technology may well lead to expectations of a more “video-like” learning environment, consisting of attractive visual displays and quick changing backgrounds, contexts, and even topics. We need to be careful that we are not being driven by a technology we begin to believe is forcing us into these kinds of changes regardless of the value to learning and educational environments. As educators we do not want to put computers and technology to use simply “because it’s there”, we want to learn about the ways in which the uses of technology can enhance the educational environments we wish to create to support the learning goals we plan. Sometimes existing technology while improving certain aspects of the learning environment causes deficits in other areas. An impetus behind the exploration of new technologies was stimulated in part by just such an eventuality.

Audio Context
A technology in present use at my university is a telephone bridge to support what we call “audio” classes. These are classes in which the instructor meets at one location with a small group of students and other groups of students meet at sites around the southern part of the state where they dial in on a speaker phone to a designated “phone bridge”. The class meets weekly over the phone lines from five to ten different sites, where there are anywhere from one to several students at each site. Students (except for those at the instructor’s site) meet with the instructor and class speaking into a microphone and listening on a speaker phone. Although the use of this technology allows students from a wider area to “attend” such classes, the opportunities for activities to support student learning during class can be severely limited by this audio context.

Although this setting is suited to a “lecture” style presentation, it is impossible to track students’ attention and status during the class. One is led to create many small activity requirements for students to share as a way of
ensuring their participation and attention. Everyone has access to a mike and speakerphone at their site, but the quality of either the mikes or the speakers sometimes leaves much to be desired. Many times what is spoken or heard is incomprehensible to the listeners. This setting is ideal for experimentation with additional uses of technology to support a closer association between teaching and learning.

The familiar technologies of reading and writing find a new high light and cause celebre in this setting. It is easy to convince individuals attending a class that substantial amounts of writing can be required as one of the few ways of staying in close touch with students. Written reports, critiques of professional literature, weekly journals, brief reflective book reviews and outlines of practical activities all take on real meaning as the only mechanisms for communication between teacher and students. Without the possibility for personal communication between class members and the professor, it is likely completing a paper through subsequent drafts can help the instructor be in closer touch with the students’ writing. Students themselves who value the access to coursework that audio courses provide quickly seem to put high value themselves on their written work. It is that much more important for them too, it seems, to provide their best work to the professor. But even with the increased benefit and valuing added to an even greater load of written assignments, there are drawbacks added.

The forced and continued distance between Professor and students causes a greater sense of distance in communication. The time it takes for assignments and papers to be exchanged via the mail system causes a forced delay. It is difficult to discuss in class any relevant aspects of assignments or issues that arise without the documents in hand. This technology that facilitated simplistic communication over distances creates new problems and breaches in communication. However, other forms of technology can provide new bridges across these distances. Interactive exchange across the Internet can create a medium for immediate communication and contact. But if entering any message and submitting it. This creates an illusion of immediate communication and contact. But if you read a message and wish to respond, that respond becomes coded in the bulletin board listing, as a response to the first message. In fact, it is not even coded with an identifiable subject heading. Although this bulletin board seems to allow for a free flow of communication, once you are involved and responding to messages you soon find it is actually more cumbersome than talking. The groups participating typically had a large number of students relatively unfamiliar with computers, some with keyboarding. Extra time had to be assigned to provide sufficient training for students to participate. “On-line” responses had subject headings which could be perused prior to selecting and reading according to class assignments. But responses, which were required of students, and often led to interesting discussions, did not receive a subject heading. After each subject heading listed for each original entry, Notes simply provides the “number” of responses to that note. This made it difficult to get engaged in a discussion on a topic without tediously reading through all responses before finding those of interest and responding.

Local Area Network. The computer network that provides the easiest access for use as well as training is the local area network (LAN). This technology of linking a number of computers together (usually 20 or 24) simplifies the ability of each computer to access a databank of software housed in one of the computers on the network. It has been found that each user can access the software more quickly if it is in his or her own hard drive. It was not long before I found we had all the necessary software available on each computer in a network.

VAX Notes. Another network setup we have tried is Notes, a bulletin board communication software available on the mainframe. Such software supports email exchange, file exchange, and an ongoing bulletin board communication. This bulletin board allows users to read messages posted by anyone else in the group. Each message appears in order, allowing those in the system to read each message in order as it is sent and anyone may choose to respond to any message. Looking at this as a medium for communication it is interesting that no one is required to respond, yet everyone has access to read and to respond if desired. One of the aspects of the way this system is configured may actually create more of a problem than is immediately obvious.

The Notes bulletin board displays each message as it is entered. There is a very short delay between typing and entering any message and submitting it. This creates an illusion of immediate communication and contact. But if you read a message and wish to respond, that respond becomes coded in the bulletin board listing, as a response to the first message. In fact, it is not even coded with an identifiable subject heading. Although this bulletin board seems to allow for a free flow of communication, once you are involved and responding to messages you soon find it is actually more cumbersome than talking. The groups participating typically had a large number of students relatively unfamiliar with computers, some with keyboarding. Extra time had to be assigned to provide sufficient training for students to participate. “On-line” responses had subject headings which could be perused prior to selecting and reading according to class assignments. But responses, which were required of students, and often led to interesting discussions, did not receive a subject heading. After each subject heading listed for each original entry, Notes simply provides the “number” of responses to that note. This made it difficult to get engaged in a discussion on a topic without tediously reading through all responses before finding those of interest and responding.
Internet Email. Eventually, the simplest network setup proved the most useful. In search of a solution of the amount of training time required for novices to learn the necessary commands to participate, and to find a way around the cumbersome set up of “numbered” responses to “named” Notes, as just described, it was decided to simply provide students with computer addresses and NOT require the use of notes. A Group was created and named, so that, any message sent to the group name would go to all members of the group. Separate or individual messages could also be sent to the professor or to any student in the class. All that was necessary for the group to be established was for the email addresses of the entire group to be named as a group and for this list to be accepted as a file by each of the members of the class group. This enabled anyone in the class to be able to send to the entire group. This simple format was noticeably the best for providing the exchange of communication needed: e-mail exchange, file exchange, group access to communication, and relatively easy access for each member of the class.

Video Support
Whenever there are more than one student at each site, it is possible to institute small group discussions at these sites and then report back to the entire group, but there are usually one or more sites with only one student in attendance. It became evident that the pace of discussion in the class, whether of lectures, questions, or group discussion was greatly slowed if not disrupted across this audio setting. This was made considerably more difficult when equipment did now allow for easy change from one speaker to the next. There is typically too much of a delay for this to be like “discussion” and with voice-prompted mikes, the slightest noise can cause disruption. It was necessary to find some alternative forms of communication to add to the setting.

Besides the uses of computer communication already discussed, brief videos of “mini-lectures” were created, copied, and sent to each site. This enabled students at each site to go “off-line” during the class time and view the week’s video before returning to the whole class setting on audio. Students responded favorably to the addition of these video mini-lectures.

The use of video “mini-lectures” was expanded to allow for student in-class activity assignments related to literacy learning to be video-taped and sent to the instructor. Not only did this enable the instructor to see a student teaching reading in his or her actual classroom, it also allowed for excerpts to be re-taped and a “class demonstration” tape to be subsequently shared by the entire group of students. These tapes became a means for using technology to establish greater communication in the group.

In conclusion, the positive effects and responses from students related to these demonstrated uses of technolog-
cal support for learning were enormous, by their accounts. The great benefit students themselves write about in comments on line and about the class suggest that the extra effort and time required to set up and provide these elements of support are certainly worthwhile. What the students have to say about how their own learning was enhanced provides excellent justification for anyone considering implementing these uses of technology to support students’ learning experiences in any class.

Thomas A. Caron is an Associate Professor of Reading Education at West Virginia Graduate College, Sout Charleston, WV 25303. 304-746-2023.
E-mail: tcaron@wvgc.edu
As part of the curriculum in LAE 4360, students are required to read and respond to a variety of articles. These readings and responses are coordinated with the students' experiences in LAE 4941. The instructor of LAE 4360 makes the request that responses should be at least a page in length.

**The Web-enriched Environment**

Prior to the Fall 1996 semester, Web-sites were created for all LAE 4360 and LAE 4941 classes. (See the attachments to see how the site was set up). The creator of the web-sites gave all instructors of both courses a mini in-service concerning how to use the Web-site so that they could incorporate it in their classes. The faculty who taught the LAE 4941 course were initially excited about the prospect of not lugging home thirty spiral notebooks every weekend. They all became familiar with the Web-site in a trial run.

The Websites included sections for the following: class roster, syllabus, readings (some articles in their entirety were placed on the Web — a new article about every three weeks), conference rooms, and an interactive message board, where students were to write their responses to the articles available over the Web. The responses posted to the Interactive Message Board (IMB) on the Web were assigned to be "of similar length" to those done off-the-Web (written in pen and paper or word-processed — no student ever handed in copy written on a typewriter).

When students signed on to the Interactive Message Board, they could read other students' comments, then post a response, themselves. If a student wanted to respond specifically to a comment made by one of her peers, she would have one of three options:

1. Click on the person's e-mail address at the end of that student's response and send an e-mail message directly to them.
2. Post a second response to the individual on the Interactive Message Board.
3. Contact the student via e-mail (or in person) and move the discussion into one of the three conference rooms, designated for just such a purpose.

During the semester, the 22 students of LAE 4360 posted three responses to the IMB and wrote out three responses using pen and ink or a word-processor. Initially, it was thought that computer availability would not pose a problem for students, as the College of Education had over 100 Internet-accessible computers available in their lab, another nearby building had 60 Internet-accessible computers, and there were several hundred others available in the three libraries and scattered around other locations on campus. Although no student said that they were ever "closed out," many students complained that it was "just a hassle" to come into campus to respond to the topic rather than being able to "scribble something on a sheet of notebook paper." Few complained of a wait to gain access to a computer, and, of those who did, none complained of a wait longer than five minutes.

**The Differences of Language in the Two Environments**

Of the 132 possible responses, there were 116 samples of writing in all, 59 on the Interactive Message Board and 57 handed in on pen and paper (some students failed to turn in particular assignments or turned them in late and were not counted). For each response, I calculated the number of words written, the number of sentences per
response, and the number of words containing more than three syllables. I also made notes on the kinds of language used.

In general, when students did NOT use the Interactive Message Board, they tended to write 2.5 times more words and tended to write sentences that were twice as long. In addition, the number of grammatical and spelling errors in the Interactive Message Board responses were about three times higher than when students wrote handwritten or word-processed responses. Given these three conditions — that students tended to write fewer words, compose shorter sentences, and have more errors, it is a little surprising to note that the vocabulary used by students over the Interactive Message Board tended to be a little more polysyllabic.

A Closer Look at Some Student Responses

Below are some sample excerpts taken from student responses in both conditions — from the Interactive Message Board and from handwritten/word-processed papers.

Bess (Interactive Message Board)

"The one thing I’m confused about with the project is the sequencing. Have the students already read the play at home, so that the class can begin discussing it together? I assume we don’t ask them to figure it out on their own and then come together. Also, is this six weeks set up for black [sic] schedules or hour classes? Also, how are grades given? I didn’t understand the 10-%/20% deal. I also think I might leave out the summary option — it seems kinda lame compared to the other projects."

Bess (Word Processed Response)

"This article brings up another important issue: that pedagogical theories often become limited when we as teachers jump on the bandwagon of what’s ‘fashionable,’ without thinking of what’s good for our individual students. While I do believe wholeheartedly that I should be open to revising my teaching practices, to always listen to new ideas, etc...I also know what it feels like to try, even in small things, to fit into a certain mold because of pressure not to be too (gasp) traditional."

Randy (Interactive Message Board)

"But, what I’ve found over the last year with the increasing popularity of the Web, that the Web is actually becoming as complicated to find specific [sic] material on specific subjects due to time constraint [sic]. How will the [sic] become organized as it continues to grow bigger and bigger everyday?"

Randy (Handwritten Response)

"As teachers, we are said to be a sense of authority in the classroom to our students. We didn’t go through four years of college for nothing. So, yes our jobs are to guide the classroom learning environment, but also to be an authority figure on the subject of English."

Pearl (Interactive Message Board)

"I like the ideas in this article — especially the hints about links to Web sites around the world. Students will find an interactive approach to the language arts fresh and relevant."

Pearl (Word Processed Response)

"At this stage of the process, whether as a result of peer editing or teacher conferences, students will have had several opportunities to work on content, grammar, punctuation, and form. Thus, bringing in the red pen for objective comments enables the teacher to ‘be constructive, but should also provide enough encouragement to make students want to keep writing’ (2)."

Sarita (Interactive Message Board)

"Would even a great approach to studying Shakespeare, as the one in this article, be capable of getting these students involved in the Bard? Can’t hurt to try, I guess! I was also curious to know, when arriving at the mention of ‘discussing’ the text, exactly how a discussion of the play would transpire in this non-traditional approach to Shakespeare."

Sarita (Word Processed Response)

"While I believe a certain emphasis on these philosophies is healthy, I also firmly believe in the teacher as role-model, mentor, and authority (in the sense that you’ve gone to school for many more years than your students and, hopefully, know a little more than they do). So, I believe there is plenty of room for both systems to coexist in the classroom, but I also strongly believe that teachers shouldn’t be afraid of pushing their students, of challenging them beyond what they think they are capable of and then, when the student founders, providing students with their expert guidance."

Table 1
A comparison of the language of responses on the Interactive Message Board and handwritten/word-processed responses

<table>
<thead>
<tr>
<th></th>
<th>total number of words (mean)</th>
<th>number of words per sentence (mean)</th>
<th>number of words using 3+ syllables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interactive Message Board</td>
<td>178.3</td>
<td>9.0</td>
<td>1 per every 10 words</td>
</tr>
<tr>
<td>Handwritten or word-processed responses</td>
<td>431.3</td>
<td>17.8</td>
<td>1 per every 12 words</td>
</tr>
</tbody>
</table>
Even a cursory examination of the differences in these pairs of student responses will reveal that the tone and style of the writing on the Interactive Message Board differed markedly from the handwritten/word-processed responses. In the Web environment, word choices are much more like oral language than written — Bess wrote, "kinda lame," Randy made many proofreading errors (and used the phrase "bigger and bigger" to describe the growth of the Internet), Pearl and Sarita wrote in noticeably less sophisticated language on the Interactive Message Board.

Conclusions

While there is much evidence to support the contention that students writing on the Interactive Message Board tended to be more conversational, to employ simpler sentence structure, and to utilize many features of oral language, the high use of polysyllabic words makes categorization more complex. Anyone who has ever transcribed an oral interview from audiotape knows that informal oral speech has many, many more false starts, repetitious language, and nonsensical sentences than were evidenced by the four excerpts of student writing on the Interactive Message Board. Indeed, it appears as if student responses on the Web were somewhere between the sophistication of written language and oral speech. Because the assignment was identical in both conditions, the disparity in the language used by students may be attributable to student perceptions of the limitations and propensities of the Interactive Message Board.

Student Observations of the Different Writing Environments

For a final assignment, students wrote a ten-minute response (using pen and paper) concerning the differences between posting a response on the Website and writing one otherwise. Most of the students reported that they perceived ease of use to be the major advantage of posting responses on the Interactive Message Board.

“It's pretty tough to lose the article once it's assigned — and with the amount of loose paper in my life, this is a wonderful thing.” (Sunny)

“I like to post things on the Net because I don’t have to worry about turning it [sic] in.” (Cathy)

“I feel less pressured to turn in perfect copy when using the Net.” (Katrina)

“The whole issue is [one] of convenience. Using the computer seems to be a lot easier for me.” (Mykeisha)

“I am so used to writing on my dated word processor that I think that I am used to writing on a screen.” (Cody)

“By using the Net, I am forced to do my response while the article is fresh in my head.” (Craig)

“I prefer the Internet because I feel like it can be more of a freewriting response. I don’t worry as much about grammar and mechanics.” (Leigh-Anne)

“When we write on the Net I am a lot more comfortable with my writing language. It sounds more casual to me and doesn’t feel very well thought-out.” (Coleen)

Two disadvantages to using the Interactive Message Board listed by most students were the difficulty of revising written responses and inconvenience of reading articles on the screen.

1. Difficulty of revising written responses

“I like to write in the margins, and use a highliter pen when I read and write. Posting the answer to the bulletin board was quick, but I felt unsure of what sized response to make.” (Pearl)

“I felt myself having to abandon writing to go back up to the text so that I could refer back [sic]. If I had the actual text I could simply look up and see the part of the text I needed. I just felt restrained.” (Larry)

“I don’t feel I ever do my best writing on the Net. I feel everything I do is like my e-mail correspondence — random connections, stream-of-consciousness.” (Bess)

2. Inconvenience of reading articles on the screen

“When I have a hard copy I have the luxury of reading outside and writing my response at the park, in the pool, or wherever. I lose that once I log on.” (Deidre)

“I like having the text in front of me to refer to which you cannot do on the computer. It's most irritating that I do not have a computer at home.” (Janie)

“I tend to read more carefully and my writing is generally of a better quality when I write on paper.” (Sarita)

“When responding to an article, I like to have the article in front of me so I can refer to it. This is pretty much impossible since the article is on a totally different page than the IMB.” (Cade)

Only a few students chose to mention what initially was considered to be a major advantage for posting responses on the Internet — the ability to read other students’ responses.
"I like reading what other people have already posted. I like a little time to 'digest' what I've read before I respond to it." (Rose)

"With the Net, I feel like I'm sending my ideas out into nowhere for anyone to criticize them. It's kind of a defenseless feeling." (Bertha)

Plainspeak or Technomorph?

In a study of participants' use of "long-distance conversations over computer," Wilkins (1991) found that correspondence over the computer tended to share many linguistic similarities to oral speech, including lexical repetition, false starts, and prevalence of informal language. These features were evident to some degree in most of the students' responses on the Interactive Message Board.

Although Walther (1996) has suggested that computer-mediated communication might allow for even more ego involvement and personal interaction (called "hyperpersonal interaction" by Walther) than face-to-face encounters, no such hyperpersonal interaction was detectable in student responses. In fact, the feature of a student being able to respond immediately to the response of another student via e-mail was rarely utilized. No group of students ever established a sufficiently compelling conversation to take it to a conference room, which had been expressly created for such a purpose. To be sure, the e-mail and the conference room features were not utilized much.

What is most interesting about this semester-long study is students' perceptions of the limitations of the Website. Indeed, one disadvantage to the Interactive Message Board which was cited often by students — the difficulty in revision — could have been easily solved by word-processing a response first.

A word-processed response could be copied to the Interactive Message Board easily. Although students were shown how to perform such an operation early in the semester, none chose to try it during the course of the term. It was as if, once students logged on, there was a sense of urgency to fire off a rapid reply that was not present offline.

Similarly, students could have avoided the inconvenience of having to read the articles on the computer monitor by printing out the article on one of the many printers available. At the time, all laser and dot-matrix copies were free of charge. Yet, few students ever printed out copies of the articles.

While the language of the Interactive Message Board had many qualities of plainspeak — an easily accessible, easily comprehensible almost oral type of language — the prevalence of polysyllabic words and the unexpected perceptions of students regarding the limitations of the technology, seem to characterize the language of the Interactive Message Board as a sort of technomorph — a language that exists somewhere between the oral and the written, moderated by the individual's perception of the capabilities of the technology at-hand.

References

The Internet (Net) is a powerful and versatile environment for literacy development. Teachers can actively engage students in writing by providing individual students with opportunities to communicate with one another on-line, to locate current literature for a research report, or to compose a World Wide Web (Web or WWW) page for the class. However, the Internet can also become a complex and uncontrollable learning environment if not monitored properly. Internet users may sometimes get lost in the large amount of information which might be either inappropriately presented or useless. To obtain the best results using the Internet in the writing class, it is crucial to plan adequately and implement tasks only after careful analysis of how each component of the Net meets students’ literacy development needs.

There are many different services or components of the Internet, such as electronic mail (e-mail), Gopher or File Transfer Protocol (FTP) for information exchange between remote computers and the local computer, discussion lists, and the World Wide Web. These components, as briefly described in this article, make the Internet versatile and interesting. More importantly, these components can facilitate a rich and exciting learning environment for reading and writing instruction. With good planning, teachers can set up highly engaging and authentic activities that make extensive use of Internet components.

Examples of Internet-based instructional writing activities include the following:

- Learning to find resources on-line. On-line databases, files, and information accessible via the World Wide Web greatly expand the speed and immediacy with which students can conduct research. Students can track weather conditions in far-away places to write reports for earth science or geography classes; in a history or government class, they can read and discuss the texts of candidates' speeches on the same day they were delivered, and can then write responses to be sent immediately to the candidate; they can extend their interest by writing messages to be posted to discussion groups, where they will be read by hundreds or thousands of others with similar interests. They can explore careers by visiting sites on the World Wide Web that allow them to learn about the work of individuals in many fields, or by downloading information about educational programs and requirements.

- Presenting the results of their research in a variety of interactive formats using multimedia and hypermedia programs. To enhance the traditional oral or written report, students can create graphical slide shows, or even Internet home pages, to share their knowledge and interpretations with others.

- Establishing interpersonal exchanges, including "keypal" (electronic penpal) connections and on-line "mentoring" of students to facilitate language learning, to improve precision and clarity in writing, and to learn directly about other people and places.

- Posting questions to solicit other people's opinions about books and other media, current events, or issues in their research projects.

- Engaging in critical and creative thinking through on-line simulations. Through vivid programs that replicate the experience of being in a place, or through interacting with others in a MUSE (a real-time, multi-user simulated environment that may be text-based or object-oriented), students can come to know about an era, a locale, a social dilemma, or a political decision in a way that was not possible without the technology. These virtual experiences, like actual experience, can form the basis for vivid and detailed writing and more active, engaged learning.

Fig. 1. Internet-related activities.

Types of Internet Activities

When considering the many components and services available on the Internet, three different areas (or types) of...
activities related to writing instruction can be identified (as shown in Figure 1), according to their function: resource-based, communication-based, and publishing-based. Resource-based activities are those in which students use the Internet to locate information relevant to various projects that involve writing. For example, when writing research papers on career choices or health issues, students can visit Web sites of schools, corporations, or support groups. Communication-based activities are those in which the main purpose is to engage students in use of written or oral language for "real" communicative purposes, so that they become more fluent and comfortable with interactive language processes. An example of a communication-based activity would be an e-mail exchange between students at two different schools collaborating in data collection for a science project. Publishing-based activities also involve communication, but to a wider audience than e-mail. By creating home pages that can be visited by anyone in the world browsing the Web, for example, students can publish their work for a wider audience than was possible before the Internet.

Within these three areas, two types of activities are identified to engage students in active learning: a) activities that develop basic skills and knowledge about Internet components; and, b) activities that require application of Internet tools for integrative writing tasks.

Once students have mastered the basics of the Internet through assigned activities, the goal should be for them quickly to start using the Internet as an essential tool for learning their school subjects. In doing so, they will develop literacy skills such as organizing information, considering audiences, spelling and punctuating correctly, reading critically, and formulating ideas clearly in writing.

Using the Internet for Communication

Using the Internet for communication means e-mail, but it now can involve much more (as in Figure 2). E-mail remains one of the most popular applications of the Internet. If there is no other use of computers for communication in schools, teachers will probably want to use the Internet's capacity for one-to-one message exchanges between teacher and student, student and student, and students with others outside the classroom as ways to develop an understanding of how to use written language effectively. Mail provides not only an immediate, real audience for students' writing, and therefore a motivation to write, but also an opportunity for users to see each other's written work, to offer critiques and comments within a community of writers, and to develop a sense of the relationship between oral and written discourse.

The potential of electronic mail expands when students have access to listserv discussion groups and Usenet newsgroups. With these facilities, the audience for student writing is expanded and students' literate communities can begin to encompass a much wider world than their individual classrooms and neighborhoods. With proper precautions, participation in discussion groups can introduce students to the ways that common interests and purposes help to define different styles of communicating within subcultures. The tone and style of messages, and not just the content, differs greatly between sites, ranging from the whimsical, spontaneous postings on alt.rec.MST3K groups to the polished, thoughtful, and knowledgeable postings on alt.rec.music.classical groups. Teaching about "netiquette" and the discourse conventions of on-line discussions can enhance students' appreciation of the relationship between language forms and social contexts, audiences, and purposes.

Additional communication-based activities include Internet Relay Chat (IRC) and videoconferencing. These real-time modes allow several individuals at separate remote locations anywhere in the world to exchange instant messages, viewing the messages as they are entered, or actually seeing moving pictures and hearing audio of others in the group during a conference. Already, on-line services such as Scholastic On-line have provided students with many opportunities to interact with well-known adults such as the authors of children's books in on-line forums; these new technologies make it easy for teachers themselves to arrange for on-line "guest speakers" with knowledge directly related to students' reading and writing assignments, and in an even more vivid and immediate way than could be done before. Also, if students in classes at different sites are collaborating on projects, conferencing technologies can allow them to contribute ideas for immediate evaluation by the whole group.

These communication-based activities all allow teachers to engage their students in dynamic activities for meaningful discussion. Rather than completing static and predictable exercises, students focus on issues that are important to them while interacting with others via language.
Finding Resources

Students can use the Internet to find a wide range of resources using several different technologies (as shown in Figure 3). Kinds of information to be found on the Internet include complete texts of famous speeches and works in print, high-resolution pictures from recent space exploration, sound clips, digitized movie clips, and application programs with educational value. The latter are available in demo versions, as shareware, and sometimes as freeware. Some materials available on the Net have been placed there by other students, including pictures, maps, and local information related to particular schools, artworks, stories, poetry, and research results developed by students in all grades, and requests for information and correspondence.

How students obtain these resources depends on the kind of hardware and software they have for accessing the Internet. Even the least sophisticated forms of Internet access usually allow for file exchange through FTP, which can be used to move files directly to and from any site for which students know the current address. Students can also use FTP to make their own files available to others by uploading to a server. Beyond basic FTP, different degrees of searching capacity are available through Gopher and the World Wide Web. Many sites still use Gopher to organize information and make it searchable. With a Gopher client, students can select from hierarchically organized menus that enable ever more narrowly defined searches. With a web browser, the possibilities for organized information searching become much more diverse. Students can learn to use a half dozen or more search engines easily accessible through the World Wide Web.

Recently, a wide variety of directories and maps have become available on the Internet that might be interesting and useful for students. By simply entering an address, students can obtain a detailed street map, weather report, and listing of local attractions. Names and telephone numbers of potential research sources are more readily available than ever on the Internet. Companies, colleges and universities, government agencies, and media outlets have sites on the World Wide Web that are rich with possibilities for browsing, analysis, and criticism.

Opportunities for developing organizational and locational skills and critical reasoning abound as students learn to recognize the most efficient pathways to the information they need to complete writing projects. If, in their searches, students discover many different pieces of information that are useful and would like to plan return visits to specific sites, they can use bookmarks to keep track of their paths to information. Through their use of the Internet, students can develop inquiry strategies and cultivate an attitude of curiosity. They continually practice problem solving as they attempt to find the most useful information in the most expedient way possible.

Publishing

Using the Internet gives students an unprecedented opportunity to have their work seen and responded to by others. With the ability to make files available through and especially on the World Wide Web, any student can reach a potential audience of countless, diverse individuals easily. To make the most of this potential for students' literacy development, teachers can help students develop an increasingly sophisticated sense of audience and can guide them toward an appreciation of principles of design as well as of appropriate forms of language.

Developing a personal home page can be the occasion for exploring and discussing the many different elements that go into an effective publication. In addition to text
elements that must be concise and informative, students need to produce pages that are visually attractive and easy to navigate, or else risk having few visitors to their site. Learning about screen design can involve collaboration among art, business, and English language arts teachers. Students can quickly learn from visiting sites on the Web that the best home pages are under constant development, which demonstrates the importance and authenticity of revising one’s work.

While learning how to design a home page, students can integrate other aspects of their reading and writing skill and their knowledge of school subjects. They can gather information about timely issues, perhaps the themes of their literature units such as family, friendship, or survival, through surveys of those who visit their site. They can make their reactions to individual reading or viewing available to others in a “critics’ corner,” which also might spark the interest of remote peers to read a well-reviewed children’s book or young adult novel.

There are practical considerations in Web publishing more complex than those associated with either e-mail or Internet searching. Some community leaders have advocated the sale of advertising on school home pages—similar to the sale of sponsorships in a school yearbook or newspaper—as a way not only to forge a mutually supportive school-business partnership, but also as a way to teach students about the reality of how all kinds of media operate in society. Also, Web pages are currently based on HyperText Markup Language (HTML), which is difficult to learn. Teachers can facilitate their students’ publication on the Web through use of specific Web editing programs, or through use of newer office suites that provide for easy conversion from word-processed documents to Web pages.

Suggestions

Whether the Internet is used for interactive communication, for resource gathering, or for publication, teachers may want to consider the following suggestions.

Get on-line. Just as teachers of reading must read the material carefully before showing students how to read, and just as the best teachers of writing write along with their students, teachers who use the Internet should take time to explore the Net themselves. Only by negotiating the complex links and the many pathways to information can teachers develop a true appreciation for what their students must do to learn with the Internet. Internet technology is growing and changing so rapidly that it may be especially true in Internet-using classrooms to say that the teacher is learning along with students; even so, it is important for the teacher to try to stay at least a few steps ahead.

Provide necessary guidance for students as they explore the Net. Perhaps because it is still largely unregulated and conducive to many forms of free expression, the Net incorporates material representing a wide range of accuracy and appropriateness. Teachers need to insure that students’ use of the Internet remains educationally productive and focused on appropriate content. The same strategies teachers use to encourage careful, critical reading of books and articles are even more important when the materials students encounter may not have been subjected to rigorous editing. It is important for teachers to know which sites their students visit, and sometimes it is appropriate to limit access to the most educationally relevant sites.

Let students explore. For the Net experience to remain authentic and for students to develop the habits of inquiry and problem solving mentioned above, students need to seek their own pathways to information. This implies developing open-ended assignments that allow for dynamic and interactive searching and exchanges of information with others.

Encourage students to define their own topics and interests. When students’ literate activity is grounded in their own experience, their ability to manipulate language is least constrained, and they have the greatest motivation to work and to learn.

Encourage sharing. Whether by exchanging messages or drafts with a partner, by working collaboratively in pairs or teams of students on publishing projects, or by seeking replies from others via e-mail, students learn best about the nature of language when they are engaged with others in meaningful discourse.

Take full advantage of off-line browsers for safe and efficient browsing. Off-line browsers help to avoid not only inappropriate kinds of interaction and information, but also the bottlenecks that occur increasingly when too many people try to access the Web at once, or when too many people try to access the same site at the same time.

Develop integrative tasks for the Internet. Because of its dynamic and interactive nature and the variety of resources available, the Internet lends itself to cross-disciplinary and integrated learning across the content areas. Communicating, finding resources, and publishing on the Internet can be the occasion for more integrated and applied learning than was possible before Internet tools were available.

Checklist

The following checklist includes items that teachers will need to consider when planning instructional reading and writing activities that employ Internet components:

1. Do students have sufficient access (time, computers, etc.)?
2. Are the materials on-line appropriate for students to explore?
3. Are project objectives clearly defined?
4. Which inquiry and problem-solving skills will students apply in their search for information?
5. Are students encouraged to take the initiative to find materials of interest to them?
6. Do students have adequate direction in their choice of subject matter?
7. Do resources obtained actually satisfy the students’ need for information?
8. How will each student who writes something be insured of an individual response?
9. Will exchanges among students be structured to maximize useful feedback?
10. Has the target audience for writing and publishing been clearly identified?
11. Are the various elements in students’ web sites coherently presented?
12. Does each student have an opportunity to contribute to publication?
13. Can students integrate several different components (text, graphics, sound) in their projects?
14. Are follow-up activities arranged so that students reinforce their learning through debriefing and sharing?
15. Are students’ Net experiences exciting?

Conclusion

The Internet has provided an environment which is conducive to literacy learning. With the amount of information available and the speed of access to the Net both increasing, the distance between people is greatly shortened. While effective strategies for communication within one’s own culture are critical, cultural awareness of other people and other countries has become increasingly important. With the help of the Internet, students’ literacy skills, such as reading, writing, and communication, can be immensely enhanced and directed toward expanded cultural horizons. Once teachers and students get on-line, they arrive at a wide, mostly informal arena where they can locate countless up-to-date resources relevant to the topics they are interested in. They can also develop effective communication with people all over the world in a short time.

The Internet, if employed dynamically, can facilitate a great variety of activities for teaching and learning. This paper identifies three different types of activities for reading and writing instruction: resource-based, communication-based, and publication-based. These activities are not isolated, but should be integrated to address individual student’s needs, and to inspire students to explore various resources, and to learn to think and communicate effectively. Teachers should become actively involved by updating their own knowledge and skills about such a new, yet powerful globally networked learning environment.

John M. Zbikowski is an Associate Professor of the Department of Curriculum and Instruction, College of Education, University of Wisconsin, Whitewater, WI 53190. Phone: 414-472-4860. E-mail: zbikowsj@uwvax.uww.edu

Alex C. Pan is Assistant Professor of the Department of Curriculum and Instruction, College of Education, University of Wisconsin, Whitewater, WI 53190. Phone: 414-472-1831. E-mail: pana@uwvax.uww.edu

More Internet-based reading and writing projects should be developed to further enhance the value of the Internet for learning.
EXPERIENCE STORIES TEACH THE WRITING PROCESS AND FOSTER TECHNOLOGY SKILLS

Jan Rader
The University of Mississippi

The language-experience approach (LEA) has been traditionally used as a means of teaching students to read by "capitalizing on their interests, experiences, and oral language facility" (Nessel & Jones, 1981, p. 1). Young students typically dictate experiences to their teachers, who print them on paper, recording the students' exact words. These "experience stories" then become the basis for reading instruction. Since students "write" about their personal lives at their expressive language levels, experience stories are not only meaningful but also highly motivating.

The LEA in Special-Needs and Traditional Classrooms

The flexible nature of the LEA makes it ideal for use with special-needs children (Hansen-Krening, 1982). As a teacher of the hearing impaired in the late '70s and early '80s, I used experience stories on a daily basis in my total communication classroom, providing real-life, language-rich adventures for students to write about and read. This helped counteract the utter frustration many hearing-impaired students met, trying to develop literacy skills during formal reading instruction using the required basal reading series—one that was designed for children with normal language proficiency.

Later, when I moved from special-needs to traditional classrooms, the LEA moved with me. Experience stories proved a valuable tool for teaching and learning with these students as well. Experience stories were used to document classroom activities and special events, to teach and reinforce appropriate classroom behavior, to express and promote the beauty and value of both cultural diversity and similarity, and to motivate students to keep reading, reading, reading.

The LEA and Computer Technology

The introduction of computers have provided a new dimension in LEA. Michael Corey Alger, currently a third-grader at Franklin Park Magnet School in Fort Myers, Florida, won a first-place ribbon in last year's district-wide Young Author's Conference for his experience story, The Biggest Fish Story. Michael first wrote his story by hand. Later he keystroked it into the computer at home and added clip art from Corel Draw.

Robert, Michael's father, is dedicated to using experience stories to motivate Michael to practice his reading, writing, and thinking skills. This year, Michael has written Bob the Bass and The Peacock Story, using the computer for both text and graphics, including scanned images. (See Figure 1.)

Figure 1. Cover for Michael's Experience Story, Bob the Bass.
Robert noted that Michael has a much easier time composing experience stories when he has photographs, drawings, clip art, or other visual cues to prompt his writing. So now, the creation of experience stories has become a family activity. Father and son plan stories together, developing sequences and time lines. They capture appropriate snapshots of events or situations and compile them into beautifully finished, desktop published works. Truly family treasures! As a result of these technological features, coupled with more recent research on writing have enabled LEA to evolve.

**Using the LEA at the University Level**

At the Ole Miss (University of Mississippi), preservice and inservice teachers enrolled in EDRS 557 Computers in Education learn about the LEA, the writing process, and computer technology concomitantly while creating their own experience stories.

![Diagram: The LEA, the Writing Process, and Computer Technology Are Combined in the Creation an Experience Story.](image)

Figure 2. The LEA, the Writing Process, and Computer Technology Are Combined in the Creation an Experience Story.

First, university-level students are introduced to the LEA. They are provided with not only the educational philosophy associated with this approach but also with examples of its application for young learners.

Students are encouraged to begin thinking about the experience stories they intend to create, the key question being, “Is it meaningful to me?” Students must determine whether the stories they chose to develop are meaningful to them as educational practitioners, as parents, as students, as individuals, or as children at heart. The more meaningful the stories become to the writers, the greater the chances for their successful completion of rich, interesting, exciting experience stories for all of us to share.

After discussing writing, in general, and the use of style, tone, and voice, specifically, participants learn that the parameters of the experience stories they will create are an expansion of the traditional LEA. They have the options of creating experience stories with their students at school, their children at home, or by themselves. They can use their own voices and write from adult perspectives, or they can write from the perspectives of children, animals, plants, or inanimate objects. They can take on the roles of narrator, storyteller, main character, instructor, distant observer, etc. Their stories can be based upon single experiences or a multitude of experiences with unifying themes. The stories can be factual or fictional, serious or humorous, etc.

**Incorporating the Writing Process**

Students are introduced to the writing process that will be used during the creation of their experience stories. This process includes prewriting, drafting, revising, proofreading, and publishing. At first, the writing process appears linear to students. They soon discover, however, that it is dynamic.

Although many preservice and inservice teachers seem to have an intellectual understanding of the writing process, few have ever truly used it in their classrooms with their students. Even fewer have used the writing process for their personal or academic compositions. However, once students apply the process to their own writing of experience stories, it soon becomes a personal educational tool for them.

**Incorporating Computer Technology**

At the same time, students are introduced to several software applications and computer technologies that they can use in the production of their experience stories—from using simple word processing applications for brainstorming during the prewriting stage to using scanners and digital cameras for importing pictures during the drafting and publishing stages.

**Establishing Experience Story Guidelines**

This semester, student were provided with the following Experience Story Guidelines:

1. Your experience story must be created, developed, and produced using the writing process. This process includes prewriting, drafting, revising, proofreading, and publishing. Remember, this is not a linear process. It is dynamic, challenging, and fun!

2. During the prewriting stage, your idea(s) for an experience story must be presented to your instructor and other classmates for consideration, questions, comments, and discussion.

According to Hubbard (1988), author of *How Writing Works: Learning and Using the Processes*, “One of the richest resources in your writing class is the other people in it, not just the teacher but the teacher plus all the other students” (1988, p. 10). The sharing of experience story ideas at the
The prewriting stage also helps establish a learning community within the classroom. It sets the tone for a cooperative learning environment. Such cooperation will be essential in later stages of the writing process, when fellow students are called upon to edit and proofread the experience stories.

3. Although the initial rough drafts of your experience story may be done by hand, the first draft that you submit for the revising stage should be desktop published.

Students in these classes vary greatly in their computer technology comfort and ability levels. Some have barely touched computer keyboards. Others have already published Web pages. Therefore, a wide range of publishing options and expectations are presented.

Students who are new to the world of computers are expected, at a minimum, to desktop publish the text for their experience stories in a word processing program, such as Microsoft Works, Microsoft Word, or WordPerfect, and adhere photographs to their printed pages. For novice computer users, just dealing with margins, page orientation and numbering, text alignment, and changes in font size and style offer sufficient technological challenges.

Students who are more experienced computer users are expected, at a minimum, to scan photographs for importing into their experience stories. Some students have abandoned the scanner route, using digital cameras to capture and download images. Others have created their own illustrations using paint programs. Some students have developed on-line experience stories using multimedia authoring tools, such as HyperStudio.

As an instructor, it is gratifying to watch students challenge themselves to go beyond their initial technological capabilities. Motivating students to do so has never been an issue. The experience stories themselves seem to be the greatest motivating factor. Because they are based on some aspect of students' personal lives, the experience stories seem to capture their authors in whirlwinds of creative self expression.

4. Your first published draft must be edited by at least two classmates. Make sure you and your editors have discussed all questions, concerns, special style considerations, and revisions recommended for your experience story. Afterwards, your editors must sign the Experience Story Tracking Sheet, including comments as necessary.

Prior to this step, students were introduced to proofreader’s marks. They completed practice exercises in reading short compositions and marking them for revision. They were also introduced to basic page layout and design specifications and standards.

Students also learned the “rule of the pen” when marking for revisions. The rule of the pen dictates that writers use blue pens, editors use green pens, proofreaders use red pens, and the instructor uses a purple pen. This avoids confusion when determining which marks to follow. For example, when a page is marked with conflicting green and blue revisions, indicating a point of contention between a writer and an editor, the purple pen prevails!

In addition, students were introduced to using the Experience Story Tracking Sheet, a form used in the writing and publishing process. (See Figure 3.) The tracking sheet provided students with a visual means of monitoring the progress of their experience stories.

Figure 3. The Experience Story Tracking Sheet Used by University-Level Students.

5. You have the option of submitting the draft of the experience story to your instructor for review now or later, after you have incorporated the recommended revisions. (This depends upon your personal preference and the extent of the recommended revisions.)

6. Following the revising stage, your experience story must be proofread by two of your classmates. The proofreaders will check for the incorporation of recommended revisions and mark any additional corrections that are necessary. Therefore, you need to provide your first draft, as well as your revised version for the proofreaders. (It is recommended that you keep previous versions in a pocket folder with the Experience Story Tracking Sheet attached.) After completing their review, your proofreaders must sign the Experience Story Tracking Sheet.

7. Following the proofreading stage, your experience story should be turned into your instructor for review. If necessary, you may repeat numbers 5 and 6 above.
8. Be prepared to share your published work with the entire class during the final week of the semester.

Some Samples of Students' Experience Stories

Just like show-and-tell time in the primary grades, there is an excitement in the air when the university-level students share their experience stories. Not surprisingly, the stories were as varied as the students themselves, and provided individual insights. Some students wrote about their children, while others wrote group experience stories with their classes based on field trips. One student even used the narrative genre to help clarify educational theories.

The Need for Life-Long Learning with Computer Technology

Of course, there were several measurable instructional objectives that these students mastered during the creation of their experience stories. However, the most important instructional objective can only be measured over time: students will become life-long learners, always striving to improve their computer technology skills in education.

The Teaching of Writing course was first taught in 1980, the same year that the Master’s Computers in Education degree program was initiated at Lesley College. For many years there was no connection between the two. Then, in 1993, two faculty in the School of Education collaborated to bring writing and technology together. The venue for the course shifted to a computer laboratory where students had easy access to the tools that facilitate composing. Over a four year period the course has continued to evolve by adding new technologies that extend and enhance the writing process.

The Teaching of Writing course was first offered as an elective in the Lesley College Graduate School elementary education certification program. In its original conceptualization, it was based on the research done at Atkinson Academy in New Hampshire by Donald Graves, now Professor Emeritus, the University of New Hampshire, and the Bay Area Writing Project (BAWP), a summer program initiated at the University of California, Berkeley. The Graves research established the importance of teaching writing as a multi-step process rather than through a red ink product model. The BAWP brought groups of teachers together during the summer to experience the process of writing as well as to study the research in the field. The ongoing work at both of these institutions created a new paradigm for the teaching of writing.

The course offered at Lesley combined these two approaches in a fifteen-week model that involved students in the stages of writing such as prewriting activities, multi-draft writing, peer response groups, conferences, self-selection of topics, and Author Chair. Pre-service teachers were asked to write memoirs, poetry, personal interest and research pieces and to live through the stresses and successes that their students from kindergarten to middle school might experience.

When the course was first offered the term “writing process” was just entering the glossary of education and most students had little formal training in writing. Although they often were intimidated at first about writing and sharing early drafts in small peer response groups, this quickly became an empowering experience that facilitated revision and heightened pride in publication via Author Chair. The point repeatedly made was that ownership and audience encourage students to find a suitable voice and to strengthen their writing. Students consistently comment that having been through the process lessens their anxiety about teaching writing.

The course, which had not at first been wildly popular, began to be selected more and more frequently. It is now required in the Consultant Teacher of Reading program and is a starred elective in a number of other Master’s degree programs. But what also began to happen was the looming presence of the computer, especially word processing. The writing course needed a new look and this time the faculty found it right down the hall in the pioneering and exemplary Computers in Education degree program.

Writing and computer technology are natural bedfellows. Each in its own way terrifies novices and each requires considerable exposure, training, and trial and error to become a comfortable tool for teaching and learning. It was the vision and the gentle prodding of one of the technology faculty that emboldened the faculty of the writing course to entertain the entry of technology. The collaboration began in a tiptoe fashion with suggestions of software that might motivate students.

The paradigm shift took place when several members of the literacy faculty were invited to a summer computer faculty training session in Snowmass, Colorado. This gave the two faculty who had applied for permission to team teach the Teaching of Writing course in a computer lab the opportunity to develop an entirely new syllabus. What made it possible for the writing faculty to view this shift with a manageable level of panic was the reassurance by the computer faculty that the content of the course would remain the teaching of writing and that the technology would support and extend that purpose.

This has, in fact, been the case, and as new tools have appeared they have been integrated as appropriate within the context of the course. These include: writing and graphic tools including word processors, publishing programs, digital cameras, and paint programs; CD-ROMs.
Fall arrived quickly. It was time to launch the Web page and to begin using Net.Thread conferencing software. During the planning stage it was all excitement, but reality set in when we faced the actual implementation.

During Fall 1996, we taught two sections of the course. The on-campus section was based on a fifteen-week semester. The off-campus section met in Westford, Massachusetts, on two weekends (one in September and one in October).

Our original hope was to have the two groups use the Internet to share their published work and to do on-line peer editing. This did not happen. The timing of the two classes was out of sync. The Westford group was always far ahead of the on-campus section. This might have been overcome if the Westford group had Internet access outside of class but only a fourth of the class had it.

We quickly realized, we would need to change our plans. To develop the on-line community of writing teachers we envisioned would take more than a semester to achieve. Although we tried everything we had planned, we did not do everything with both groups.

Throughout the two weekends in Westford, we used software to enhance the writing process. At the end of the course, we requested, but did not require, students to select one piece of their writing to be published on our web site. Eighty percent of the students signed the permission forms. The students submitted disks and hard copy. Digital pictures of each student were taken during the first weekend of the course; these too would be published. The timing of the two classes was out of sync. The Westford group was always far ahead of the on-campus section. This might have been overcome if the Westford group had Internet access outside of class but only a fourth of the class had it.

We quickly realized, we would need to change our plans. To develop the on-line community of writing teachers we envisioned would take more than a semester to achieve. Although we tried everything we had planned, we did not do everything with both groups.

Throughout the two weekends in Westford, we used software to enhance the writing process. At the end of the course, we requested, but did not require, students to select one piece of their writing to be published on our web site. Eighty percent of the students signed the permission forms. The students submitted disks and hard copy. Digital pictures of each student were taken during the first weekend of the course; these too would be published. The students used a variety of word processing programs and, of course, some students used Macintosh's while others used PC's. When the page was complete, students received the Uniform Resource Locator (URL) of the site. We have heard from a few of the students who are pleased with the published work of the class.

Meanwhile, the on-campus group marched on at the orderly pace of one three-hour class each week. As in the past, students used a variety of writing and drawing tools for the composing process.

The first Internet activity for this group was using the Web for research. The students were working on a personal interest non-fiction piece. Our intention was to have them use the Internet to do research for their projects. After a brief explanation of search strategies and search engines, we turned the students loose. For many of them this was their first experience using the World Wide Web. Frustration reigned as students found either volumes of information to be waded through or nothing at all. Some were successful; one student located relevant information on the rescue of greyhounds. She was ecstatic, unlike most of her classmates. The instructors tried in vain to respond to all the requests for help in developing search strategies. Students seem to expect immediate results when using the web. We doubt that they would expect this when using traditional library resources. It is interesting to note that, although we feel this session was problematic, many students forgot their frustration and subsequently commented on how pleased they were to actually use the web.

But a second technology calamity was lurking. We were curious about how students would respond to their readings if they wrote responses on Net.Thread. They could create a dialogic notebook by responding to one another in a series of entries. One of the instructors had used Net.Thread successfully with another class. She found that students who never participate in discussion in class, suddenly found a voice. With this success in mind, we were excited to try Net.Thread in the writing class. The demonstration of the software went smoothly. The students moved to the computers with enthusiasm only to be met with a technical problem. Only three or four students accessed Net.Thread; all the other computers hung up at various points in the process. The next morning the e-mail correspondence with the system operator went as follows:

Dear Vincent,

Net.Thread was a disaster last night. The demo went fine, but when we put the students on the machines, all hell broke loose. It worked properly on 3 machines out of 16. Some people could not get in at all. For others, Net.Thread hung after they typed the password. Some got in but got crazy looking icons for the navigation tools. I am hopeful that you can figure this out. We are planning to use Net.Thread again next week. Angie

Dear Angie,

The WWW server on that day experienced tremendous problems, we lost electronic mail, Web access, and Net.Thread access. These utilities were brought back during the course of the day. I believe the machine is now stable. Vincent

Even with this calamity the students who did get into Net.Thread were able to use the software without difficulty. We are not sure why one student posted so many "No More Barney's." One of the limitations of the software is that the teacher cannot go in and remove undesirable material.
Electronic Writing Workshop

The third faculty member to join the team had taken the class several years before and was familiar with the instructors and their work on incorporating computer technology into the writing class. He had previous experience designing Web sites. The intention of this group was to develop a Web site that would encourage and enhance the writing process.

The initial plan was built around the idea that students would have Internet connections, Web browsers, and e-mail. Most of our students do not have access to the Internet from home and the college does not provide dial-in access. Therefore, students would be interacting with the web site from a computer lab which made the e-mail feedback links on the student pages a problem. Since the students were working on lab computers, the Netscape Navigator browser was not set up with their own settings and preferences, such as their return e-mail address. The browser would have to be configured in the lab by the student each time, using the mail preferences for their return e-mail address. This seemed like a cumbersome way to accomplish the task. We wanted technology that was fairly transparent and easy for the students to learn and remember.

Late in the fall, the college began to use Net.Thread, conferencing software that had been used by The New York Times On-line Web site. This software had many advantages over our earlier model of individual student web pages with feedback links. Net.Thread runs on the World Wide Web within the Netscape browser and was easy to use. Students would be able to learn it quickly in one session and be up and running without a lot of instructor intervention. It had clear directions and a help area and worked in an intuitive way. We found that Net.Thread would hold longer pieces of writing (5 to 10 pages), and that students could write a piece in a word processor and then paste it into Net.Thread after spell checking their work.

There were problems with the Net.Thread software. The first time the class tried to log on and use it, the program froze and caused many problems on the Lesley network. The whole class came to a halt. This brought up the idea of a backup plan, which we will develop in the future.

Once Net.Thread was running, it worked very well. Students can look at pieces and write comments, and whole threads of conversation can be built. The software shows topics in outline form, and it is easy to navigate the discussions and to post messages.

We have decided that the conferencing software will be the basis of the electronic writing workshop, and that the student Web pages will be used to publish final drafts.
Conclusions

The integration of technology into The Teaching of Writing course has had three major positive effects. First, the gradual expansion of publishing formats from small peer response groups to Author Chair to a class magazine to the World Wide Web has increased student confidence in their writing. Second, the use of visual media added measurably to motivating the writing process.

Finally, the most significant conclusion is that the seamless integration of technology into a content course provided the catalyst for a paradigm shift in the teaching of writing. Students have been surprised by their mastery of both writing and technology. When the focus is on the assignment rather than the technology, the course works for students whether they are computer literate or not.

Some questions remain. Where does the Internet fit into this course? With a Web page, students in different geographic areas can share published work. While this is a desirable goal, it is not clear whether, given faculty time constraints, this is feasible. In addition, searching the Web for research produces mixed results. It takes too much class time, and we question whether this is the appropriate course for teaching search strategies.

On the other hand, we think the potential for Net.Thread or a similar conferencing program is enormous. It encourages informal writing, conversations about readings and responding to each other's writing, and, perhaps most important, seems to give shy students a way to become a part of class discussions.

As this semester ended, we were sobered by the amount of additional time it has taken to add the Internet-based features to the course. Our immediate task now is to weigh the advantages of the technology while maintaining the central focus of the course which is to provide strategies for the teaching of writing.

Efficient Use of Story Writing Programs

Karen Smith-Gratto  
North Carolina A & T State University

Marcy A. Blackburn  
Cameron University

Anyone who has ever observed or used one of the story writing programs, such as StoryBook Weaver Deluxe, knows that hours can be spent deciding which graphics to incorporate into the story. Hundreds of items (which include people, objects, animals, buildings, foregrounds, and backgrounds) can be combined in a multitude of ways. The decisions about which graphics to use takes up time that students could use for writing. Students spend time selecting items, changing their sizes, repositioning the items, deleting items, and then adding more items. Often computer time is over and the students have not written a word. Indeed, the graphics often overtake the story and become the focus for the young writers.

While observing students who were working in one of the story writing programs, one of the authors noticed that the students spent the majority of their time on selecting graphics. Some students never wrote during the time, while others wrote very little. If the purpose of the program was to encourage story writing, the program was failing. On the other hand, if the purpose was to explore graphics, the program was a smashing success. With advance planning, we believe the program can do both and still allow the students’ creativity to emerge.

Program Choices

First consider, the choices available in one program, StoryBook Weaver Deluxe. There are a large number of items students can choose to complete their graphics. For example, there are 78 foregrounds and backgrounds (not counting the patterns or colors that can be used) and 256 adult figures. In addition, there are categories for animals, decor, kids, make-believe animals, nature, shelters, storybook people, things, and vehicles. Additional graphic changes can be done by changing the brightness level of the pictures to indicate day, night, or twilight. Therefore, thousands of combinations can be achieved when using the graphics. This can translate into hours of graphics production with little or no attention to the writing or to story structure. Graphics are not the only thing that can sidetrack students.

In addition to graphics, there are many sounds and musical selections which students can choose to include with their story. Of course, this involves the students listening to the sound effects and music several times in order to make decisions. The musical selections are less time consuming than the sound effects as far as entertainment value to most students. When observing, we noted that students spent more time listening to the sound effects and choosing how to place them with their graphics. For example, in Storybook Weaver Deluxe the sound effects are triggered by the use of buttons. The buttons are seamless, in that they are attached to different graphic objects in the picture. Some students put a sound effect with every object in the picture. Again, time is diverted away from writing. With all of these choices, it is understandable that little or no actual writing gets done. More writing can be done if the choices can be limited. There are several ways that teachers can do this and meet additional curricular requirements by advance planning.

Advance Planning for Using Writing Programs

One of the simplest ways would involve the teacher creating totally graphic stories. Teachers can prepare stories that have the graphics prepared in advance so that students could write the story that goes with the graphics. These prepared graphic stories may be used in several ways. One way to use these stories is to have a whole class pre-writing, drafting, editing, and publishing session. This can be conducted using overhead transparencies made from the graphic pages. Using the overheads, the teacher can guide the students through the writing process. Using the overhead transparencies is particularly useful when introducing the elements of stories for the first time.

Another way to use the predesigned graphic stories is to print out the graphics and laminate the pages. This allows for both group and individual activities using the laminated pages. Working in small groups, students can discuss how the story should be written and complete both drafting and editing together. When the groups are finished working on the same story, they can compare how each group worked on their story and compare and contrast the stories. This activity provides several aspects which are
useful for meeting objectives in many curricular guides. Not only are the students working on story structure and writing skills, but the after writing activities involve them in comparing and contrasting which is one of the thinking skills many curriculum guides address. The laminated graphic stories can be used by individuals in the same type of activity which would engage individual students in the writing process. When using the laminated pages, students can write on the pages with water-based erasable markers, or students can write the text on separate paper. In either case, when students are finished the stories can be orally shared with the whole class or published and bound. There are other ways to maximize time when using these programs.

One more way to maximize time and effectiveness is for the teacher to create a story that needs the writing and graphics for the beginning or the ending. Notice this is not a story starter. The whole story has been written except for one or two beginning or ending pages. Students would then plan how they would handle the graphics and writing, then complete the story at the computer. Both of these strategies would involve printing out what the teacher made so that students could think about what they wanted to do before going to the computer. This would require students to prewrite and predesign graphics, so that placing the information into the computer would take less time. The additional time would allow for rewriting and editing.

In using these programs to help students develop a clearer understanding of story elements, each element can be worked on individually and then put together. For example, setting can be explored in terms of foregrounds, backgrounds, and time of day. In addition, other factors which affect setting, such as, weather changes can be explored. Students can develop setting with the graphics only and then talk about how they can translate the visual display into words. When the curriculum calls for adjectives and adverbs, activities which have students develop lists of different ones and use them in their setting description can be used. Next students can add characters to their first page. If this is their first time working specifically on characterization, have students limit themselves to the use of two characters (people and/or animals). Once the students have decided on their characters, they should be asked to describe what their characters think, how they act, and what kind of feelings they have. This can lead to further discussion about descriptions. If one of the curricular objectives is to use dialog and quotation marks, their use can be incorporated with characterization (or later with plot). Students could then move into plot development. In this manner, curricular objectives are addressed as the students use the software.

Another way to approach some curricular objectives is to have students explore genre through the use of the software. As students are learning the differences among genre, they can plan stories within that genre. Genres students could work with are fantasy, westerns, historical, mystery, science fiction, realistic, and adventure. In order to save time, teachers should print out foregrounds and backgrounds; people; animals; and other items that would be appropriate for the genre being studied. In addition, the number of items for students to choose from could be limited. A teacher can make booklets using either folders or a loose-leaf which are labeled with the genre. In the notebook the type of genre that is addressed and the characteristics found in that genre. A copy of the graphics which would be appropriate for the genre would also be included in the notebook. As the notebook is used appropriate lists of descriptive words, adverbs, action verbs, and nouns could be included. Students could add other words to the word lists. Here we extend student understanding of literature by genre and address vocabulary through practical application in their story planning and writing. While limiting what students can choose can increase the writing productivity, it's also possible to let students use some of the other capabilities of the program, such as the music and sound effects.

**Advance Planning for the Incorporation of Music and Sound Effects**

The first method for incorporating music and sound effects would involve having students use stories that they have already written. One computer period could be spent in letting students choose music they want to attach to each page of their story. Another computer period could be spent letting the students choose sound effects to attach to different objects in the graphics. Both of these methods are not as productive as they could be, but none the less would give students the opportunity to use the full capabilities of the program. It would be better to prepare an audio tape with the musical selections in the program. A page or pages of the music icons from the program should be prepared to go with the tape. The icons for each musical selection can be given a number and on the tape, the number should be recited before the music represented by that icon is recorded. The students can listen to the number and compare it with the numbered icons. In this manner they can plan what music they will use in advance. An additional tape can be prepared for the sound effects. Again, putting a number with each sound effect icon can facilitate the students' recording of sound effects they wish to use. Students can plan which objects will have sound effects attached and write the name of the object and the sound effect they want to attach to the object in their notes. So far, we have taken small aspects of the program and isolated them into smaller portions in order to save computer time. It is possible to let students use the full capabilities and all of the choices available, even with limited instructional time and limited computer time.
One way we can let students use all of the bells and whistles in these programs is to plan ahead. Just as we prepared tapes for the music and sound effects, we can prepare notebooks for the graphics. The notebooks should have tabs which identify the categories where the items in that section can be found. Students can then examine the loose-leaf notebook and begin planning what they want to do once they are at the computer. This would allow better student choice and greater student creativity. The previously discussed tapes discussed could also be incorporated, letting the student use all of the choices the program has to offer. Students can write prewrite text and plan music and sound effects. Once the students are finished with their preplanning, they can take their notes with them when they work on the computer. At times the students may have to refer back to the pages with the icons and numbers for their music or sound effects, but this method should allow students to produce very nice publications with even limited time at the computer.

**Conclusion**

Story writing programs can help students publish books which can be bound and placed on the classroom shelves for sharing. One of the authors did this in her elementary classroom and found that her students were more anxious to write and share their work when they were printed in the same form as “the books we usually read.” This contributes to the development of student writing skills and to the development of a love for writing and sharing what has been written. Further, this makes the programs well worth using and we can expand their usefulness by tying what we do with them more firmly to the curriculum.

In order to effectively and efficiently use story writing programs, it is necessary to limit the choices or provide students with the means to make choices prior to computer time. In addition, we believe that story writing programs can be used in a more effective manner with relation to the school’s curriculum, if preparations are made in advance.

This paper focuses on the use of computer technology in a Summer Reading/Writing Program designed to teach Reading Specialists to work with K-8 elementary school students. This paper describes a study that was conducted on the usefulness of computer technology for developing skills of Reading Specialists and for tutoring struggling readers. Additionally, several recent software programs that can be used to diagnose developmental literacy skills are discussed.

In recent years, many new technological tools for enhancing reading and writing skills and strategies have become available. These include a variety of computer software packages for word processing, for creating writing products, and computer assessment of language arts skills, as well as for CD-ROM storybooks. It is important to ascertain which of these new software packages are most beneficial for helping children who are struggling readers. Researchers have investigated beneficial aspects of software usage by both elementary student and university students. A key factor for effectiveness identified by several studies is the focusing of student interactions with software on identified learning objectives or specific needs of students (Millman & Clark, 1996; Pan & Zbikowski, 1996). It has been found that elementary students often use software in ways that do not lead to intended learning if they are not supervised and guided during the experience (Castori & Paprzycki, 1996; Goldstein, Olivares & Valmont, 1996).

At Eastern Kentucky University for the past two years a Summer Reading/Writing Program has been conducted that served two purposes: to teach reading specialists, and to help struggling readers and writers at the elementary school level. The program consists of individual and small group tutoring based on specific areas of identified needs in reading and writing. These settings provide opportunities to structure usage of computer software on specific literacy objectives.

During the first year of the program, children were given the opportunity to use computers for word processing of stories they wrote as part of the program. Teachers also brought some skills-based software from their own classroom for use during tutoring. It was observed that children enjoyed working with computers and gained some computer use skills as part of this experience. However, there was no organized attempt to use this experience systematically for developing literacy or computer skills.

As a result of these observations, the authors decided to conduct a study to investigate available software and technology and how it could best be used to work with struggling readers. An additional purpose of the study was to investigate ways to use technology to facilitate the process of refining skills of reading specialists in the areas of reading diagnosis and tutoring.

**Project Description**

Children from local elementary schools were recommended for the program by their regular classroom teachers or parents as needing help with reading and writing. A survey was designed to establish baseline information on levels of computer skills and knowledge for both teachers and children. Each of the twenty children who were enrolled in the summer program was also assessed using an informal reading inventory and other measures to determine specific strengths and weaknesses in reading and writing.

Nine experienced classroom teachers, enrolled in a graduate program leading to state certification as Reading Specialists, served as tutors for the children. A media specialist demonstrated to the teachers the process of loading software and gave tips on software usage. Teachers spent one class period exploring the software before using it as part of the tutoring process. The teachers diagnosed the students’ literacy needs, administered the computer skills survey, then planned and implemented remedial lessons for a time period of five weeks. The remedial sessions focused on identified strengths and needs, and incorporated the use of computer software as a regular part of the instructional program.

At the conclusion of the five weeks, students were given a second form of the informal reading inventory to determine progress in reading and writing. Teachers reflected on the experience, and using a second computer survey form, described their own progress as well as that of the children in acquiring computer skills. They wrote
Results
The results of this research showed the positive impact of computers on the teachers and their students.

Use of Computers: Teachers
Demographic data from the baseline survey instrument revealed that the teachers involved in the study ranged in age from 26 to 45. Seven of the teachers had 3 to 5 years classroom experience, two had one year experience, and one had 23 years experience. Seven of the participants were currently employed in education, while the remaining two were full-time graduate students. The baseline data revealed varied levels of computer experience and knowledge at the beginning of the five weeks. All of the teachers had some training in-service computer training or a college credit course on computers. The teachers reported personal skill levels ranging from being able to turn on a computer to being comfortable with word processing. They reported feeling "somewhat confident and positive" about using the computer.

At the end of the program, teachers completed an open-ended questionnaire to indicate whether their computer skills and knowledge had increased through the experience of tutoring children with computer software. All indicated increases in one or more areas, and the amount of progress made in improving skills was directly related to the amount of previous experience. Those who had little previous experience reported larger gains than those who had used computers on a regular basis. It is interesting to note that using computer software as a part of literacy tutoring was new to virtually all the teachers. Their reflections described their reactions to and evaluation of the software as well as providing insights for using computers with students as part of the program. The most common response was that they had learned about new software programs and how to use them. They also reported feeling more comfortable with using the software and awareness of the benefits to students. Actual comments included: "I am learning to use more options." "I'm still unsure of installing programs but am comfortable using them."

Use of Computers: Students
Of the twenty students involved for the full five weeks in the program, eleven were primary, four were intermediate and five were middle grades. The students had previously used either Apple IIe, Macintosh, or IBM-compatible computers. The frequency of reported use was about evenly split between using every day, once a week, and once a month. When asked what kinds of things they had done on the computer, the students listed reading, writing, and math games most often. Data collected at the end of the five week program in comparison to the initial assessments indicated that the elementary students did improve in computer usage skills. Specific gains cited by the teachers included typing, process writing, operating the software programs and finding things in them, saving work, and mouse skills. Teachers also cited improvement in student reading and writing skills. Specific areas of language arts improvement cited by the teachers included reading, composing, spelling, editing, revising, using more description in writing, and producing longer pieces of writing.

Primary level students reacted to reading stories on the computer with eagerness and anticipation. They especially enjoyed the graphics and sound associated with some software, which was the overwhelming favorite program for primary students. Teachers used this software program to enhance reading fluency and comprehension in several ways. For example, they used the on-screen text to provide practice with word recognition by asking students to read along in chorus with the computer narration. They also incorporated such phonic skill activities as having students highlight words beginning with particular sounds, or finding words that rhyme.

An overall favorite with intermediate and middle grades students among the writing software packages used was a package that was more novel in its use of graphics and sound than other writing programs. While the middle grade students initially enjoyed this program, they switched their preference to another toward the end of the five week period. Reasons cited for the switch included the fact that this other program allowed more flexibility in format and ease of word processing for the longer compositions of the older students.

Teachers found that students created better products when they did preliminary work with prewriting and creating a first draft before coming to the computers. It seemed necessary to allow students time to focus on content first, then on the mechanics of keyboarding, revising, and editing with computer software.

Gains in Reading Scores
Three of the twenty students were absent during the post test sessions with the Analytical Reading Inventory (ARI) (Woods & Moe, 1995). In addition, a five-year old student, an emergent reader, was given an alternate assessment because the ARI was inappropriate for him. For these reasons, there were sixteen students for whom both pre- and post-scores were available. An examination of the scores revealed that nine of the sixteen showed gains on the post-test of at least one grade level on both word recognition and comprehension. Three other students showed gains on one of these two areas, and one other student showed a gain in listening comprehension. No gains on the ARI reading measure were found for three of
the sixteen students. The five-year old student showed gains in several areas of emergent reading skills.

Conclusion

The Summer Reading/Writing Program was successful in terms of gain scores in reading. Work samples and teacher observations also indicate gains a variety of gains in student writing. In addition, both teachers and students gained computer skills and knowledge of software programs. The positive results from computer software usage that were achieved by the students may have been due to a close monitoring provided by the teachers and the tutoring situation. Teachers used the computers and software as tools to help students toward specific learning outcomes that had been identified. The authors plan to refine procedures and repeat the project with a new group of teachers and students in the summer of 1997.

The need to incorporate technology into our teacher preparation courses has become so self-evident that we are now faced with the question of how are we going to accomplish this goal. The need for technology-using teachers is beginning to receive more attention in accreditation standards, in state certification programs, and in reforming and upgrading teacher education efforts. But according to Teachers and Technology: Making the Connection, the report by the Office of Technology Assessment (1995), state policies and leadership vary widely, as does the implementation in colleges of education. Additionally, there has been virtually no connection between reforms in colleges of education and reforms in the K-12 schools, nor are there many incentives to make those linkages. Our research attempted to address some of these findings, specifically regarding technology and teacher preparation and modeling by teacher educators.

Description of the Project

During the summer semester of 1996, the course instructor and co-author of this research effort decided to expand technology usage in her section of a corrective reading course. This course is the final required reading course for elementary preservice teachers before they begin student teaching. Part of the requirements for this course involves each university student tutoring one K-12 reluctant reader, referred to in our program as a client. The whole language philosophy guides the literacy activities. Prior to this summer, technology was incorporated into this one section by using several CD-ROMs with only one computer-on-a-cart rolled into the classroom for each class, but more integration of technology was needed. With the assistance of the co-author, a doctoral student interested in helping faculty integrate technology into teacher education courses, we developed ideas for authentic uses of technology.

Review of Literature

Reviewing the literature, it was apparent that a number of considerations should guide our design. In the theoretical framework of Bruner (1960, 1966), learning is an active process in which learners construct new ideas or concepts based upon their current and/or their prior knowledge. Learners select and transform information, construct hypotheses, and make decisions, relying on a cognitive structure to do so. We recognized that most of the students had taken, or were taking, a general introduction to technology course whereby they learned productivity tools, for example, word processing, spreadsheet, database management, some graphics, some exposure to e-mail, and an introduction to the Internet.

Additionally, we wanted to use technology that was not only non-threatening, but that had proven effectiveness. Johnson (1996) described the success she had in incorporating e-mail into a reading methods class. She felt that the combination of real life application and effective instructional practice increased the likelihood that these preservice teachers will use the technology in the future. Brovey (1996) also indicated how his use of e-mail and e-journals provided preservice teachers with purposeful computer-based experiences and led to more responsiveness between him and his students.

Matthew (1996) pointed out the effectiveness of using CD-ROM storybooks to enhance the literacy experience of young children and the lessons learned by the preservice teachers while observing the youngsters interact with the multimedia. Land (1996) demonstrated the efficacy of integrating the Internet into his teacher education course. His home page organizes Web resources into categories that are appropriate for his students.

Both Dertouzos (1991) and McKenzie (1994) have shown the importance of availability and accessibility to successful employment of computer technology. The location and the number of machines per person are critical factors affecting usage. Until the advent of the graphical user interface browsers, the man-machine interface of the Internet was anything but user friendly. Busy students and teachers will find struggling with unreliable hardware or difficult to use software unrewarding, and will consequently refrain from using it. Because we did not have a
state-of-the-art telecommunications lab to use until the end of the 1996 spring semester, this research could not have been carried out before the summer semester.

Since usage of e-mail, e-journals, interactive multimedia CD-ROMs, and the Internet, have been found effective before, we decided to use a combination of these technological applications in our program. We felt that a combination of all of these approaches would give the students additional tools to use with their teaching strategies. For example, in order to show the usefulness and application to instruction of e-mail, both authors e-mailed the university students regularly, and in fact, we even e-mailed messages to the clients. The clients were also given a choice of having an e-mail pen pal in another state. Although not required to use e-journals, the university students were encouraged to do so.

Participants

The class was composed of twenty female students, nineteen undergraduates, and one graduate student working on elementary education certification. Eighteen students were majoring in elementary education, one was in middle school, and one was a special needs preservice teacher. Nine students were 18-25 years; six were 26-35 years, and five were 36-50 years. Three identified themselves as African-American, thirteen as Caucasian, and one as Spanish-American. Although three students left this field blank, they appeared to be Caucasian, bringing that total to sixteen.

Research Setting

The course was conducted in three separate buildings, the College of Education (COE), the University Computer Center (UCC), and the Learning Resource Center (LRC). The corrective reading course is designed to teach students how to implement various strategies for assessing and teaching reading, and to provide university students practical experience in tutoring a client. During the summer, the course met twice weekly for about three hours per day for six weeks including the tutoring experience. Both before and after the students tutor their clients, there are discussions about strategies to help their clients become better readers.

The students met their clients for a total of fifteen contact hours spread over five weeks, meeting twice weekly for an hour and a half each day. For two hours per day during the first week of class, the university students met, without clients, in a twenty station IBM telecommunications lab in the UCC. This training was for introducing basic e-mail and Internet. In addition to showing the students how to use this technology, a further purpose was to get them thinking about how they could integrate this technology into their teaching. Although no effort was made to directly teach technical vocabulary, equipment and software were named as they were used. An integral part of the lab is the Liquid Crystal Display (LCD) panel that facilitates whole group instruction. The CD-ROM software that the students used with their clients was installed on six multimedia pentium computers in the LRC.

During the five weeks that the undergraduates worked with their clients, they were given the opportunity to use the twenty station lab for a half-hour each class period. This meant that the clients had an opportunity to use this technology for at least one hour per week or for five hours for the session. Students were not required to use the lab, since science, writing, art, and math centers were set up in their regular classroom. The undergraduates made use of the technology as their comfort level increased, and as the needs and interests of their clients required it.

Data Sources

A survey was given on the first day of class to assess the students' levels of technology familiarity, usage, and their general attitudes toward technology. This survey was readministered on the last day of class to allow for pre-post statistical analyses. In addition, students' e-mail dialogue with the instructors and their weekly entries in a technology journal provided narrative data that would be used to document changes in knowledge and attitudes regarding technology.

Results and Discussion

Although twelve of the twenty students indicated they had computers at home, only ten had modems, and most only used computers to do word processing. By the end of the semester, their computer usage included finding lesson ideas on the Internet, conducting on-line database searches, using CD-ROMs in their lesson plans, and regular and continued use of e-mail. One interesting observation was an increase in the language of technology that occurred within e-mail dialogue, journal entries, and during informal conversations with other students and the instructors. Another observation revealed their initial e-mail to be full of typographical errors and strange letter and word spacings. By the end of the semester, as students became facile with the editing feature, much of their e-mail looked as if it were done with a word processor.

Examination of the pre-post survey items indicate positive changes in familiarity and usage for computer LCD projection panels, CD-ROMs, modems, local area networks, wide area networks, computers in the classroom, database searches, New Orleans Freenet, Internet, World Wide Web, and e-mail.

In Their Own Voices

The most meaningful way to indicate the changes in attitudes toward technology by the students is to examine their own statements. Students were required to keep weekly anecdotal notes of their tutoring session, including
For the week of June 20, 1996, she wrote, "L. was amazed demonstrated very little knowledge of the mouse and keyboard."

After using the computer in the UCC, she demonstrated very little knowledge of the mouse and keyboard. For the week of June 18, 1996, she was typical of clients who came to the class with little or no computer skills. For the week of June 23, 1996, she said, "O. loved working with Seaside Adventure [1995]. He did not take his eyes off the screen. He laughed and danced like never before." By the end of the course, she stated, "O. has advanced so much on the computer. He works it all by himself - taking complete control of it. He can even control the mouse." This is an excellent example of why we need to try different computer applications. Although O. did not respond to the Internet, his attitude toward computers completely changed when he found software that met his needs.

The following indicates a remarkable change in the attitude of one client toward computers. In her anecdotal notes about technology, for the week of June 6, 1996, this student noted about her client, "O. hates the computer! I tried to find info about the sanddollar with him through Netscape, but he didn't want to look at the computer. He didn't even want to read e-mail." Continuing, for the week of June 23, 1996, she said, "O. loved working with Seaside Adventure [1995]. He did not take his eyes off the screen. He laughed and danced like never before." By the end of the course, she stated, "O. has advanced so much on the computer. He works it all by himself - taking complete control of it. He can even control the mouse." This is an excellent example of why we need to try different computer applications. Although O. did not respond to the Internet, his attitude toward computers completely changed when he found software that met his needs.

Increased Student Technology Knowledge. The enthusiasm for using technology that the students gained by watching the effect of technology usage with their clients can be seen in this excerpt from a student's final reflection:

This summer has given me a new perspective about using the Internet in my classroom. I had...
heard about the Internet but this was the first time I had used it. I found it to be very helpful with gathering information for lessons and catching my student's interest in learning about new things. ... The ideas and lesson plans available are great, having the students write back and forth to other students is just amazing. The student becomes so involved in writing and reading on the Internet it is just great. As for the CD-ROMs I have worked on the computer in the LRC lab, I found them to be very informative and interesting not only to the student but myself as well.

The following is representative of how students felt about themselves as they mastered the technology, used the Internet from their home computer, and realized that they could learn from their clients.

One of the areas that I have truly grown in this semester is in the area of technology. ... I have Kermit [the only telecommunications software program supported by the UCC] up and running and have been using e-mail, surfing Lynx [the only browser that UNO students have access to from home] to surf through Yahoo, and ERIC. I now have a better understanding about using CD-ROMs. I am now pretty good at e-mail. ... I am really pleased that I finally got "hooked up" [to the VAX from home]. ... I feel that is quite an accomplishment. I have learned a lot about computer technology, from both my teachers in this course and from my client, S. So it is important to realize that our students are not the only ones who do the learning. I feel I am off to a good start and am looking forward to the future.

The above was a typical example of how proud the students felt when they were able to use the Internet from their home computer.

Although students are required to take a computer literacy course early in their curriculum, many of the students were still only in the word processing stage of computer literacy. Since they had no authentic uses for some of what they learned, many forgot what they had learned. This can be seen in the following, and again it is tied into the client’s learning also:

This was the first semester that I had so much time and availability to use the computers. I am very grateful for the experience. I learned more this semester than I did when I took Computer Literacy 1000. ... I also believe this was a good experience for my student. ... She especially enjoyed the CD-ROMs.

... I got my greatest joy out of receiving and responding to the little notes from Dr. Gipe and Joan Lamare. Every semester that I had an account I was never able to access the e-mail again and so my notes all went unread. But this semester was different.

... As for the pen pal, that was very exciting. ... it was quite exciting to communicate via the computer. I feel like I have made great strides towards becoming computer literate and will continue to do so in the future.

Challenges

We would be remiss if we were to leave the impression that all proceeded smoothly. The major obstacle to overcome was the logistics of conducting this course, especially since there was no Netscape lab in the College of Education building. Because of this we had to conduct the technology part of the course in two other locations, away from the regular classroom located in the COE building, - the University Computer Center and the Learning Resource Center. Consequently, for the technology component, there were times when the class met in the UCC and times when it met in the LRC. If there had been a telecommunications lab in the COE building that also ran the CD-ROM software, the students and clients would have had more time with the technology, and less travel and interruption time.

Since this was the first time the course was conducted with an emphasis on technology, there were some course delivery problems, for example, we gave out too many handouts at first, and didn’t allow enough instructional time before the students had their clients. Because of switching locations so frequently, some students forgot to bring their earphones when we met in the LRC. Even though the LRC had multimedia computers, there were no speakers, since it was an open lab and the computers were used mostly for word processing.

Conclusion

Although we anticipated a positive change process, it was fascinating to observe it. Some of the students were intimidated by computers originally, but, by the end of the course, most of these students were making full use of all of the technology. Many students indicated they will use technology available to them during their student teaching experience. We attribute this willingness to use technology, as well as an increased technology vocabulary, to the fact that students had authentic experiences using technology.

In conclusion, we would like to present the voices of two students, taken from their final reflections. The first student wrote about her own personal growth and development as a result of this course. The second student reflected on the impact that this technology had on her and her client. The first student wrote:

During the course of the summer I have grown tremendously with my computer knowledge. I have grown comfortable with the Internet, e-mail, and CD-ROMs. At first I was very hesitant to accept why I was being forced to learn the computer and why I was being forced to use it with my student, much less in my classroom. My whole outlook is different. I now feel that I must grow
with technology and become technologically literate if I am to become a teacher in the 21st century. I can use the Internet to gain access to lesson plans and information for my lessons. I was not aware of the amount of information that I could obtain through the use of the computer.

The e-mail part of the computer is such an advance in technology that I don’t know how we survived without being able to communicate through a screen and keyboard. My student was the real driving force behind my knowledge and enjoyment with the e-mail system. I feel very confident with the system that I could use it on computers other than at UNO.

My first thought about CD-ROMs was “Why didn’t I find out about these sooner?” I will definitely use them in my classroom given I have the resources to do so. They are so easy to use and the children enjoy them. Lots of learning and teaching can be done with CD-ROMs. ... To sum up my experience on the computer — FANTASTIC AND ENJOYABLE, not to mention enlightening.

The second student reflected:

The most important aspect that I learned was the different attitudes/reactions that I as an adult have towards computers versus that of a child. During the sessions I struggled with using the computer because I felt so computer ignorant. I knew that the computer was benefiting B., but I felt so dumb because I did not know what I was doing. ... B. had no problem using the computer. She loved the CD-ROM programs. She especially liked reading the new information on various sea creatures. This was beneficial to me because I was able to observe some of her reading strategies.

... This is the first class that has allowed me to experience computer technology with a student. I think this is extremely significant ... computer knowledge is essential. Therefore I think it was very important for me to have had this experience because I was able to explore the use of educational computer programs. ... Through watching B. this summer I can see the impact the computers have in relation to student learning. Computers allow learning to be challenging and at the same time fun.

Inasmuch as this was only one class, this project has shown that undergraduates can effectively incorporate technology into their lessons when provided authentic learning experiences in a supportive environment.

Technology has increasingly played a critical role in the professional development of teachers. Colleges and universities have progressed from offering a basic introductory computer course to the inclusion of technology within other education courses such as reading and language arts methods (Williams & Matthew, 1995). Consequently, reading and language arts professors have continued to respond to the challenge of fostering the use of technology within authentic contexts for teaching literacy theory and applications. Specifically, the use of the Internet for e-pals (Johnson, 1996) and book dialogues (Williams & Matthew, 1996), the development of teaching materials such as big books (Long & Reehm, 1996) and fostering children's writing (Parson & Johnson, 1996) have motivated both preservice and inservice teachers to use technology as one many ways of constructing literacy lessons.

Innovations in education are not isolated to the inclusion of technology. More recently, many colleges and universities have recognized the success of field-based learning environments, and have provided opportunities for students to practice theories of learning in public elementary school classrooms under the supervision of both university and public school teachers. Although most participants in this type of teacher preparation program are excited about the practical applications of teaching, they are challenged by the additional complexity of teaching preservice teachers within a different technological context. Many universities may have the necessary equipment and teaching materials to illustrate the potential for using technology to engage students in literacy events; however, the reverse may be true in many public elementary schools. Therefore, if preservice teachers are encouraged to use technology within the confines of the university, but are not able to use it during their field based experiences or during student teaching, it is most unlikely that they will continue the practice as inservice teachers (Johnson & Harlow, 1993; Wright, 1993). Based on the premise that technology is best learned and appreciated when implemented within authentic contexts, the authors investigated the role of technology in a field-based reading and language arts course. The purpose of this study, then is to describe how reading and language arts professors and instructors implemented technology in a field-based setting. Specifically, the study sought to address the constructivist processes of both preservice teachers and the university instructors as they met a technological objective for the reading/language arts methods course.

Method

Participants

The participants for the study included five university instructors and 132 preservice teachers enrolled in a comprehensive field-based teacher preparation program at a large metropolitan university. The five reading/language arts professors and instructors taught the reading/language arts in the elementary school methods course as part of the teacher preparation program. Three had doctoral degrees in reading/language arts and were full time assistant or associate professors at the university, while two participants were doctoral students in reading/language arts at the same university and were part time instructors. All of the professors and instructors were experienced classroom teachers at both the elementary/middle school level and at the college level. Additionally, they had experience working with field-based teaching and were comfortable working with technology. All had access to a computer at their homes and/or their offices. The preservice teachers were all senior level students who have completed the majority of their coursework including the basic educational technology course and had varying degrees of...
competence and confidence with computers. They were enrolled in the pre-student teaching phase of the teacher education program and consequently, took all of their methods courses at an elementary school site, called a cluster. Therefore, all of the students were assigned to a cluster of approximately 25 students, four methods teachers, and the cluster coordinator. This format enabled the students and the instructors to not only learn about content information and to practice it within an authentic context, but also established a classroom community. However, the establishment of this type of educational milieu was a two edged sword. On the positive side, the students had access to elementary and middle school students on a daily basis. The negative aspect was that the students did not have an easy access to the university and all its offerings, particularly the computer lab. This component limited the students’ access to a computer to the elementary site, or their homes. As full time students to the university, they were still invited to participate in the technology available there, and though some did, many found the inconvenience too cumbersome and opted to “make do” with their limited resources.

Course Description and Procedures

Prior to the start of the semester, we were informed that each of the five school sites would be provided with a Macintosh Performa, a printer, and an LCD panel, and that all methods professors were encouraged to utilize technology in their teaching and in assignments. In keeping with the overall expectations for the preservice teachers in the comprehensive program, the literacy instructors decided to include an assignment based upon technology. Here, the students were required to develop curriculum material to teach reading and/or language arts using technology. Reflective of a constructivist philosophy, and keeping in mind the challenges that may face these preservice teachers, we decided to frame this assignment according to the needs, abilities, and interests of the individual students. We gave the students several options for this assignment, including the development of big books, concept books, games, slide shows, or other types of presentation. Additionally, we allowed the term “technology” to be interpreted according to the students’ concept of curriculum development. Although we anticipated a product that was completed using the computer, we allowed the use of more traditional means of technological instruction (i.e. audio or video taping). Once the participants understood the concept of the assignment and began working with students with their site-based elementary and middle school teachers, they began developing materials to enhance literacy development. As they progressed in this area, we anticipated that we would have the needed hardware and software that would enable us to encourage the students to share their ideas and have in-class time to work on the materials following a writing workshop approach.

Unfortunately, the use of technology varied at each elementary or middle school site. At some schools, the computer was set up in the university classroom and students had regular access. Several schools even supplied access to the Internet. At other sites, where our classes were held in portable classrooms or on a stage, the computer was housed in an inconvenient room, or not at the site at all if security posed a problem. Adding to the complication was that there was only one computer for the entire class, and that the additional technological support (the printer and LCD panel) was not delivered to the sites until the final week of classes. Consequently, student response to the assignment resulted in various approaches. We differed in the ways which we fostered and guided the students, based upon our own experiences with technology and with the resources available to the students at each of the sites. For example, several of us were able to approach the assignment through a “workshop” strategy where students were given in class time to construct their materials. Others offered the students time to share their ideas in class while still others suggested that the students visit the computer labs on campus, or in the homes of fellow students or the instructor.

Results

All of the students presented their technology project at the conclusion of the semester. These projects varied according to the abilities and interests of the students. Although most of the participants shared big books that were developed for use in an integrated unit, required of all students, others applied their own constructivist philosophy by developing curriculum that encouraged student dialogues about literature. They also ranged in the amount of technology that was utilized. Again, most used the computer to write the text for their books, but some downloaded pictures from the Internet or used pictures from a variety of computer programs. Interestingly, most of the students reported that they did not complete the project individually, and often stated that they had assistance from family members or close friends. Therefore, many viewed this assignment as an opportunity to interact with others and responded favorably to the assignment and were pleased with the connection to the overall technology assignment of the comprehensive program. Many of the students also expressed their interest in using technology created teaching materials in their future classrooms, as well as using technology to create literacy events for their elementary and middle school students. Others were reluctant to use computers, and limited the technology component to fulfilling only minimal requirements. These students were primarily those who were faced with the challenge of little to no resources,
and were greatly frustrated about completing this assignment. Not surprisingly, these were the same students who shied away from technology through the entire semester, turning in other assignments in more traditional mediums such as paper and pencil.

**Conclusions**

At the conclusion of the study, we met to discuss the types of student projects and compared both successes and failures of this assignment in the reading and language arts methods course. The results of this study indicate that despite some of the difficulties, these preservice teachers recognized the value of using technology to develop instructional materials that would be helpful in the planning and implementation of literacy lessons. They also enjoyed the social aspect of technology planning and expressed interest in using technology in their own future classrooms. We agreed that the assignment was valuable and should be continued. We believe that it is essential that university professors remain proactive in our commitment to technology in the schools, and continue to stress its importance, particularly as it pertains to creating valuable literacy events for elementary school students.

In addition to being proficient in employing effective instructional methods and materials, teachers who are fully prepared to succeed in today's world must also have technology skills. One of the most rapidly developing areas is the use of the Internet and World Wide Web (WWW) as teaching tools, communication channels, and information resources. Recognizing these trends, I concluded that it was important for the preservice teachers in my "Introduction to ESL (English as a Second Language) Methodology" course to gain experience with the Internet and World Wide Web early in their academic careers. This paper recounts my experiences as a teacher educator integrating these telecommunication tools in my methodology course and, concurrently, convincing and teaching my students to use them. It also reports on my students' changing attitudes and developing skills regarding their use of these technological tools.

Method
Participants

The participants in the study were 18 graduate students (16 females, 2 males) and 2 auditors (1 female, 1 male) enrolled in Linguistics 577, Introduction to ESL Methodology, at Brigham Young University. One third of these students were native to countries other than the United States—Australia, Indonesia, Italy, Japan, Taiwan, and Tonga. In addition, most of the U.S.-born students had previous experience living abroad—in Australia, China, Germany, Israel, Japan, Korea, Taiwan, and Russia. For the most part they were pre-service teachers in their first semester of a teacher preparation program. Most of them were in their early twenties, but a few were in their thirties and forties.

A survey conducted at the start of the semester revealed that over half the course members had access to a computer either where they lived (60%) or where they worked (50%). For those without such access, campus computer labs provided a means whereby they could access the Internet. Fifty percent of the participants ordinarily used an IBM-compatible PC, 25% used a Macintosh, and the remainder did not know what type of computer they used or did not respond to this item.

Virtually all the students claimed to have basic computer skills, but they used them almost exclusively in "traditional" ways. For instance, 85% reported normally using computers for word processing. Only 20% had used spreadsheets, and the same percentage had experience using e-mail. Only 15% had "surfled" the Internet. When asked if they considered themselves "computer literate," 45% replied, "Yes," 40% indicated they were somewhat or semi-literate, and 15% said, "No."

As noted above, few of the participants (15%) had any experience with the Internet, and only two of them considered themselves "Internet literate." A few others said they were marginally Internet literate, but the great majority (70%) reported they were not Internet literate at all. When asked what they knew about the WWW, 20% responded that it was "useful" and/or "enormous," but only 15% had actually experimented with it, and 65% wrote, "Very little," "Not much" or simply left this item blank.

When asked about their feelings toward learning to use the Internet and WWW, some participants were initially enthusiastic about using computers in these new ways, some were "technology reluctant," and a few bordered on being technophobic. How their feelings changed in the course of the semester will be reported in greater detail below.

Treatment

An experiential learning approach was employed to involve the participants in the use of computers and the Internet and develop their technology-using skills. Aside from a few quick in-class demonstrations, very little direct instruction on how to use the Internet and World Wide Web was provided. Instead, the students were almost immediately immersed in technology-dependent activities. These activities involved instruction as well as information gathering/sharing and included the following:

- Accessing the course syllabus (objectives, requirements, calendar, descriptions of major learning activities, etc.) on the WWW.
- Following links from the syllabus to various other WWW sites, including many ESL teaching and employment resources.
Learning the evaluation criteria for major assignments via the course WWW site.
Viewing sample “model” assignments on the same site.
Contacting the instructor via e-mail.
Subscribing to TESL-oriented listservs and electronic journals.
Using e-mail for communicating announcements and conducting other course-related business.
Using e-mail for inter-student communication.
Submitting assignments (journal article reports, lesson plans, etc.) electronically.
Finding the answers to in-class quizzes on the WWW.
Accessing electronic reserve readings from our university library.

This experiential approach was chosen for two reasons. First, the course calendar was already full; there was no additional time for teaching computer and Internet skills. In addition, following the overall experiential learning philosophy of the course, I felt that the most efficient and effective way for my students to learn about technology would be for them to actually use it.

Data Collection Procedures
Participants’ feelings toward computers and technology in general, as well as the Internet and the World Wide Web, were surveyed at the outset of the course and at approximately one-month intervals thereafter. With the exception of the first survey (which, as reported above, went into considerable depth concerning their experience, skills, access, and attitudes regarding computers, the Internet, and the WWW), these were rather informal. Typically, they consisted of just two questions. Participants’ responses were analyzed qualitatively and grouped longitudinally.

Results
The results of this study are organized into two main sections. The first looks at the advantages as well as the problems of using the Internet and World Wide Web (hereafter I/WWW) from the perspective of the teacher. The second presents the reactions of the participants to using the I/WWW.

The Teacher’s Perspective: Advantages and Difficulties
In my view, implementing the use of the I/WWW into my existing, introductory ESL methodology course produced a number of definite advantages, including the following:
• Quick and easy updating of syllabus materials.
• The ability to add new materials as the semester progresses.
• “Paperless” electronic reserve readings, study questions, and even quizzes.

A significant reduction in the number of pages in the printed packet.
A corresponding reduction in the cost of the packet.
Access to useful material for students enrolled in my other courses.
Student access to syllabus materials and guidelines at any time.
Links to a multitude of other ESL-related resources on the WWW.
Connections with several on-line ESL-related journals.
Students’ becoming computer and I/WWW literate early in their academic program.
Simplified, “paperless,” and extended sharing among students of their lesson plans and journal article reviews.
Connections with various WWW sites and Internet listservs where students can learn about ESL jobs almost as soon as openings occur.
Direct connections with professional organizations so students can learn for themselves about membership, conventions, resources, and other services.
Improved coordination of 577 students’ “practicum” teaching assignments in our English Language Center.
Saving of class time previously devoted to announcements and business (now conducted via e-mail).
Immediate distribution of urgent e-mail messages.
Distribution of messages in their entirety, instead of a quick, oral in-class summary.
The assurance that e-mail announcements reach all students in the course—not just those who are in the classroom.
More efficient (and less threatening) teacher-student communication via e-mail.
Increased inter-student communication (ranging from academic discussions to informal conversations) out of class via e-mail.

On the other hand, technology is certainly a mixed blessing. Even with some of the new software tools, converting my syllabus and packet materials into Web pages was time consuming. Fortunately, I had a graduate assistant who helped with this task, but in order to accomplish it we both had to learn the basics of HTML.

Some students had difficulty setting up their e-mail accounts and Web browsers—especially on their home computers. Fortunately, friends and family usually came to the rescue. Then, when they finally got everything working, the College server would go down, giving students a new excuse for not doing their homework.

The Students’ Perspective: Reactions to Using the I/WWW
After being introduced to the course and its I/WWW-based assignments, the participants were surveyed in September, October, and November. The survey sought to
address both their feelings about the I/WWW and the course materials they accessed on the WWW.

Survey One. Administered only a few days after the I/WWW had been explained to the class, this survey consisted of only one question: "What one word best describes your feelings about the use of the Internet and WWW for this course?" Participants' positive and negative responses were fairly evenly balanced, with a few students remaining cautiously in the middle. The positive responses used words like exciting, dandy, comfortable, fine, colorful, resourceful, and convenient. Those in the middle employed terms such as necessary, curious, possibilities, and progressing. One respondent ignored the instructions and wrote, "It has been both encouraging, and frustrating [emphasis hers]." Two students indicated that the I/WWW was "challenging." The rest used more negative descriptors: unfamiliar, frustrating (two respondents), and undone—although whether it was the work or the student that was "undone" remains unclear.

Some students expressed their feelings through other channels. For example, a couple of weeks into the course, one student sent the instructor an e-mail message. In it she explained that, in addition to carrying out her course assignments over the Internet, she was excited to begin sending and receiving e-mail to/from her family, former colleagues, and friends back home in Asia. A few weeks later, another student complained: "This is all new to me! I'm too old to learn these new tricks!"

Survey Two. A month later, students had more experience with the I/WWW and more to say. At this point, they were asked two questions: "So far, what course-related activities or purposes have you used the Internet or World Wide Web for?" and "What one word best describes your current feelings toward the Internet and World Wide Web?" Seventeen students responded. Once again, the reactions were mixed, but this time they were much more positive.

In response to the first question, at least two participants indicated considerable use. One wrote: "I do at least half of my work (homework, study, research, communication, etc.) via the Internet and World Wide Web. I have found it extremely valuable with the limited time I have. It offers vast resources at home that would require much more time otherwise." Another reported, "I use the Internet extensively in searching for information and materials for my classes." The other students had not yet mastered the technology so thoroughly, but they were not far behind. They had used the I/WWW for the five main purposes listed below. The percentage of respondents who mentioned each purpose is indicated after the category title, and the categories are arranged in descending order.

- Course syllabus (assignment information, instructions, and criteria; course calendar; answers to quiz questions) (71%). Consulting the syllabus for course information was the most frequently mentioned use. Many respondents wrote, "I look certain things up on the syllabus (the links are very helpful)" or words to that effect. One also noted, "I printed out a few pages I lost from the syllabus."
- TESL-related resources—ideas for lesson plans and teaching materials (35%). Only half as many respondents mentioned this category, but this use was still substantial. Responses included: "I've searched for ideas for my materials file. I wanted to check on songs, CNN News, and materials for the ESL classroom." and "I've used it for looking up things that would help me with my teaching. I've found some fun locations such as cartoons, songs, etc."
- E-mail communication (35%). An equally large number of participants reported using e-mail to communicate with classmates, professors, and friends/family. A few also mentioned "E-mail with TESL-L," an ESL-oriented listserv with some lively and pertinent discussions.
- Information about TESL jobs (12%). Even though 577 is an introductory course, a couple of students were already combing the WWW for information on "ESL teaching opportunities." One reported enthusiastically, "I've also found places where I can look up TESL jobs, etc."
- More general WWW surfing and searching (12%). Two of the respondents also reported "surfing" or conducting more formal "Net searches" regularly.

At this stage, students also reported considerably more enthusiasm and less apprehension about using the I/WWW. Ten (59%) of the responses were decidedly positive: "Invaluable," "Impressed," "Feeling better and better," "Fascinating & scary," "Great!," "Interesting," "Comfortable," "World-wide," "Useful," and "Excited neophyte." Even the less enthusiastic responses tended toward the positive: "Learning," "I'm getting there," "Progression," and "Getting used to it!" Two responses were realistically balanced: "Amazing (but sometimes it's confusing)" and "Fun, but takes a lot of time to find what one wants." Only one was still decidedly negative, using the word frustration.

Survey Three. After another month had passed, the participants were surveyed again. This time, however, participants were even more comfortable with, and enthusiastic about, the Web. An even greater percentage of them reported uses of the I/WWW in four of the five main categories used for analyzing Survey Two. In addition, a new category of WWW use emerged.

- TESL-related resources—Ideas for lesson plans and teaching materials (88%). As the course moved into the phase where students started doing more actual teaching, their interests naturally turned to the resources needed to support that teaching. Nearly 90% of the participants reported searching and "finding things for teaching—poems, songs, etc." as well as "pictures, story, games, etc." In sum "Hunting for materials" and "looking for lesson plan ideas" on the WWW became extremely common activities.
E-mail communication (56%). In comparison with the results of the previous survey, an even greater number of participants now mentioned using e-mail to communicate with colleagues, professors, and friends. In addition, more sophisticated e-mail uses were reported. For instance, more students reported subscribing to TESL-L and other on-line forums to “read up on current (T)ESL topics.” One class member had even become actively involved in several specialized sublists, such as one for ESL materials writers.

Course syllabus (25%). Consulting the course WWW syllabus and ancillary materials was the most frequently mentioned (71%) use of the I/WWW in Survey Two. Apparently, with the passage of time, students became familiar enough with the course requirements and activities that they no longer needed to consult the WWW syllabus so often. Only a fourth of the respondents to Survey Three mentioned looking at it.

Information about TESL jobs (19%). In contrast, the number of mentions of ESL “job-hunting” increased in Survey Three. At least one student had even started using specialized TESL employment listservs.

More general WWW surfing and searching (13%). The number of respondents who mentioned “surfing” or “just browsing and seeing what’s there” remained the same as in Survey Two, although an additional student wished she had “more time to search.”

Research (new category) (13%). With no specific urging or guidance from the teacher, at least two students apparently started using the WWW for an additional purpose. In this survey, they mentioned doing “research” (“on topics such as English only and English plus, humor, grammar, etc.”) on the Web.

All but one of the responses to the “one-word” I/WWW reaction item were favorable. Expressions participants used to describe their current feelings toward the I/WWW were exciting, resourceful, comfortable (three respondents), acceptance, fine, necessary, interested, great!, fascinated, and interesting/fun! A few could not confine themselves to just a word. One gushed, “My skills are improving!!” Another, who had experienced considerable frustration with the I/WWW earlier in the semester, wrote, “Finally sent a message. Just needed time.” One realist commented, “I like it, but it takes a lot of time.” An enthusiast wrote, “With my schedule, I heavily rely on the Internet to survive.” Possibly the most rewarding comment of all, however, written by a student who had earlier shown some resistance to “learning new tricks,” was a simple “Thank you!”

Conclusions

Changing from a paper-based course to one which relieves heavily on the I/WWW is not a simple task. Such a step should not be undertaken on a whim, without support. Nevertheless, it offers many rewards, among which is seeing students overcome their fears and learn to use a technological tool that will be of great use to them in the future.

The most obvious pattern in the data is one of steadily increasing confidence, competence, and enthusiasm on the part of the students regarding their use of the I/WWW. Another interesting pattern which appeared in the data was the rise and fall over time of certain categories of use (i.e., consulting the course syllabus).

More important than any general pattern that might be deduced, however, is the realization that people react to new technology in individual ways—based on their personalities, talents, or previous experiences. When introduced to the advantages of technology, many people will almost immediately put them into practice, quickly mastering the technology and becoming enthusiastic “opinion leaders.” Not all students, however, follow this path. Some continue to resist the technology and have difficulty mastering it. For example, toward the end of the semester, at least one of my students still spoke of “going to do battle with the computer” when she needed to submit assignments via e-mail.

The amount of confidence that these findings merit is limited. The sample was small, the length of the study was limited, and the data-gathering methods were rough. The “one-word” responses on the monthly surveys were not sufficient to capture the complexity of students’ true feelings about the I/WWW. Also, there was a potential for a “halo effect” in the responses, as participants might have tried to make a good impression on their teacher. Additional experience in future semesters, with additional participants, and in other research settings will be needed before any solid conclusions can be drawn.

An important question, which this study only raises, is whether the participants will continue to use the new technology once the course is finished. While the answer to that question lies beyond the limits of this study, the data did provide some encouraging signs. For example, one formerly reluctant WWW user commented, “I plan to continue using it as a resource.”

Those interested in seeing the actual Linguistics 577 course syllabus and related materials used in this research can find them on the WWW at the following URL: http://humanities.byu.edu/linguistics/Henrichsen/577ReqCalF96.html

Lynn Henrichsen is a Professor in the TESL Program of the Department of Linguistics, 3178 JKHB, Brigham Young University, Provo, UT 84602. Voice: 801-378-2675, fax: 801-378-8295. E-mail: Lynn_Henrichsen@byu.edu
The goal of teaching reading to ESL/EFL students is to help them become strategic and independent readers. Teaching students how to read has become increasingly important in the ESL/EFL curriculum today.

Reading is a complex process; even more so in a second language because readers need to construct meaning through culturally determined cognitive frameworks. Teaching ESL/EFL students reading strategies is a complicated but worthwhile task for ESL teachers. Preservice ESL/EFL teachers, in particular, should be aware of the fact that teaching reading strategies will lead students to become proficient readers. It is crucial that ESL/EFL teachers understand the process of using strategies and have the ability to teach them.

The Importance of Using Reading Strategies

According to Block (1986, 1992), good readers are more capable of monitoring their comprehension, are more aware of the strategies they use, and are more flexible in using strategies than poor readers. Specifically, good readers adjust their strategies to the type of text and to the purpose for which they are reading. Good readers distinguish between important information and details as they read and are able to use clues in the text to anticipate and integrate new information.

Reading is an active process in which the reader makes efficient use of strategies to understand printed information (Goodman, 1970). Research in reading English as a second/foreign language (ESL/EFL), (Alderson, 1984; Benedetto, 1984; Coady, 1979; Goodman, 1973; Hudson, 1982; Koda, 1990) indicates that the reading process is similar in all languages and that reading strategies transfer across languages. Reading strategies developed in a first language can be transferred to a second language, regardless of how similar or dissimilar the second language is. Therefore, it is thought that an individual who is a good reader the native language will be a good reader in a second language.

Reading strategies determine how readers conceive a task, what textual cues they attend to, how they make sense of what they read, and what actions they take when they do not understand (Block, 1986; Johnston, 1983). Strategies reveal a reader's resources for understanding (Langer, 1982). Readers employ a range of strategies in order to read efficiently. This includes such strategies as adjusting the reading speed, skimming ahead, previewing titles, headings, pictures and text structure information, and anticipating information to come. A proficient reader has knowledge of cognition, including language, which involves recognizing patterns of structure and organization and using appropriate strategies to achieve specific goals. The reader must also search for specific information and formulate questions (Grabe, 1991).

Teaching Reading Strategies

ESL/EFL teachers should consider teaching their students how to use all information sources available to them (i.e., language, text, and reader) to make sense of what they read. In other words, teachers should consider teaching reading strategies as part of the teaching process in order to help their students become strategic independent readers. Teaching efficient reading strategies such as comprehension monitoring, using text organizational patterns, and making predictions about what they read can help nonnative speakers compensate for language difficulties while reading (Alderson, 1984; Carrel, 1989).

Effective teachers need to be aware of the reading process and the strategies students use while reading. When they understand the process of strategic reading, they will be able to teach strategies to their students. To make the concept more appealing to preservice ESL/EFL teachers, a computer program was developed to facilitate assessing the strategies used and developing awareness of using them, through a series of reading tasks. The program allows individuals to work through all the strategies. It provides practical opportunities to apply the strategies while reading, which helps them to understand the efficiency of the reading strategies. At the same time, the computer program helps reduce the in-class practice time.
In addition, while being exposed to the use of modern technology, the preservice ESL/EFL teachers will be able to gain personal experience in the appropriate use of technology to make the learning more interesting. They are encouraged to utilize appropriate technology to enhance teaching and learning. This program is available for them to use later during their teaching careers.

The Use of Computer Technology

The computer program (available on the CD of the annual conference proceedings) includes a series of reading tasks, such as skimming and writing, scanning and writing, reading and predicting, and so on. Each task requires a specific reading strategy or strategies. The correct answers are included in the program. Thus, the students will be able to get feedback immediately. It is designed as a self-study tool to help them learn the theory and the application. By examining the reading performances, preservice ESL/EFL teachers will be able to find out what strategies students use in reading and what strategies they don’t use while trying to comprehend the text. These tasks help them to discover their students’ strengths and weaknesses in reading. By increasing their awareness of students’ reading skills as well as their teaching skills, they will improve their teaching and be better prepared for the new challenges of their profession.

By utilizing a popular commercial software program, HyperStudio, the software is designed for the students to use a mouse and other features, similar to word-processing, to complete the tasks. It provides feedback for the user and the ESL/EFL teachers can use the tool directly in their reading classes. It is also designed to let the ESL/EFL teachers have control of how much time should be used to finish a given task. With increased familiarity with HyperStudio and technology in general, they should be able to use the program as a shell and replace the original tasks with new material for more practice. In addition, the program is designed for the teacher to use as an assessment tool. It automatically stores test results, allowing only teacher access. All the correct answers are on the last card. Thus, the students will be able to get feedback immediately. It is designed as a self-study tool to help them learn the theory and the application. By examining the reading performances, preservice ESL/EFL teachers will be able to find out what strategies students use in reading and what strategies they don’t use while trying to comprehend the text. Formative Evaluation

A formative evaluation is critical after the students have used the program. Therefore, the ESL/EFL teachers will need to discuss the results of the performance with the students. This evaluation can be best achieved through one-on-one conferences or through peer reviews. Such feedback will become the key to improve their instruction, especially in the issue of the length of time for each task and the levels of difficulty included in the content.

Research has been a section in the Annual since the first Annual was published in 1991. It is an odd category in many ways. Most of the sections in this book contain papers on a particular type of technology such as telecommunications or the use of technology in a particular level or subdiscipline of teacher education such as graduate and inservice or social studies teacher education. The Research section is different. Papers in this section are here, not because they relate to a particular type of use or a subject area like reading or language arts, but because they have taken a "research" approach to considering a topic. Not long ago, "research" generally meant one of three things: studies based on experimental or quasi experimental designs, correlational studies, or surveys. All three types of research were based on the same empiricist or postempiricist philosophy of science, and they all sought to discover the "truth" about something. Today, with the rising popularity of many types of qualitative research, the term research covers a much wider range of approaches.

The papers in the 1997 Annual reflect the emerging diversity of the definition of what constitutes research. The papers also reflect a growing interest in research as a topic. The first set of papers, for example, make research itself the subject matter rather than using a research approach to address other questions.

Research as a Topic. The first paper in this section, by Randall Parker at Louisiana Tech University, is a good, brief introduction to the use of computers in qualitative research. His paper is a good beginning point for anyone in education who is thinking about doing qualitative research but is unfamiliar with the many types of software that can be used by qualitative researchers. A second paper, by Bauder, Carr, Mullick, and Sarner, is also takes a broad brush approach. These authors offer some guidelines for researchers on how to do research that has an impact. The third paper, in contrast, is a study of using technology in a graduate research course. It was written by Clara Young at Mississippi State University.

Research on a Topic in IT and TE. Most of the papers in this section are reports of a study on a particular topic in the area of IT and teacher education. The topics covered include hypermedia CAI and cognitive apprenticeships (Chyung, Repman, Lan, & Winiecki), using ISTE guidelines (Matthew), how teachers use and learn to use computers (Galloway), factors that influence teachers to learn about computers (Pan & Lee). Several studies dealt with teacher education students' perceptions and attitudes (Dennison, Long, & Reehm; Dunn; Algozzine & associates at the University of North Carolina at Charlotte, Liao, Huang and Padron, and McCoy and Baker). The last paper in this group, by Christensen and Kzezek, looked at the reliability (internal consistency) of 14 of the computer attitude scales available in the literature.

Conceptual Issues and Questions. A third group of papers looks at broad issues relevant to the technology and teacher education. In some cases, these papers include reports of research conducted by the authors; in others, the papers are more like reviews of existing literature with a discussion of the implications of that literature for teacher education. The first paper in this section, by Jones and Paolucci, for example, looked at articles published in nine of the refereed journals in the field of educational technology. The authors analyzed the articles published in the period 1991-1996 in terms of the general focus of the papers and the type of data reported. The authors draw conclusions about the policy decisions being made today relative to technology versus the research available to support those decisions. Other papers in this section look at cooperative learning in distance education (Ichiko), navigating in hypermedia (Gedge), network-based learning (Gradinarova), distance learning in higher education (Hillesheim), electronic textbooks (Chen & Willis), telementoring in methods courses (Weiss), mentorships for teacher education faculty (Phillips & Walker), virtual worlds (Peretti), the Synergistic Curriculum (Harnish, Migotsky, Gierl, & Maskell), workshops, distance education for adults (Dudt & Dean), instructional technology programs in American and
Canadian universities (Smith & Smith), and Virtual Reality systems (Sims and Elson).

The 1997 Research Section is the largest, and most diverse, thus far. It provides some indications of the directions this field will take in the coming years.

Penny Williams is a doctoral student in the College of Education, University of Houston, Houston, Texas 77204.
The development and increasing availability of computers and software programs to help record, sort, retrieve, and analyze data is perhaps the greatest recent change in research technology (Bogdan & Biklin, 1992). The use of computers in research design and analysis continues to be a growing phenomena. While access to mainframe and PC programs has traditionally been used to analyze quantitative data, there is a growing use of this technology in the field of qualitative research. Almost ten years ago, Brent, Scott, and Spencer (1987) reported that over 70 percent of their respondents acknowledged using computers in qualitative studies. With continuing advances in software development and Personal Computer (PC) accessibility, one can surmise that this percentage is now even higher. With these advances in technology, it is important for the researcher to be informed as to the available and appropriate uses of technology, so that the most appropriate methods may be selected (Tesch, 1990).

The use of qualitative research designs and aspects of qualitative research in program evaluation are also increasing (Fink, 1995). Such evaluation methodologies are often useful when the goals of a program are in the process of being defined or when more quantitative data regarding the validity and reliability of program outcomes are unlikely to be available in time to complete an evaluation report. Qualitative methods are also often employed in program evaluations to complement and to add emotion, tone, and phenomenological meaning to otherwise purely quantitative data (Fink, 1995).

The application of computer technology in qualitative research and evaluation ranges from simple word processing to doing sophisticated data sorting and retrieval (Tesch, 1990). Researchers are encouraged to consider the use of computers in data analysis in light of their own familiarity and comfort level with technology, the types of data to be collected, and the planned analysis (Miles & Huberman, 1994). Most word processing programs have indexing or search-and-find features that allow the researcher to quickly locate key words or specific codes. Programs with data base managers can also be helpful in retrieving and sorting data. Software programs specifically designed for data coding, sorting, and retrieving are increasingly available for both IBM(QUALPRO, TAP, and ETHNOGRAPH) and Macintosh(HYPERQUAL) platforms.

Word Processors
Word processing programs are basically used in the production and revision of text. Whether IBM or Macintosh platform, these programs are useful in recording, transcribing, and editing field notes; for preparing files for coding; and for writing report text. Once information is saved in this format, it is easily retrieved, edited, and revised. Some popular word processing programs are WordPerfect, Wordstar, Microsoft Word, and MacWrite.

Word Retrievers
This type of program is useful in finding all instances of words, phrases, and word/phrase combinations that you are interested in locating. Some have the capability to present words in context, count the number of selected words in a file, and create word lists. Examples include Metamorph, Sonar Professional, The Text Collector, and WordCruncher.

Text Base Managers
This type of program will organize text more systematically for efficient search and retrieval. These programs essentially search for and retrieve numerous combinations of words, phrases, coded segments, or memos. Some of them can highly organize the text into specific cases while others are more useful in managing free form text. Examples are askSam, FoliosVIEWS, and ZyINDEX.

Code-and Retrieve Programs
These programs will help you divide text into segments or chunks, attach codes to the chunks, and allow you to find and display all instances of the recorded and coded chunks. Examples are HyperQual, NUDIST, QUALPRO, and The Ethnograph.
Theory Builders

These programs are often researcher developed. In addition to code-and-retrieve systems, they also allow you to make connections between codes, develop new classifications and categories, and to imply a conceptual structure that fits the data. Examples are HyperRESEARCH, and NUDIST.

Conceptual Network Builders

This type of software not only allows you to build and test theory, but also to work with systematically built graphic networks. The researcher can view the variables linked with other variables by specific relationship (looks like, leads to, is a kind of). The networks develop from the data and the concepts and relationships seen among them. Examples include MECA, and SemNet.

Considerations in Software Selection

In addition to the main programs that specific programs can carry out, there are other criteria to be considered regarding all software collection. The first criteria is the flexibility of the program — does the program only do what it is built for or can it be used in additional ways to do other types of analysis. One should also consider if the program can be customized to create new routines as the needs emerge.

A second fundamental criteria is the degree to which the program is user friendly. Is the time and effort needed to learn the new program justified by the results? Are there adequate supports for learning the program — in effect, how useful and understandable is the manual, what tutorials and help screens are available, and will anyone respond when you call for technical support?

Other criteria to be considered are the match between the available hardware and the software, the researcher’s own level of expertise with the specific program, as well as with the needed hardware and software; and his/her general comfort level with technology.

An Initial Study

After acknowledging the general criteria to be considered in the selection and use of computer software in data analysis, interviews and observations were conducted with twenty doctoral students enrolled in one of two sections of a doctoral course in qualitative research. In addition to several IBM and Macintosh word processing programs, students were also provided with the NUDIST and ETHNOGRAPH software programs. Students were observed in the computer lab analyzing data on selected programs, and were interviewed by the researcher to determine the value of using computers in analysis. Results of these observations and interviews can be summarized as follows: (a) participants who were more familiar with technology before the course were also more easily engaged in using new programs for data analysis, (b) participants felt more comfortable with word processing programs and tended to stay with analysis through word processors, even when other, more complex programs were available, (c) the greatest impediment to using computers in analysis appears to be the vast amount of time needed to learn the new programs, (d) access to the computer lab, (e) lack of knowledge of software, and (f) hardware interface problems.

It should also be noted that participants appeared quick to share their success with others in the class and to assist others in learning new aspects of analysis with the selected programs. Participants also acknowledged the efficiency of using computers and several have inquired as to how to acquire additional programs and/or upgrade their own, personal computer hardware.

Pitfalls and Promises of Computer Analysis

Although computers and various software programs can be of great aid to the qualitative researcher and evaluator, there are some inherent dangers associated with their use in data analysis. The attitude and assumptions of the researcher toward the use of computers in analysis can dictate the success of the technology.

In using computers for data analysis, one must first realize that the technology is the servant and not the expert — it will do only what it is told to do. The computer program will not set up the initial organization of data, determine interpretation, or “create” phenomenological meaning. Data retrieved by code may not show the context of the word or phrase. There is also a danger that data will be deconceptualized or reconceptualized in inappropriately. The researcher must always keep in mind that using technology is not a substitute for competence.

Just as with quantitative analysis, the speed and convenience of technology may lead the qualitative researcher to perform inappropriate tasks. A program such as TAP will take key words and create codes very easily. This may lead to the development of very convenient but unnecessary codes and categories.

In addition, the researcher may be tempted to design inappropriate analyses based on what the computer can do, rather than on what is needed and relevant. There is also the danger that the inherent structure used in any particular program can predispose researchers to view, manipulate, or interpret data in specific or different ways. Effective analysis may require the use of two different types of programs in order to broaden and enhance the interpretation of data (Horney & Healey, 1991).

Finally, the programs and processes that are most convenient for the researcher or evaluator may “freeze” his or her thinking which, in turn, may lead to the same types of analysis for all projects even when a different process would be more appropriate. It is easy for researchers to “stick to what they know” and in so doing limit the types of analysis.
used. Qualitative researchers should be open to divergent ways of thinking so they can attempt to "expand rather than confine understanding" (Bogdan & Biklin, 1992, p. 42).

**Conclusion**

The use of technology and computers in qualitative research analysis and program evaluation is an ever increasing and fast moving field (Miles & Weitzman, 1994). As new programs continue to emerge that address new aspects of data analysis in improved ways, it is incumbent upon researchers to consider the appropriateness and usefulness of computers in their analysis of data. By understanding the broad range of common functions and unique features of available software programs, while at the same time being aware of the dangers of relying too much on technology for analysis, qualitative researchers can be liberated to make a "truly informed choice of methods" (Tesch, 1990, p.299).

The goals of research are to build a body of knowledge relevant to a profession, to inform practice, and to provide leadership. The first of these goals is the narrowest, suggesting research for its own sake and studies that appear to have no practical relevance. Concerns with this aspect of research are expressed by Schön (1983), “Is professional knowledge adequate to fulfill the espoused purposes of the professions? Is it sufficient to meet the societal demands which the professions have helped to create?” (p. 13). This perceived inability of professions to use professional knowledge to solve societal problems has lead to a “crisis of confidence in the professions” according to Schön.

Schön (1983) suggests a shift from the paradigm of technical rationality, where research is separated from and considered superior to practice, to reflection-in-action as a link between the practitioner’s context and the art of research. Schön recognizes that the technical rationality emphasis on problem solving ignores the conditions of problem setting, which frame the problem and possible approaches to solutions. It is this setting and framing of the problem which leads to relevant solutions that inform practice, the second stated goal of research.

The third goal of research is to provide leadership. Gustafson (1996) asserts that “…all members of the profession have both the opportunity and the obligation to exercise leadership through writing, publishing, and presenting” (p. 15). Maddux (1993) points out that research is “…particularly important in all areas of educational technology since the field in general, and educational computing in particular, seems especially vulnerable to being driven by new products” (p. 11). In exercising leadership, researchers and practitioners have an obligation to set and adhere to standards of research that will both advance the knowledge of the profession and inform practice.

Research Issues

What are the standards in the field of Information Technology and Teacher Education (ITTE)? Stemming from educational technology, with roots in education, psychology, cognitive science and communications, ITTE research reflects the both the variation and the commonality of its beginnings. In describing the distinction between a research methodology as a specific technique and a research paradigm as a belief system that guides the methodology, Waxman and Bright, (1993) suggest that technology may influence both paradigms and methodologies in ITTE research.

Clark, (1983) set off a debate that still reverberates in the profession when he stated that no evidence exists to support the notion that media affects learning. Instructional designers, teachers, and budgetary gatekeepers began to question the questions asked by research. Ross (1994) suggests that misinterpretation of Clark’s argument limits research to narrowly defined media comparison studies employing rigorous internal validity standards at the expense of external validity. Suggesting a paradigm shift from a natural science to a design science orientation, Kozma (1994) asserts that it is time to reframe the question from “do media influence learning” to “will media influence learning”. Research should therefore be grounded in the interaction between information, cognitive processes, and the contextual environment of instruction. The suggestion to restructure the debate gives evidence of the maturation of the profession. Media are no longer viewed as simply delivery mechanisms, but have many roles, from facilitators of knowledge construction to mind extension devices and resource enabling tools (Jonassen, Campbell, & Davidson, 1994). Willis (1993) contends that for maximum benefit, current ITTE research should reflect an Instructional Development (ID) model that uses theory and basic research in the development of validated instructional packages, rather than a research-to-support-theory model.

Another crisis of confidence that plagues the profession is the perceived quality of research. While some argue about rigor versus relevance, it is clear that poorly defined problems, faulty research methods and sloppy interpretation of results have resulted in the perception of educational
research as less than professional. The rest of this paper describes current trends in ITTE research and provides some guidelines for those interested in quantitative research. 

**Research Paradigms**

Tellez (1993) examines research paradigms typically used in instructional technology research. The two qualitative methods include narrative studies and case studies. A review of the literature suggests that these techniques are heavily relied upon in ITTE even at the present time. Not all narrative studies exhibit sterling design. Gunn (1991) for example, reports on experiences in a single first grade classroom in which the researcher introduced the classroom teacher to word processing, assisted in the development of a strategy to incorporate word processing, observed the class three mornings a week over a six month period, participated as a teacher's aide, and later interviewed the students in her capacity as researcher. Having contaminated the process, she used the results to establish an elaborate ten-component staff development model and conclude that under certain circumstances computers are appropriate for a first grade classroom.

According to Tellez (1993), qualitative research designs have received much attention over the past few years because of backlash against quantitative research. The three types of quantitative research described by Yarger and Smith (as cited in Tellez, 1993) include correlational studies, quasi-experimental, and experimental designs. Much of the "bad press" received by quantitative research is due to the narrow Research-to-Support-Theory (RTST) model involving a one-time experimental study attempting to support a specific aspect of a theory (Willis, 1993). One problem with this type of research is that in educational settings, it is usually impossible to select and assign students randomly to conditions. In addition, the measures of performance used as dependent variables, may not be indicative of cognitive changes but use measures that are easy to obtain. Finally, the researcher must control other variables such as instructional methods, media, and context in ways that alter the teaching/learning process to the extent that results are not meaningful.

Maddux (1993), Tellez (1993), and Willis (1993) suggest that appropriate research designs for understanding the impact of technology on the teaching/learning process must take place over time and consider the interaction of teacher/learner variables on students' performance. Many experimental and quasi-experimental studies take some of these variables into consideration. The assumption in experimental designs is that random selection and random assignment will ensure that the groups are as similar as possible prior to the interventions. Other techniques that may achieve comparability of groups include matching subjects on some relevant variables related to dependent variables. If significant differences are found between or among the groups, the most likely explanation is in the interventions.

Cathcart (1991), in a particularly well-designed study, monitored mathematics and language arts achievement of two classes of third grade children over a two year period. In the experimental group, there was one computer for every two children during the first year and one computer on each child's desktop for half of each day during the second year. The experimental and control intact classes were closely matched on IQ score. Post test scores were reported after adjusting for pre-test differences using one-way analysis of covariance. In educational settings, researchers are confronted with intact groups. Campbell & Stanley (1963), offer several designs to circumvent the problems of controlled experimental designs. One type is a correlational design in which a group is selected and two or more measures of performance are obtained. The interrelationships between the variables are determined. Even when significant correlations are obtained, the researcher must be cautious in interpreting the results. The researcher must recognize that a significant relationship does NOT imply causation. A second problem in interpretation of correlations is a failure to consider the Coefficient of Determination ($r^2$), the amount of total variance accounted for by the relationship between variables, and $(1-r^2)$, the amount of unexplained variance or variation due to error.

A second type for dealing with intact groups is to use the subjects as their own controls using a pre-post test of performance. This quasi-experimental design meets the criterion for longer duration. The pre-post design has several variations; it may consist of only a single group, two groups, or more. Campbell & Stanley (1963) suggest that this design is particularly suited for situations in which researchers must use intact groups, cautioning about such threats to internal validity as maturation, history, sensitization, to the performance measure and mortality.

Data analyses should take the effects of the pre-test into consideration either by using change scores (not without problems) or by statistically controlling for the effects of the pre-test. Even after these precautions have been taken, the researcher should interpret the results with care, recognizing that alternative explanations for the findings are possible. Care should also be taken in generalizing the findings to other groups.

Weller and Dodl (1991) designed an intervention intended to alter naive conceptions about science. A "representative" sample of students (n=60) was selected from eighth grade science students in two schools. From that group students with naive conceptions were divided into two groups of unspecified size. The experimental group was exposed to computer simulations of scientific properties; the control group did not do the simulations. A post test was administered to both groups, and a retention test
was given to seven members of the experimental group (but apparently not to the control group) 1.5 months later. Having failed to control for initial differences between the groups, and neglecting to post test the control group, Weller and Dodl nonetheless conclude that computer simulations help students to “...alter their naive conceptions to a significant degree” (p. 101)

**Research Guidelines**

**Phase I: Conceptualization Stage**

**Devising or identifying a problem.** The research questions may be obtained from existing theories in the field resulting in Research-To-Support-Theory types of studies criticized by Willis (1993). Alternatively, questions can arise from interesting problems or contradictions found in the literature. Personal observations or observations made by others may be extended or investigated more fully.

**Formulation of the research question.** The literature review should present the researcher with alternative frames of reference including alternative conceptions rather than looking for one true definition. Once the literature has been reviewed, the researcher must articulate the research question in unambiguous terms. In formulating the questions there are three areas of concern. Who are the subjects? What is the program or intervention and how will it be carried out? Finally, what are the goals and the expected effects on participants’ performance? As the questions are formulated, additional literature review may be necessary. One approach is to list all the questions that come to mind considering all possible alternatives without judgment. This list can be revised and refined to yield the final questions.

**Definitions of terms and concepts.** Overlapping conceptualizations obtained from the literature review can be used to identify dimensions specific to the study. This allows researchers to recognize that other studies using different conceptualizations of similar concepts cannot be directly compared. Once the specific dimensions have been identified, all terms must be clearly and objectively defined.

1. **Participants.** Who will be involved in the study? What are the relevant characteristics of participants and from where will they be selected or chosen?

2. **Program or intervention.** The intervention may consist of multiple factors having an effect on the outcomes of the teaching/learning process. These will become the independent variables. One guideline that can be used in selecting program factors is to select features that can be modified or manipulated by the researcher.

3. **Define the goals and objectives.** This phase of conceptualization involves the development of outcome criteria. The goals must be clearly stated; specific and measurable. These become the major dependent variables for the study. Guidelines for selecting the goals are usability and practicality. If goals identified are unachievable ideals they should not be included as major dependent variables; however, goals that are easily identified and easily measured may not reflect the underlying intent of the research. For example, when measuring the effects of instructional technology on learning, standardized achievement tests for reading and mathematics are often used, even if the learning was defined as creative writing.

The major issues that should be addressed in operationalizing the dependent measures follow.

1. **How should indicators be measured using existing instruments or should researchers develop their own?** As Tellez (1993) suggests, researchers should try to make use of “tried-and-true” measures used in previous research. When existing scales do not fit the conceptualization of concern to the study the scales will have to be tailor-made.

2. **How many indicators are necessary to carry out research?** Is one overall, global measure sufficient, or should there be several specific measures to tap various aspects of the intervention? If more than one measure is used, when should the assessment occur? Should it be taken proximally, soon after the participants have been exposed to the intervention, distally, after the material has had some time to “sink-in”, or longitudinally to determine the longer term effects of the intervention?

3. **Finally, what general types of information are required?** Should subjective reactions of the participants be assessed? Should objective behavioral measures be taken? Is formative assessment required? Formative measures allow the program or intervention to be fine-tuned as participants proceed. The researcher must keep in mind that altering the intervention also alters outcomes. Should summative measures be obtained? If the intervention involves development of instructional materials to be disseminated to others following the research, summative data is imperative.

**Phase II: Developing the Research Design**

After all components have been defined in unambiguous terms, the appropriate research design must be developed. The research design is determined by: a) the research question, b) the scaling and number of independent and dependent variables, and c) the pragmatic concerns of conducting the research including accessibility of subjects, availability of physical and financial resources, feasibility of conducting the research, staff, and time. A multi-step approach integrating various methodologies should be considered.

There are five major research methodologies from which to select. The first set, descriptive studies, yield qualitative results and make up the major body of research in ITTE. This type should be considered preliminary, requiring further investigation using more rigorous techniques. Another type
of research is the quasi-experimental, using intact groups. Although quantitative, the results must be interpreted with caution. Experimental design allows the researcher to identify causal relationships with a high degree of confidence. While the most rigorous quantitative method, it is also the most difficult to carry out in an action setting. The nature of the intervention and the teaching/learning process may be obscured by the strict requirements for control dictated by this type of design. With an understanding of various types of design methodologies available and the strengths and weaknesses of each, the researcher is in a good position to develop an appropriate design for the problem at hand.

Phase III: Carrying out the Research

The next phase involves setting up a procedural plan to conduct the research. After data collection, the researcher must decide on appropriate data analyses. Data analysis is dictated by the research design, level of scaling and the number of independent and dependent variables in the study. Careful and appropriate interpretation of the results is essential; researchers must be careful in the types of conclusions they draw. Care must be taken not to draw causal inferences on descriptive or correlational findings.

The literature is replete with examples of poor design and/or interpretation. Brody and Lange (1991) conclude that reading and writing skills of students improve after use of a hyper-card like tool named HyperStories. Their sweeping conclusion fails to note that (a) their subjects were atypical - they were Deaf and Hard of Hearing students spanning elementary grades through high school; (b) their single quantitative measure of writing ability was the word count of student writing samples; (c) the pre- and post test assessments were made eighteen months apart without consideration of other intervening variables nor controlling for pretest differences; (d) there were no tests for significance; and (e) there was no control group.

Manus and Denton (1996) examined two schools; one an intermediate school encompassing grades five and six, no description is provided of the other. In one school participation in a staff development program was mandatory; in the other it was voluntary. Over a three year period, a sample of ten teachers accrued 513 hours of staff development time in school one and a group of ten teachers accrued 503 hours in school two. Participants in both schools were observed on multiple occasions using the Stallings Observation Instrument. From these observations, the mean percentage of classroom time spent was calculated on various indicators such as teacher-student interaction, teacher involvement in instructional activities, and student involvement in instructional activities. The research design did not provide for measuring changes over time and there was no pre- or post test. No control group was provided. Undeterred, the researchers confidently conclude that “...staff development training has resulted in greater use of technology for classroom management and instructional purposes,” that “…off-task behaviors...diminished significantly when technology was integrated into the instruction,” and that “…technology can alleviate, but not eradicate ineffective teaching” (pp. 437-438).

Carey (1991) designed an “informal” study to ascertain the effects of classroom visitations upon the computer confidence of preservice education students. Using a six-point Likert scale, levels of computer confidence were calculated at the beginning of a semester for two small groups of students - one group made the classroom visits, the other did not. The instrument was readministered at the end of the course. After (a) failing to control for the initial differences, and (b) not finding statistically significant changes in computer confidence, Carey proceeds to interpret the results anyway.

Sometimes sophisticated statistical methods are employed without apparent reason. Pelton and Pelton (1996) administered a 42 item questionnaire designed to assess attitudes toward technology to a single class of 60 college students. A principal component factor analysis was then employed to reduce the 42 questions to eight factors. The first factor accounted for 18.6% of the variance, the remaining factors for 12.0% to 6.9%. Having engaged in this elaborate statistical calculation, scant use is made of the results with the authors merely concluding that “attitude is indeed a multi-faceted variable,” (p. 171) and that students are enjoying the course.

At the other extreme are studies where measures are primitive or unreported but substantive interpretations are still made. Breithaup and Wentworth (1996) divide college students enrolled in a Teaching Methods course into two self-selected groups based upon section of enrollment. One group received instruction on integrating computer based technology into the secondary curriculum, the other group did not. A survey instrument was given to all 103 subjects; the response rate was about 12%. After acknowledging the poor response rate and presenting no quantitative analysis, the authors nonetheless conclude that “these results firmly imply that the inclusion of formal computer technology instruction...has some impact on the way computers are used to support secondary education curriculum” (p.361).

Conclusions

No matter how carefully a researcher conceptualizes the problem, defines the terms, develops the design, analyzes data and interprets and draws conclusions, difficulties arise. No research paradigm is perfect and no study is free from pitfalls. Researchers should follow the guidelines closely. In interpreting and reporting results, researchers should use the “self-critical” approach described by Tellez (1993), recognizing the limitations of the research in light of threats to internal and external validity.

Why Infuse Technology? As this world continues to convert information to an electronic form, students in almost every area of academic endeavor will have greater access to existing, evolving, and new electronic data bases. Utilizing and understanding these databases will frequently serve the student well beyond the classroom (Kawamoto, 1994). However, when that same statement is made to graduate students, utilizing electronic information appears to be more frightening. Poling (1994) asserted that students feel as if they are dragged, kicking and screaming into the realm of computerese. How can educators encourage graduate students to utilize technology if the aforementioned attitude is present? How can educators utilizing technology in the classroom enhance learning, especially in a graduate research course?

Most students, in education, pursuing a graduate degree are required to complete a course in educational research. However, many enter the course with anxiety due to previous conversations with students, writing apprehension, and limited use of the computer. These aforementioned concerns, in addition to the difficulty level of the course, creates even more anxiety. This researcher was concerned with avenues to ease the anxiety level of students who must take a required course. Crossman & Behrens (1992) postulated that a means of easing some anxiety in a graduate course is a teaching collaboration, but for institutions that have more specialized instructors, other means need to be implemented. The means for this study was technology.

Technology, in a graduate research course, should emphasize simulation, direct instruction, and interactive modes of instruction to enhance student learning. Maley (as cited in Wright, J.R., 1991). According to Rodriguez (1993), the aforementioned emphases can also motivate graduate students in finding the work more challenging. Technology should serve in providing the student with the opportunity to engage in significant research activities, disciplined inquiry and serve as a prerequisite to a scholarly career (Householder, 1993). Therefore, implementing technology in a graduate research course is extremely relevant if institutions want to produce effective researchers.

Variations in electronic information gathering can be utilized very well in a graduate course. Availability may not be the question in choosing to utilize technology as much as the attitude of the student utilizing it. Some students fail to realize that technological innovations allow both teachers and learners the ability to interact with each other beyond the confines of the classroom (Redmond & Waggoner, 1992a; Hiltz, 1994). Technology is essential can also provide encouragement and further interactions among students, which in graduate studies.

Therefore, the purpose of this study was to investigate the attitudes towards technology of graduate students in a research course prior to and after the implementation of technology. This study also addressed the type of technology that was implemented in the course and how students utilized it.

Methodology

Subjects
The subjects for this study were 40 graduates students who were completing an educational research course required for their program. These subjects were in various stages of their programs and ranged from 22 years to 50 years of age. Some subjects were taking their first graduate course and some were taking their last graduate course. The subjects volunteered to participate in the study.

Instrument
A modified version of the CARTS II Attitudinal Survey was utilized in this study. This survey is designed to address the attitudes of students regarding technology implemented by instructors and the library assistance available. Another data collection procedure included the instructors perceptions of students attitudes.

Procedure
The instructor was asked to participate in the study by utilizing the class available and by implementing technology in the course. The listing of computer-assisted instruction available for use included:

- E-mail
- Computer Conferencing
At the beginning of the course, students were administered the survey. They were then assigned an E-mail account. After assignments were received, the students were taken to the computer lab to access their e-mailbox. Instructions were provided regarding how to access, obtain and send messages. The e-mail was used as a means of communicating with the instructor and other students, it also was a means of browsing the web to obtain literature regarding their proposal as well as using the information to refine their topic. The next exercise in technology included a bibliographic demonstration to obtain information for the review of the literature. This demonstration also introduced students to the use of the Internet, Netscape, and web sites. The demonstration required one (1) hour of their time, after which each student was required to begin a literature search. As part of their review of literature, one source was required to have been retrieved from the web site. Each student was also required to join a listserv to obtain additional information from sources. All information required for submission in the course had to be completed using a word processing program. The students were also required to check e-mail for messages from the instructor. The instructor answered questions via e-mail daily and also sent messages regarding class information.

Results

The results indicated in this study are based on the perceptions of the instructor who has taught the course for 6 semesters. The course at this particular institution has been identified by most students as a difficult and much anxiety and fear enters the classroom. Some of the issues include a lack of understanding of course information, fear of conversing with the instructor, and accepting the magnitude of time required to excel in the course.

Based on the implementation of technology in this graduate educational research course, the attitudes of the students changed and the classroom environment became more comfortable. Eight (8) hours of the course time was assigned to the computer lab. In the lab time, students were allowed to access e-mail, browse the web, access the library, and construct a proposal with the assistance of the instructor. Students also had accessibility to the computer lab beyond class hours. Based on the perception of the instructor, students interacted more via e-mail and demonstrated more comfort when making an office visit. Several students lived over an hour away from the institutions and utilized the e-mail as a continual communication network with the instructor. Because writing apprehension is so high in a graduate research course, many students took the opportunity to e-mail parts of the proposal for the instructor's comments and corrections. One student utilized the listserv to assist in formulating a proposal topic.

Conclusions

Because of the experience of this instructor with perceptual difficulty in the level of the research course, implementation of technology eased a lot of anxiety, addressed issues for the students, and created a comfortable climate for the classroom. Students were able to converse with each other over the Internet as well as in the classroom, especially during the computer time. Two (2) students stated their gratitude for the implementation of technology. Prior to their graduate program, technology utilization was limited. Technology was also used as a avenue to vent frustrations comfortably. Students took advantage of the technology which helped to improve their productivity in the coursework and thereby increased academic performance. Future implementation of technology will include accessibility of previously submitted proposals for viewing on the Internet.

Recent innovations in hypermedia computer technology permit learners to have highly individualized and interactive computerized instruction. However, adapting hypermedia computer technology to computer-assisted instruction (CAI) does not guarantee effective learning. Research studies have revealed that when learners were not fully aware of or responsible for what they needed to learn from CAI, they made poor decisions on their completion levels of learning (Kinzie & Sullivan, 1989; Kinzie, Sullivan, & Berdel, 1992; Steinberg, 1989). Therefore, consideration should be given to designing hypermedia CAI environments with appropriate instructional strategies, which guide learners to acquire necessary knowledge and skills.

Our current computer authoring system technology enables instructional software developers to incorporate special constructivistic instructional strategies such as the cognitive apprenticeship method into sophisticated CAI environments (Lajoie & Lesgold, 1989; Parkes & Self, 1990). Researchers and practitioners of the cognitive apprenticeship teaching method suggest that cognitive knowledge and skills can be effectively learned by “learning-through-guided experience” (Collins, Brown, & Newman, 1989, p.457). The learning-through-guided experience occurs through the sequence of modeling, coaching, fading, and reflecting. A cognitive master (i.e., a teacher or a computerized coaching system) shows the appropriate way of performing learning tasks, and apprentices (i.e., learners) practice the tasks with the strategic hints or scaffolding provided by the master. As the apprentices improve their skills or knowledge, the master gradually withdraws the guidance, and the apprentices take on the responsibility of performing the learning tasks. When completed, the learning responsibilities and the expertise have been shifted from the master to the apprentices. This learning-through-guided experience technique is beneficial when the learning subject is a type of situated problem solving or dilemma handling, which students in pre-service teacher education especially need to practice before they become classroom teachers.

The processes of learning responsibility and expertise shift can be observed by the utilization of self-regulated learning (SRL) skills as well as in academic outcomes of instruction (Schunk, 1989; Zimmerman, 1989, 1994). According to Zimmerman (1989), self-regulated learners are metacognitively, motivationally, and behaviorally active in their learning processes. When constructively taught how to use the SRL skills such as self-monitoring or self-evaluating, novice learners, or ineffective impulsive learners, have been shown to successfully shift themselves from being ineffective, low academic achievers to effective, responsible high academic achievers (Schunk, 1989; Zimmerman & Martinez-Pons, 1990). SRL skills can be taught and learned at any age (Butler & Winne, 1995). The positive effectiveness of SRL skills on learning has been shown in many research studies across a wide range of learners from young children (Pintrich & DeGroot, 1990; Zimmerman & Ringle, 1980) through college-level students or adults (Lan, Repman, Chyung, & Bradley, 1996; Zimmerman & Paulsen, 1995).

An important approach for pre-service teacher education is hypermedia CAI that implements the cognitive apprenticeship method. A hypermedia CAI program incorporating with the cognitive apprenticeship method may monitor an individual’s performance, evaluate his or her progress in mastering the content, and provide guidance through learning sequences with strategic hints and scaffolding at appropriate moments. This innovative hypermedia learning environment may enable pre-service teachers to learn in constructivistic ways exploring a rich information world, help them develop and use SRL skills, and increase ownership of the learning process and expertise with the content. This will
eventually lead them toward becoming successful academic and professional performers.

Based on this theoretical framework, a research study was conducted to compare the effectiveness of two forms of hypermedia CAI. The goal was pre-service teachers' acquisition of knowledge and performance in professional problem-solving situations. One instructional method was based on the cognitive apprenticeship teaching method and the second used a total learner-control method. The effectiveness of the two hypermedia CAI environments was evaluated by the pre-service teachers' utilization of SRL skills and their academic performance.

Method

Participants

Seventy-five pre-service teachers, who were enrolled in undergraduate courses in the college of education at a west Texas university, participated in this study. The participants were predominantly Caucasian (90.7%), female (93.3%) and between 20 and 29 years old (86.7%).

Variables

There were two independent variables: (a) hypermedia CAI with two levels: cognitive apprenticeship hypermedia CAI environment and a totally learner-controlled hypermedia CAI environment and (b) a personal factor as impulsivity or reflectivity. The SRL skills were measured by self-evaluation levels, self-efficacy levels, and self-learning activity levels. These variables were derived from Zimmerman's SRL model: i.e., how metacognitively (self-evaluation level), motivationally (self-efficacy level), and behaviorally (self-learning activity level) active students were. Academic achievement was interpreted to support the outcomes of utilizing SRL skills.

Instruments

The instruments used in this study were (a) the adolescent-adult version of the Matching Familiar Figure Test (MFFT, Kagan, 1981), which was converted to a computerized version, (b) hypermedia CAI programs, and (c) a computerized achievement test with 15 questions.

The Computerized Version of MFFT. The adolescent-adult version of MFFT was converted to a computerized version and used to rate the participants' personal factor as impulsivity or reflectivity. The MFFT contains 12 problems. Each problem requires a participant to match a standard figure with the identical one from eight alternative figures. Each participant was evaluated according to how fast and accurately he or she answered each problem.

The Hypermedia CAI Programs. The hypermedia CAI programs were developed to teach the pre-service teachers about educational measurement and its application on the Texas Assessment of Academic Skills (TAAS). The hypermedia CAI with the cognitive apprenticeship teaching method employed coaching and scaffolding techniques using an interactive agent, "coach." The coach offered guidance on pacing and the sequence of lessons. The hypermedia CAI with total learner-control allowed the participants total learning responsibilities in terms of the pace and sequence of topics covered during learning. Both hypermedia CAI programs contained two lessons with identical content, each of which recorded the number of mouse clicks made by each participant. The number of mouse clicks was used to assess the participant's self-learning activity level. The hypermedia CAI programs also recorded the participants' levels of efforts in learning measured by the total number of completed lesson items and the elapsed time spent for learning with CAI.

The Computerized Achievement Test. The participants' self-efficacy levels, academic achievement scores, and self-evaluation levels were obtained from the computerized test. Self-efficacy levels were measured by asking the participants whether or not they were confident in solving each question. There were two possible self-efficacy responses, "I think so," or "I doubt it." Academic achievement scores were recorded in terms of right and wrong. Self-evaluation levels were calculated according to the discrepancies between the expressed self-efficacy levels and the actual performance on the tests. For example, if a participant's prediction of performance matched actual performance, the participant's self-evaluation level on the performance was reported as high.

Results

Two-way MANOVA revealed that, in hypermedia CAI environments, there was a significant difference in the pre-service teachers' SRL skills and academic scores due to the different instructional strategies, $F(4, 68) = 10.82, p < .01$. Implementation of the cognitive apprenticeship method was significantly more effective on encouraging the pre-service teachers to exercise SRL skills than the totally learner-control strategy. A univariate test showed that the self-learning activity levels were the most significant contributor to this significance, $F(1, 71) = 38.50, p < .01$ (see Table 1). That is, the pre-service teachers who received the cognitive apprenticeship teaching method were significantly more active in terms of the numbers of clicks during the learning processes ($M = 111.39, SD = 16.56$) than those who were allowed to have total control over their learning processes ($M = 81.29, SD = 24.44$). No significant interaction was found between the pre-service teachers' personal factor (academic impulsivity or reflectivity) and the different hypermedia CAI environments.

There was also an evidence that the pre-service teachers in the cognitive apprenticeship group significantly shifted their behavioral learning responsibilities from the computerized coach to themselves, as lessons proceeded. A MANOVA repeated measures analysis within the cognitive apprenticeship CAI group was conducted on the ratios of the frequencies of utilizing the coaching features to the self-learning activity levels between the first lesson and the second lesson. There was a significantly reduced ratio of frequencies of requesting help from the cognitive “coach” per learning activity, $F(1, 37) = 5.55, p < .02$ (see Table 2 and 3).

An additional significant effect of CAI on the efforts in learning was detected. The pre-service teachers in the cognitive apprenticeship hypermedia CAI environment showed significantly higher efforts in learning than those in the totally learner-controlled hypermedia CAI environment: $F(1, 71) = 22.27, p < .01$, for the lesson completion levels, and $F(1, 71) = 17.47, p < .01$, for the time spent for learning. That is, the cognitive apprenticeship hypermedia CAI group spent significantly more time in learning ($M=139.05$) and accomplished significantly more lesson items ($M=95.61$) than the totally learner-controlled hypermedia CAI group ($M=110.84$ and $M=75.48$, respectively).

**Discussion**

The findings of this study support Clark’s argument (1983, 1985, 1994) that computers themselves are merely delivery tools and do not influence learning. Computers are not a guarantee of effectiveness (Pea, 1987). Adapting the new hypermedia technology to instruction does not cause effective learning. Research designs that select different delivery media as independent variables and measure the effectiveness of delivery media on learning outcomes as dependent variables have been criticized for confounding independent variables. The effectiveness of instruction does not depend on the selection of delivery tools but relies on the use of effective instructional strategies.

In this study, enhancement of learning responsibilities and expertise shift was proved to be due to the effective instructional method that was appropriately selected and employed in the hypermedia CAI environments. This intra-media research study used computers as the instructional delivery media and revealed that use of an appropriate instructional strategy such as the cognitive apprenticeship method was the critical factor (Salomon, 1988; Salomon, Perkins, & Globerson, 1991). In particular, the hypermedia CAI environment that incorporated a cognitive “coach” encouraged the pre-service teachers to employ behavioral SRL skills that helped them become self-responsible learners. Effects of using the cognitive apprenticeship method in hypermedia CAI environments on other SRL skills such as self-efficacy and self-evaluation skills were not significant in this study. A possible explanation for this is the difficulty in designing instruments to measure those categories. The instruments used to measure the self-efficacy and self-evaluation levels in this study may need to be reconstructed.
for improved validity. Another possible explanation is that human overt behaviors (i.e., the self-learning activity levels) were more easily manipulated by the explicit modeling provided by the coach than the cognitive, metacognitive, and affective behaviors (i.e., the academic achievement levels, self-evaluation levels, and self-efficacy levels). The interactivity of personal factor as impulsivity or reflectivity with the two different hypermedia CAI environments was not significant. This could be due to the small sample size or the homogeneous sample selection. Recommendations for future research are larger sample with a longer period of treatment and a careful design of instruments.

 USING ISTE GUIDELINES TO ASSESS STUDENTS' PERCEPTIONS OF COMPUTER LITERACY LEARNING

Kathryn I. Matthew  
Louisiana Tech University

The International Society for Technology in Education (ISTE) has developed a set of content guidelines to be incorporated into courses for initial computer/technology literacy certification. The three major instructional areas addressed in the guidelines are: 1) prerequisite preparation, 2) specialty content preparation, and 3) professional preparation. These guidelines can be used to provide structure and guidance for course curriculum development to insure that teachers have the competencies to effectively teach students with technology.

ISTE's guidelines provide one definition of computer literacy. Kay (1992) and Woodrow (1992) found a plethora of definitions of computer literacy. Kay's review of the literature found that definitions of computer literacy paralleled the stages of development of hardware and software and asserts that this has led to defining computer literacy based on the personal needs of the computer user. The individual user determines what is needed to be personally computer literate. Personal definitions of computer literacy are influence not only by the personal needs of the user but also the technology available to the user, access to that technology, and the support needed to use the technology. Overbaugh (1993) proposes that the critical elements of computer literacy for teachers should include the knowledge to effectively use the technology available in their classrooms. They must apply their knowledge of technology to make it personally meaningful and useful in their current situation. Kay contends that these changes require educators to "help students learn how to apply the computer" (p. 454), rather than learn to use the computer.

The ISTE guidelines provide a framework for the development of computer literacy endorsement courses, but within this framework teachers must also develop their own personal definition of computer literacy. They must construct their own knowledge of and add personal meaning to it. Only then will they become competent, confident technology users who can teach effectively.

A survey was developed to determine the extent to which the three courses in the computer/technology literacy sequence at one university are meeting ISTE guidelines and preparing teachers to become competent, confident technology users. The results of the survey are being used to determine if the students feel the courses prepare them to be effective teachers based on the guidelines.

Methodology

Survey methodology was used in this study to determine the students' perceptions of the courses' content as an aid to further course development.

Participants

The participants were ten students who completed a three course sequence for computer literacy endorsement in the summer of 1996 at Louisiana Tech University. Of the fourteen students enrolled in the course, only 10 responded, or 71%. One participant was male and the other nine female. Seven of these participants took the course for graduate credit and were practicing K-12 teachers. One participant was a graduate student with limited teaching experience. The other two participants graduated in May, had not been admitted to graduate school, and would begin teaching in the fall.

Instrument

The instrument used was a researcher designed survey based on the ISTE matrix guidelines for initial computer/technology literacy endorsement program. The survey consists of 55 items measured on a five-point Likert scale. Items were constructed from the three major instructional areas addressed in the guidelines: 1) prerequisite preparation, 2) specialty content preparation in computer/technology literacy, and 3) profession preparation. Prerequisite preparation includes a foundation of fundamental concepts and proficiencies. Specialty content preparation encompasses an in-depth knowledge of technology operation and impact, programming, application tools, information access and delivery tools, and hardware/software selection and support. Professional preparation is concerned with teaching methodology specific to using technology. Each guideline was rewritten to reflect an individual personal response and to facilitate accurate responses. For example, guideline 1.1.12
states “Use computer-based technologies to access information to enhance personal and professional productivity.” It was rewritten as follows: 1.1.12a “I can use computer-based technologies to access information to enhance personal productivity,” and 1.1.12b “I can use computer-based technologies to access information to enhance professional productivity.”

Procedure

The computer literacy endorsement sequence involves three courses EDUC 445 Using the Microcomputer in the Classroom, EDUC 447 Software Applications and Teaching Methods, and EDUC 448 Instructional Software Design and Development. In recent years, EDUC 445 has been taught in the fall, winter, spring, and summer quarters with EDUC 447 and 448 taught only in the summer quarter.

Prior to the last class period the purpose of the survey was explained to the students. They were told that their responses would facilitate course revisions as well as provide a measure of the effectiveness of the course. The surveys were mailed to the students in late August with a consent form and a cover letter explaining the purpose of the survey. Two return address envelopes were included, so that the consent form and survey could be returned separately to help assure anonymity of their responses. On the survey respondents were asked to indicate the degree to which they agreed or disagreed with each statement by circling the appropriate letter(s) to the right of each statement. A five-point Likert scale, Strongly Agree, Agree, Undecided, Disagree, and Strongly Disagree, was used in this survey.

A follow-up mailing of the surveys was done in late September which resulted in additional surveys being returned. As changes are made in the courses and additional students complete the courses, the survey will be readministered as an ongoing assessment of the program.

Results

The first area examined in the survey dealt with prerequisite preparation which includes building a foundation for the use of technology in education. Responses to 16 of the 19 statements in this section elicited either strongly agree or agree. As noted in Table 1, one respondent answered undecided to three of the statements. Forty percent of the students strongly agreed and sixty percent agreed with the statement “I can use telecommunications to support instruction.” This was the only instance in this section when the majority of the respondents selected agree over strongly agree. Since the college of education is not wired for Internet access, telecommunications usage was limited to a total of ten hours over five days during which we had access to a computer lab with Internet access. This lab was located across campus in the College of Engineering. The lack of readily available Internet access is further noted to responses in Table 5.

The second area of the guidelines matrix focuses on specialty content preparation which is subdivided into four subsections. Subsection 1 deals with providing in-depth knowledge for teaching about computers and related technologies. Students responded to ten items in this subsection. Four items were marked undecided by at least one respondent. (see Table 2). Regarding their awareness of future directions in technology, 30% of the respondents strongly agreed and 70% agreed. This is reflective of the students' lack of access to current materials regarding technology developments. Fifty percent of the students marked strongly agree or agree to the second statement in this section regarding having a functional knowledge of technology terms. Students did not feel completely comfortable with technology vocabulary.

Subsection 2, Section 2 examines programming and problem solving abilities. Students felt the most unsure of their abilities in this area. (see Table 3) Programming was only presented in the last course of the sequence and involved teacher modeling and the completion of ten classwork exercises requiring students to use Logo in HyperStudio stacks. Students worked in groups to complete these exercises. Only three of the students in the class had previous programming experience. Prior to the start of the summer session two students expressed concern about learning programming and were hesitant to take the class because of the programming component.

Subsection 3 looked at students perceptions concerning application tools. (see Table 4) Students were required to use and evaluate teacher utility tools, such as gradebooks and paint programs. These are important tools for teachers that need more emphasis in the classes as reflected in the responses.

Subsection 4 addresses students use of information access and delivery tools. (see Table 5) During the last two courses in the sequence students worked in groups or alone to create HyperStudio stacks incorporating images, graphics, audio, video, and laser discs. This emphasis is reflected in their responses to their knowledge of multimedia resources. Once again the lack of Internet access in the college is reflected in answers to this portion of the survey. Only two students had Internet access in their homes and used it on a regular basis. Students enjoyed their Internet explorations and had little difficulty completing classwork assignments using the Internet. However, the limited access prohibited them from becoming proficient users.

Hardware/software selection, installation, and maintenance is the focus of Subsection 5. (see Table 6) The first course in the sequence focused on the Windows platform. During the last two courses, the students had a choice of platforms, Windows or Macintosh, for many of the activities. However, in these courses students were required to use a scanner, a QuickTake camera, a QuickCam, and a laser disc player connected to Macintosh computers, hence, they spent more time on Macintosh computers. These peripheral devices were new to the students. They also had opportunities to work with a Newton MessagePad 130 during the last two courses. As reflected in their responses, six weeks is not enough time to become expert users of this technology, nor to feel comfortable with maintenance of the technology.

The third section of the guidelines addresses professional preparation. As noted in the responses, all of the participants realize the need to continually update the curriculum to reflect changes in technology. Students do not feel comfortable with their ability to plan technology lessons reflective of changing teacher/learner roles including using technology to teach problem solving.

Discussion

Marcinkiewicz (1993-94) found that self-competence and innovativeness were variables effecting elementary teachers use or avoidance of computers. Mindful of these findings it is imperative that technology courses for teachers focus on building their self-competence and encouraging their innovativeness. Technology courses need to be evaluated by the preservice and inservice teachers they are designed for in order to meet their needs and insure that they use technology for their personal benefit and to benefit their students. Results of this survey indicate that there are areas that need strengthening in the computer literacy sequence.

The results of the analysis of responses indicate that additional emphasis should be placed on the evaluation of technology and awareness of human issues related to technology. Students' responses regarding their knowledge of the resources available for staying current in technology are reflected in their uncertainty of the future directions of technology. Additionally, students seem to be unsure of their knowledge of technology terminology. The inclusion of additional readings on technology would make students aware of the resources available for staying current in
technology, provide them with information on future directions, and increase technology vocabulary.

Regarding programming and problem solving, students did not feel comfortable with their competence in this area. Woodrow (1992) briefly explores three different views on the need to teach programming in computer literacy courses. Some advocate that teachers should be proficient programmers, others argue that only a general understanding of programming is required, and a third group contends that teachers do not need to know programming to be computer literate. However, since compliance with ISTE guidelines are required for NCATE accreditation, programming will continue to be taught in these classes with modifications to lessen teacher anxiety and increase their competency.

Responses to questions concerning teacher utility tools and applications tools indicate that perhaps more emphasis should be placed on these software programs. However, students used all modules of Microsoft Works in one class, and evaluated and used teacher utility tools in all of the classes to complete classroom specific activities. Since students indicated their uncertainty with technology vocabulary, perhaps they were unsure of what was meant by application and utility tools.

Students' perceptions of their lack of competence in using information access and delivery tools should be alleviated when the College of Education computer lab is wired for Internet access in the next few months. Students in future class will be able to spend more time exploring the Internet. Students' Internet projects reflected an understanding of the Internet and demonstrated their ability to use the Internet to enhance their own learning. However, they lack the confidence and experiences needed to use the Internet to enhance student learning.

Students responses to the questions on the selection, installation, and maintenance of hardware and software indicate that they did not feel competent in all of these areas. Since many of the surrounding school districts lack technology support personnel, it is imperative that the students have more experiences in these areas. The development of a support system among the students would also be of use to them. Most of the respondents took the computer literacy sequence in a nine week summer session. They were overwhelmed by a collection of peripheral devices they had never used. The next group of students to take the computer literacy sequence will have taken the courses over three quarters during the academic year. It will be interesting to note if long term exposure to technology enables them to feel more competent in their abilities.

Responses to the last section on professional preparation indicates that more emphasis should be directed toward helping teachers learn to teach with technology. They need to practice teaching with technology in these courses if they are to feel confident to teach their own students with technology. Students need to practice teaching with problem solving activities that emphasize critical thinking and higher order learning using the same technology available to them in their classrooms. It is interesting to note that all of the students realized the need to continually update the computer/technology literacy curriculum.

The results of this survey are generalizable only to the specific courses in which these participants were enrolled. However, the survey does provide a useful tool for other Colleges of Education interested in determining how students' perceptions of their learning match the ISTE guidelines. Also, the survey provides some information regarding the teachers' development of their own personal definitions of computer literacy. The results of this survey provide useful information that is being used to make changes in the courses to insure that the students are computer literate.

The post-industrial/information age is profoundly effecting the field of education, primarily due to changes in technology. Technology is effecting education in two ways that are symmetric. It is changing the content and methods that teachers use to instruct and it is changing the methods by which students learn.

In order to produce students with the skills and knowledge they will need for the 21st century, many states throughout the nation are revising their K-12 they are also establishing competency standards so that teachers become more effective through the use of technology. One of the areas is covered in these revisions is evidenced in a survey of Minnesota and North Carolina curriculums. It is in computer competencies (Minnesota Department of Children, Families, and Learning, 1996; North Carolina Department of Public Instruction, 1993). K-12 schools have approximately 4,278,958 computers for instruction with a ratio of 12 students per computer (Peterson's Guides, 1995). This number is growing. National education organizations such as the National Council for Accreditation of Teacher Education (NCATE) and International Society for Technology in Education (ISTE) are supporting this trend by establishing computer technology standards for their constituents (ISTE Accreditation and Professional Standards Committee, 1995). In addition, educational organizations such as the National Education Association (NEA), American Federation of Teachers (AFT), ISTE, the National Parent Teachers Association (PTA), the American Association of Community Colleges (AACC) and NCATE are supporting a Presidential initiative to develop staff development programs for 21st century schools (Milone, 1996). As a result, teachers will need more competency with computers to effectively teach their students.

Currently, most teachers using computers feel the need for more training (Seigel, 1995; Tenth Planet, 1995). Nearly half of all elementary school teachers are not comfortable using computers (Tenth Planet, 1995). These figures are based upon surveys of practicing teachers. As educators know, self-reporting of knowledge and skills is not always accurate. Objective measurement is usually a preferred form of assessment. This type of measurement could indicate the extent of training programs required for the to two main groups of teachers, in-service teachers and preservice teachers.

This study is concerned with the preservice teacher group. Research on preservice teacher programs indicates that most curriculums do not integrate much computer technology into the training (Hunt, 1994; Office of Educational Research and Improvement, 1986). The programs that do require a technology component tend to rely on minimal courses (Office of Educational Research and Improvement, 1986). One however, given the rapidly growing use of technology and reasonable cost of computers, this may change since one of the major barriers to integration of computer technology into teacher education programs is the availability of computers in higher education. The American Association for Higher Education’s Teaching, Learning, and Technology Roundtable program also addresses faculty computer compency as another area of concern.

Since qualitative research is more common than quantitative research for program evaluation, this study has attempted to develop a quantitative tool for measuring very basic computer competencies. To extend the application of this tool, the results have been compared to two also used. These surveys were self-evaluations of the subjects’ competencies and their expectations of future needs as teachers. This may permit the extrapolation or extension of other surveys into performance prediction. Further study may also permit the extension of this tool for competency testing in other educational levels, for example, in-service, and K-12 groups.

Methodology

Participants

Participants were juniors, seniors, or graduate students enrolled in one of two required courses. One course is in the Special Education Department and the other course is in the Education Department. These are courses at Winona State University (WSU), a medium-size comprehensive state university in southeastern Minnesota.
Instruments and Procedures

An interview questionnaire, two surveys, and a performance-based assessment were developed and used for this study. Prospective participants were interviewed to gather some demographic data and to determine their microcomputer operating system experience and preferences. Due to the focus of this study, only students who felt comfortable using the Macintosh operating system were invited to participate. A pilot study using the steps described was completed resulting in minor changes to the content and the length of time students were allowed for completion of the performance-based assessment.

Interviewees who were selected to participate in the study were then surveyed to determine their perceived computer competencies in four areas: word processing, spreadsheets, data bases, and electronic mail (e-mail). A parallel survey was also given to obtain info on te level of teachers’ computer skills. A performance-based test in four areas: word processing, spreadsheet creation and computation, database creation and management, and e-mail. Comparisons were made between the students’ perceived level of competence, their expected level of competence for practicing teachers, and their demonstrated level of performance. Both surveys used a 5-point Likert scale for responses. A score of one equaled no skills while a score of five equaled proficient skills.

To insure reliability, the participants used the ClarisWorks 2.1 software package for the Macintosh. ClarisWorks is an application that includes word processing, database management, spreadsheet computation, and communications. It is the integrated software package installed in the College of Education computer lab at WSU and therefore the students were more likely to be acquainted with this program. It is also one of the most widely-used packages in K-12. User’s guides for ClarisWorks 2.1 were made available to participants for reference.

Participating students scheduled appointments to take the performance-based assessment. The students were each given a booklet of exercises and exhibits, and a diskette with a file they needed to edit. The booklet was divided into three sections: word processing, spreadsheets, and data bases. The exercises required the students to complete certain tasks in each section, print their work, and save their work on diskette. When the students finished, their completion time was recorded.

The word processing section required students to demonstrate their skills in several basic tasks. These included creating a word processed document, retrieving and editing a file, setting new margins, changing the size, type, and style of fonts, and aligning text. They were instructed to change a document’s line spacing, center a line of text, move text, and insert or delete text where necessary. The final tasks were to correct all typographical errors using the spell check, print the documents, and save them as files on the diskette.

To demonstrate competence with spreadsheets, students were asked to create a . Information for the data was provided. After the spreadsheet was created, the students had to increase the width of a column, edit a cell, use a function to calculate the average, add a title, and create a bar graph. The students were to print a copy of the spreadsheet and a copy of the bar graph before saving their work on the diskette.

The database section required the students to create, edit, and sort a database of records. Students were directed to create a database using the fields and data that were provided. They were then instructed to edit a record, delete a record, sort the database according to specified criteria, and print the records. The students were then asked to create and print a report and save their databases on the diskette.

Following completion of the booklet practices, the students were given an exercise to demonstrate their competency in using e-mail. They were asked to send the project administrator a message using an e-mail account created expressly for this study. In the body of the message, they were to identify the client server (e-mail program) that they used, and make comments about the performance portion of the study.

After the e-mail materials were received, the participants’ performance-based assessment was scored. For this initial study, all tasks were assumed to be of equal value (weight). The score for a particular task (for example, setting new margins) was assigned based upon the percent of occurrences performed accurately. The range of possible scores was a five-point scale to permit easy comparison with the surveys. The range of possible scores for a particular task will be based upon the complexity and importance of the task.

Results

Results and discussion of this study will be presented at the Conference. Preliminary results indicate that students who were taught to use productivity software were likely to forget what they learned if the skills were not utilized throughout their coursework. Results from the pilot indicate competency tests must be set within a time frame. Students do not have unlimited time to complete their tasks. An intervening factor might be the timing of when the participants took the test vis-a-vis the academic term. It appears that students taking the test earlier in the term spent more time on the test. It is conjectured that this is a function of the time available to the students based upon the demands of their coursework.

The past decade has spawned a host of studies devoted to issues of gender and technology (Sutton, 1991; Sanders, 1985; Turkle, 1984). During this same period, research on self-concept and math education has revealed significant differences between males and females (Reyes, 1984; Meyer & Fennema, 1988). Despite evidence that teachers feel unprepared and resist the integration of computers, a common exemplar of technology, into their instruction (Heinich, 1991; Piña & Harris, 1993), there is little in the current research that examines preservice elementary teachers' experiences learning technology, explores their self-concepts with regard to technology, or investigates how these self-concepts emerged.

While studies of self-concept have generally primarily employed quantitative methods (McLeod, 1992), this study utilized a qualitative research framework to explore the nature of preservice elementary teachers' experiences in learning and utilizing technology. The use of a qualitative research framework illuminated the perspectives of the preservice teachers and enabled the researcher to gain an understanding of the ways in which they constructed and utilized technology. Specifically, this qualitative study was designed to: (a) examine the nature of preservice elementary teachers' experiences in learning and utilizing technology; (b) probe the formulation of their technology self-concepts; and (c) determine what factors influence the formation of these self-concepts.

**Theoretical Framework**

The prevailing image of technology represents it as an abstract, formal discipline, conceptually linked to the domains of mathematics and science. It has been suggested that the field of educational technology has been designed on a male model of hierarchy and scientific objectivity (Damarin, 1990). Because of its perceived association with the “masculine” disciplines of mathematics and science, there is a common perception that female students are less likely to be interested in technology than their male counterparts (Laboratory of Comparative Human Cognition, 1989; Jones, 1987). While some researchers offer biological explanations for gender differences in mathematics (Benbow & Stanley, 1980; Benbow, 1992), others advance sociocultural explanations, suggesting that societal expectations of gender identity and sex roles play a greater role than biology in influencing such differences among male and female students (Woods and Hammersley, 1993; Meece, Parsons, Kaczala, Goff and Futterman, 1982).

Males are more likely to exhibit greater confidence in their mathematics and science abilities, view themselves as mathematics learners, and have higher expectations of future mathematics courses (Linn and Hyde, 1989). Research has determined a positive relationship between self-concept and achievement in mathematics (Marsh, 1986; Marsh, 1992). Self-concept, a generalization of confidence in learning (Reyes, 1984), is a person's perception of self constructed through experience with the environment and influenced by both environmental reinforcements and the reinforcement of significant others (Shavelson, Hubner & Stanton, 1976). In symbolic interactionist terms, people actively construct and reconstruct their self-concepts within limits set by social norms (Shott, 1979). Given the relationship between teacher self-concept and student achievement (Midgley, Feldlaufer & Eccles, 1989; McLeod, 1992), and the pivotal role that teachers play in implementing technology in the classroom, it is possible that preservice teachers with low technology self-concepts may have a negative influence upon their own students' formulation of technology self-concept.

**Methods and Data Sources**

A symbolic interactionist theoretical framework provided a basis to consider the nature of preservice teachers' technology self-concepts. The methodological underpinning of this study is derived largely from orientations to research that draw attention to the importance of detailed qualitative fieldwork and the observation and analysis of preservice teachers in context. Consistent with the purposes of the study, qualitative methods were utilized to explore the preservice teachers' responses to technology, distinguish the processes by which these responses are mediated, probe the formulation of their self-concepts in technology; and identify how these might inhibit, repress, or constrain their
ability to effectively utilize instructional technology in their own classrooms.

Setting and Participants

The participants were fifteen preservice teachers (twelve women, three men), seniors, 21 to 24 years old, enrolled in the elementary education program at a large, public research university located in the northwestern United States. Three theoretical and practical criteria were employed for the selection of the preservice elementary teachers to include in the study. The criteria were established to insure that the preservice teachers who participated in the study were: (a) elementary education majors, admitted to the teacher certification program; (b) enrolled in an educational technology course designed for K-8 preservice teachers; and (c) had no social or personal ties to the researcher.

The eight-week educational technology course, a requirement for all K-8 preservice teachers, emphasized multimedia authoring, virtual environments, and telecommunications. In addition to attending weekly one-hour lectures, the preservice teachers participated in weekly four-hour computer labs. Course components included working with general-purpose and educational software packages, utilizing e-mail, navigating the Internet, creating homepages, participating in online discussion groups and learning communities, and designing on-line learning experiences for K-8 learners.

Procedures and Data Collection

Data were gathered by three methods: (1) semi-structured, open-ended interviews; (2) observations of the technology classes; and (3) examination of classroom artifacts, including the students’ on-line assignments, projects, and final exams. Information about the preservice teachers’ educational background and prior experiences with technology were collected through individual interviews. Additionally, during the course of conversations, personal demographic and biographic data were gathered from each participant.

In-depth interviews, each lasting between one and two hours, were conducted with six of the preservice teachers (four women, two men). The interviews, which took place over a four-week period, were tape-recorded, transcribed, and supplemented with the field notes. The participants’ own words provided an insider’s view of the world of a sample of preservice teachers, offering insight into their experiences with technology.

Data Analysis

The researcher’s approach to data collection and analysis was iterative: data were analyzed as they were collected and emerging themes were identified and utilized to guide further data collection. An iterative design was selected in order to ensure the credibility of the research. As the study proceeded, the data collection/analysis cycles informed subsequent questions. During the course of the interviews, new questions emerged and existing ones were redesigned. The iterative design allowed for the testing of concepts, themes and theories throughout the study. In addition, the researcher triangulated the data via multiple sources of evidence including informants, events, and documents. As the study progressed, the researcher’s thoughts, reactions, and assumptions were recorded in a journal in an effort to identify the researcher’s own preconceptions, biases, and conflicts (Henry, 1996, p. 34).

Theory in this study was emergent and arose from the experiences and understandings of the participants. Theory was grounded in the details, evidence, and examples of the data generated during the course of the research; it followed rather than preceded the research (Glaser & Strauss, 1967). Initially, the interviews with the preservice teachers were relatively open-ended. As themes and theories emerged from the interviews, the research questions became more focused. In order to elicit in-depth responses related to the research questions, the interviewer introduced a topic then guided the discussion by formulating more focused questions. As the data were collected and analyzed, the preservice teachers separated into two distinct categories of participants: those with high technology self-concept (1 woman, 1 man) and those with low technology self-concept (11 women, 2 men). The anticipated gender differences between male and female participants’ self-concepts did not emerge. It is possible that the large number of low technology self-concept participants, male and female, may be a result of the relatively low levels of mathematics and science knowledge possessed by preservice elementary teachers (Leinhardt, Putnam, Stein, & Baxter, 1991).

Results

During the analysis of transcripts and field notes, the lines of text were counted and coded for the most salient themes. Of the four most salient broad categories discovered and coded in the data, the themes that emerged were focused on: (a) gender beliefs; (b) technology beliefs; (c) perceived control; and, (d) educational background. This constellation of four variables appears to have played a role in the formulation of the participants’ technology self-concepts.

Gender Beliefs

In the present study, the perception that computers appeal more to males than females was shared by all of the participants, both male and female, low- and high self-concept. However, the participants’ responses were mediated by statements which suggest sociocultural explanations for gender differences.

I think that technology is probably like math - you might have guys who are more interested and are going to do better - but I think it’s basically because girls are probably going to want to do something else - not sit at a computer.
think that some guys expect that girls just aren’t going to know as much about computers as them - you find this attitude with teachers also - it’s funny because when a girl does do well - it’s a big surprise to everyone - the boys and the teacher! (Interview, Female, low self-concept).

It may seem stereotyped, but I think that you just expect males to be more interested and better in technology and computers and fewer females who are - this just increases at higher levels of computing. I’m not saying that females just don’t have what it takes, it could be that something goes wrong somewhere along the way - you know, the girls are encouraged into other areas (Interview, Male, high self-concept).

Guys seem to like technology better than girls and they do better than girls [pause] but I think there is more to it [pause] when I watched the kids at Roosevelt [elementary school], it was the boys who were always crowded around the computers - the girls couldn’t get a chance in (Interview, Female, low self-concept).

I think you will always find that girls will be more interested in things like writing or art, those areas, the boys will always like doing things with machines, science-type stuff. Who knows why? You just have to watch little kids and the kinds of games they choose - the boys go for computer games, Nintendo, action heroes - where are the girls? - with the dolls - they just naturally end up not doing as well with computers (Interview, Female, low self-concept).

Technology Beliefs

Beliefs about the nature of technology appear to play a critical role in the formulation of self-concept. Technology was pedagogically and conceptually associated with mathematics by the majority of the preservice teachers. Both low- and high self-concept participants expressed a belief that success in technology results from a prerequisite talent or competency in mathematics.

Math and technology go hand in hand. If you’re like me and always had terrible experiences in math, facing a computer is a lot harder. I think that if you don’t have a math brain, this is all going to be much, much harder. It sort of gives me the same feelings I had in math class, definitely (Interview, Male, low self-concept).

I think you can say that you’re going to find the same kind of people that you find in math in technology. It’s the same for teachers - you find they have a different attitude about their students - they know if you’re the kind of student whose going to do well in those areas. It’s just something about those subjects, they just go together, I don’t know, I can’t really explain it any clearer, but I think it’s true based on my experiences, that connection is real (Interview, Female, high self-concept).

In addition to expressing a belief that technology was related to mathematics, several of the low self-concept preservice teachers articulated a belief that the presence of technology in the classroom could be problematic for both teacher and student.

It is possible that computers might make things difficult for children who struggle with technology. I know that I will have to consider ways to help students who find technology confusing (Interview, Male, low self-concept).

Well, computers in the class definitely make things different for the teacher. She is going to have to know a lot more about computers so the kids don’t get ahead of her. As a future teacher, I know this is going to be a big challenge for me in my future teaching (Interview, Female, low-self concept).

Perceived Control

Perceived control, developed from the concepts of perceived self-efficacy (Bandura, 1982) and locus of control (Rotter, 1966), is the perceived ease or difficulty of performing a particular behavior (Ajzen, 1988). Low self-concept preservice teachers’ were more likely than their high self-concept peers to express a lack of control with regard to the technology.

Things move so fast - and once you’re behind, if you need to go back - no one waits for you - you have to catch it the first time - and if you don’t, you know, you think, you really don’t fit in this - this whole computer thing. I just shake my head, ok, I’m into something I can do but it’s moving along too fast for me, I can’t take the time to really understand it (Interview, Male, low self-concept).

My main thing with computers is that they’re so unforgiving [pause] it’s not that I expect it to know what I want to do, but there is something missing [pause] I don’t trust it - it bombs suddenly, ‘error!’ - what is it? - ‘an unexpected error has occurred’ Sometimes, it’s I think that I have to know how to think for it - to me, there is nothing logical in what it does (Interview, Female, low self-concept).

What I really hate is having to do stuff over and over. I have no control here - I get messages, it wants this, tells me to do that, that’s not how I work - it doesn’t cooperate (Interview, Male, low self-concept).

Educational Experiences

Prior educational experiences appear to play a significant role in the development of technology self-concept. The majority of low self-concept participants had negative experiences with school mathematics and believed that these negative experiences adversely impacted their ability to learn and utilize technology.

All of my experiences with math have been horrible. I have come to believe that I’m not good in math so I just don’t see myself as being good in technology either (Interview, Female, low self-concept).

I didn’t get a chance to take any computer classes in high school. The way it was, if your grades weren’t high enough and you didn’t have a strong math background, which I didn’t - I was a ‘two-oh’ in math - you were shut out.
of taking any computer classes (Interview, Female, low self-concept).

For me, I would say that all of my experiences in technology have pretty much been like my experiences in math. Both have been very scary for me. I don’t feel comfortable in class or asking questions. I also have a feeling of constantly being lost and not really knowing exactly what is going on (Interview, Female, low self-concept).

**Significance**

Like the discipline of mathematics, technology is commonly presumed to be culture and value-neutral, independent of social intentions, power, and privilege (Apple, 1989). However, technology reflects the society out of which it came and is open to shaping by social structures and cultural meanings (Harding, 1986). Because teachers bring their own self-concepts about technology into their classrooms, they not only teach content, but also implicitly transmit their own attitudes and understandings about technology to their students. Teachers’ self-concepts mediate not only what they teach but also influence the ways in which their students develop their own self-concepts.

The present study began with an examination of preservice elementary teachers’ technology self-concepts. The mission statement of the teacher preparation program in this study reflects its commitment to guiding preservice teachers toward an understanding of the benefits of multiple instructional strategies, including educational technology. Although preparing preservice teachers to effectively meet the educational needs of all students through a variety of instructional strategies is a key component of the teacher preparation program’s strategic plan, the data from this study offer little evidence that the preservice teachers who participated in this study feel confident about implementing technology in their own classrooms.

By providing insights into preservice elementary teachers’ technology self-concepts, the present study has theoretical, substantive, and practical significance. At a theoretical level, the study contributes to the knowledge base concerning preservice elementary teachers’ technology self-concepts. At the substantive level, the study adds to the literature concerned with the ways in which preservice elementary teachers perceive the nature of technology and their attitudes toward teaching and learning with technology. At a practical level, the study provides some guidance to university faculty and staff seeking to design programs to enhance preservice elementary teachers’ technology self-concepts.

It is possible that a teaching force composed of low technology self-concept teachers will result in the reproduction of low technology self-concept among learners. For those concerned with the improvement of teacher preparation programs, it appears that there are three crucial issues: (a) a recognition of the significant number of low technology self-concept preservice elementary teachers; (b) an awareness of the impact of low technology self-concept teachers on learners; and, (c) an understanding of the roles that educational background, perceived control, and gender and technology beliefs play in the development of preservice elementary teachers’ technology self-concepts.

Technology can succeed in schools only if it is built into the curriculum as an essential element of the instructional delivery system. Before this can occur, it is imperative that teachers become proficient in the use of technical tools. Teacher education programs must be able to assess students’ level of technical competency in order to evaluate the curriculum and implement changes. The purpose of this paper is to introduce an instrument for assessing basic technology competencies that are needed by educators.

Background Information

In 1995 the North Carolina University System and the North Carolina State Department of Education announced a major initiative to develop a comprehensive plan for addressing the technology-related professional development needs of the state’s current education workforce. A regional delivery structure was proposed to bring together community colleges, public schools, and constituent institutions of the University of North Carolina to plan and organize a program that would work best for each region.

Out of this technology initiative came a mandate that all graduates of teacher education programs in the state of North Carolina be technology competent. At the end of the 1997-98 academic year, initial licensure of teachers and administrators will require demonstration of basic and advanced competencies, the former by means of a state test and the latter by means of a portfolio assessment.

The University of North Carolina at Charlotte responded to the state technology initiative by forming a steering committee to design, implement, and evaluate activities related to seven implementation objectives: (a) clarify and refine technology competencies, (b) articulate curriculum linkages, (c) acquire necessary resources, (d) develop faculty competence, (e) evaluate faculty competence, (f) develop student competence, and (g) assess student competence. This paper discusses the last objective, the assessment of student competence.

An instrument, Technology Competency Self-Assessment Instrument for Educators, was developed for assessing the technical competency level of preservice teachers. This information will serve as a “needs assessment” and baseline for deciding appropriate methods needed to develop and implement programs, activities, materials, and other mechanisms of integrating technology into the teacher education curriculum. The same protocols and procedures will be used for assessing and documenting the degree to which preservice teachers at The University of North Carolina at Charlotte have and use the basic and advanced technology competencies in their professional education courses and in their own teaching.

Technology Competency Self-Assessment Instrument for Educators

The Association for Educational Communications and Technology (AECT) and the International Society for Technology in Education (ISTE) have identified fundamental concepts and skills for applying a range of information technologies in educational settings. Using these identified concepts and skills, two clusters of technology competencies were defined and adopted by both The North Carolina State Board of Education and The University of North Carolina Board of Governors. Basic competencies are essentially entry-level skills related to basic computer
operation, word processing, spreadsheets, graphics, databases, other media, and multi-media production. 

Advanced competencies deal with the application of basic competencies in teaching, administration, and counseling and in other professional activities of both students and faculty. A total of 207 skills were identified. 

The Technology Competency Self-Assessment Instrument for Educators is currently being pilot-tested at The University of North Carolina at Charlotte. The original 207 skills were divided into nine competency domains: 1) basic computer operation skills; 2) setup, maintenance, and troubleshooting of equipment; 3) word processing; 4) spreadsheets; 5) databases; 6) networking; 7) telecommunication; 8) media communication; and 9) social, legal, and ethical issues. Within each domain, four competencies are sampled, reducing the original 207 competencies to 36 items. The competencies were chosen to represent an easy to difficult progression within each domain. In addition, the participants are asked to give an overall rating of their competency within each of the nine domains. Participants are instructed to self-assess using a four-point Likert scale (“Very competent” to “Not competent”). Below are the 45 items on the instrument.

Basic Computer Operation Skills:
1. Insert and eject floppy diskette
2. Store files in a folder/subdirectory
3. Access information on CD-ROM, floppy drive, and hard drive
4. Create and delete folders/subdirectories
5. Overall rating of basic computer operation skills

Setup, Maintenance, and Troubleshooting of Equipment:
6. Protection of floppy diskettes
7. Virus protection
8. Connecting peripheral devices
9. Managing memory
10. Overall rating of ability to setup, maintain, and troubleshoot equipment

Word Processing:
11. Set Margins
12. Change font size and type
13. Cut, copy, and paste in and between documents
14. Insert files, graphics, and tables in a document
15. Overall rating of word processing ability

Spreadsheets:
16. Enter data in cells
17. Move data within a spreadsheet
18. Use formulas
19. Create charts
20. Overall rating of spreadsheet management ability

Databases:
21. Enter data in a database
22. Sort and search in a database
23. Produce a report in a database
24. Queries using “and” and “or”
25. Overall rating of competencies using a database

Networking:
26. Logging on a network
27. Working in a network environment
28. File sharing
29. Knowledge of advantages of server
30. Overall rating of networking skills

Telecommunication:
31. Send and receive email
32. Navigate the WWW
33. Subscribe to a list-serve
34. Develop programs in Hypercard/Hyperstudio
35. Overall rating of telecommunication skills

Media Communication:
36. Use an overhead
37. Develop an electronic slide show
38. Develop an interactive electronic slide show
39. Develop a presentation utilizing graphics and sound
40. Overall rating of media communication skills

Social, legal, and ethical issues:
41. Knowledge of copyright laws
42. Knowledge concerning shareware
43. Knowledge of software piracy
44. Knowledge of intellectual property rights
45. Overall rating of social, legal, and ethical issues

The above portion of the assessment attempts to measure technical competencies. Since the instrument is self-report, the validity is related to the honesty of the respondent. To detect intentional attempts to respond dishonestly, an additional scale has been developed to assess “faking good.” A four-point Likert scale (“Strongly agree” to “Strongly disagree”) was provided. Below are the items on the “faking good” scale.

46. Only teachers who use technical tools can be effective in the classroom.
47. Technology can make a drastic improvement in the educational system.
48. All classes need a technical component incorporated into the lessons.
49. Students will not succeed in society without technical skills.
50. Technology can solve most of the world’s problems.

Validity and Reliability

The validity and reliability studies are scheduled to be completed in February, 1997, before the 1997 SITE conference. The results will be presented at the conference. Reliability will be reported using coefficients of stability (i.e., test-retest) and internal consistency (i.e., coefficient alpha). A variety of activities are planned for the validity study. Initially, participants will be administered the Technology Competency Self-Assessment Instrument for Educators. The
participants will then be given a performance-based assessment of selected competencies. The scores on the performance-based assessment will be correlated with the participants' scores on the Technology Competency Self-Assessment Instrument for Educators. Results from the "faking good" scale will be used to determine if this response bias has a relationship with the participants' discrepancy score (i.e., difference between performance-based assessment and Technology Competency Self-Assessment Instrument for Educators).

Conclusions

What began as a state mandated initiative has developed into a valuable change process for The University of North Carolina at Charlotte. This paper presents only one of the many activities that are being utilized to help produce technically proficient educators. Only by being aware of students' technical proficiency levels can teacher preparation programs develop and implement curricula which will produce effective teachers.

Technology offers great potential in the educational environment. Before technology can achieve its fullest potential in the classroom, teachers must possess basic and advanced technical competencies. The Technology Competency Self-Assessment Instrument for Educators can provide valuable information to professional teacher preparation programs that are working to build these competencies.

How Teachers Use and Learn to Use Computers

Jerry P. Galloway
Indiana University Northwest

There is a strong emphasis today on computer integration into the classroom with a usual focus on the available technologies (Barron & Orwig, 1995), effects on traditional classroom design and operation (Heide & Henderson, 1994), and the student learner (Dockterman, 1991). Unfortunately, there is little concern for what prerequisites or training is needed for teachers themselves. What training or experiences do teachers need in order to be ready to integrate technology into teaching? How do teachers actually use technology? And, how do educators learn to use and adopt technology? This information is generally missing in today’s research as well as from integration literature.

There are many elaborate planning models with protocols designed to yield successful technology growth and integration for schools. Heide and Henderson (1994) describe a number of classroom designs for the integration of technology. They describe the advantages and disadvantages of the one-computer classroom, the lab or shared classroom, and a specialized multimedia or highly-developed technology room. They even outline a so-called well-mannered and safe technology classroom. Their planning guide also addresses evaluating student progress and students with special needs. However, while this integration guide is typical of most, severely neglected are the important areas of preparing novice teachers to adopt technology to use in teaching students.

Virtually all models include a component for staff development with general suggestions for support, but how well are such models based on how educators actually learn to use technology? Typically, such models primarily emphasize the principle of planning and focus little on the nature of the educators who must implement the plan. For example, if teachers benefit from inservice programs over formal college courses then that fact should influence the nature of staff development programs and planning for integration. If teachers would benefit more from working one-on-one directly with a mentor then resources should be planned for that approach.

Indeed, far too often integration programs are started with little or no planning, let alone an informed approach which takes into account facts about how teachers learn to use technology. Bailey and Lumley (1994) say “...one major problem stands as a stumbling block in the path of the impending technology revolution in education - lack of planning.” (p. 35). They do stress the value of inservice training for staff development but with an emphasis on skills and the notion of training. There is virtually no mention of a more general education or development of a conceptual understanding of computing which might enable a teacher to adapt to changing and emerging technologies.

New and emerging technologies are as plentiful as there are ways to use them (unfortunately, sometimes more plentiful). An excellent review of technologies can be found in Barron and Orwig (1995) who outline in some detail a variety of technologies from audio to video, from hypermedia to CD-ROM, from networking to teleconferencing. However, the vast majority of teachers are, if not beginners, nevertheless still working to develop value and efficiency in the facility of computing. Teachers often feel thankful to have access to a word processor. For most, the many technologies available today are still an unknown and planning must take this into account.

As school districts plan for support for technical personnel, inservice programs and other training for teachers as well as guidance on computer integration into the curriculum, coordinators and committees must consider how teachers are actually learning and using computers. It is important not only to examine what teachers do with computers but also to consider how teachers learn those skills.

Methodology

Teachers and administrators of school districts across Northwest Indiana responded to surveys on their use of computers. The surveys targeted how teachers use computers, what kinds of software, frequency of use, and other aspects of their teaching experience. Questions specifically addressed personal and professional uses (for the teacher’s needs or interests) as compared to planning for, assisting with, teaching with or directing students’ learning with computers.

Personal and professional uses would include any use for managing projects or information, producing printed materials such as letters, flyers, charts. Also, teachers might prepare graphic images for use in anything from hobbies to...
professional organization materials. Teachers may have avocations which call for record keeping or the generation of letters and other materials. Certainly, the profession of teaching generates such needs. These personal and professional uses of technology were distinguished from the instructional application of technology to students.

Using computers with students involved everything from administering typical drill and practice software on some particular topic to more generic activities designed to enhance students' problem solving skills and such. Also included would be the use of technologies used to deliver instructional information, to present audio or video information and to demonstrate software applications for students to adopt. This category of use even included activities directed toward assisting or managing students' use of software and technology.

Other questions specifically categorized applications with which teachers regularly work: word processing, database, spreadsheet, graphics, desktop publishing, programming & hypermedia authoring systems, multimedia involvement, telecommunications, and work with operating systems or other applications unspecified. Teachers were invited to submit separate entries for each title/type/use of software with which they were involved. They documented their frequency of use. Of specific interest in the survey was how teachers had learned to use computers and the various software applications. Categories of training and education included college courses, technical schools, seminars, workshops, commercial classes, inservice programs, assistance from colleagues, personal study of texts and manuals, and even simple trial and error experimentation.

Results and Discussion

A total of 92 teachers and administrators responded to the survey not all of whom were computer-users. They had a variety of backgrounds and years of experience in education ranging from 1 to 35 years. The overall average number of years for the whole group was 18 years teaching experience. Approximately 66 percent owned their own computer compared with approximately 17 percent owning none (17 percent no response to this question). Although there were almost 4 times as many who owned their own computer as not, computer ownership was spread evenly across the range of years of teaching experience.

Respondents had experience across the curriculum including a small number of administrators. Table 1 illustrates the percentage of respondents per each of the subject areas reported. As the table shows, aside from those who tended to teach all subject areas (primarily elementary school teachers), language arts teachers were most plentiful with computer science teachers the least.

Clearly, the most used application of computing was word processing, generally twice as much, if not 3 to 1, over the next highest categories, dedicated educational software and graphics. As shown in Table 2, this was true for all categories except software used on only a monthly basis where graphics usage was equally high.

Very surprising, it seems that for educators using computers with students database activities are almost never included. In fact, with the exception of the primary 3, it seems that students are exposed to very little. The application areas of spreadsheet, multimedia, desktop publishing, programming, hypermedia, telecommunications and more, all seem relatively neglected for students. The personal and professional uses of computers, on the other hand, seem somewhat more diverse and possibly further developed. There were almost twice as many entries or accounts of software usage on a weekly basis as compared with daily or monthly usage. The significance of this is unclear although teachers' and students' access to computing equipment might account for this time difference.

One of the more interesting discoveries from the survey was that most teachers had not learned to use computers from courses, seminars or workshops, inservice programs or college courses. Only 17% of respondents accounted for learning computing from all external sources. Over 83% of respondents taught themselves to use computers and to use the various software applications. This seems significant since virtually none of today's integration planning models seem to take this phenomenon into account.

For example, learning to effectively use computers may be similar to learning the backhand shot in tennis. No matter how many videos are watched, no matter how many tennis matches one observes, no matter how many seminars one attends, it is inevitable that personal study, repetitive practice and some trial and error will be required. One learns for oneself over time exactly what works and what does not work - longer for some, shorter for others.

The final important area of inquiry addressed whether teachers integrate computer technology into use with their students with no commitment to and experience in using computers personally and professionally. It is not uncommon in this author's experience to be asked to train teachers to use computers with students. Unfortunately, the participants often don't know which side of the keyboard to type on. After being told that there are no funds to support teacher training, the activity is expected to produce teachers ready to integrate equipment and creative activities into student experience.

The notion of primary use in this study was defined as over 70 percent of one's time, computing activities and energies devoted to one particular type of use. Table 3 illustrates the primary focus (not exclusive focus) of these respondents and how over 75% have a commitment to personal and professional usage of computers. It is significant that one does not tend to find teachers using computers with students who do not also have a real commitment to using computers themselves in their personal and professional lives. The majority of respondents used computers with their students to varying degrees but less than 10 percent did so without also having a significant personal involvement with computing. And, 15 percent of respondents did not use computers at all.

The two most striking results from this study are (a) that educators learn to use computers primarily on their own, and (b) that it is unlikely that teachers will integrate computer technology into classroom instruction without the inclusion of personal and professional usage. It seems that planning models and integration programs should consider these factors more heavily when addressing teacher training.

Educators should emphasize the importance of a personal commitment from teachers who are learning to use computers or who intend to use computers in teaching. Whose responsibility is it when a teacher must adapt to and master the skills of using computers? Ultimately, it's everyone's problem in different ways. But, in addition to the inservice training programs which school districts tend to support and the traditional courses which colleges tend to provide, maybe teachers should be supported more directly in their own efforts to learn computing. Maybe support should be directed toward helping teachers acquire personal machines or provide technical support for completing the kinds of tasks we face in our personal lives which can be adapted to student activities as well.

Even though computer use with students still includes a large focus on dedicated educational software, future computing is moving toward more diverse multimedia work stations. Teachers and students alike all face the need for increased productivity using multimedia computers and access to telecommunications in personal and professional computing. The educational computing activities for students are more and more the same activities of everyone's personal and professional lives.

In any event, it seems clear that non-computer-using teachers will be less likely to accomplish a successful integration of technology into teaching. Teachers should alone assume the responsibility and make a personal commitment to incorporating computer technology into all aspects of their lives which will then flow more readily into their instructional programs.

THE COMPARISON OF INSERVICE AND PRESERVICE TEACHERS' ATTITUDES TOWARD EDUCATIONAL COMPUTING IN TAIWAN

Yuen-kuang Cliff Liao
National Hsinchu Teachers College

The fact that teachers are reluctant to use the technology resources such as computers, due to lack of training and experience is not unique in America (Carlson, Lambert, 1995). A similar situation is found in Taiwan. Teachers in Taiwan usually complain that they are willing to learn new technology, but the government does not provide adequate inservice training. On the other hand, with a limited educational budget, the educational policymakers in Taiwan must spend money carefully. They are confused about whether to provide more technology-related training in preservice teacher education, or to provide training to inservice teachers. Do teachers really have high motivation to learn new technology if adequate training opportunities are provided? If this is not the case then work may be required prior to graduation. There is no simple solution for this problem, but understanding inservice and preservice teachers' attitudes and perceptions about educational computing may provide some information which can help the policy makers reach an appropriate decision. Other variables such as gender may also need to be addressed in order to investigate the affect these variables have on inservice or preservice teachers' attitudes.

The major purpose of the present study was to compare inservice and preservice teachers' attitudes and perceptions about educational computing in Taiwan. More specifically, this study attempted to examine the effects of groups (i.e., preservice and inservice), (b) gender (i.e., male and female), (c) level (i.e., currently a freshman, sophomore, junior, and senior) on teachers' attitudes and perceptions about educational computing.

Method

Subjects

There were two groups of subjects. The first group included 947 inservice elementary-school teachers (including 160 kindergarten teachers) and the second group included 1247 preservice teachers. These inservice teachers enrolled in the summer session at a national teachers college located in the North of Taiwan. The 4-year summer program was designed specifically for the inservice elementary-school teachers who would like to pursue a bachelor degree in education. The total number of inservice teachers enrolled in the summer program at a teachers college in 1994 was 1,779. They were divided into 43 classes. Then 26 classes were randomly selected from the 43 classes.

The 1247 preservice teachers were randomly selected from all nine teachers colleges in Taiwan. Subjects for both groups were selected from 9 different educational departments (e.g., Department of early childhood education, Elementary Education, and Art Education). The subjects selected at each department represented a broad spectrum of backgrounds and academic interests. The background characteristics of the participants are shown in the Table 1.

Instrument

Two surveys, *The Teacher Computer Attitude Scale* (Violata, Marini, & Hunter, 1989) and *The Ability Differences in Computer Use* (Waxman, Huang, & Padron, 1992), were integrated into one instrument. A Chinese language version was administered to all subjects in the present study. The Teacher Computer Attitude Scale consists of four scales: (a) Sex Differences — teachers' perception of gender-related differences in working with computers; (b) Comfort — teachers' level of comfort in using computers; (c) Value — teachers' perception of the value of computers; and (d) Liking — teachers' liking for using computers. The Ability Differences in Computer Use has five items on a teachers' view of ability-related differences in their students' computer utilization. All the scales use a 5-point Likert rating with 5 indicating strongly agree and 1 indicating strongly disagree (Huang, Waxman, & Padron, 1995).

Every attempt was made to provide a Chinese version that was a faithful representation of the English version. Once the Chinese version was prepared, two other Chinese colleagues, both from the English Department, were requested to verify the instrument and compare it to the English version. A few minor changes in the Chinese wording resulted in the final version of the Chinese instrument. A section on background characteristics was also included on the final instrument.

The instrument's reliability, each scale's internal consistency reliability (alpha coefficient), was calculated using 466 preservice teachers as sample. These scales presented adequate reliability (with alpha coefficients ranging from .71 to .91). Table 2 displays the internal consistency reliability for each scale.

Procedures

Participants were selected and administered the instrument at two stages. At the beginning of the Spring academic semester, 1994, 1800 preservice teachers were randomly selected (200 for each of the nine teachers colleges) and were administered the instrument. A total of 1323 (74%) surveys were collected and, of them, 1247 (69%) were complete and coded. The inservice group was administered the instrument at the beginning of the summer session, 1994. The instrument took approximately 30 minutes to complete. The data was collected and coded.

For the data analysis, a 2 x 2 x 4 Factorial analysis of variance (ANOVA) was used to investigate if there were any statistically significant differences (at .05 level) on teachers' attitude toward computers: (a) between groups (i.e., inservice and preservice), (b) between gender (i.e., male and female), (c) among different levels (i.e., years in the college program coded as first, second, third, and fourth), and (d) the interactions among these factors (i.e., groups, gender, and grades).

Results

Table 3 displays the means and standard deviations for variables on each scale. In general, descriptive results from the present study indicated that teachers in Taiwan valued educational computing highly (M=4.05, SD=0.51). Their ranking of liking was positive (M=3.59, SD=0.55) and feelings about computers were quite comfortable (M=3.39, SD=0.71). Their perceptions of differences in computer use between low- and high-achieving students were mild (M=2.93, SD=0.70). However, their perceptions of gender-related differences in computer use were low (M=2.36, SD=0.63). Results of the three-way ANOVAs indicated that there were significant main effects (a) between groups on sex difference, F(1,2178)=4.27, p<.05, comfort, F(1,2178)=14.53, P<.001, liking, F(1,2178)=23.82, p<.001, and ability difference, F(1,2178)=58.74, p<.001, (b) between gender on sex difference, F(1,2178)=58.79, p<.001, comfort, F(1,2178)=88.23, p<.001, liking, F(1,2178)=49.05, and ability difference, F(1,2178)=7.61, p<.01, and (c) among grades on sex difference, F(3,2178)=3.59, p<.05, and comfort, F(3,2178)=2.98, p<.05. Table 4 displays the summary of the three-way ANOVAs.

Significant interactions were obtained (a) between groups and gender on sex difference, F(1,2178)=26.4,
Follow-up analyses were performed for each significant main effect and interaction. The results showed that for group, inservice teachers scored significantly higher than preservice teachers on all scales except value. For gender, results showed that male subjects scored significantly higher than female subjects on all scales except value. For level (grade), results showed that first-year subjects scored significantly lower than other subjects on sex difference; fourth-year subjects scored significantly higher than second-year subjects on comfort.

The significant interactions between group and gender on sex difference show that male preservice teachers' perceptions of gender-related differences in computer use were significantly higher than those of female preservice teachers. In addition, male inservice teachers valued educational computing significantly higher than male preservice teachers and female inservice teachers. Finally, the significant 3-way interactions on sex differences, comfort, and liking indicated that, overall, preservice teachers had more varied perceptions of gender-related differences, degrees of comfort and liking in using computers than inservice teachers.

**Discussion and Conclusion**

The findings of the present study indicated that, in general, inservice teachers in Taiwan valued educational computing very high, felt quite comfortable with computers and liked to work with computers. Previous studies reported that teacher education students in Taiwan had mild positive attitudes in terms of low anxiety, high confidence and liking toward computers (Liao, 1993; 1995). Results from the present study were partially consistent with previous research. However, when comparing the group differences, results obtained in the present study in which inservice teachers scored higher than preservice teachers on the comfort and liking scales suggests that inservice teachers in Taiwan seem to have more positive attitudes toward educational computing than preservice teachers. This may be because inservice teachers realize the needs for using technology in instruction. On the other hand, the fact that inservice teachers' perceptions of gender- or ability-related differences were higher than preservice teachers is somehow atypical. Padron (1993) in her study of teacher education students' attitudes toward equity issues in technology found that these students did not view gender or ability level as an issue in terms of students being able to learn and enjoy computer applications. A study on teacher education students' attitudes toward educational computing by Huang, Waxman, and Padron (1995) also reported that a majority of prospective teachers did not perceive any differences in computer use between males and females nor between low- and high-achieving students. Further research needs to be conducted to explore why the results of the present study differed from the American studies.

Gender differences were also found in the present study. Male teachers scored significantly higher than females on all five scales except value. Collis and Williams (1987) reported that there were fewer gender differences among Chinese students in attitudes toward their computers. Obviously, the results of the present study did not agree with their findings. A possible explanation for this is that students in Taiwan are strongly affected by society's reinforcement of sexual stereotypes. Most people in Taiwan, for instance, view technology/science majors in colleges (e.g., electronic engineering, physics, chemistry) as male domains while literature/art types of majors (e.g., Chinese literature, English literature, and arts) are seen as female domains. This cultural bias may therefore result in gender differences for teachers in viewing gender-related and ability-related differences, feeling comfortable, and ranking of liking in using computers, when the computer has been viewed as a male domain. The study by Collis and Williams (1987) did not use subjects
in Taiwan and that may therefore be one reason for the different outcomes.

Grade differences were obtained only on sex difference and comfort. The results suggest that first-year teachers in the program seem to view gender or ability differences less than senior teachers in the program. In addition, the finding that fourth-year teachers felt more comfortable than the second-year teachers in using computers was probably because the seniors have more computer experiences.

The significant interactions between group and gender on sex difference and value were interesting. Male preservice teachers valued educational computing lower than female preservice teachers but their perceptions about gender-related difference were significantly more than their female peers. On the other hand, although male inservice teachers also perceived gender-related differences significantly more than female inservice teachers, they valued educational computing as high as their female peers. Apparently, male teachers seem to be affected by the cultural bias of sexual stereotypes more than females.

The results of this study suggest that, although the technology-relate training for preservice teachers should not be ignored, the educational policy-makers need to allocate more funds for training for inservice teachers. Computer-using-educators in teacher training institutions also need to address the important role of technology in instruction to preservice teachers. In addition, the equity issues in technology in terms of perceptions of gender- or ability-related differences ought to be emphasized in the educational computing curriculum for all teachers to reduce the influence of sexual stereotypes.

DIFFERENCES IN PROSPECTIVE TEACHERS' PERCEPTIONS OF COMPUTERS: A CROSS-NATIONAL STUDY

Shwu-yong L. Huang
University of Houston - Clear Lake

Yolanda N. Padron
University of Houston

In the past few decades, there has been a growing body of literature on preservice teacher perceptions of computers and educational technology. A number of these studies focused on strategies to reduce anxiety and increase preservice teachers’ confidence in using computers in education (Byrum & Cashman, 1993; Handler, 1992; Handler, 1993; Pina & Harris 1993; Petrakis, 1992; Stephen & Ryan, 1992). Others dealt with the development and validation of attitude instruments (Delcourt & Kinzie, 1993; Kay, 1993; Kim, 1994). It is important to examine this issue because research has found that teachers who were comfortable with technology use and aware of ways it could help them do their job better (Sheingold & Hadley, 1990).

Cross-national or cross-cultural studies on computers in education have also gained considerable attention. The questions pursued tend to center on (a) comparing college students’ computer attitudes with respect to gender difference, confidence, and anxiety (Leuter & Weinsier, 1994; Marakis, 1992; Marcoulides & Wang, 1990; Sensales & Greenfield, 1995), and (b) assessing computer in education at elementary and secondary schools (Pelgrum, 1992; Pelgrum & Plomp, 1993). Very little research has specifically investigated cross-nationally preservice teachers’ perceptions of computers.

The present study takes the cross-national approach to investigate prospective teachers’ perceptions of computers in education in the United States and in Taiwan. The rationale for this approach includes: (a) testing the generalizability of preservice teacher attitudes toward computers originated in the United States, (b) broadening the perspective of researchers and thus helping to strengthen our sensitivity for idiosyncratic features of our own educational system, (c) contributing to a better understanding of the relative influence of some significant variables on educational computing, and (d) looking for universal variables and relationship between variables that are cross-culturally valid (Wubbels, 1993). Consequently, the purpose of this study is to examine cross-nationally prospective teachers’ perceptions of computers in the dimensions of liking, comfort, value, their beliefs in gender-and ability-related differences in computer use, and the variables that significantly associate with their perceptions.

More specifically, the present study addresses the following research questions:

1. Are there significant differences in computer perceptions between prospective teachers in the United States and Taiwan?
2. Are there significant differences in demographic compositions between these two groups of prospective teachers?
3. Are any teacher characteristics significantly related to their perceptions of computers? If so, are the relationships vary by nation?

Methods

Subjects

The participants in the study were 360 teacher education students in their junior or senior year of study. Among them, 180 enrolled in teacher education institutions in Taiwan, and 180 in universities in a southern state of the United States. Among these prospective teachers, 21% were male and 79% were female. Over 72% of them were between the ages of 18 and 25, 21% were between 26 and 35, and 7% were beyond 35 years old. Nearly 6% of them had never used a computer, and over 40% had used computer(s) for more than two years. However, the two groups of prospective teachers varied greatly in the compositions of these demographic variables.

In the aspect of formal computer education, a computer course has been mandated as a teaching certification requirement in the southern state of the United States, and a “computer literacy” course was offered at the undergraduate level. In Taiwan, although a computer course has not been mandated, an “introduction to computer science” was provided as an elective course for undergraduates, and
about 70% of the prospective teachers took this course as part of their educational plan.

**Instruments**

Two instruments were integrated into one survey: The Teacher Computer Attitude Scale (Violata, Marini, & Hunter, 1989), and the Ability Differences in Computer Use (Waxman, Huang, & Padron, 1992). The Teacher Computer Attitude Scale consists of four scales: (a) Liking — Teachers’ liking for using computers; (b) Comfort — teachers’ level of comfort in using computers; (c) Value — teachers’ perception of the value of computers; and (d) Gender Differences — teachers’ perception of differences between males and females in working with computers. The Ability Differences in Computer Use consists of five items on teachers’ view of ability-related differences in computer utilization. All the scales are on a 5-point Likert rating with 5 indicating “strongly agree” and 1 indicating “strongly disagree.” A brief section on these prospective teachers’ background characteristics was also included in the final instrument.

The survey instrument was translated into Chinese to be usable by subjects in Taiwan. Verification of the content validity of the Chinese version was done by reversing translation of it into English by English teachers in Taiwan who had not seen the English version. As a result, a few minor changes were made to make it most adaptable to the two cultures.

The survey instrument has been found to be reliable and valid in prior studies (Huang, Waxman, & Padron, 1995). For the present study, the internal consistency reliability (alpha coefficients) ranged from .72 to .92 for the five scales for both subject groups, and ranged from .70 to .95 for separate groups. This suggests that the instrument is reliable in measuring computer perceptions of these future teachers in both the United States and Taiwan.

**Procedures and Analysis**

The survey instrument was administered at the beginning of the academic year to the prospective teachers by experienced researchers in both nations. Prospective teachers responded anonymously. A multivariate analysis was conducted to determine whether there were significant differences between prospective teachers from the United States and Taiwan in their perceptions of computers. Chi-square analyses were performed to reveal if there were significant differences in the demographic variables between the two groups. Finally, a series of multiple regression was used to determine the relationship between demographic and perception variables of the two teacher groups.

**Results**

The MANOVA results reveal that there were significant differences between the two groups of prospective teachers’ computer perceptions ($F=47.57, df(5,354), p<.001$). Table 1 presents the follow-up analysis of variance (ANOVA) results, means, and standard deviations of the two groups on the five scales. In general, prospective teachers from both groups perceived positively of computers in education. All responded with a mean value greater than 3.00 in Liking, Comfort, and Value of computers, and a mean value lower than 3.00 in Gender- or Ability-Related Differences. The ANOVA results, however, indicated that prospective teachers in the United States perceived greater comfort and value than prospective teachers in Taiwan. They also liked to use computers more than their counterparts in Taiwan. On the other hand, prospective teachers in Taiwan indicated significantly higher concern about gender-related and ability-related differences in students’ computer utilization.

Table 2 shows the chi-square results. The results indicate that the two groups also differed significantly in the demographic and computer experience variables (all had $p<.001$). There were five times more males among the prospective teachers in Taiwan than in the United States. The ages of prospective teachers in Taiwan were generally lower than those in the United States. Nonetheless, prospective teachers in the United States had more experience in computers than those in Taiwan, with over three times of them having longer than two years’ of computer experience.

Table 3 presents the multiple regression results. The results reveal similarities and differences of the effects of gender, age, and computer experience on computer perceptions of the two groups of prospective teachers. In the United States, computer experience was related positively with these prospective teachers’ comfort, liking, and value of computers ($p<.001$). Older prospective teachers tend to like computers more than younger ones. In addition, gender and computer experience were related significantly with prospective teachers’ perception of gender-related differences in working with computers. In other words, females and prospective teachers of longer computer experience
disfavored the view that males work better with computers than females.

***p < .001.

In Taiwan, computer experience was also related positively with these teachers' comfort, liking, and value of computers. Female prospective teachers also disfavored the view that males work better with computers than females, but unlike their counterparts in the United States, their views of sex-related differences in computer utilization were not associated with computer experience. Above all, none of the gender, age, or computer experience variable was related significantly with prospective teachers' perceptions of ability-related differences for either group.

Discussion

Findings of this study indicate that, in general, prospective teachers in the United States had more positive perceptions of computers than their counterparts from Taiwan. They felt more comfortable with computers, valued computers higher, and like to use computer more than prospective teachers in Taiwan. These findings echo Kim's (1994) results from his comparison of computer attitudes between college students from the United States and South Korea.

Prospective teachers in the United States were less likely to believe that there were gender- or ability-related differences in computer use than prospective teachers in Taiwan. In other words, prospective teachers in Taiwan were more inclined to feel that using a computer is more important and enjoyable and easier for males than females. Plausible explanations of the discrepancy in their perceptions of sex-related differences may include that (1) Sociocultural concepts and stereotypes differ between the two countries, (2) more prospective teachers in the United State had longer computer experience and thus less likely to stress the role gender plays in working with computers, and (3) more males were presented in the participants from Taiwan than from the United States. As shown in the regression results, females prospective teachers from both groups were less likely to think males do better with computers.

Length of computer use is the predominant factor that determines prospective teachers' perceptions of computers for both groups. The longer they had been using computers, the greater they liked, valued, and felt comfortably with computers. This finding supports previous research that found that increasing computer experience corresponded to more positive attitudes toward computers (Liao, 1993).

Prospective teachers in Taiwan were also tend to believe that working with computer is easier and more enjoyable for high achieving students than low achieving students. Computer experience, however, like age and gender, did not

affect prospective teachers’ view of ability-related difference. Thus, the difference between prospective teachers in the United States and Taiwan in this regard may be attributed to distinctive educational philosophy, cultural, social, and other variables.

Findings from this cross-national studies have provided information leading to better understanding of teachers' perceptions of computers across countries and identified some universal variables related to prospective teachers' perceptions of computers. For future research, educator may need to (a) examine other factors that are significantly related with prospective teachers' computer perceptions in the United States and Taiwan, (b) include in-service teachers, and (c) include other countries for comparison.

FACTORS THAT AFFECT PRESERVICE AND INSERVICE TEACHERS’ LEARNING ABOUT COMPUTERS

Alex C. Pan
University of Wisconsin-Whitewater

Doris Lee
Pennsylvania State University

Many teachers choose to take computer courses for recertification or for advanced degrees as a means for individual enhancement or professional development. However, the teacher-oriented computer application courses offered in teacher education programs are facing various obstacles to meet the inservice or preservice teachers’ needs. The most common obstacles are listed below:

- insufficient technology resources are allocated to show teachers what is current in the leading edge computer technology
- incompatible resources are provided for participating teachers as compared with resources used in the school
- inadequate access to computer labs is provided to students in terms of time, resources, etc.
- time spent on computer tasks is insufficient to establish a solid computer literacy background
- students have diverse backgrounds, interests, needs, and skill levels and this makes the computer courses difficult to have a clear focus on specific tasks
- inappropriate hardware and software are provided due to lack of funding for update and maintenance
- insufficient time and resources for faculty to keep current with the emerging technology and provide leadership to school teachers

All these obstacles require the faculty of the teacher education program to take another look at the existing computer courses. Some adjustments are needed for restructuring the technology components in the teacher education programs to address teachers’ needs appropriately.

Computer Tasks in the Computer Courses

The content covered in the computer courses taught by the authors include a wide range of computer literacy tasks: 1) knowledge about computer hardware and software, 2) skills of using and exploring programs, 3) ability to apply software features to produce the desired result, and 4) integration of individual elements to develop a large scale project.

To meet students’ needs, a wide array of activities are included to address the skills and knowledge. Specifically, these activities are as follows.

- Exploring the Internet (e.g., using the WWW and e-mail)
- Using hypermedia (e.g., recording audio and video segments, creating multimedia elements, preparing images from scanning or screen capturing, organizing a hypermedia presentation)
- Using productivity tools (e.g., creating a document using word processing, spreadsheet, database, and graphics tools)
- Teaching content subjects with computers

Through these computer tasks, students are to establish a solid background for their computer literacy. They should also be able to develop meaningful projects to satisfy practical needs at work, such as producing handouts, writing newsletters, generating reports, and organizing student portfolios.

The computer application classes are structured so that participants are engaged in hands-on activities to gain insights about how computers can be used to improve teachers’ efficiency and productivity, and can be integrated into the curriculum. Once the participating teachers became accustomed to the new technology, they would continue to use technology and grow with the future expansion.

A Survey of Factors that Affects Computer Learning

To further examine what may contribute to successful learning for the preservice and inservice teachers, and how to increase their appreciation of computers in education, the researchers administered an informal survey and interviewed with a number of students. This provided a perspective about possible decisive factors and how the students felt these factors affected their computer learning experience in the courses. Descriptive data were collected from 34 undergraduate and 43 graduate students in two semesters. The survey questions contained items concerning students’ attitude toward computers, their perception about the
Novice vs. Experienced computer Users

There is an obvious gap between experienced and novice computer users in all the computer courses. Some students do not even know how to turn on a computer but other students already had extensive professional experiences working with computers, e.g., trouble-shooting, developing computer-related projects, or working as computer consultants. As the semester goes, the “fast” learners may easily feel bored while the “slow” learner are still struggling and seeking help for rudimentary tasks.

Seventeen or about 40% of the inservice teachers were novice computer users, and five or about 15% of the preservice teachers were novice computer users. However, both novice and experienced computer users expressed positive attitudes towards the power of computers and value of using computers in education.

Preservice versus Inservice Students

From the authors’ observations of students’ computer performance, assumptions were formulated about what students may need. The researchers often make predictions about what computer application topics are useful to students, what difficulties they may encounter, what strategies may work to inspire students to learn more, and so on. Very often, it was found that there were two extremes in the class: some found the learning material too easy and others found it too difficult; some felt the class is exciting and others felt it boring; some considered the learning tasks useful and others considered them useless; some students were very creative in carrying out the computer assignments and others felt at a loss and needed more help; some students appreciated the power of existing instructional software for teaching, and others did not appreciate it as much.

There were a number of differences between preservice and inservice teachers in our computer classes. Most of the preservice teachers were registered in the undergraduate teacher education programs. Most of the inservice students were school teachers registered in the graduate teacher education programs. Most inservice teachers were between 30 and 40 years old. Most preservice teachers were in their early 20’s. Most preservice teachers tended to be flexible about what to learn and which platforms to use. Most inservice teachers, to the contrary, preferred to learn things that they could use for their work and preferred to use only the computer platforms that are compatible with their school machines.

Most inservice teachers seemed to have stronger motivation than preservice teachers. They found the computer tasks interesting and useful, and showed higher appreciation of the computer resources and the instructors’ efforts. Most preservice teachers, although they could get their computer assignments completed faster than inservice teachers, seemed to lack enthusiasm in their computer tasks.

Inservice teachers also seemed more creative than preservice teachers. The students saw demonstrations of some features of a word processing program for developing newsletters and were shown some examples created with those features. When asked to produce a similar project for the school settings, the majority of the inservice teachers produced a significant project accordingly. The preservice teachers, however, found it difficult and requested more examples and even asked for permission to duplicate in their project the examples provided.

Most Teachers do not Have Concrete Ideas about What Computers Can Do for Them

Most teachers strongly believe that computers can help teachers do a better job. However, when they are asked to name a few things that they think computers can help teachers do better, most teachers fail to make a significant list. Ideally, if the computer learning tasks are linked to what teachers are doing everyday, the learning tasks would become more meaningful and motivating to them. Since most teachers were not able provide a concrete list with items to address in the computer classes, the researchers asked of the question-"What tasks do you do everyday in the school?", instead of another question-"How can computers help with your job?". A list was derived from the practicing teachers’ answers to the question. From the teachers’ responses, the researchers included task items such as calendars, newsletters, lunch count, memo, grades, database, and searching for electronic resources. These tasks were then recognized by some teachers as the most valuable part of the class.

Understanding the Computer Task Procedures Helps Teachers Master the Tasks

After these teachers were introduced to the basic features of a program, they could accomplish simple tasks as required. However, when they were asked to produce a complex project which involved many simple tasks and features that they had accomplished before, they became anxious and frustrated. Taking graphics as an example, after these teachers had learned how to create basic shapes (such as square, lines, polygons, etc.) with computer drawing tools, they were asked to create a stop sign which involves putting a few different shapes together. Even after the task was demonstrated a few times, many students, especial the older or the inexperienced ones, still felt unclear about how to carry out the project.

To improve such a situation, participating teachers were asked to do some think-through exercises. They worked...
together in pairs to think (and talk) through the detailed steps to organize a project. After the think-through exercise, the abstraction level for the task was reduced. Most novice users then became more comfortable with the intended tasks and were able to carry out the project by themselves.

**Prior Teaching Experience Can Contribute to More Meaningful Learning**

Most inservice teachers were older but less experienced with computers than preservice teachers. However, they showed better attitudes toward computer tasks and they came up with good ideas to apply what they learned in the computer class and demonstrated higher appreciation of the possibilities of computers. The preservice students, on the other hand, did not seem to appreciate the computer experience as much, and seemed less creative in applying what they learned to projects in real school settings.

When engaged in some practical tasks for productivity purposes, such as computer supported gradebooks, lunch counts, on-line tests, and monthly calendars, many inservice teachers would express great excitement. For example, one teacher said, "I really appreciate the gradebook. From now on, I am going to put all my students' grades on the computer." Another teacher commented, "Using computer for lunch count is a fantastic idea. It can simplify my daily task so much. I can even have one of my students do it for me." However, most preservice teachers' reactions were not as fervent. They seemed to treat the class tasks just as requirements they needed to fulfill.

The preservice teachers did not have the practical school experience which may be why they did not understand the urgent needs to improve their work with computers compared to the inservice teachers. The inservice teachers' positive attitudes helped contribute to more meaningful learning and higher appreciation about the computer tasks.

**It Takes Time and Patience to Master Computer Tasks**

The time required for tasks varies. Tasks that take some users ten minutes may require others to spend hours to complete. However, there was no denying that time and practice are the crucial elements for mastering intended computer tasks. In the computer classes, those who did not have access to computers after the class tended to have difficulty keeping up with the rest of the class. Almost all the preservice students had access to the campus computers on a frequent basis. Eleven, or about 25%, of the inservice teachers did not have an easy access at their school and choose not to come to the campus computer lab. These teachers had serious difficulty in keeping up with the class. They were persuaded to secure a computer by purchasing, loaning, or borrowing one. Almost all the teachers agreed that spending sufficient time on the computers was crucial for teachers to consolidate the skills. It was especially true for novice users.

**Cooperative Learning is Desirable**

Both inservice teachers and preservice teachers enjoyed learning on a computer with their peers. Their peer's good performance could trigger their creativity. Learning in a cooperative (or sometimes competitive) setting was fun. Teachers found the learning tasks challenging and interesting. Novice users felt encouraged when they saw their peer produce quality products. They also developed good rapport with each other through learning with computers.

**Detailed Step-by-Step Written Instruction is not Always Necessary**

Students learned about computer tasks mostly through hands-on activities. Most teachers learned to use software and trouble-shoot problems via exploration and logical thinking. Only a few teachers tended to rely on the software manuals. As to detailed step-by-step written instructions, most experienced computer users didn't consider it necessary at all. However, novice users, especially the older teachers, who felt nervous about computer tasks, demanded detailed written instruction at the early stage of the computer classes. After they became accustomed to the general features of the computer and had used a few computer programs, they could handle the hands-on tasks without detailed written instructions.

**Students’ preferences**

Below is a list of items that represent students' preference of the desired characteristics in the computer courses.

- Having sufficient time to work on computer tasks on their own
- Being shown good ideas of how to integrate useful features for computer projects
- Learning cooperatively — learning from each other
- Using open-ended software such as storybook maker or simulation programs
- Using hypermedia applications for project development
- Learning at their own paces
- Having hands-on approach to learn about computer programs
- Learning about things that they can do on a computer at home or in the school

**Suggestions**

Based on the findings in this study, some suggestions about how to construct appropriate approaches for effective computer courses are as follows:

- Provide concrete examples that can address their needs. If the computer tasks can connect to students' daily work, they become more interested.
- Address the tasks which are compatible to the school platforms so that students can carry out the tasks when they return to school.
- Provide practical tasks and challenges to the preservice students to provide insight about what can be done to meet the reality needs in the future.
• Minimize the differences between students by setting pre-requisites for the course so that students can have a similar start.

• Provide a wide variety of activities to satisfy the “fast” students. Provide sufficient challenges to inspire those students who are able to accomplish more.

• Encourage cooperative learning to bridge the gap between novice and experience computer users.

• Encourage students to gain sufficient access and time on computer tasks. Encourage them to acquire their own computer.

• Address issues about how to use computers to become efficient and productive as well as for effective teaching.

Conclusion

Learning about computers is becoming crucial for school teachers. There are many issues that instructors should consider in order to provide better computers courses to address teachers' needs. This paper examine many factors (such as age level, prior computer experience, prior teaching experience, individual learning preferences, access to the computers, etc.) related to meaningful learning of the computer tasks.

From the survey of 77 inservice and preservice teachers, it was concluded that students learn about the computer tasks best through hands-on activities, cooperation from peers, sufficient time for practice, adequate models/examples, appropriate procedures to analyze and to synthesize information for projects. The computer course should provide a meaningful experience for teachers so that they can continue to grow in the future. To improve educators' computer literacy and to prepare them to use computers for productivity and for content area instruction, the technology courses offered should address the teachers' practical needs. The hardware and software selected should be compatible with the school settings. The contents and tasks covered in the course should be made useful for teachers' daily work. Once teachers learned how easy and practical technology can be to their work, they would continue to use them.

In this study, it was learned that inservice teachers hold stronger motivation and more positive attitudes and appreciation towards computer tasks than the preservice students. This suggests that the preservice students' lack of real classroom experience and practical needs to apply computers in the school settings may explain why they don't perform and appreciate as well as the inservice students. Teachers can learn to use computers better if they can relate their learning experiences to their work. The practical experiences of the inservice students should be used to provide the insights to the inexperienced preservice students. Thus, the computer components for teacher productivity and effective teaching should be incorporated into various stages of students' field and clinical experiences.

Doris Lee is Assistant Professor of the Great Valley Graduate Center, Pennsylvania State University, 30 East Swedesford Rd. Malvern, PA 19355. e-mail: dlee@psugv.psu.edu.
Educators at all levels are rushing to integrate computers into instruction. While there are exciting and appealing applications, we must be careful to assure that these activities are equally appropriate for male and female students. It is important to consider the computer in the context of the content, the pedagogy, and the characteristics of the students to be taught. There is a need for more research examining teachers' attitudes toward computers and the use of computers in their classrooms.

Equity issues have received considerable attention in the research in recent years. The differences between male and female students in mathematics, science and technology are long-standing and well-documented. Identifying the causes and solutions to these problems is more problematic. Males typically have more experiences with computers and more positive attitudes toward technology and they continue to outperform females on computer skills (Grossman & Grossman, 1994). Research has identified the background of this male-dominance as including computer experience and computer course-taking (Arch & Cummins, 1989; Levin & Gordon, 1989; Martin, Heller & Mahmoud, 1992; Massoud, 1991).

Studies have found gender differences in attitudes, defined as being more confident, having less anxiety, having a higher self efficacy, liking computers more, or having more interest in computers. In a study of 902 boys and 828 girls in high school, Shashaani (1994) reported more boys than girls intended to take additional computer classes, 35% to 20% respectively. In the same study, on a scale of 1 to 5, with a higher score meaning a higher interest, boys scored a 4.1 and girls a 2.6. Two studies (Busch, 1995; Colley, Gale & Harris, 1994) found that males not only had lower computer anxiety, but also higher computer confidence and greater liking of computers than did females. Therefore, because females do not get encouragement from their friends, they do not see their mothers as equal computer role models, their computer teachers are mainly males and the computer software they use is predominantly masculine, the typical female attitude toward computers is not positive (McGrath, Thurston, McLellan, Stone & Tischhauser, 1992).

It is important to consider the attitudes of teachers who will interact with male and female students as they learn about computers. There are pervasive stereotypical beliefs that computers are more appropriate for males than females (Grossman & Grossman, 1994). This attitude is particularly dangerous when held by teachers because it influences their interactions with students. In part, students learn their attitudes toward computers from their teachers (Fennema, 1990). Sanders (1995) writes that teachers’ inadvertent biased behavior lowers girls’ achievement, aspirations, and persistence in computing. Similarly, girls need female role models who enjoy working with computers. Only when teachers are competent and comfortable working with computers can they model behavior that will empower their female as well as male students (Campbell, 1995).

Hakkinen (1994) evaluated how a computer course affected the anxiety level, computer attitude, and feelings about computers of 29 first-year education majors (25 females and 4 males). Results indicated that as familiarity with the computer increased, computer anxiety levels decreased and attitudes improved. A related study compared education students in a computer course with a control group (McInerney, McInerney & Sinclair, 1994). The students who had taken the computer course had lower anxiety scores and higher self-perceived ability than those who had not.

Okinaka (1992) provided information on teachers’ attitudes toward computer use and examined gender differences. The 92 education students in the study reported some prior computer use, but most were not regular computer users. However, most of them felt confident using the computer in the classroom, even with limited experience. Males and females did not differ on attitude issues except on the measure of pursuing further computing courses. Males were significantly more interested in taking additional computer courses than females.

Even though there is considerable research on computer attitudes, there is not yet evidence of attitudes toward the internet. Additionally, there is a need for additional informa-
tion about computer and internet attitudes of male and female teachers.

**Methods**

The purpose of this study was to investigate male and female preservice teachers’ attitudes toward computers, toward the internet, and toward computer and internet use in the classroom. These attitudes included personal attitudes and also the application of those attitudes to teaching situations. The study examined the computer attitudes of thirty-six preservice secondary education students before and after an intensive three-week computer course. Further, these attitudes were studied in relationship to gender, major, and prior computer experience.

The pretest and posttest included a semantic differential section which was divided into three specific questions. The students were asked how they felt about (1) computers, (2) the Internet, and (3) using computers in their classroom (See Figure 1). The test also asked other relevant questions, including self-reports of proficiency and likelihood of use of computers in teaching.

**COMPUTER EXPERIENCE**

On a scale of 1-10, one being very little, how proficient are you in using a computer? ________

2. On a scale of 1-10, one being not likely, how likely are you to use a computer in your teaching, if they are available? ________

The required computer course was taught in a computer lab by an experienced computer instructor. Topics included graphics, word processing, database, spreadsheet, presentation program, location of internet resources, lesson planning integrating internet resources, and construction of a personal internet homepage. Ten assignments were required:

**Graphics Handout.** A one-page handout for use with high school students, prepared with KidPix.

**Abstracts.** Read two current journal articles, one dealing with general computer education issues, and one dealing with your particular discipline. Each one-page abstract must be word processed and include a reference in APA format, a one paragraph summary, and a one paragraph reaction.

**Email.** Send an email message to the instructor, talking about feelings about the use of computers in teaching.

**Newsgroup.** Locate one newsgroup related to teaching. Read at least 10 posts and summarize (one page) the topic.

**WebSites.** Locate ten WWW sites that could be used in secondary teaching of your subject. Record URL, Title, Subject, Description, and Teaching Idea in the class database (ClarisWorks).

**Lesson Plan.** Plan a complete lesson in your subject area which requires students to use the WWW as an integral part of the lesson.

**Gradebook.** Set up a gradebook on a spreadsheet (ClarisWorks).

**Group Presentation.** In randomly assigned groups of 3-4, choose some aspect of social issues of computer use, and prepare and present to class using PowerPoint.

**WebPage.** Design and publish a personal homepage, including text, graphics, and links.

**Quiz.** Computer vocabulary.

Following this treatment, the posttest was given to all participants, and the data were analyzed.

**Results and Conclusions**

Results revealed that 26 of 36 students owned a computer, 82% of females (24 of 29), and 29% of males (2 of 7). Females reported a slightly higher number of average hours per week of prior computer use than the males, but the difference was not significant (t (32) = 0.561, p > .05). This data may be affected by the disproportionate numbers of males and females in the sample. Of the 36 students, only 7 were male. While these numbers are somewhat representative of gender proportions in the teaching profession, the small number of males in the sample opens up the question of whether this small sample is representative.

Three different attitudes were examined: attitudes toward computers, attitudes toward the internet, and attitudes toward the use of computers in the classroom. After the three-week class, students showed positive increases in all three aspects of attitudes. There were significant increases...
in attitudes toward computers \((F(1, 32) = 4.630, p < .05)\) and
in attitudes toward the internet computers \((F(1, 32) = 7.597, p < .05)\). There was a positive, but nonsignificant, improvement in attitude toward use of computers in the classroom computers \((F(1, 32) = 1.053, p > .05)\). There were no gender differences in attitude, either before or after the treatment. See Tables 1, 2 and 3. This suggests that the experience in the class was positive, and improved the attitudes of the preservice teachers. However, there was no differential improvement for males and females.

*p < .05

The self report of computer proficiency for the total group was significantly increased after the class, and there were no gender differences. See Table 4. After the treatment, the students' reported likelihood of using a computer in the classroom was slightly higher for females, though this difference was not significant \((t(7) = 1.206, p > .05)\). This difference may have been partially due to the differences in major for the males and females. The seven males were all either mathematics or social studies majors, and the computer may have more appeal for these subjects than for the larger number of females in English, science, and second languages.

**Implications**

This study found that after an introductory technology course, both female and male preservice teachers showed a significant increase in positive attitude toward computers. Even though further study is recommended to explore the causes and treatments of gender differences, these results support the inclusion of an extensive technology course as a means to improve attitudes of all students toward computers.

1. In addition to providing positive computer experiences for preservice teacher, Jo Sanders provides seven principles for educators to help counteract the “computing is male” message sent to girls.
2. Teach technology as a tool to solve real-life problems rather than as a glitzy toy.
3. Do not permit sexist materials, “jokes,” or behavior in your classroom, ever.
4. Notice the girls who hang back and pull them in, and make sure that girls take their turns at more than keyboading and note taking.
5. Encourage girls to participate in friendship groups at the computer.
6. Eliminate biased teaching behaviors you may have by becoming conscious of them.
7. Make a point of praising girls for real achievements and urging them to develop their skills further. Urge the especially talented ones to consider careers in technology.
8. Be aware of little, picky, trivial things and keep them from adding up. Teach your colleagues how to recognize them too (Sanders, 1995, p.157).

In conclusion, our world is a world of computers. The internet is a key component of that world. In order to be sure that our students, both female and male, are successful in this computer world, all teachers must become confident and competent computer and internet users.

A compendium of 14 previously-published instruments for assessing teachers' attitudes toward computers was administered to 621 educators in Texas, Florida, New York, and California during 1995-96. A total of 284 items extracted from 14 previously-published instruments, and falling on 32 Likert subscales, were included on the instrument entitled the Teachers' Attitude Toward Computers Questionnaire (TAC). Since many of the subscales were a decade old, one initial question to be resolved was whether the scales as originally published were still reliable. This paper focuses on that question.

Positive teacher attitudes toward computers are widely recognized as a necessary condition for effective use of information technology in the classroom (Woodrow, 1992). At least fourteen instruments with acceptable measurement properties have been reported in the literature over the past decade (Woodrow, 1991; Chu & Spires, 1991; D'Souza, 1992; Francis, 1993; Gardner et al, 1993; Kay, 1993; Knezek & Miyashita 1994; Pelgrum, Janssen Reinen & Plomp, 1993; Loyd & Gressard, 1984). This paper contains a description of how well each instrument measures what it claims to assess. The question is addressed for three related groups, notably: a) preservice teachers, b) practicing K-12 teachers, and c) teacher educators.

Instrumentation

The Teachers Attitudes Toward Computers Questionnaire (TAC) was used for this research. It is a 10-part composite instrument including 284 items spanning 32 Likert subscales. The following 14 computer attitude questionnaires contributed to the TAC:

- Computer Attitude Scale (Gressard and Loyd, 1986)
  - confidence, liking, anxiety, and usefulness
- The Computer Use Questionnaire (Griswold, 1983)
  - awareness
- Attitudes Toward Computers Scale (Reece & Gable, 1982)
  - general attitudes toward computers
- The Computer Survey Scale (Stevens, 1982)
  - efficacy and anxiety
- Computer Anxiety Rating Scale (CARS) (Heinssen, et al, 1987)
  - technical capability, appeal of learning and using computers, being controlled by computers, learning computer skills, traits to overcome anxiety

ATC (Attitudes Toward Computers) (Raub, 1981)
  - computer usage, computer appreciation, societal impact
CAIN (Computer Anxiety Index) (Maurer & Simonson, 1983)
  - examines avoidance of, negative attitudes toward, caution with, and disinterest in computers (anxiety and comfort)
BELCAT (Blombert-Erickson-Lowery Computer Attitude Task) (Erickson, 1987)
  - attitudes toward learning about computers and towards computers themselves
Attitude Toward Computer Scale (Francis, 1993)
  - affective domain
Computer Attitude Measure (CAM) (Kay, 1993)
  - cognitive (student, personal, general), affective, behavioral (classroom and home), and perceived control components of computer attitudes
Computer Attitude Questionnaire (CAQ) (Knezek & Miyashita, 1993)
  - computer importance, computer enjoyment, computer anxiety, computer seclusion
Computer Attitude Items (Pelgrum, Reinen, & Plomp, 1993)
  - computer relevance, computer enjoyment
Computer Attitudes Scale for Secondary Students (CASS) (Jones & Clarke, 1994)
  - cognitive, affective and behavioral attitudes
E-Mail (D'Souza, 1992)
  - attitudes toward e-mail

Results

Table 1 lists the name, place of origin, 1995-96 combined internal consistency reliability and alpha by K-12 teacher, preservice teacher, and teacher educator group, plus the original reliability (if published) for 32 Likert subscales.
included on the TAC. Results indicate that most of the attitudinal subscales that were originally strong have held up well over time. However, there are notable exceptions, such as the widely-used Loyd & Gressard Confidence subscale, with an internal consistency reliability of .86 reported in 1986, but an average alpha of .75 (which is still respectable) in 1995-96.

Several lesser-known attitudinal subscales would appear to warrant wider use. Examples are Email, CAM, ENJ, KT, Anxiety, and CASA, all of which exhibit high internal consistency reliability across the three groups examined, and each of which includes no more than 11 items. The items for these 6 subscales are listed in the Appendix. A rank ordering of the top 9 subscales independent of number of items used, is provided in Table 2.

Appendix

EMALI subscale from D’Souza, 1992
1. Email is an effective means of disseminating class information and assignments.
2. I prefer Email to traditional class handouts as an information disseminator.
3. More courses should use Email to disseminate class information and assignments.
4. Email provides better access to the instructor.
5. The use of Email creates more interaction between students enrolled in the course.
6. The use of Email creates more interaction between student and instructor.
7. The use of Email increases motivation for the course.
8. The use of Email makes the course more interesting.
9. The use of Email makes the student feel more involved.
10. The use of Email helps the student to learn more.
11. The use of Email helps provide a better learning experience.

**CAM subscale**
from The Computer Attitude Measure (CAM), Kay, 1993

Computers are:
1. Unlikable _ _ _ _ _ _ _ _ Likable
2. Unhappy _ _ _ _ _ _ _ _ Happy
3. Bad _ _ _ _ _ _ _ _ Good
4. Unpleasant _ _ _ _ _ _ _ _ Pleasant
5. Tense _ _ _ _ _ _ _ _ Calm
6. Uncomfortable _ _ _ _ _ _ _ _ Comfortable
7. Artificial _ _ _ _ _ _ _ _ Natural
8. Empty _ _ _ _ _ _ _ _ Full
9. Dull _ _ _ _ _ _ _ _ Exciting
10. Suffocating _ _ _ _ _ _ _ _ Fresh

**ENJ subscale**
from Pelgrum & Plomp, 1989
1. I like to talk to others about computers.
2. Computers can be exciting.
3. I like reading about computers.
4. A job using computers would be very interesting.
5. Computer lessons are a favorite subject for me.
6. I want to learn a lot about computers.
7. I like to scan computer journals.
8. When I pass a computer shop, usually I stop for a while.
9. Computers interest me little.

**KT subscale from CAM, Kay, 1993**
1. Computers would help me organize my work.
2. Computers would increase my productivity.
3. Computers would save me time.
4. Computers would help me learn.
5. Computers would help me organize my finances.

**Anxiety subscale**
from Computer Attitude Questionnaire, Knezek & Miyashita, 1994
1. I think that it takes a long time to finish when I use a computer.
2. I think that computers are very easy to use.
3. I get a sinking feeling when I think of trying to use a computer.
4. Working with a computer makes me very nervous.
5. Using a computer is very frustrating.
6. I will do as little work with computers as possible.
7. Computers are difficult to use.
8. Computers do not scare me at all.

**CASA subscale**
from Computer Attitude Scale, Loyd & Gressard, 1984
1. Computers do not scare me at all.
2. Working with a computer would make me very nervous.
3. I do not feel threatened when others talk about computers.
4. I feel aggressive and hostile toward computers.
5. It wouldn’t bother me at all to take computer courses.
6. I would feel at ease in a computer class.
7. I get a sinking feeling when I think of trying to use a computer.
8. I would feel comfortable working with a computer.
9. Computers make me feel uneasy and confused.
PUTTING EDUCATIONAL TECHNOLOGY IN PERSPECTIVE: THE QUESTION OF LEARNING EFFECTIVENESS

Trevor H. Jones
Duquesne University

Rocco Paolucci
Cabrini College

In today's information-driven society, the call for resources required to maintain the impetus of technological use receives much attention. This is no less evident in the realm of education, where significant effort (time and cost) is invested in identifying and bringing to the arena the latest in technology-based products for application in the instruction/learning process — educational technology.

Educational technology has historically played a central role in the delivery of instruction in the classroom. Over the years, teachers have used books, televisions, projectors, and many types of lab equipment as tools to help them transfer knowledge to their students (Hawkins, 1993). In the past decade, computers have been added to teacher's technology toolbox. Like no other technology, it has been able to capture the imagination of educators. Today, computers can be frequently found in classrooms and laboratories throughout our schools, colleges, and other educational and training institutions.

In the classroom, the applications of computers have evolved from the provision of drill and practice for remediation, to later providing structured curriculum and instruction. Today, the computer is often used for knowledge explorations and construction (Jonassen, 1993). On the technological front, during the past decade, the computer has evolved from being a command-line instructional machine. Graphical and friendlier user interfaces have made human-computer interaction much easier and more effective.

Today, computers inexpensively and easily provide highly interactive multimedia information (text, sound, images, and video) to its users. Furthermore, these interactive multimedia systems may now be programmed to deliver hypermedia — multimedia information stored in networks of nodes connected by links (Dede, 1992). These systems come in a variety of formats (CD-ROM, authoring software, etc.). However, the most popular hypermedia technology within many educational institutions is the Internet's World Wide Web. The wide reach of the Internet network (global in scope), coupled with the multimedia capabilities of the computers it interconnects, have made the World Wide Web a truly international and highly distributed hypermedia system. Today, the Web is increasingly being used for a multitude of educational applications, most notably “distance learning”.

The above technological capabilities have not come cheap. Recently published analysis of key U.S. Department of Education national studies reveal that:
- In the 1994-1995 school year, schools spent approximately $3.3 billion on educational technology.
- Today, there are an estimated 5.8 million computers for instructional use, approximately one computer for every nine students.
- Between 1989 and 1992 alone, K-12 schools increased their computer inventory by nearly 50%, jumping from 2.4 million units to 3.5 million units.

It is worthwhile to note that the above numbers are for basic educational institutions only (K-12), and do not include investments made by higher-educational institutions (Fulton, 1996).

However, after more than a decade of significant technology investments by America's schools (as described above), many educational administrators and policy-makers are asking the questions, "Do computers and other related technologies make a difference in learning? Do they improve achievement and performance scores?" The brief answer to these questions, based on scientific research, seem to be mixed and inconclusive. Many reasons are given as to why this is the case. Some researchers claim that evaluation of educational technology effectiveness is not easily captured by the use of current standardized tests (Hawkins 1993, Rockman, 1993). Still others claim that a major reason why educational technology has not had a more positive effect on learning outcomes is that appropriate staff development has not taken place (Fulton, 1996).

On campuses of all levels today, the cry is for more money to support the investment in technology. The resultant investments are often made at the expense of other resources. There is an obvious economic trade-off required.
by the sharing of limited resources, in this case funding for other educational initiatives. This trade-off, currently weighed towards technology, is often supported by bodies oblivious to their applications and use in their particular domains. Regardless of the reasons why, as we approach a second decade of educational technology applications and infusion, it is important to pause and assess the research focus (or lack of) presently given to educational technology effectiveness by the academic community.

Research Question

In this paper, we attempt to question the research associated with the adoption of technology in the educational environment based on the question of learning effectiveness, and the degree to which this effectiveness issue has been demonstrated in technology adoption. In the context of this analysis, we define educational technology research in a broader scope as not only including the latest hardware, but also the various software products being made available for the classroom, along with the various research studies undertaken to develop the environments of teaching and learning.

We also look at the use of technology in the context of providing a communication channel or conduit for the dissemination of the educational process. This is distinguished from the use of technology as a “subject matter” or course content (i.e., technology education). We are interested in the effectiveness of technology as a substitute, or partial substitute for traditional teaching/learning methods.

We question the outright adoption and acceptance of technology, and the associated expenditures, based on current research results in this domain. We present a meta-analysis of the research literature in the domain of educational technology. We classify the literature according to their research content. Content areas identified are as follows: Technology, Analysis & Applications, Design, Implementation, Educational Issues, Instructional Process Evaluation, and Learning Performance Evaluation.

Our intent is to identify the weighting and attention given by the research community to the last classification item (Learning Performance Evaluation). Classifications reflect the visibility and work accomplished on testing, measuring, and comparing results from differing educational delivery channels which incorporate technology. Furthermore, we identify the emphasis within these classifications by addressing research concerned with high-level educational outcomes, versus those associated with specific variables within these high-level models. The study is a review of nine major educational technology journal publications, spanning the last three-year time period, and includes the classification of almost one-thousand articles.

Our paper includes the results of this meta-analysis indicating the breakdown of publication content into the specified research categories. We intend to investigate the percentage of work that is directed at measuring the learning effectiveness with technology as it is currently used or is proposed to be used, and contrast this with the acceptance of technology adoption. Furthermore, we test the content of that limited amount of research concentrating on learning outcomes measurements by identifying those subcomponents that address high-level variables versus domain-specific model variables. Lastly, weaknesses in present technology adoption decisions are discussed, along with a call for an increased emphasis on learning outcomes and/or development of more effective educational measurements.

It is our intention that the results of this study will stimulate discussion of this issue among all parties involved in education and educational delivery systems, including all levels of academia as well as educational institutions and private corporations. This includes administrators as well as private practitioners and policy-makers, since the issues raised pertain not only to the application of educational technology, but also to the policy issues addressed at the highest levels of decision-making.

Research and Data

Our research was derived from a review of nine major refereed journals addressing technology in education. We attempted to cover a consecutive three year time span for each journal. Consequently, the dates covered by the review range from 1991 through summer 1996, due to the availability of the articles and journals. This resulted in a review of 932 individual journal articles. The journals reviewed were:

- Journal of Educational Technology Systems
- Computers and Education
- Journal of Research on Computing in Education
- Computers in the Schools
- Educational Technology
- Educational Technology Research and Development
- International Journal of Instructional Media
- Journal of Educational Computing Research
- Journal of Research on Computing in Education

Each article was reviewed and categorized according to its major content. The categories used were developed from the framework used for classifying papers by the Association for the Advancement of Computing in Education (AACE) at the Ed-Media & Ed-Telecom, 1996 Conference. Our intent was to identify the percentage of journal articles that specifically addressed the impact on learning outcomes of a particular technology or combination of technologies. The categories used for classifying the articles were:

- Technology (TEC): explanations and introduction of new and developing technologies (as distinguished from application development - see APP below).
- Applications (APP): applications of technology including analysis of applications.
- Development (DEV): development of educational technology design methods including evaluation of
methodologies, models, guidelines, frameworks and taxonomies.

Implementation (IMP): implementation of educational technology including case studies, organizational, management, and personnel issues (e.g. gender, minority, age issues).

Pedagogy (PED): discussion of pedagogical, learning and other issues.

Evaluation of instructional process (EIP): quantitative and qualitative assessment of instructional processes and outcomes.

Evaluation of learning and performance outcomes (ELO): quantitative and qualitative assessment of affective, cognitive and physiological outcomes.

The final category listed above (ELO) was the category of interest. In addition to the broad analysis, we further subdivided the articles in the category of interest, “evaluation of learning outcomes”, into two further subcategories, quantitative and qualitative. This was done in an attempt to further quantify the empirical research being undertaken, and to identify specifically that percentage directed at learning outcomes from the use of educational technologies.

</table>

Our overall strategy was to gauge the research effort being applied to assessing learning outcomes from the application of technology and make some comparison against the level of expenditures in this area. This was to provide us with a basis for raising questions and/or answers as to the applicability of the groundswell of support for technology in education. To achieve this, we conducted a meta-study of the literature to identify what percentage of research, and potentially the types of research, that support the adoption of technology. We hypothesized that there exists a lack of significant research to substantiate the level of technology expenditures and adoption.

We observe from the results in Table 1 above that 20% of the research is directed at identifying the learning outcomes derived from utilizing technology in education. While this may seem like a significant proportion, we compare this with over 50% which is directed at developing methodologies, applications and installing those same technologies. Additionally, when we further investigate the research category aimed specifically at learning outcomes (Table 2), we find that approximately 20% of this research is subjective (qualitative). When this percentage is applied back to the original analysis, we estimate that only 16% (78.8 * 20.2) of work is of a quantitative and objective nature.

One additional issue to consider in the questions raised here is not fully documented from our review, but is added in terms of subjective observation; much of the quantitative research is aimed at specific channels of technology and very specific content domains. For example, empirical studies included measurements of attitudes towards technology in particular disciplines; the effects of computers on anxiety; the addition of computer-aided instruction (CAI) to traditional delivery methods; measurements of communications among students using E-mail. While studies such as these have their place in the research arena, and individually can be considered aspects of the learning process, they add little when questions are raised regarding the cost/benefits associated with the massive expenditures on educational technology when compared with student achievement. In summary we conclude that approximately only 16% of total research being published is associated with quantitative documentation of learning outcomes and achievement, which we deem the effectiveness of the technologies being adopted. Our observations suggest that approximately 5% of total research is conducted using formal methods such as control groups with comparative learning outcomes (i.e. experimental).

Conclusion

When we consider the broader issues of the learning effectiveness of technology, we see a large discrepancy between the scale on which the expenditures are being made and the level at which the research is being conducted. To a large extent, the expenditures and adoption of technology are discussed at a policy level whereas the research being conducted is at an individual variable level. Our point here is that the research is not of a sufficiently high (complex) and formal level to support conclusions being made by technology adopters when learning outcomes are considered.

What are the implications of this? The answer probably lies in the perspective from which education is viewed, and possibly what position is held regarding the future of education and the direction in which education delivery should take. Perhaps the first issues to be raised must the purpose and definition of education. Whatever they may be,
we believe that the level of student achievement and learning outcomes are of central importance. Many argue, already, that the quality of U.S. education received at any level has already declined, not only with respect to historical levels, but also with respect to other nations, worldwide. Surely then, it is incumbent on the education system to establish that future delivery methods provide some added value without possibly contributing to any further decline.

Certainly many questions surround the quality and methodologies of current education. The answers to these questions tend to be in the form of intuitive expressions from individuals, and work which supports those answers tends to be in qualitative form with little formal research support. We emphasize here the distinction of formal research directed at learning outcomes from other types of assessment concerning technology adoption. Many individuals, groups and institutions claim quantitative support for adoption of various technologies. However, these tend to be in the form of superficial assessments indicating little more than satisfaction for the delivery channel used, and again provide little input to the question of “technology effectiveness”.

In response to these issues we maintain that a missing component is the establishment of research agendas utilizing formal experimental methodologies. We argue that we must be able to demonstrate that quantifiable learning outcomes can be achieved and sustained through technology adoption. This can only be established through research methodologies. It is reasonable to expect “educational technology delivery” models, with recognized variables (e.g. delivery channels, content types, etc.) and quantifiable dependents (learning outcomes).

With this lack of a formal and quantifiable approach to the introduction of technology, few if any measures or guidelines exist which help in distinguishing which types of technological delivery channels are suitable and effective for the various contents found at differing levels of education. If indeed, there is no formal support for the various technologies, is it not valid to question the expenditures of resources on the scale on which we are progressing? Is it not also valid to question the motivation for these expenditures if the motivation is coming from a source other than educational learning outcomes? Should we compromise outcomes (however defined) for the sake of other factors and if so, do we have, as educators, some obligation to make this fact apparent to all interested stakeholders (students, employers, parents, teachers, etc.)?

The questions of technology’s place in education are not new. Apple (1991) has previously stated:

Whose idea of progress? Progress for what? And fundamentally, who benefits? These questions may seem rather weighty ones to be asking about schools and the curricular and teaching practices that now go on in them or are being proposed. Yet, we are in the midst of one of those many educational bandwagons that governments, industry, and others so like to ride. This wagon is pulled in the direction of a technological workplace, and carries with it a heavy load of computers. (Apple, 1991, p. 59)

While Apple goes on to discuss the potential social impact resulting from the adoption of technology, our aim is to question the foundation on which these initial technology adoption decisions are based. Our work raises questions regarding the quantifiable support for the adoption of technology in educational delivery when considered from a learning outcomes perspective. Our preliminary data indicates that this support does not exist to the extent that justifies our expenditures and adoption strategies. Ultimately, we believe that technology must be appropriately combined with content to provide the most cost effective combinations for delivery. These combinations will be driven by a number of different factors which themselves have various combinations; but we can find little evidence that the cost/effectiveness of combinations is being addressed in any formal and acceptable research agenda.

884 — Technology and Teacher Education Annual — 1997
In the electronic distance education approach described in this paper, the emphasis is on developing a more interactive interface for smoother communications among humans and computers by introducing the concept of hypermedia and a pen tablet similar to conventional pen and paper most people are comfortable using. This enables the realisation of bidirectional cooperative learning in an easier manner and is expected to remove the boundaries between learning and teaching.

Regardless of the arrival of the information age, most of educational systems are based on the indoctrination method. This is derived from both the curricula (as exemplified by the concept of way of or doh in Japanese) and from the conventional one-sided information giving (knowledge imparting) in education. However, as the end of this century approaches, a wide range of philosophies, concepts, and paradigms are being reviewed in educational systems, both as frameworks for evaluating the current situation and as frameworks for thinking about future prospects. A number of frameworks have significant implications for a very important question that is increasingly relevant when the use of technology in education is discussed: How can an electronic community be realised in a stricter sense so that it overcomes space-time dimensions?

Computer Media and Education

The author has studied electronics from a variety of angles in areas such as computer graphics (Hosaka, 1974), computer architecture, Very Large Scale Integration (VLSI) semiconductors, Fifth-Generation Computer Systems (FGCS) for knowledge information processing, multimedia technologies in research and development, and science education. So far, many advantages in using electronics have been discussed for educational applications. Moreover, not only companies, research laboratories and universities, but in Japan various schools are already equipped with advanced personal computers for higher training and education and for elementary/middle education. However, it cannot be said that we are maximising the use of electronics in our daily life. One of the main reasons for this is the communication interface between humans and computers. In short, most people are reluctant to use personal computers even if a Graphical User Interface (GUI) is introduced. For computers to become a part of our daily life, the widespread distribution of such personal computers to offices and private homes is required. It is more important, however, to be able to maximise their use in a similar fashion as other conventional electronic equipment. The same applies to wider use in education. In fact, some investigators in Japan believe that the Japanese are not so adept in using the current personal computers as our European and American counterparts are, especially in the educational area.

Basic Schemes

In this research, the emphasis is on achieving a more interactive interface in order to improve communications between humans and computers by introducing the hypermedia concept and a pen tablet similar to conventional pen and paper which are frequently used without reluctance. Since computer graphics was initially advocated here in the 1960s (Hosaka, 1974), interactive technologies have been researched and developed for various kinds of educational situations (Kommers, 1993; Ichiko, Yamamoto & Hanano, 1994). Especially in educational environments it should be noted that one of the most important matters to be improved is communication. Both learners and teachers need ways to share their mutual information space through more convenient individual communication-channels. Information space sharing involves interaction based on many types of personal knowledge such as experience, expertise, and even wisdom. Cooperative learning environments which are oriented toward multimedia computing are expected to be one of the most feasible solutions. From this point of view the author has been studying electronic distance education.
environments that incorporate easy-to-use communications tools. Educational hypermedia means hypertexts with multimedia databases. Figure 1. shows an example of the overall final environment. The individual circles represent personal participants (learners and/or teachers). Here, the scale of the environment can be assumed to be flexibly constructed according to the learning situation.

Figure 2. An Example of Instructional Materials in a Media-integrated Environment.

Figure 2 shows one form of the substantial parts of the media in a multimedia-integrated environment. Media may be as simple as text and as complex as video. Media that is difficult to transmit using current local area and wide area network technology, such as dynamic images (video), are reduced to static line-based ones by extracting graphical features to make processing and communicating over distances easier. This enables the realisation of bidirectional cooperative learning in an easier manner and is eventually expected to remove the boundaries between learning and teaching.

Cooperative Learning Environments

In this cooperative learning environment the instructional materials are originally prepared beginning with a constructive database utilising various forms of information media such as symbols/text, sound/voices, graphics and images (e.g., video-based dynamic image). Of course, gradual enrichment of the instructional materials is always possible using the input/output facilities (e.g., pen tablet, scanner, microphone and so on) of a multimedia-oriented computing system. If desired such materials can be transferred to be newly integrated at a distance. This environment can be assumed at the final R&D phase, not in the form of conventional CAI which generally runs on a simple personal computer or local area network, but in an up-to-date multimedia-enhanced network with a greater integration and parallelising/multiplexing of information media and professional collaboration. The requirement of conventional professional skills in computing, media and education will be less, not only for operation/activity, but also for multicontextual manipulation, as compared to that in the conventional environment.

Figure 3. shows the contextual orientation from upper to lower conceptual refinement through pen-based communications. This facilitates the processing of instructional classification, association, exploration, generalisation, and so on, in the participants' basic concept formation in a field. It enables learning and the maintenance of attention through cooperation among the participants of a network in research environments. They can think through some aspects of a certain concept in a handwritten manner (Togashi, 1992). Not only is browsing, but also various digressions are feasible in a more interactive manner in this multimedia computing environment. On the other hand, formal conceptual expression with semantics of concept entities can be introduced into the cooperative learning situation. This also contributes to semantic expression in a meaningful way and the integration of meta information/knowledge in an efficient manner (Ichiko, Takeuchi and Nango, 1989).

Examples of Application

For example, assume that individual participants having different potential in the environment are mutually trying to understand the concept of AI (artificial intelligence) for higher science education. At first some information about the difference between human and artificial intelligence based on logic and neural network can be obtained, if desired, from instructional materials composed of a card image component network with links and nodes.

Figure 4. shows an example of the contents of an instructional unit. In this material many kinds of information (symbols/text, figures, sound and so on) are included and
can be linked to the compositional texts and images in the instructional database. A sound button gives a preliminary explanation in human voice. Individual nodes containing instructional multimedia such as symbols/text, graphics, sound/voices, images, and other hybrid forms of information media are connected by links which enable arbitrary manipulation in such a network and generate semantics with multicontexts by using a more interactive interface between humans and computers. Moreover, this environment is equipped with a communications ability (expandable on the basis of LAN and WAN) and cooperative learning is also feasible at a distance through handwriting in the form of the participants' pointing, writing, drawing and creating graphics.

Figure 5. shows an example of artificial intelligence (AI) computing. If the button is pushed by a pen the participant can go into the next, more refined, information space dealing with neural network applications and can learn more detail there (Togashi, 1992). In this case, if they cannot find the desired information and learning process by their manipulation, they can communicate with other participants, sharing ideas and suggestions in this cooperative environment. Such cooperative learning processes can be stored and integrated into the existing information media/instructional materials for further improvements. Some examples of practical applications can be given in the basic concept formation and gradual refinement of the cooperative learning process (on the basis of screen-sharing).

Fig. 6 shows an example of the result of person-to-person communications for the participants' concept formation by using handwritten multimedia information such as characters, symbols/text, images (static/dynamic) and so on. Sound-based communications are more convenient for better understanding in this cooperative learning. Originally, many different kinds of information/knowledge (e.g., principal, experimental, functional/structural, and also everyday knowledge) in the range of ordinary intelligence to scientific knowledge in various levels can be found in the participants' brain. Formal paradigms prepared in an educational environment are not enough in order to grasp more in-depth knowledge in a network, and therefore, a device like the pen tablet which is convenient for humans enables the flexible formation and dynamic tracking of human recognition. Of course, it should be noted that in the near future further research into the better matching between/among different kinds of media will be undertaken.

Concluding Remarks

This paper described an example of cooperative learning in electronic distance education. The result of our research is expected to be one of the next-generation schemes in cooperative learning in order to improve upon the conventional one-sided indoctrination style teaching/learning that dominates many educational systems today.

Navigating in Hypermedia - Interfaces and Individual Differences

Renee Gedge
Monash University, Melbourne, Australia

The 1990's has seen an explosion of increasingly sophisticated computer based information applications such as multimedia and hypermedia, both in general education areas such as history, art and medicine and more commercially oriented applications such as information kiosks. Teachers will encounter hypermedia applications both in their training and in the classroom. Despite the many perceived advantages of hypermedia, there is evidence of significant problems. Some of these problems are present with all computer based applications - such as the widespread dislike of reading large pieces of text on a screen. Other problems are unique to hypermedia. The ability to jump in a non-sequential way around a hypermedia application often results in significant user disorientation and cognitive overload. (Edwards & Hardman, 1989, Wright, 1991). A tendency for some users to spend their time in cursory and non-directed browsing, has also been identified, and shown to result in shallow processing, few elaborations, and poor retention (Hammond, 1993). Knowledge of these potential difficulties is an important addition to the education of teachers at all levels.

Many studies have found wide variation in the ability to utilize computer interfaces effectively. In a review of research on human-computer interaction, Egan (1988) described performance differences as high as 20 to 1 in tasks such as searching an application for specific information. Using any computer interface involves the development of a cognitive model representing the structural and procedural properties of the system. Previous research has indicated that individual differences such as spatial ability and cognitive style may affect the development of a useable cognitive model of a complex system. Conflicting evidence has emerged as to the role of interface tools and training in catering to individual preferences and abilities. Some investigators have reported that the provision of appropriate interface tools compensates for the differences between individuals in areas such as verbal and spatial ability. Others have reported a consistent disadvantage experienced by low spatial ability users which still needs to be addressed by further interface refinement.

Despite a considerable body of both theoretical and experimental work dealing with the problem of navigation in hypermedia, there has been very little research actually investigating individual differences. This paper presents a review of recent research in this field, and reports the results of two recent studies investigating the relationship between spatial ability and navigation through a hypermedia application.

Psychological Theory and Navigation in Hypermedia

It has been suggested (Wright, 1991) that excessive cognitive load is the cause of the disorientation and frustration experienced when using hypermedia applications. Apart from learning new material, the user of a hypermedia application is engaged in other complex cognitive processes including:

- using the interface (e.g., determining which button brings up the index)
- trying to establish the size and complexity of the information available
- determining their current position and maintaining a sense of that position, and
- remembering what sections/screens have already been visited

Wright demonstrated that using hypertext jumps was easy for the designer but tended to disrupt the users train of thought and therefore their capacity to fully assimilate the material. Two adjoining pages frequently constitute an important semantic link - but hypermedia applications deliberately allow (even encourage) the learner to disrupt this link by jumping to another section. Navigating back to the original screen may involve complex cognitive processing, thereby disrupting the main information thread.

The users of a computer based application will have some sort of existing schema involving both the content and structure of such applications, based on past experience.
Cognitive models and maps are developed for more specific instances of a schema. Carroll and Olson (1988, p. 51) describe a mental model as “a rich and elaborate structure, reflecting the user’s understanding of what the system contains, how it works, and why it works that way.” A cognitive map may be thought of as a subset of the mental model, dealing specifically with the structural properties of some environment or system.

A computer application may be considered to evoke both a cognitive model (how the application works, what this button does etc) and also some sort of mental map of its structure (ie the structure of the information contained in it, such as sections, subsections, relationships between them, total size). It will also connect with the user’s basic schema of computers and information presentation, and may utilise metaphors such as a book metaphor. However, hypermedia removes the spatial relationships between pages/sections which are implied by metaphors such as books and conventions such as screen numbering. Keeping track of relative position will involve using tools such as maps which often require significant cognitive processing.

**Navigation in Space and Hyperspace**

The very use of the term navigation to describe the process of using a hypermedia application indicates the potential involvement of the spatial processing system. Some writers have drawn parallels between navigation in the physical environment and navigation in hypermedia. In a study of navigation strategies in the physical environment, Streeter & Vitello (1986) found that many of their subjects had difficulty reading maps and preferred to navigate using landmarks and verbal instructions regarding the route.

Dillon, McKnight & Richardson (1990) proposed that route knowledge, because of its predominantly verbal form, might suit individuals with higher verbal than spatial abilities. Individuals with higher spatial ability may be well suited to make use of survey or overview knowledge provided by maps. However, reliance on route knowledge (a remembered set of directions), can cause problems when a wrong turn is made (or in hypermedia, when a hypertext jump is made to a new section). If other familiar landmarks are lost, the user applying only route knowledge may have to return all the way to the start screen (the only known landmark accessible to them). Returning to the start screen is a common strategy for users who become lost in hypermedia (Norman, 1994).

Spatial ability seems particularly relevant to both hypermedia and the problem of cognitive map and model development in computer use generally. However, it is widely recognized that individuals vary widely in their ability to process spatial and verbal information. Paivio (1971) proposed a now widely accepted dual code theory of memory, in which verbal and visual information are separately processed and encoded in memory, and individuals vary in their ability and tendency to think in one of these modes.

Visualization or spatial ability is represented in most tests of general ability or aptitude. Tests developed to assess spatial ability tend to involve either mental rotation of objects, the imagined construction of an object from a pattern, or a combination of these. Logie (1991) cites convincing evidence for the involvement of the visuo-spatial system in navigation through the physical environment and in the traversal of an imaginary matrix. It seems reasonable to suggest that this same system is engaged when moving around a complex computer application structure. One contributing factor to the disorientation frequently experienced by users of hypermedia applications may be the difficulty of maintaining a sense of position using the visuo-spatial system, when that same system is also being used for other tasks involving the application such as scanning the screen. Users may also unconsciously choose to focus attention on the content of the new screen and hence have no cognitive resources available to address the problem of where they are now in relation to the overall structure.

Using a computer interface - whether it involves understanding icons, maintaining a sense of position in a hierarchical database or navigating through a complex information space such as hypermedia - involves the visuo-spatial system and the construction and manipulation of a cognitive model and map. Spatial ability has been shown to be closely related to the formation of cognitive maps by a substantial body of research, both in the field of real world navigation and in conventional computer interface studies. Thorndyke & Goldin (1981) divided subjects into good and bad cognitive mappers on the basis of the accuracy of their spatial knowledge of their environment. The major difference in characteristics found between the two groups was spatial ability. They tested these subjects’ ability to use related skills such as interpreting maps, spatial judgements based on remembered maps, and navigation in the environment. They found that while there was little difference in the ability of subjects to use a map effectively, good cognitive mappers were much better at encoding, maintaining and manipulating an internal representation of spatial information.

Jennings, Benyon & Murray (1991) examined individual performances on 5 different interfaces to a computer database system in relation to subjects scores on 5 aspects of cognitive ability and personality - spatial ability, verbal ability, field dependence, logical-intuitive cognitive style and short term memory capacity. Interestingly, the only interface where high spatial ability users showed a significantly better performance than lower spatial ability users was on the command line interface, in which there were no overt spatial elements involved such as a graphical interface, map or hierarchy diagram. However, the navigation tasks were implicit and involved maintaining a sense of position in the system, as different system levels exist which required different syntactic interactions. There were no onscreen cues indicating these levels, meaning the user had to be able
to maintain and manipulate some representation of this information in an abstract form.

Vicente, Hayes & Willeges (1987) investigated the effects of a number of individual differences on performance of a search task in a hierarchical database. Only computer experience, verbal ability and spatial ability were found to be related to task performance, with spatial ability being the largest single factor. Low spatial ability subjects took substantially longer to perform set search tasks, and tended to use larger numbers and more varied commands in the search task. Vicente et al concluded that low spatial ability subjects were becoming lost in the hierarchy. Further, they concluded that experience was related to performance only because most of the experienced group also scored high on spatial ability, suggesting a connection between spatial ability and computer use - either as a cause or effect.

In a subsequent study, Vicente & Willeges (1988) found that while the provision of tools such as maps and hierarchy traversal tools increased the performance of both high and low spatial ability groups, the gap in performance between the two groups remained essentially unchanged. This implied that the spatial information provided such tools did not substitute adequately for the mental mapping ability of the high spatial ability subjects. However, a series of studies by Sein, Olman, Bostrom and Davis (1993) found evidence to the contrary. Training materials including the provision of conceptual models and a visual interface design improved the performance of low spatial ability subjects to the point of matching the performance of high spatial ability subjects.

Choice of interface tools represents another area of potential difference between high and low spatial ability users. However, the study by Jennings et al (1991) indicated that high spatial ability subjects showed superior performance over low spatial ability subjects using a text based command line interface. This indicates the need for caution in equating the use of apparently verbal or spatial tools with underlying verbal or spatial processes. The more highly developed cognitive map and model of a high spatial ability users will facilitate the choice of the most appropriate and efficient tool for any particular task. This method may be a text based search rather than spatially oriented tools such as a map. High spatial ability users with a well developed cognitive map of the application may find a map largely obsolete. However, hierarchy traversal tools seem more innately spatial in nature and their use may more closely reflect an underlying sense of the structure. The other major contributing factor to choice of interface tools is their saliency, particularly for inexperienced users. If tools are not visible until additional actions such as pointing and clicking bring them onto screen, users may never take the time to discover their relative efficiency.

There is conflicting evidence then, regarding the importance of interface tools, training and experience in countering the spatial ability factor. Familiarity with the tools and methods of navigating the information space may mean an experienced subject is able to compensate for lower spatial ability. A well developed cognitive model which draws on past experience with similar systems may allow efficient use of the system even without a easily manipulated structural map of the system. However, none of these previous studies used a hypermedia system as the testing software, where the navigational and orientation complexity is potentially of a much greater order due to the facility of hyperjumping.

Report on Recent Studies

These studies examined the relationship between spatial ability, computer expertise and a number of variables including navigation efficiency, subjective measures of disorientation and sense of structural organization, and the use of various search and navigation tools. The application used in the studies was an hypermedia educational program on HIV, developed by the Monash University Medical Informatics Unit for use by students and medical professionals. It includes just over 1000 screens, comprising text, some short animations and a substantial number of medical images. Users’ interactions with the application were recorded by logging the subjects path through the application screen by screen, and a summary count of accesses to each of the major navigation and search tools was produced at the completion of the session.

The method chosen to measure navigation efficiency, and thereby cognitive model/map development, was error based rather than time based. It is assumed that if the user fully understood the structure and tools available, they would choose an optimum route. Users who are unsure either of where they are or how to get to the next place of interest frequently backtrack over old ground to reach a recognisable screen (landmark) or simply jump back to the beginning to reorient themselves and restart a search from there.

Many users of hypermedia report disorientation as they move through the application. However, there have been few attempts to quantify this sense, or to examine its relationship to variables such as spatial ability. Measures of a subjective sense of disorientation and the subjects reported confidence in understanding the logical organisation were used to provide additional measures of the degree of success in constructing a useable cognitive map.

The navigation measures made were:
1. the steps taken to access specified parts of the media.
2. user accesses to tools such as the map, hierarchy traversal button
3. subjective disorientation using Likert scale questionnaire.
4. subjective sense of understanding underlying structure
5. subjective impression of usefulness of tools using Likert scale questionnaire.

Results

Screen by screen analysis revealed that subjects generally made use of the hierarchical text based menu structure, hot words and sidelinks when browsing in the application. Very few subjects used the map or index to navigate at all, even though they represent a very efficient way of moving around and maintaining a sense of current position. Subjects generally only used the full text search facility when completing the structured search task. Most subjects moved through the application in an apparently systematic way, often exploring a particular area in depth rather than browsing at shallow levels for the allocated time.

Means and standard deviations of spatial ability for each experiment group were calculated. Pearson product moment correlation coefficients were calculated between the subjects scores on spatial ability and the variables of navigation tool choices, navigation efficiency and the subjective sense of disorientation, underlying structure and usefulness of tools. Finally, the group was partitioned into high and low spatial ability subgroups using the median split method. Independent t-tests were then used to examine the relationship between spatial ability and those variables where correlations had indicated a possible relationship.

Non-computer Expert Group

The results show a strong positive correlation between spatial ability and navigation efficiency. The only other variable which approaches a significant correlation was the subjective sense of underlying structure of the application, as shown below. However, the correlation between navigation efficiency and spatial ability in this group was much weaker.

The only t-test to reach .05 level of significance was for subjects reported disorientation ($t = -2.54, df = 10, p = .03$).

Discussion.

In the experiment using non-expert subjects, there was strong support for the major hypothesis that high spatial ability is related to greater navigation efficiency. Higher spatial ability appears to increase the ability to formulate and use a cognitive map of the hypermedia application even when the user has a limited model of computer systems in general, and even when extensive tools such as full-text search, map and index are provided. These findings are consistent with previous research using non-expert subjects which has established a link between spatial ability and computer task efficiency.

In the experiment using expert computer users, experience did appear to compensate for lower spatial ability when engaged in navigation tasks. This finding is consistent with the study by Sein et al (1993) which found that the performance of subjects with lower spatial ability can match that of high spatial ability subjects if training such as cognitive models of the system are provided. However, the differences in navigation efficiency between high and low spatial ability subjects, although not reaching statistical significance, did indicate at least a tendency for greater efficiency by high spatial ability subjects which would warrant further investigation. The subjects in the expert group showed a wide range of spatial ability from below average to very high. This is of interest in itself, in that all of the expert group were involved by choice in computing as a profession. Low spatial ability had apparently not deterred any of the group from this choice.

The strength of the relationship found here between navigation efficiency and spatial ability, at least for the non-expert group, may be a reflection of the additional load being placed on the spatial system by the unique navigation difficulties caused by the hypermedia application. High spatial ability may confer an even greater advantage in hypermedia navigation than it does for a more conventional computer interface. Lower spatial ability subjects in both experiments had a greater tendency to use inefficient strategies such as going back to the start, or backtracking screen by screen to reach the beginning of a section again. They did not appear to have confidence in traversing the hierarchical structure, or commencing a search from wherever they currently were in that structure. This is consistent with the behaviour that would be expected if users had a poorly developed cognitive model of how the application worked.

**Computer Expert Group**

The results indicate moderate positive correlations between spatial ability and some of the navigation measures, as shown below. However, the correlation between navigation efficiency and spatial ability in this group was much weaker.

T-tests indicated a significant difference in navigation efficiency between high and low spatial ability subjects ($t = 3.38, df = 14, p < .005$) and in the subjective sense of underlying structure ($t = 2.3, df = 14, p = .025$).
and a poorly developed mental representation of its structure and their position in that structure. However, it appears that spatial ability may be of less importance in navigation and task performance when the subject is an expert computer user. The general cognitive models and elaborate schema developed by expert computer users can apparently compensate for the effects of low spatial ability, by providing a well developed foundation on which to construct models and maps of the new system. However, the provision of interface tools such as maps, position marker and a history trace provided in the HIV system did not remove performance differences due to spatial ability in the non-expert study group. Design factors associated with the specific interface may be more or less effective in making tools salient, and communicating a useful cognitive model.

Although Bulgaria is passing through a major economic crisis and the education budget is insufficient. However, due to the efforts of local and international sponsors an increasing number of schools and universities are being connected to the Internet. Unfortunately, the Internet in school is so new, there is “little systematic understanding of the issues which shape its implementation, adoption and use in that environment” (Eurich-Fulcer & Schofield, 1995, p. 211). Presently, teacher education institutions have not done enough to support and encourage this innovation in the teaching and learning process.

As a minimum, future teachers need to learn and understand how the Internet can become a part of their professional work; and they should be supported in identifying, acquiring, and evaluating sources of information that can facilitate their teaching. The problem is how future teachers will take advantage of Internet educational potential.

The study which was carried out in the Technical University of Varna in the past three years was aimed at answering the following questions concerning Internet connectivity:

- How is the Internet used among future educators?
- What factors contribute to the use or lack of use of the Internet connection?
- What compelling pedagogical reasons are there for using the Internet?
- What special problems or barriers do educators encounter in using the Internet?
- What role or behavioural changes do future educators experience from using the Internet?
- In what ways does the Internet affect future educators views on education?

Method of Research

“Effective evaluation should encompass both the scientific and naturalistic paradigms, with emphasis placed upon the interactions between the programme and its context” (Hose, 1991, p.2). This view of enquiry is significant for the study of technology in distance education since many of the issues and questions which need to be addressed cannot be answered by assessing individual programs in isolation from the broader understanding of the field.

Sampling and Subjects

As the idea was to include future educators and to identify information-rich sources, the target group included 30 students from the faculties of sciences and education which were frequent Internet users. By “frequency” it was meant that they should have Internet interaction at least 5-6 hours per week. Information about users was taken from the e-mail addresses and from the Computing Centre.

Data Collection and Analysis

Primary data collection methods included personal reports and a standardised open-ended interview format. The interview process was conducted after receiving the completed personal report. All data collection occurred on-site at the University at times that were convenient to the subjects. Transcripts of all data sources were thoroughly searched for key patterns or themes (i.e. common occurrences of concepts) from the data, and labels were assigned to them. In reviewing and searching for patterns and themes, data analysis included “participant verification”, that is going back to the respondents with tentative results and refining them in the light of their reactions.

Results

The findings of this investigation were categorised into four primary domains:

1) situations in which student-users used the Internet;
2) factors that influenced student-users’ connections to the Internet;
3) problems student-users encountered when using the Internet;
4) changes student-users experienced as a result of using the Internet.

Types of Usage

The types of Internet usage varied according to the student-users’ interests. There was, however, a trend toward using the Internet more as a research tool for identifying relevant literature and for communicating with peers and experts in their research fields. The most frequently cited
functions were: e-mail, ftp, telnet, Word Wide Web (WWW), and IRC. Of the e-mail programs available, Eudora and Trumpet were singled out as the two widely used, while Netscape was mostly used for the WWW. Some of the participants were members of various lists and discussion groups according to their own interests. A small group of participants began to explore ways of designing simple WWW applications through HTML.

The time profile for each application ranged from 5 to 12 hours per week. Evidence shows that the amount of time devoted to different functions will be accelerating. It is worth pointing out that the application usage was more easy to ascertain than the time profile, perhaps due to different concepts of access and time usage. It seems that two different concepts of use can be constructed: the ‘actual time’ use and the ‘access time’. The first refers to the productive time devoted to a certain task, and the second, to the total time spent accessing and fetching the information.

Factors Influencing Use
The factors that were perceived to influence participants in getting involved on the Internet can be classified into intrinsic and extrinsic. Among the intrinsic factors, the most common reasons reported were: curiosity, excitement, addiction, empowerment and emancipation. Curiosity seems to be the first motivating factor. As they got involved, curiosity changed to excitement, due to the vast amount of information available on the Internet and the way it was presented. For some respondents excitement became addiction. As one respondent metaphorically stated: “If I miss the Internet, I feel like a smoker without cigars”.

Among the extrinsic factors attributed to the Internet, the data analysis and interpretation suggested the following concepts: the ‘super highway of learning’ and the ‘global village’. The first is explained by the vast amount of the information available, and the second by the potential of the Internet to reduce isolation and build a sense of global interrelation.

Problems
The problems encountered by the respondents derived from three main sources: educational, technical and administrative. From an educational point of view, most respondents cited the lack of guidelines concerning the use of the Internet as an educational tool. Technical problems were related to the low speed and hardware configuration. Participants also agreed that the problems associated with the support of the Net could be minimised if there were more personnel. Clearly, without a robust network system, the educational potential of computer networking cannot be realised.

Changes
There was a relatively clear consensus about needed changes concerning new technologies, the teaching and learning process, and the new roles assigned to educators. Respondents indicated an attitudinal transition from teachers as passive receivers of information to teachers as investigators or active information seekers was needed. Access and use of the Internet encouraged respondents to think of learning as a collaborative process and of educators as facilitators of teaching rather than transmitters of information and knowledge.

Conclusion
The Internet is used to retrieve information from a wide range of sources, to exchange information and messages, to discuss topics of mutual interest with people all over the world, and much more. This study indicates that a new vision of learning is emerging in educational establishments that have integrated the Internet as a communication and education tool.

Similarly, a new mode of human mobility that may be called ‘virtual mobility’ emerged which seems to add significantly to the globalization and internationalisation of information and knowledge. The Internet challenges the traditional flow of information and knowledge from the ‘centres’ to the ‘peripheries’. This implies that under-represented people and cultures have the opportunity to contribute to this ‘highway of information’. “In such open and flexible learning environments the emphasis is placed on the importance of constructing personal meaning” (Guba, 1990, p.19). “The collaborative nature of learning can expand the student’s collective intelligence” (Idrus, 1993, p.181).

The Internet is emerging as a new motivational, enabling, and empowering tool for teaching, learning and research. However, the problem is that future educators need help in learning how to use this technology and how to apply it to teaching and learning. For educators, technology should be a means to new ends, to more dynamic learning, but technology in itself should not be the issue. Technical support is required to establish and maintain a robust connectivity, while curriculum support is necessary to make pedagogically relevant usage possible and meaningful. It must be stressed that the Internet by itself is not a panacea for educational reform. The Internet can enhance classroom activities and professional development by creating global awareness, providing access to the latest information and enabling communication on a large scale, but we cannot just connect the Internet into an educational institution and to expect change to occur automatically.

The teachers need educational programs that are rich in use of media and easy to use, adopting a more familiar, television - like “look and feel”. Moreover, these programs can provide coherent and comprehensive information about a knowledge domain, assist the learner in forming conceptual frameworks that provide a basis for other kinds of learning, and place what is learned in a rich, real-world, human context.
References

Walden University is a graduate level degree granting institution. From 1970 until 1995 Walden granted strictly doctoral level degrees. In 1995 they began offering an on-line Master of Science degree. During the first year of programming, teacher evaluation data were gathered. Many barriers to adult, student success are related to characteristics of the students themselves. The relationship between students and faculty is a second area of influence on student success, and problems related to the technology of the on-line course a third.

The purpose of this paper is to explore these barriers for students and faculty, compare the current literature on barriers to success with the data gathered from this program, and develop strategies for students and faculty in an on-line, asynchronous delivery model.

### Student Success Factors

#### Personal Characteristics Related to Barriers

Many students returning to graduate school as adult learners have personal characteristics and life situations affecting their performance. A study by Bernt & Bugbee (1994) listed several characteristics.

- Lower expectations for success (Hugh, 1984 in Bernt & Bugbee, 1994).
- Having been away from the discipline of learning (Feasley, 1983 in Bernt & Bugbee, 1994).
- The need for feedback (Feasley, 1983 in Bernt & Bugbee, 1994).
- Higher level of insecurity in their ability (Distance Education, U of Idaho, 1996).
- A tendency to believe their own experiences are illegitimate (Distance Education, U of Idaho, 1996).
- Having little in common with instructors (Distance Education, U of Idaho, 1996).
- A tendency toward isolation (Distance Education, U of Idaho, 1996).
- A potential to procrastinate (Beaudion, 1990).
- Increased anxiety (Beaudion, 1990).

Many of these characteristics closely match characteristics of Walden University students. The gender distribution of Walden MS students is 67% female and 33% male. The average age is currently 42 years. Six percent of student received a grade of “incomplete” for not finishing their work during the course of the quarter. We have also seen a high level of anxiety in the first quarter of the program, along with a tendency toward isolation from the class if they are uncertain of their ability.

### Situational Characteristics Related to Barriers

#### Career expectations

Career expectations. Adult students have high expectations that their educational program will relate to their career aspirations (Council of Graduate Schools, 1994). As active participants in the learning process, adult students demand their education be relevant in both the medium and the message (Sherry, 1994).

#### Time available for school

Time available for school. Adult learners who often have multiple responsibilities (Boston, 1992). Because of work, school, family, and social obligations they often have less time to read, but more reading to accomplish (Bernt & Bugbee, 1994). Problems can include: lack of time to prepare for assignments (Boston, 1992), missing information and discussions creating gaps in meaning (Graham & Wedman, 1989).

#### Family Obligations

Family Obligations. Students often struggle with obligations forcing choices between family commitments, school commitments and work commitments. Problems can include a lack of an environmental support system (Wagner, 1993). This lack of support may lead to guilt over potential failure as both a parent/spouse and failure as a student.

#### Funding

Funding. Most master's level, adult learners are also self-funded and hold a very strong desire to see a return on their investment (Distance Education, U of Idaho, 1996).
University Strategies for Assuring Success Related to Student Characteristics

Walden University employs two checkpoints in which the institution can evaluate the potential for success and begin the learning process for appropriate strategies.

Application
During the application process it is critical to establish the maturity level of the potential student. The student who is more highly motivated and exhibits greater self-discipline is much more likely to succeed (Souder, 1993).

Orientation
The orientation should include frequent contact from all constituents related to the program. This includes administrators, advisors, staff, and faculty creating an opportunity for students to relax and ask questions. It also serves as an opportunity to teach strategies for success related to: realistic career expectations, timing issues, funding and family obligations (Boston, 1992).

Faculty Success Factors

Personal Characteristics
While some student success is dependent on personal characteristics, life situation and support systems, the relationship between the student and faculty also has the potential to affect student success. Students place responsibility for their learning squarely with the faculty. “Program faculty have the responsibility for the delivery of academic course work and seminars, and for the advising and guidance of graduate students through the completion of their master’s degree programs. It is the faculty members who have the ultimate responsibility for ensuring that appropriate standards for academic performance are required of all who participate in the program” (Council of Graduate Schools, 1994, p. 23).

At Walden University we have established the following faculty criteria for the distance education M.S. program:
- Must hold a related Ph.D. or Ed.D. degree.
- Must have experience in the K-12 education arena.
- Must have experience teaching adult learners.
- Must have experience teaching at the graduate level.
- Must have knowledge of the content of the course.
- Must have a high comfort level with technology in education.
- Must have excellent and thoughtful verbal and written communication skills.
- Must have a high level of intuition.

These criteria are important in on-line delivery of course content when all communications are written. Written communication, due to its contextual nature can be easy to misunderstand or ignore. Miscommunication between students and teachers can easily have negative consequences (Sherry, 1994).

Faculty Situational Characteristics Relating to Barriers
Some faculty barriers to success may include the following:
- Most faculty have their primary experience in presentation style (Wagner, 1993).
- Faculty are sometimes unable to transition from a teacher led model to a student led model (Wolcott, 1993).
- Some faculty are unable to appropriately pace and respond to student queries (Wagner, 1993).
- The danger of allowing the course to lose its rigor (Klemm & Snell, 1996).
- The danger of allowing the technology limitations to support only superficial participation (Klemm & Snell, 1996).
- The danger of focusing only on technology (Sherry, 1994).

Walden University Faculty Evaluation
Within the context of course and instructor evaluations at Walden University students complete a quantitative ranking of 16 items at the close of each quarter. Five of the 16 questions asked on the final evaluation were isolated for this paper. The frequency of the responses was tracked for each instructor over the course of the first year of the program.

The questions included are:
#4) The instructor worked hard at helping the students understand the material.
#5) The instructor worked hard at helping the students understand the technology.
#7) The instructor communicated regularly with the students.
#8) The instructor responded to each assignment promptly.
#11) The instructor was genuinely concerned with student progress.

The range of responses was:
1—Strongly agree
2—Agree
3—Disagree
4—Strongly disagree
NA—Not applicable

Instructor A:
Instructor A received very high marks from the students related to her feelings of concern (#11) for their learning and her communication and feedback regularity (#7). She received lower marks in her efforts to help students understand the material and the technology. This instructor was highly successful with students, if somewhat less rigorous.

Instructor B
This instructor received exceptional marks in his efforts to help students understand the material (#4). Her highest criticism was in her ability to respond to the student's assignments (#8) promptly. This instructor was very well received and students tolerated her inability to provide prompt feedback because she was perceived as supportive and caring (#11).

Instructor H
This instructor had positive rankings and comments. He did well in the area of regular communication (#7) and genuinely caring (#11) for student progress, but less high in his ability to assist in the technology (#5) and responding to assignments (#8). This instructor was also considered successful by his students because of his obvious attitude of support and caring.

Instructor S
This instructor was clearly perceived as less successful. He received moderately high marks in his genuine concern for the students (#11), but there was more disagreement among students related to his efforts at helping students understand the content of the course (#4) and the technology (#5). There was strong belief that the instructor did not communicate regularly (#7) with students or communicate about assignments (#8), but overall the students felt he was a nice person due to his genuine concern for them (#11). This instructor needs to work on the rigor of the course and immediacy of his feedback.

Instructor W
This instructor had a moderate ranking from the students. They believed he was somewhat concerned with their progress (#11), and worked at helping them to understand the content (#4) and the technology (#5). They were less happy with his communications (#7) and response to assignments (#8). This instructor was accepted, while not liked by the students because he was teaching them content (#4). He needs to work on his feedback to students and sense of caring for their success.

Instructor O
This instructor was a clear failure in the on-line environment. He was seen as creating additional barriers for the students as opposed to assisting them in succeeding in their course. Only one student felt he was sincerely concerned with student progress, and felt he worked hard at assisting with understanding the material. All other students felt he was not communicating (#7) effectively or often enough, not assisting in their understanding of the material (#4), and not genuinely concerned (#11) with how the students were doing. In my supervision of the instructor it was clear that the instructor had expectations of the students that were not being met. He extended significant effort in attempting to assist, but exhibited a "tone" of superiority to which the students took offense. This instructor, in order to be successful in this environment, must adjust his communication style and pacing. He must increase his level of intuition with students and intervene more quickly and more frequently, with student achievement as his goal.

Instructor J
This instructor met mixed success. The instructor received very high marks related to regular communication (#7) with students, and rated quite high for providing feedback (#8) on assignments. There was some disagreement that the instructor was genuinely concerned with student progress. Her lowest ranking was on helping students to understand the material (#4), both content and technology (#5). This instructor set very high standards. She had little tolerance for their problems in meeting her expectations. She assisted them greatly by answering direct questions but showed little concern for their anxieties. While few students liked this instructor, they were aware of the great amount of learning and growth they experienced. Students seemed to tolerate this instructor as she tolerated them. This instructor needs to improve her support of the program, intuition and tone of communication to succeed in student evaluations.

Instructor E
This instructor consistently received lower marks than most of the other instructors. She established a moderate composite score, but in closer evaluation, there is a clear issue with feedback (#8) and regular communication (#7) to students. Eventually, it became clear that this instructor was very reactive with students rather than being proactive. Those students willing to ask the questions and demand service received assistance. Those who were less secure or quieter were generally ignored by the instructor (#11). This instructor needs to adjust much of her on-line style in order to be successful. She will need to develop a stronger skill set for presentations, feedback, pacing, rigor, encouragement of participation and intuition.

Strategies for Assuring Success Related to Faculty

Preparation
As instructors prepare to teach a course on-line to adult graduate students there are several strategies that can assist them. They include the following:

- Understand the roles of all the participants (Carter, 1955).
- When establishing objectives for the course, accept adult student obligations and adjust for realistic expectations (Hays, 1990).
- Prepare all materials well in advance of the course (Boston, 1992).
- Understand and be comfortable with the hardware and software of the delivery model (Boston, 1992).
- Possess a high skill level and be comfortable with word processing (Boston, 1992).
- Develop social protocols and rules for the delivery of the course and behavior of participants and include these protocols in the syllabus. Paulson (1995) in Berge (1995) pointed out instructors need to serve three functions: organizational, social and intellectual. The first two must be met to achieve the third.
- Establish pre-class study questions allowing students to prepare for discussion. (Distance Education, U of Idaho, 1996).
- Over-prepare with multiple topics that can be kept active simultaneously (Klemm & Snell, 1996).

Delivery
Gagne’s work (1985) describing the events of instruction in Graham & Wedman (1989) is an excellent starting place for a discussion on successful delivery methods for teachers.

Gain the learners attention. It is critical for instructors to know who the students are, and understand their diverse situations. Walden University begins the process of learning about the students and getting their attention through a required phone conversation between the student and the faculty. The call is placed by the faculty to discuss the course, probe for issues that might affect the student level of commitment. It can also reduce anxiety (Boone, 1996), assess learner needs for appropriate instructional strategies (Hays, 1990), bond (Boone, 1996), and if necessary assist with any
problems the student might have encountered related to the technology (Carter, 1995).

State lesson objectives. Adult students, insist on having a clear understanding of the course objectives, and the necessary output for achieving their goals. Walden University provides this through a detailed syllabus that is filed online in the classroom. The syllabus includes a course description, course objectives, faculty contact information, text and required reading materials. It also has assignments related to the course objectives, the evaluation processes and a weekly topical outline.

Stimulate recall of prior learning. Many virtual classrooms make use of the threaded discussion. This ongoing, asynchronous conversation, by use of its automatic documentation and transcription, captures easily prior conversations. The instructor is better served to facilitate the discussion to engage the learner actively (Darkenwald & Merriam, 1982 in Hays, 1990) challenging them to think critically.

Present information. Teaching on-line is new for many teachers who have a history of teaching in presentation format. For new on-line instructors there are several tactics to be learned. The adjustment of techniques to concise facilitation, instructional materials to distributed texts and on-line resources, and the adjustment of time to weekly, asynchronous postings are necessary for successful presentation of information. It is vital the instructor is able to communicate in a clear, concise, and appropriate manner (Boston, 1992). The facilitator role allows constructivist theory related to learning styles to thrive. Students must be encouraged to be active learners, applying new knowledge to their own setting, increasing both applicability and retention (Berge, 1995).

Guide learning. The on-line delivery model is based on the process of learning, which is driven by learner initiated inquiry (Teles, 1993). There is a self discipline demanded of both the instructor and the students based on regularity, pacing and feedback around certain topic areas. Instructors are encouraged to facilitate multiple learning styles. Examples might be:

- A group collaboration projects.
- Applying cases independently to experiences.
- Supporting discussion threads with activities.
- Having the students act as facilitators leading a discussion thread (Teles, 1993).

The instructor that can facilitate several learning styles (Gunawardena, 1992), initiate inquiry, sequence instruction from one on one coaching to reflection (Teles, 1993), and design structured group process (Riel, 1993) is much more likely to be successful in the on-line classroom.

Elicit learner performance. Many of the activities discussed earlier lend themselves to papers, presentations and postings by students as individuals, and in the collaborative group format. The instructor must take the opportunity to reinforce for students the role they hold in responsibility for assignments (Distance Education, U of Idaho, 1996). Adult learners with a concrete syllabus, learning objectives, assignments and evaluation process are more likely to perform to the appropriate level of expectation held by the instructor.

Provide feedback. For the expert on-line instructor, providing feedback is the key to taking advantage of the synergy within the classroom. To keep students focused and foster critical inquiry, the instructor must provide great amounts of immediate feedback to students, both collectively and individually, publicly or privately. This feedback must also be timely for it to be effective. In addition feedback creates a system of answering questions from students while the answer is still relevant to them.

Assess learner performance. Activities an instructor might use as a means for evaluation within discussion threads, both individually or within groups, might include: defending a position, creating or prioritizing a list, formulating a problem, solving a problem, or preparing a report (Klemm & Snell, 1996). Other alternative teaching methods leading to evaluation might include such assignments such as mastering a topic, detailed analysis, and formal presentation.

Facilitate retention and transfer. Adult learners, demand direct application and transfer of course content to their daily life. Instructors that promote and nurture opportunities for adults to transfer theory to applied cases will be perceived as successful, as well as having met a key goal of the students.

Technology Success Factors
Technology issues

A last barrier related to the situational aspect of adult learners in an on-line program is the technology itself. Students not having the time, experience, ability to learn the appropriate technological functions, or access to the necessary equipment often experience frustrations leading to anger and failure (Boston, 1992).

The orientation process can address some of these problems, by including training for the students, related to the technology of the distance delivery model. Understanding the technology will allow students access to their peers, facilitate group bonding, assure a positive self-identity, avoid some costly errors, and begin the creation of new support systems.

Conclusion

Teachers in the on-line environment must be aware of student characteristics and situations presenting barriers to the students effective learning and success. Instructors that are aware of the barriers can adjust for them by assisting the student in being "aware of and comfortable with new
patterns of communication, learn to manage their time and take responsibility for their own learning" (Sherry, 1995, p. 8). In addition they must integrate new strategies into their traditional repertoire of skills as teachers.

Instructors that are successful in a traditional classroom environment are not guaranteed to be successful in the online, classroom environment. However, with an acceptance of the process orientation towards learning and an adjustment of teaching styles, feedback and assessment faculty will have a much greater chance of assisting students toward success, making their teaching experience more successful. It is critical for on-line programs to provide instructors with appropriate tools to make them successful. Having dedicated, skillful faculty with a desire to learn creates an opportunity to influence faculty success, and by extension student success in the virtual classroom.

SOME ISSUES CONCERNING THE CREATION AND USE OF ELECTRONIC TEXTBOOKS

Linlin “Irene” Chen
University of Houston

Jerry Willis
University of Houston

The aim of this paper is to provide an overview of current developments in the area of electronic books. Following a discussion of the key terminology used in this field, a number of issues will be investigated: computer programs as textbooks at schools.

Looking for a Definition

From K-12 schools to universities, textbooks in part dictate the curriculum’s content, guide the teacher’s instructional plans, and model the student’s understanding. However, the term textbook is neither precise nor stable (Johnsen, 1993). If we confine the word textbook to books produced for use in instructional sequences only, we exclude books whose authors did not intend such use. For instance, when a copy of Shakespeare’s plays is used for teaching, it becomes a "textbook". The manual accompanying software or hardware is also a textbook in a sense. In order to better explain textbooks, in “Paradigms Lost: Towards a Historical Sociology of the Textbook,” Stray (1991) reserved the term textbooks for books written, designed and produced specifically for instructional use, and the term schoolbooks for books used in instruction but less closely tied to pedagogic sequences. In this strict sense, “schoolbook is first attested in the 1750s, and more commonly from the 1770s,” (Stray, 1991). “Textbook does not appear until the 1830s. Its two word predecessor text book is much older, and denotes the text, usually Latin or Greek, used for instruction” (Stray, 1991). According to Johnsen (1993), the definition of a textbook can also be so general as to include other books made and published for educational purposes, or even any book used in the classroom. The textbook may also be a subset of an even broader and increasingly more commonly-used term — teaching media. In this paper the term textbook refers to material designed specifically for instruction in either K-12 or higher education.

Computer Programs as Textbooks

Jonassen predicts that K-12 textbooks will evolve over time. “The term textbook will be applied to a growing variety of functions in differentiated, individually-tailored teaching situations” (Johnsen, 1994). The shift away from the context of textbooks as ink-on-paper products redefines in many ways the work of publishers, and authors, and it is forcing textbook publishers into association, and competition, with businesses formerly thought to be alien, such as television, movie, and other non-print media creators.

Computers have been used in K-12 education for many years, principally for tutorial and drill and practice activities but also for innovative activities such as simulations. Computers are also widely used in education as tools. Many students, for example, regularly use word processors or drawing and painting programs. Until the 1990s, however, computer software was generally a supplement to instruction rather than a focus for primary instruction. When students completed tutorials at the computer, or played simulations, they were adding a computer-supported learning strategy to others that were based on a printed textbook.

In the 1990s, the almost total dominance of ink-on-paper textbooks has been challenged by a number of electronic texts. Texas was the first state to adopt Optical Data’s Windows on Science, a videodisk-based product that replaced, rather than supplemented, the science textbook. In 1992, the state of California also adopted a number of non-print-based science programs as textbooks. Among these were the Britannic Science System and Science 2000 by Decision Development (Hopkins & Itelson, 1994). Since then, several publishers have produced electronic textbooks for a wide range of K-12 subjects and levels, and state education agencies as well as local school boards have sometimes accepted them in place of a printed textbook.

Traditional texts are still the primary resource in the great majority of classrooms, but the success of some first generation electronic textbooks may encourage wider adoption and use.

There have been a number of innovative projects that have created electronic texts. Voyager’ Expanded books series represents a commercial effort to introduce electronic books into K-12 classrooms and to the general public. One
example of a Voyager electronic text is Macbeth. The Living Books series of electronic books on CD-ROM by Broderbund are also used in many American schools and are in hundreds of thousands of homes. More recently, with the advent of the Internet, teachers and the student are able to access electronic databases from their personal computers at any time of the day or night as long as they have a valid account.

Many children's books are designed to be played on a typical home computer with multimedia features. Other types of books, such as corporate operations manuals, are often created to be distributed via a LAN (Local Area Network). Some multinational companies with proprietary Wide Area Networks even use this method to disseminate a wide range of books to locations around the world. Until recently, however, few of the individual buyers of electronic books had access to WANs. The distribution of electronic books to buyers through traditional book stores and software stores has been accomplished to date primarily by storing the books on disks or CD-ROMs. Several hundred e-books are now available on diskette or CD-ROM. At the end of 1996, CD-ROMs offered storage capacities up to about 700 MB in a small, sturdy package. The majority of electronic books purchased today are probably distributed on CD-ROM. Their characteristics of durability and compact size make them easy and cheap to ship.

CD-ROMs have many advantages but the unbelievable growth of the Internet has also made electronic distribution direct to the buyer's hard disk feasible. A few years ago, when Internet access was limited primarily to academics and the military, distribution via the Internet made little sense. Today, with millions of people using the Internet daily, it is becoming a cheap way to disseminate electronic books. Voyager, a pioneering publisher of electronic books, was one of the first to sell some of their electronic books through the Internet.

The Internet, especially the World Wide Web, may be poised to play a critical role in the easy dissemination of electronic books. It may also play another role as well - that of unofficial standards agent. As more books are created in electronic form and as more bridges are constructed to help numerous printed books pass over into the world of electronic books, there is a need for some standardization in the way text, graphic, and multimedia elements of electronic books are created, stored, and disseminated. The World Wide Web, through HTML and browsers such as Netscape that accept a variety of plug-ins, may become a standardizing influence in the electronic book publishing market. HTML, or the standard that emerges from HTML, may become the standard for most electronic books that will be disseminated via the Internet. HTML, with the help of plug-in software that supports display of many different types of media, offers developers a platform that is flexible and robust enough to support the creation of a wide range of electronic books.

There is no doubt that there is a need for some standardization, even in the face of rapid technological developments. One particularly important area in which some standards or approved alternatives is needed is in the area of search commands and indexing formats. Currently electronic books support an idiosyncratic range of indexes and data types that make it virtually impossible to use a single electronic search program to look for information or “hits” in electronic books produced by different publishers (Lu, 1993). The World Wide Web has, however, a number of search engines that were created to locate material written in HTML. The work on Web search engines could be used for electronic books as well if HTML becomes the standard format for them.

A Comparison of Print and Electronic Textbooks

Guidelines for choosing between the use of paper-based versus electronic textbooks are not well documented in the literature. Some common sense issues do, however, seem clear. If there are situations where electronic books are more useful, desirable, or effective than printed books, they are probably situations that need or require features unique to electronic books:

1. The ability to incorporate a wide range of media: text, pictures, and illustrations as well as animation, video, and sound.
2. The potential search and retrieval features of electronic books that include the ability to conduct sophisticated searches of the book (and linked resources).
3. The potential for non-linearity that allows students and teachers to create different “paths” through the material.
4. The ability to link material in the “book” to other material outside the book such as resources on the Internet. A reference at the end of a chapter, for example, could be “hot” so that the reader can jump directly to that reference if it is located at a site on the Internet.
5. The ability to move individual readers beyond the static, somewhat passive nature of book reading to an interactive, much more involved form of participation.
6. The potential for group interaction between readers of the same text as well as links to other groups and forums that deal with topics relevant to the book.
7. The ability to provide useful feedback to students and to provide interactions that involve students heavily in the exploration of the material presented. Electronic books can incorporate everything from drill and practice and tutorial exercises to cases, problem-based learning activities, collaborative projects, and simulations.
The "book" is no longer only a static, linear, and passive medium of instruction. Simply replacing what is done with paper and books with electronic versions of more of the same fails to capitalize on what the multimedia environments of modern personal computers are now capable of providing. Reading an electronic book can be very different from reading a traditional book. Different usage patterns call for different designs to facilitate new ways of reading. For example, if readers have the option of exploring the content of an electronic book in a non-fashion, designers must take care to provide appropriate navigation tools, built in a rich set of links, and make sure each segment of material can stand alone. Someone reading any single page or screen may not have seen the preceding one and may not move on the the following page. There is a sense of position readers miss when they read a non-linear electronic book. Readers thus need help to develop a sense of where they are in the material as well as how large the information landscape they are working with is (Boiling, 1994).

Where Do Electronic Books Seem Most Useful?

Electronic books using current technology seems most suited to applications that involve storage of large amounts of information that will not be read "from cover to cover" but will, instead, be searched by readers looking for specific bits of information. There are a number of uses that fit those general characteristics. "What are the characteristics of the information that scholars obtain from books to write their research monographs?" is the question raised by Kilgour in "Providing Scholars with Information from Electronic Books" (Kilgour, 1994). He conducted a series of analyses on scholarly books, journal articles, and proceedings, and found that two-thirds of the citations in scholarly books are to information on a single page of other books. Electronic publication, which allows the user to use sophisticated search strategies to locate relevant information, would be an advantage to many scholars as well as their students.

In K-12 schools, it is in the area of reference works and indexes that electronic access is often far superior to access via print (Aust, 1993). Some of the most satisfying electronic book genres sold for home use are those intended mainly for reference (The Economist, September, 1994). These electronic books are referred to as “hyper-reference” by some researchers (Aust, 1993). The Economist recognized the electronic edition of the Oxford English Dictionary as the masterpiece to date in electronic reference books to date. The article commented that what "sets it (the Oxford English Dictionary, Second Edition) apart and makes the choice of CD-ROM much more than just a means of storage, is the addition of an unusually flexible … search-programme that enables the user to isolate almost any variable — etymology, for example, or citations — and so conduct on a whim, with perfect accuracy, arcane analyses that might otherwise have taken months" (The Economist, September, 1994, p. 83).

Electronic encyclopedias share similar advantages with the Oxford English Dictionary's electronic version. Reference books thus seem to be one type of publication that is most suited to electronic publication.

The advantages of using electronic technology to deliver detailed, fact-based materials are well documented in other literature (Sutton, 1994). Encyclopedias, statistical reference works, bibliographies, technical manuals, and similar kinds of publications can be adapted to electronic environments in ways that not only improve on their traditional functions but also offer new ones, such as quicker access to information and sophisticated search options for locating material on specific topics. Hypertext also offers the designer the opportunity to create materials that include a wide variety of media, including text to images, animation, video, and sound. The links among nodes of material may be built into the document by the author/designer, or they may be constructed by the user as needed, or "just in time". Thus, a second area where electronic publication seems to have the advantage is large knowledge domains that are more often searched or browsed than read from beginning to end. These are, however, simply extensions of the basic model of an encyclopedia or dictionary.

The advantages of electronic books for texts where interpretation and the experience of reading itself are more important than quick access to facts are less recognized in literature. Richard Lanham suggests in a essay that the mass movement towards electronic texts in other fields will eventually affect arts and letters as well, altering texts of the past and our perceptions of them as well as the written word of the future (Lanham, 1989). Sutton also pointed out that a variety of efforts are now underway in the production and use of literary texts in electronic form (Sutton, 1994). In the arts and literature, computers are regularly used for certain types of research (Pickard, 1994), but the role electronic books will play in these fields is not well understood at present. There is even some debate about whether electronic books like Grandma and Me, one of the Living Books series of multimedia children's stories, is an appropriate expansion of the concept of a children's book, something quite different from a children's book, or a step in the wrong direction.

Electronic Textbooks As Elements of Change

Analyzing the place of electronic books on the basis of the type of content in the book is only one approach to answering the question, however. Another involves matching the book with the approach to instruction. Traditional teacher-centered approaches to instruction are well supported by printed textbooks. Traditional models assume the teacher has selected the content of the course, established the tasks students must complete, and developed a means of assessing student achievement. In this
linear, top-down approach, a printed textbook can play an important role. An electronic textbook may offer students additional media such as sound and graphics, but much of the flexibility of hypermedia/multimedia materials is not used in a traditionally-taught course. Students begin with assignments from Chapter 1 and proceed through the course, reading chapters in order, and completing teacher assignments.

When a course is taught from a constructivist perspective, the flexibility afforded by hypermedia/multimedia materials becomes much more important. When students make many decisions about what they need to know, the search and analysis features of electronic books become much more important, especially if the textbook contains much more material (and links) than could be covered in the course if everyone were expected to learn all the material. Constructivist teaching/learning environments also emphasize the need to explore and understand multiple perspectives. A powerful feature of electronic books is the capability they afford a learner for extensive interaction with an idea, or even a word on the screen. In fact, if Jonassen’s (1994) eight characteristics of constructivist learning environments are considered one by one, all are facilitated by the use of electronic textbooks over printed books. For example, his seventh principle, “enable context- and content-dependent knowledge construction” can be supported by providing tools students can use to build their own “textbook” on the topic and by providing links to rich information resources. The material to be developed is an electronic book to support a constructivist approach to teaching and learning.

Conclusion

The potential of electronic books has considerable appeal to teacher educators, both as options for the creation of instructional materials for teacher education courses and as a vehicle for supporting K-12 education. Teacher educators with the expertise and experience needed to create electronic textbooks may find them important elements in solutions to instructional problems in both higher education and K-12 schools.

TELEMENTORING: PRE-SERVICE TEACHERS TO IN-SERVICE TEACHERS

Kathleen G. Weiss
University of Houston

Afer surveying the literature on information technology and teacher education, Willis and Mehlinger (1996, p. 978), conclude that, on average, “pre-service teachers know very little about effective use of technology in education.” Furthermore, teacher education is indicted for “not preparing educators to work in a technology enriched classroom.” (Willis & Mehlinger, 1996, p. 978). According to the Office of Technology Assessment (1995), graduates of teacher education programs in the United States do not think of using technology as a “teaching tool.” Even though students are taking computer literacy courses for teacher certification, they are not incorporating it into their lessons when they become certified as teachers.

Technology in Teacher Education Programs

It is not enough for students to take a computer literacy course. Integration of technology must be modeled by the faculty in the college of education (Office of Technology, 1995). That usually does not happen (Willis & Mehlinger, 1996; OTA, 1995). The problem lies in the fact that many present day teacher education faculty did not receive training in technology and taught in K-12 schools that had little, if any, technology. This gap in training is part of the reason technology is not modeled in teacher education programs (Office of Technology, 1995). Furthermore, effective integration of technology into teacher education involves more than adding a single required “computer course.” Technology needs to be incorporated into content area methods courses (Office of Technology Assessment, 1995, Fullan, 1991, Novak, 1991). One step toward integration would be for students to communicate with content area professors and other students by e-mail or on a listserv created specifically for a particular class.

Telecommunication Projects

An example of an on-going telecommunications project involves biology students at the University of Illinois (Levin & Boehmer, 1994). Freshman biology students are involved in a model called teaching apprenticeship. Students are apprenticed by a community of educators through e-mail. The Internet-based Electronic Emissary Project (Jones & Harris, 1995) is still another example of an on-going telecommunications project. The Electronic Emissary Project matches teachers with subject matter experts. One of the benefits of this program is the promotion of collaborative learning.

Telementoring: Preservice to Inservice Teachers

The telecommunications projects reviewed above, and other electronic projects that have been described in the literature, influenced me to venture out on her own. Preservice teachers from the author’s Reading in the Content Area methods class were chosen for this research project. As mentioned before, the literature supports modeling of the integration of technology in methods’ courses.

Mentor teachers from all over the USA and Australia volunteered by responding to a notice on an educational listserv. The mentors had a wide range of teaching experience. Many of the mentors held master’s degrees and had their own web page. One mentor had recently published an article about her own on-line experience in the classroom.

The pre-service teachers, prior to being matched with a content area mentor, were administered the Computer Attitude Measure (Kay, 1989). The measure consists of Likert type questions about behavioral, affective, and cognitive aspects of their views about computers. The survey can easily be completed in fifteen minutes.
Next, the preservice teachers observed a short email demonstration by the instructor that modeled the way they could use the telecommunications resources available to them through the university. At that time, a computer technologist was not available to help them or provide additional demonstrations. For some students this demonstration was enough. For the students that had not obtained their university email address and thus had no experience with the system, getting "up and running" was more difficult.

Originally the preservice teachers were asked to communicate with their mentors six times during the semester. Later in the semester I reduced the minimum contact to four times. The quality of the messages was more important than the quantity. I originally was looking at the effectiveness of implementing electronic mentoring via email in a methods course. It soon became clear that other ways of using technology could also support the course and possibly influence pre-service teacher's perspectives on the implementation of technology in their classroom. Setting up a listserv for this class was another way to model technology. The listserv was aptly named, scaffold. The listserv was one mode of communication linking the classmates. Students also had the option of sharing teaching tips from their mentors with other students via the listserv. It was also a way for students to continue discussions from the class meetings. The instructor was also able to communicate with the students without having to wait until the following week.

In examining the end of the semester reflections, students that did not feel as comfortable with an electronic mentor were more comfortable communicating on the listserv. On the other hand, some of the students who had a working relationship with their mentor were not as impressed with the listserv. The instructor was able to see patterns emerge on the listserv. In the beginning, it was viewed as a place to socialize, even share jokes. As the semester progressed students shared information from their mentor regarding discipline, first year teacher anxieties, and lesson plans. Late in the semester the students were sharing websites they found on the Internet and recommending technology articles they read!

The majority of the class was excited about having an electronic mentor. Because the author matched the preservice teachers with a mentor in their content area, it was a difficult task that required considerable time and effort. The biggest problem was the effort required to find mentors for an unusually large number of all level music majors who happened to take the course. None of my original volunteers were music teachers. I had to rely on local mentors for them.

**Reflections**

Within a week after receiving the mentor's name and email address, students began to share their successes in terms of positive experiences with their mentors. I had a very good feeling, as their instructor, when students talked about their successes. The honeymoon was short lived, however. My email soon became a complaint department! Fullan's (1991, p.27) comment that "conflict is essential to any successful change effort" became my solace. Some of the students had unrealistic expectations as far as how rapidly a mentor could answer their myriad of questions. They somehow forgot that these dedicated men and women were teachers with other responsibilities as well.

Logistics was another problem for some of the students. Not all students owned a home computer. They thus had to use computers available at the university and their class schedules determined when they were on campus and when they were able to check their email messages. One of my students suggested that in future a few minutes might be taken out of class time to allow students to check and send email messages. This might be a practical suggestion worth pursuing.

Many of the preservice teachers that felt a kinship with their mentors and one remarked "we have the same philosophy of teaching, we are so alike in our thinking, we are passionate about teaching." The pre-service teachers that developed a nurturing bond with their mentors were often open to suggestions from their mentor.

Even though some students were reticent in the beginning about having an email mentor, most of the students felt it was a beneficial project by the end of the semester. Many of the students plan to continue communicating with their email mentor, especially when they are involved with student teaching.

This research project was an initial attempt of a college of education methods instructor to model the integration of technology. The rationale was based on a review of the literature. It represents one of many ways technology can be incorporated into a methods course as a means of supporting the goals of the course (as opposed to being one of the topics in the course). It is a first start, but it hints at what is possible.

*Kathy Weiss is a doctoral student in the Department of Curriculum and Instruction, College of Education, University of Houston, Houston, Texas 77204.*
According to Papert (1993), many hold the view that the only route to better performance is the improvement of instruction. But, as we are transitioning from the Industrial Age to the Information Age, we are finding that teaching methods used in the past are not the best methods to use for teaching the skills needed for this new era. If we want to help students learn how to problem solve and develop critical thinking skills, we need to integrate technology into our daily planning of lessons. Most educators agree that our students need to acquire the following “survival” skills: problem solving and critical thinking, information handling (organizing, accessing, manipulating, and evaluating), global awareness, technology skills, and ability to cooperate and collaborate with others (Simonson & Thompson, 1994). A critical aspect of the process of integration is helping educators become aware of the resources technology can offer them as professionals within the context of their jobs. According to Helen Harrington, “Preparing teachers to use technology or using technology to prepare teachers each serve a function but it is the second that addresses the most critical issues in teacher education” (Harrington, 1991, p. 55).

Our goal at Iowa State University in the College of Education is to integrate technology into teacher preparation. One of the ways we achieve this goal is through the use of mentorship. As a component of the course entitled “Technology in Teacher Education,” doctoral students are assigned by the instructor to work one-on-one with a Curriculum and Instruction faculty member as a mentor. Our objective is to provide a supportive learning environment and become a resource in technology for these volunteer faculty members. We believe that in order to help in the process of integrating technology into the classroom, we need to model the process and how it works. Mentorship has provided opportunities for our faculty members to understand technology’s role in education and to achieve the goal of being able to integrate technology within the learning environment.

The purpose of this paper is to describe the role of mentorship in the integration of technology in teacher preparation at Iowa State University in the Department of Curriculum and Instruction.

Background/Program Description

The following quotation describes the background of the mentorship program at Iowa State University and provides an overview of the program.

During the spring semester in 1994, a graduate course entitled “Technology in Teacher Education” was offered for Ph.D. students in Curriculum and Instructional Technology. The basic purpose of the course was to review the literature on use of technology in teacher education and to provide professional practical experiences for the students. For the field component of the course, each of the eleven graduate students was assigned to help one or two faculty members to integrate technology into their courses (Thompson, Schmidt, & Hadjiyian, 1995, pp.17-18).

During the fall semester of 1996, seven graduate students participated as mentors to the faculty members who volunteered. Represented were faculty from a variety of disciplines such as foundations, methods and ethnic studies, possessing a wide range of computer skills. The mentors met with their mentees for one hour each week during the semester assisting with their work with technology and teaching.

Process Description

The instructor matched the doctoral students enrolled in the class to faculty members who had volunteered to participate. Letters were sent to faculty members to identify their prospective mentor’s names, reiterate the purpose of the mentorship, and to set guidelines for the working relationship. It was important to communicate to all participants, both the mentors and the mentees, that the mentors were not being provided to do the mentee’s work, but to be available to aid in the development of the mentee’s skills in the area of technology.
The mentees were contacted through personal visits and notes. Some of the objectives of the first meeting included getting to know each other, alleviating any immediate concerns, deciding on meeting dates and times, discussing expectations, assessing technical knowledge, and setting goals. The most vital part of the first meeting was to get to know each other and to define the expectations of both parties.

**Mentee Descriptions**

Mentee Dr. A was a seasoned classroom teacher with a background of over twenty years of teaching experience at the elementary level, and ten years at the college level working and teaching in various capacities. It should be noted, also, that Dr. A earned her Ph.D. in May of 1995 and was in her first year of teaching as an assistant professor teaching multicultural education. She describes the technology skill level at which she entered the mentoring program as "pre K," and stated that she used the computer as a "glorified typewriter" to type papers, materials needed for the classes she taught, and other communications. Dr. A explained that she was confident with most of the functions of the computer as it related to word processing and was ready to begin looking at expanding her use of the computer in order to communicate more efficiently with other faculty, colleagues and students.

Mentee Dr. B was a first-year faculty member at Iowa State University. She teaches social studies methods. Her previous teaching experiences included five years in K-12 public schools (ninth grade world history and twelfth grade economics and government) and nine semesters at the postsecondary level (elementary and secondary social studies methods). Her main use of technology prior to the mentorship was using the computer for word processing and e-mail communications.

**Theoretical Framework**

The theoretical framework used in the discussion of these mentorship experiences is based on the three levels of technology use in teacher education described in the Office of Technology Assessment report on technology and teacher education. The three levels are defined by the knowledge and/or the integration of technology into teacher education. Level One is identified as discussion/demonstration where the professor may discuss or even demonstrate how technology may be used within a classroom. Level Two is identified as technology practice where the teacher provides hands-on practice in technology. The last and most involved, Level Three, professional practice, involves the students seeing the integration of technology into the curriculum and practicing teaching with technology (Office of Technology Assessment, 1995).

We have used this model as a lens through which to view our mentorship experience as it relates to the progress of the mentees toward the integration of technology into teacher preparation.

**Level One: Discussion/Demonstration**

This stage began within the first meetings after the mentees identified their specific goals for the tutoring experience. Dr. A identified the following goals:

- learn more about the basics of computers and related technology to be able to integrate it into her curriculum.
- learn how to use e-mail and Quickmail, an interdepartmental mail system, to be able to communicate with faculty, colleagues, and students.

Mentor A’s response to accomplish these goals:

- taught the basics of computers and networks.
- taught procedures for the efficient use and management of the e-mail system.
- demonstrated and help set up a spreadsheet to manage grades.
- discussed/suggested using Hyperstudio, an authoring program, for students to make curriculum projects.
- discussed/suggested using the WWW for obtaining current resources for her subject area.

Dr. B identified the following goals:

- use technology for professional purposes (i.e. use Scholar and the WWW for research).
- create a student/class mailing list utilizing the e-mail system.
- integrate technology into daily lesson plans.
- justify technology (i.e. find/utilize the best method for a given task e.g. PowerPoint vs. overheads).

Mentor B’s response to accomplish these goals:

- taught how to access Scholar through telnet—performed an ERIC search.
- provided information regarding non-accessibility of Quick-Mail from a remote site, provided information regarding the necessary logistics to access e-mail from a remote site.
- demonstrated using WWW use for class/lecture.

**Level Two: Hands-On Practice**

With a designated time set aside for meeting with Dr. A, the opportunity for hands-on experience and practice was set in place. Dr. A faithfully completed her “assignments” whether it was going through her, seemingly endless, mail list to delete or file mail documents as needed or entering student information on her newly created spreadsheet template. Seeing immediate positive results provided Dr. A with some intrinsic rewards that served to motivate and encourage her as she went through months of old and outdated messages. This proved to be of benefit and a means for Dr. A to gain the hands-on practice necessary to strengthen her technology skills. As the relationship between the mentee and the mentor grew, Dr. A readily
sought help when needed between meeting times. Messages were easily and quickly exchanged by e-mail as Dr. A became even more efficient with its use.

As the weeks progressed, a number of teachable moments occurred such as when Dr. A unintentionally changed her printer destination and printed some of her personal documents on a printer not usually accessed by Dr. A. With the use of a bit of levity to lighten the seriousness of what had happened, little or no damage was done to Dr. A’s confidence as she continued to work on increasing her technology skills.

After constructing a template together using Microsoft Excel, a spreadsheet application, Dr. A was provided, again, with hands-on practice as she found it necessary to enter data from each of her class sections. Soon she was able to paste formulas and cut and paste entries to manipulate data to personalize the spreadsheets to meet her own particular needs. Changes and additions to the original entries were completed with increased ease, as Dr. A continued to use the spreadsheet application for managing her grades.

When the end of the semester arrived, Dr. A was able to see, firsthand, even more of the benefits of using technology, as she was spared the time and effort usually needed for calculating final grades.

By the end of the semester Dr. B decided to experiment with a Technology Day for her two sections of social studies methods students. During class time the students completed three of eight possible prescribed stations set up in the Instructional Resource Center. The type of stations included: VCR, laser discs, WWW, scanner, CD-ROM software, social studies software, and a seek ‘n find of other technology located within Instructional Resource Center.

The students worked cooperatively in eight groups of three to four each. At each station, criteria sheets were filled out. The sheets were used to aid the students to critically evaluate the usage of each type of technology. Also, the students trained each other how to use the equipment.

Mentor B and Dr. B observed from the process that the students crosstrained each other on the equipment, collaborated on the project, discussed the justification of the technology, and generated lists of how to integrate the technology. From the criteria sheets the students found the technology to be realistic, interactive, and student centered. They also noted that most of the technology lent itself to supporting multiple learning styles. Some of the issues the students saw as problematic were lack of funds, lack of user-friendly software, lack of teacher training, and lack of time.

Level Three: Professional Practice

When Dr. A completed her spreadsheet containing her grades, she was able to inform her students on a weekly basis of their up-to-date progress in the class. A large number of these students, who were education majors, could see how Dr. A used technology to provide current information regarding their grades and progress. After the Technology Day experiences, Mentor B and Dr. B looked toward modeling the use of technology within the classroom. The goal was to locate equipment, find suitable software, and develop criteria for software review.

As Dr. A and Dr. B increased their use of technology in the classroom arena, the groundwork will be laid for preservice teachers to continue moving along the continuum of the three levels of technology as outlined by the Office of Technology Assessment. Hopefully, they will be able to model the same use of technology when they have classes of their own. If so, the ultimate goal of the three-year program at Iowa State to infuse technology throughout the teacher education program will have been realized. That goal is for preservice teachers to become creative classroom teachers who use technology to its fullest to facilitate the teaching and learning process.

Observations and Future Considerations

Ely (1995) lists the following as necessary elements for successful acquisition of technology skills:

- dissatisfaction with the status quo
- knowledge and skills
- resources
- rewards, incentives
- commitment
- leadership
- time
- participation

The Office of Technology Assessment’s (1995) list includes the following items:

- hands-on-learning
- resource person
- practice
- access to equipment
- administration support
- time
- learning to use as a pedagogical tool
- incentive to use and to integrate

A number of things come to mind as we reflect on this experience. Dr. A and Dr. B exercised a great deal of initiative by volunteering to be part of the mentorship program. Dr. A was an instructor who could have easily decided to bypass the experience at this stage of her teaching career, having taught over twenty-five years without using most of the technology available today. Yet, she was willing to take part. We believe this relates to one of the factors on Ely’s list of factors needed for the technology integration process to work effectively. That factor is dissatisfaction with the status quo. Dr. A was no longer satisfied to use technology
in the minimal ways she had in the past. She realized that she was behind many others who were reaping the benefits of technology in their teaching. She shared that a close department colleague had started using technology to correspond with other colleagues outside of the country. Also, Dr. A had recently returned from a sabbatical where she had traveled to other countries and formed friendships that could be maintained through the use of e-mail.

Dr. B, a first-year faculty member, saw a need to expand her knowledge of technology as she became a member of a technology-oriented department. Other factors, such as time, which appears on both lists as factors needed for successful technology integration, had an enormous impact on this experience. Participating faculty members, when asked why they thought the experience was a success, responded that having a designated time set aside each week when the mentor came to work with them in their own environment, allowed them the benefit of working in the least threatening environment. They also added immediately that the one-on-one situation provided an opportunity for them to ask “dumb questions” that they would not have been able to ask in a group setting. Finally, a key point mentioned was the fact that the relationships that were built allowed the mentees to feel free to seek assistance between sessions. The literature has repeatedly made the point that availability of technical support is a key issue relating to successful use of technology. Additionally, as these pairs and groups bonded, emotional support was easily added to the list of benefits of the mentorship experience. Dr. A is now looking forward to all of the possibilities that are available to her as she is inspired to learn how she can integrate technology into her curriculum. “I didn’t even know enough about technology to even realize the possibilities of what I could actually do with it. Also, I’m now using my computer every day, where I used to use it only twice a week because it was so tiresome. I avoided it because it was just another chore. I frankly didn’t like it. Now, that’s changed and I believe that the enthusiasm of my mentor helped to cause that change.”

Dr. B is looking forward to using technology to expand her professional development. This includes presentations at the state and national levels. This further supports that fact that the mentorship program offered numerous unanticipated benefits and it is with this in mind that we hope to see it continued at Iowa State and replicated in other settings.

Our experience was very positive and plans exist to continue with the mentorship relationship. Both of the mentees expressed feelings of increased confidence with technology. One of the positive results was the professional growth for both the mentors and the mentees. The goal is to continue to research, write proposals and papers, and to present our success as a model for others to follow.

Suggestions for others who try to replicate this model are to provide practice time for the mentees, get to know each other, set goals, be able to justify technology, create an unthreatening environment, develop a support system, provide one-on-one instruction, meet on the mentee’s “turf,” and inform appropriate administrators of the positive outcomes of the mentorship program.

Synergistics Systems Inc.

This paper will describe the effects of the Synergistic Curriculum on students and teachers in middle school settings. Why should we think carefully about interventions with technology education programs in middle-school settings? We make the argument that the evaluation process should impact technology design. We have no doubt that the promises for technology applications will ultimately come to pass, at least insofar as barriers on resources and implementation are reduced. We wish to encourage the design of educational technology that will help students learn, help teachers, and transform schools into a truly valued part of the community. What we specifically looked at in this paper was the effect of Synergistic Systems in middle-school settings in terms of design and educational benefits to students when learning about technology (Hamisch, Gierl, & Migotsky, 1995; Hamisch, Migotsky, & Gierl, 1995).

A recent report from the Congressional Office of Technology Assessment (1995) suggests that the teachers are the most important part of the education equation when considering the integration of technology in the classroom. In addition to examining the student outcomes, we examined the role that the teacher plays in the Synergistic lab. This was evaluated both through our observations in the classroom and also by visiting the teacher-training program offered by the Synergistic Systems, Inc.

Evaluation of technology education programs requires multiple levels of thinking. First, we must address whether the technology education program accomplishes its intended purpose. Synergistic Systems (1995) have the following features:

- New educational system that transfers responsibility for learning to the student
- Four primary components in the Synergistic Systems necessary to ensure success for student & teacher
  - Learning environment
  - Learner organization
  - Module curriculum
  - Instructor enablement package
- Learning environment that features a lab configuration which conveys a sense of order and excitement. Ergonomic workstation design, storage capability, and aesthetics are fully incorporated in the furniture.
- Learner organization that is based on a two-by-seven principle where students are paired for seven days to complete a module of the Synergistic curriculum. Teachers respond to student questions when they see a call light at their workstation. Students use computers, videos, hands-on activities, and other educational materials to complete the educational activities of the module.
- Synergistic module curricula integrated with the learner organization resources to ensure a consistent delivery of information with a specific format which allows the teacher to monitor student progress and success.
- Instructor enablement package that allows the classroom teacher to realize their role as a facilitator of learning and allows the teacher to gain philosophical insights and hands-on experience with the Synergistic Systems. Instructors are given software resources to handle student scheduling in addition to professional technical assistance via phone, electronically, and newsprint. All of these support features are designed to help teachers succeed.

New technology education programs are likely to suffer from ills related to its novelty, its integration into existing systems, and its high initial costs. Technology education,
provided in the Synergistic Systems, represents a new start and a program that helps to attain new goals which may have attitudinal effects and provide additional time for other important outcomes. Our evaluation examined outcomes beyond the instructional goals. Our approach used multiple techniques to determine the outcomes, both positive and negative, of the technology education program. In the next section of this paper we describe the methods used and discuss the evaluation questions and approaches along with their merits.

The Synergistic Systems were used to enhance and supplement technology education in middle schools. The system we observed contained 16 modules that allowed students to interact with different forms of technology. Modules included computer problem-solving, rocketry and space technology, and applied physics. Each module was self-contained providing instruction through videos, reference books, hands-on projects, progress log books, and tests. Students worked in pairs and typically spent eight days in each module, with the final day as a “Discovery Day.” The teacher served as a facilitator of learning by organizing the modules, coordinating activities, and troubleshooting problems. The Synergistic Systems are purchased by a school, and includes software, teacher-training, technical support, lab furniture, and reference materials. The school provides computers and other hardware (for example, schools purchase the cassette recorder for the audio broadcasting module).

The effects of the Synergistic Systems on the students and teachers at Washington Middle School and Fremont Middle School in a Midwest community were evaluated. The focus of this evaluation was on cognitive and affective engagement in the participating students as they worked in the Synergistic lab. We also assessed the effects of the system on the culture of the school. Although the system has been endorsed by teachers and students, this evaluation was both timely and important because no systematic empirical studies have been conducted. Consequently, the results of our evaluation yields important information about the effects of a Synergistic lab experience.

Research Questions and Evaluation Overview

The evaluation was developed around seven focus questions.

I. Student Level
1. Do students understand the material presented in Synergistic modules?
2. Do students find lab tasks interesting and engaging?
3. Do lab activities instill self-confidence in learning and self-esteem in the learner?
4. Does cooperative learning occur in the lab and does this style of learning transfer to other classes?
5. How has the relationship between student and teacher changed as a result of the Synergistic lab experience?

II. School Level
6. How have other teachers responded to the Synergistic lab, and the style of learning that it promotes?
7. How has the Synergistic lab influenced the culture of the school?

In order to address these questions, our evaluation design contained six main components: shadowing pairs of eighth-grade students through a rotation of a module, interviewing the shadowed students along with their parents about the impact of the system, conducting focus groups with eighth-grade students about their impressions of the system, talking with teachers and administrators about the Synergistic Systems, surveying students, and critiquing Synergistic Systems modules. Eighth-grade students were the unit of analysis in this evaluation because the Midwest sites had well-equipped Synergistic labs where eighth graders completed a semester of lab work.

Methodology

The evaluation questions were addressed within a quantitative and qualitative research paradigm. A multimethod, multi-site approach provided the evaluators with a complex assortment of data from which to evaluate the system. This approach also ensured that our conclusions were triangulated across data sources. The quantitative modes of inquiry included the use of surveys and district standardized test scores. The qualitative modes of inquiry included observations, interviews, and document reviews.

This evaluation was conducted at two school sites, Washington and Fremont Middle Schools. Our primary focus was at Washington Middle School which was the site chosen by the sponsor, Dr. Harvey Dean. A second site, Fremont Middle School, was introduced to provide a comparative element to the evaluation. Five visits were made to WMS totaling ten days of on-site observation. Three visits were made to FMS totaling three days of on-site observation. The activities 1-5 outlined below were conducted at WMS but only activities 4 and 5 were conducted at FMS. We also saw Synergistic labs in Texas, Indiana, and Illinois.

1. Shadowing of Dyads. Two pairs of eighth-grade students were followed through a rotation in the Synergistic lab at Washington Middle School. Shadowing simply refers to the unobtrusive nature of our observations. We followed students throughout the school day observing and interpreting behaviors. For example, we examined students' cooperation, effort, and attention toward activities in and out of the lab. The students were chosen by Mr. Lincoln, the technology education teacher, and represented a typical pair of eighth graders. Both students were observed in the lab setting and then followed throughout the school day.
Each of the two pairs observed came from different classes. The evaluation questions guided and structured our observations. Student, parent, and teacher consent were obtained before the beginning of our shadowing component.

(2) Interviewing the Shadowed Students and their Parents. The impact of the lab was assessed by interviewing the shadowed students and their parents. The students were asked to comment on the lab experience using a structured interview. The protocol contained questions about student attitudes, understandings, and impressions. The interviews were based, in part, on our observations of the shadowed students that developed during the week. Parents were also asked to comment on the impact of the lab for their child using a structured interview. The students were interviewed during the school day. The parents were interviewed during the parent-teacher conferences held at the school. These audiotaped interviews allowed for closure of the shadowing process and provided an outlet for discussion about the Synergistic lab and its perceived effects on both the students and the school.

(3) Focus Groups. Focus groups were conducted and videotaped. The purpose of these groups was to allow students to discuss the lab experience, compare the lab to other classes, and critique their technology education program. Both evaluators interviewed their shadowed pairs at the end of the module rotation. In addition, the pairs were interviewed along with other students in the class to get a broader view of potential outcomes and benefits associated with the technology education program.

(4) Supplemental Activities. In addition to the shadowing, interviews were conducted with the Synergistic lab teacher, principal, and five other teachers in the school. The interview questions covered both student and school-wide effects of the Synergistic lab. Both researchers also observed and informally interviewed students participating in the end of semester display activities. This end of semester activity was videotaped.

(5) Surveys. Three different surveys were developed for this evaluation. The first survey contained four questions intended to measure both positive and negative effects of the Synergistic Systems. This survey was administered to 85 eighth grade students at WMS in November, 1994. The second survey contained the same four questions as the first survey plus additional questions addressing specific concerns raised by the sponsor. This survey was administered to 90 eighth-grade students at WMS and 79 eighth-grade students at FMS in May, 1995. The third survey was developed to measure the effectiveness of the teacher training session. It was administered to the 24 participants at the Synergistic Revolution Seminar, Pittsburg, Kansas in June 1995.

(6) Critique of Synergistic Modules. The instructional materials (i.e., video tapes, workbooks, reading materials) used in Synergistic modules were critiqued at the University of Illinois at Urbana-Champaign. Six modules were selected: two used during the shadowing of students (Engineering Bridges and Applied Physics), two selected by the WMS lab instructor (Transportation and Computer Applications), and two selected by the sponsor (Biotechnology and Career Explorations). These modules represented a diverse set of tasks used throughout the Synergistic Systems. The modules were evaluated on seven criteria: (a) logical sequencing of activities and materials, (b) clarity of instructions, (c) quality of instructional materials and equipment, (d) balance between content knowledge and experiential, hands-on learning, (e) complexity of tasks and activities, (f) application and relevance to real-world and future careers, and (g) appropriateness of research activities and test questions.

Results

In this evaluation, both quantitative and qualitative methods were used to document the engagement of students who worked in the Synergistic Systems. To conclude this paper we answer and discuss the findings for each of the evaluation questions listed as well as elaborate on themes that emerged during the study.

Do Students Understand the Materials Presented in the Synergistic Modules?

For the most part, students seemed to understand the materials in the Synergistic modules. Results from the module post-tests indicated high levels of mastery but these findings require qualification. First, assessments in the Synergistic Systems were weak. Our case studies, classroom observations, and module critiques revealed that module tests contained cognitively low-level items that required little effort or careful thought. Students were also given few opportunities to demonstrate their new understandings. In addition, the module tests were poorly connected to the module activities and to the real world. Thus, the module tests shed little light on this question. Second, our case study observations confirmed what Mr. Clark called "a mixed bag" as some students clearly understood the activities and concepts while others did not. Ryan and Teresa, for example, consistently excelled at their module activities. They were motivated middle school students who demonstrated an understanding of the concepts in the Engineering Bridges module by what they said, by what they did, and by what they wrote. Yet in the second case study, Christina and Matt rarely demonstrated a thorough conceptual understanding during the module activities. They often completed their activities in a mechanistic manner with limited understandings. Third, our interviews and observations supported the view that the level of understanding varied across students. The technology education teachers both believed that most students had a good understanding of the concepts presented in the modules even though the effects were not
visible to the non-technology education teachers and parents. The principals at WMS and FMS were much more optimistic, as both believed that students did understand the content in the technology education curriculum.

Do Students find Tasks Interesting and Engaging?

Students clearly enjoyed module assignments and were frequently on-task. Case studies, surveys, and interviews all provided strong, consistent evidence for this conclusion. More specifically, survey data demonstrated that most students were more interested in the technology education class compared to their other classes and that most students preferred the multimedia approach to learning. Students in both schools reported that the best parts of the technology education lab were related to the hands-on constructivist nature of the module tasks and the frequent use of high-tech equipment. Student comments and module critiques also suggested that a balance between hands-on, experiential learning and content knowledge was important. Students were dismayed with modules that presented too much information while the evaluators were concerned with an overemphasis on experiential learning—both features are needed. Indeed, we found several modules that failed to balance and integrate content information with hands-on activities.

Do Lab Activities Instill Self-confidence in Learning and Self-esteem in the Learner?

The lab may instill self-confidence and self-esteem although we found little evidence to directly address this question. During our visits to WMS and FMS, technology education teachers and administrators frequently reported anecdotes about student successes in the Synergistic lab. For example, Mr. Clark identified two FMS students who could not successfully complete their coursework in most classes. Both students were “incompatible with the system,” he said. In technology education, however, these two students found an outlet for success, and they consistently completed their work in Mr. Clark’s class. Mrs. Winston had a similar story to tell. We did not observe such a case. Rather, we consistently encountered, through interviews with teachers and parents, indefinite and unsubstantiated claims. Most respondents simply stated that they could not tell if the lab influenced a students’ self-esteem. However, some indirect evidence was available. For example, students reported that they were more comfortable working with high-tech equipment as a result of this technology education class experience. Case study and classroom observations also indicated that many students who successfully completed their activities were proud of their achievements. The impact of this pride, which may have been fleeting or enduring, was almost impossible to assess with our evaluation design.

Does Cooperative Learning Occur in the Lab and Does it Transfer to Other Classes?

Cooperative learning consistently occurred in the lab whereas transfer was rarely, if ever, observed. The case studies demonstrated that students consistently worked well together. Ryan and Teresa were a model example. They frequently helped one another through an effective exchange of ideas and information. They also critiqued one another. During the course of the evaluation we saw many examples of students who worked well together. The survey results suggested a slightly different picture as students reported that partners were both a help and a hindrance in the lab. Apparently, the quality of the relationship influenced the success of the partnership and the cooperative learning experience. In other words, partners must work well together in order to have a meaningful learning experience. Students were quick to point out that inadequate partners were detrimental to the learning process. Another factor that likely influenced cooperative learning was class time. Students and, surprisingly, parents reported that class time was often inadequate to complete module activities. Christina and Matt failed to finish their work more than once.

Transfer of learning was difficult to document although we found some evidence that transfer was occurring. In most cases, the parents and non-technology education teachers could not identify a transfer of learning to the home environment or respective classrooms, with one exception. Surveys also suggest that transfer was possible as students reported that they thought about module activities outside of class. Our observations on this point were more pointed: transfer of technology-related skills was slight, if not impossible, because the lab differed dramatically in instructional format and physical structure compared with most other middle school classes. The technology education lab was unlike other classrooms in these two respects, thus limiting the opportunities for transfer of knowledge and skills.

How has the Relationship Between Student and Teacher Changed as a Result of the Synergistic Lab Experience?

The relationship between student and teacher has changed in the Synergistic lab but not as much as many people would have us believe. We heard a great deal of rhetoric on this point in both the schools and in the teacher-training seminar. However, our case studies and observation at WMS and FMS clearly demonstrated that the teacher is the single most important factor related to the success of the system. The teacher’s success depends on a core set of principles that likely transcends content areas and grade levels; namely, a carefully structured classroom with well-organized instructional materials, high expectations for students, strong content knowledge and interest in the content area, clearly defined boundaries for behavior and conduct, leadership, and mutual respect between students.
and between other teachers, parents, and administrators. Mr. Lincoln was an exceptional technology education teacher who possessed and continually demonstrated these skills. The role of the facilitator in a Synergistic lab has changed, but good facilitators are still good teachers.

**How have Other Teachers Responded to the Synergistic Lab, and the Style of Learning that it Promotes?**

Teachers in WMS strongly supported the Synergistic lab. Almost every teacher we interviewed was proud of the technology education program and almost every teacher had seen the lab. Again, we heard anecdotes related to the lab—that it was the “showpiece” of the school, that many of the school faculty brought visitors to the Synergistic lab, that teachers and parents wanted to work through module activities. Despite this enthusiasm and support, the lab was isolated in WMS. The mathematics teacher saw opportunities to combine math principles with module principles but viewed Mr. Lincoln as an elective teacher who was not closely related to teams in core subject areas. The science teacher was also open to collaborations but felt isolated and burdened by a lack of time. The language arts teacher was optimistic about establishing links to technology education but didn’t really know what Mr. Lincoln covered in class. In addition, Ryan’s father wanted the opportunity to enhance the teaching of technology education but didn’t know what activities were occurring in the technology education lab. Mr. Clark reported that some teachers still sent students to his lab with broken glasses and torn shoes, even though his role as an industrial arts teacher had changed more than two years ago. Intentions were good but collaborations were limited despite the apparent opportunities that existed. We consistently noted these missed opportunities during our site visits at WMS.

**How has the Synergistic Lab Influenced the Culture of the School?**

The Synergistic lab has had a positive influence on the culture of WMS. Administrators, teachers, parents, and students spoke without hesitation of the lab’s merits. We did not encounter one disgruntled respondent. All of our interviewees stated that the Synergistic lab made an important contribution to WMS, citing different reasons. Mrs. Winston viewed the lab as middle school philosophy in action, something good for education today that would likely serve students in the future. Teachers identified the importance of middle school philosophy and the use of hands-on, collaborative learning that Mr. Lincoln promoted in the lab. Parents consistently saw links between the lab and the real world of jobs and careers. Students liked the lab because it required hands-on work with interesting equipment in a multimedia environment that was self-directed and interesting. Everybody had their reasons for proclaiming the benefits of technology education thus it was clear that the Synergistic lab had a positive effect at WMS.

The University of Illinois evaluation team agreed that the Synergistic Systems were an educational success. Consistently we observed students working as responsible, independent learners across different modules and in different sites. Students were frequently engaged in solving real world problems. Students were guided by different forms of educational technology that they manipulated with ease and with comfort. We saw, in practice, middle-school philosophy in action.

We also agreed that many questions remain unanswered—we list but three. First, the Synergistic lab was effective at WMS, but how typical was WMS? And how much of the success at this site was attributable to Mr. Lincoln? Our visits to other schools, most notably FMS, suggested that the teacher’s role was central to the success of the lab. But how flexible and how tolerant is the system to different styles of teaching? Second, how would a Synergistic lab operate with a diverse student population such as a large Hispanic population or in an inner city school? Does the teacher’s role change in these circumstances? Again, our limited observations suggested that these factors would influence the success of the lab. Third, what types of assessments should be used in the Synergistic Systems? Our evaluation continually identified assessment as a weak link in the system. But how should an alternative assessment program be developed? What types of performance-based items are appropriate? How would a change in assessment influence the rest of the Synergistic Systems? Our evaluation provides a starting point as many of the concerns raised by our sponsor were addressed. Predictably, however, we raised more questions than we answered. Much work remains.

RUNNING FUTURE WORKSHOPS TO IMPROVE AND ENHANCE EDUCATION PRACTICE

Urban Nulden
Goteborg University, Sweden

This paper presents a theoretical and practical framework for Informatics research in the area of education. The context for this research is Sweden where schools often have an advanced infrastructure of computers and networks but the use, by teachers, of the technology, is very limited. The reason for this is two highly interrelated issues. First, teachers do not know what to do with the technology, and second, many of the teachers are sceptical about technology as well as conservative and reluctant to change their current practice. This paper presents an alternative where both these issues are addressed.

Motivation
A new society is emerging and there are many notions of what this society is: post-industrial society, information society, learning society, digital society, and so on. However, despite different notions, most agree that computing technology (CT) is an important part in this new society. The importance of CT is of course recognized in the education system. Community leaders, school boards, legislators, parents, etc., proclaim the value of this technology. Therefore, a large number of schools have an advanced infrastructure of computers and networks due to a ‘push’. By this, schools ensure that students are exposed to computing technology as it will be a major part of their future lives. However, in this push, most teachers had no chance to assimilate and explore the technology on their own terms, and as a result of this, combined with a conservative attitude, their use of CT is very limited and this is a problem.

This paper discuss three issues related to this problem. First, adapting CT as a natural element in their work involves considerable change to most teachers. Second, the use of CT in schools, by teachers, must be more innovative and creative than currently. Third, institutions training teachers will benefit from an arena where educational aspects of CT is explored and discussed before they enter their profession.

In this paper, an Informatics perspective is put forward. The practical departure to the three specific issues are through future workshops (FW). This is a technique for approaching a problematic situation, generating visions about the future, and discussing how the visions can be implemented. FW is a means to utilize the power and competence that appear when people experience that they have common interests, needs and problems. Groups of teachers, or education students, are here guided by a facilitator who ensures active and equal participation, and makes the participants aware of current CT trends and development. Users possess the practical understanding necessary as the basis for the design, but to support their technical imagination they must gain insight into new technological possibilities as well (Ehn, 1988).

Education System in Change
From one perspective, we can see that the education system is opening up and the borders of the past are slowly dissolving. And in line with this, the main tendency on all levels of the education system is to question the disciplinary borders, e.g., thematic approaches, where real life situations and problems are taken as a point of departure is strongly emerging as an alternative to a subject focus. However, mature organizational cultures, such as the education system, experience change, or the challenge to change, most significantly as a disruption, an intrusion, or as a failure of organizational defense. We can see that the form of schools and education has remained fairly unchanged over hundreds of years, and so has the technology used in teaching, despite both pedagogical and technological influence. Summarizing the critique of the current education system is that the underlying mission of education can not remain the inculcation of knowledge and skills, values and behavior, not the transmission of information and authority.

From another perspective, enthusiasts in the education system bring forward new ideas about pedagogy and technology. However, it is obvious that teachers and other school staff, as individuals, are well adapted to a particular niche and it is understandable that their first response to attempts at innovation would be one of resistance. The norms of 'the teacher culture' are profoundly conservative and teachers' resistance to change plays an important role in shaping their response to both pedagogical and technological innovation. We can also see that the more innovative the suggestions for change, the grater the critique, and hence its threat to existing principles, that is, the underlying ideas and
insights. For years educators have tried to come up with ways to reform the system, yet many people have reached a point where the enormity of the task resulted in abandonment of the ideas. Over time the idealism and enthusiasm of the novice teacher will fade away.

Today the culture of the educational system and its technology is challenged. CT is here the main vehicle for implementing change and may help bring about some important reforms (Barker & Dickson, 1996). The ability to change is embedded in the culture of the organization. Historically, technology that reinforces existing lines of power and information have been adopted but this assures at the same time that the traditional approaches to teaching will be cemented. The convergence of computing and communication technologies and the pervasiveness of computer networks—the Internet in particular—have strong potential for transforming education.

**Struggling with Technology**

Computing technology can be used to enhance existing traditional methods. This is what we do in most cases today. This means that no changes, at least no major changes, are made to the content and form of teaching. CT is used just as another technology for fact or information transfer. If we continue to re-implement conventional models borrowed from classroom based education focusing on passive transmission, we can expect only marginal improvement of the quality in our teaching.

Just providing schools with an infrastructure, that is computers and networks, will not have the desired effect. This push action may actually result in a continuation of the technology rejection. Teachers will begin the process of ‘pull’ when they know for what and how to use the technology. Today most educators have no idea where to begin and what to do with this technology. One reason for this is that ‘most technology instruction in Colleges of Education involves teaching about technology as a separate subject, not teaching with technology by integrating it into other course work to provide a model for instructional use’ (From the U.S. Office of Technological Assessment, in Wetzel & Chisholm, 1996)).

‘Outsiders’ have tried to introduce computing technology into high schools. After proclaiming its potential in the classroom, the teachers use CT only slightly, if at all. Even if CT artifacts are used, classroom practice remains fundamentally unchanged. As a matter of fact the last technologies that made a substantial influence on the general organization and practice of teaching were the textbook and the blackboard.

Educators often work in isolation and could especially benefit from sharing with other professionals. If teachers do not have the commitment to apply CT in their work, it is not going to happen. Instead of educators isolating the learning process within the confines of their own classroom and the particular school, they should forge links to the outside community to find ways of refining and sharing their knowledge with others.

A large number of teachers are confronted with new pedagogical principles as well as new technology. It is not easy to switch to a different mode of teaching and learning for those with years of experience of a traditional teaching. For them the view of the authority or the professional who is the ultimate source of all knowledge is threatened.

Teacher education has been out for long standing critique as most education of teachers, in CT use, focus on using software products, not the technology itself. Far too many training sessions emphasize computer hands-on, instead of discussing computing technology in a wider context. The ignorance of the technology comes apparent in cites like, ‘computers are a good thing, but there are no programs available.’ The teachers do not know enough to utilize the possibilities with the technology. Most teachers graduate from teacher preparation institutions with limited knowledge of the ways the ways technology can be used in their professional practice. However, there is work going on to integrate CT and its possibilities. These institutions has only recently discovered the pedagogical usefulness and advantage of the technology.

**An Informatic Perspective**

The major theoretical foundation as well as the practical guidelines in this paper originate from informatics. Informatics is the “design oriented study of information technology use with the intention to contribute to the development of both the use and the technology itself” (Dahlbom, 1996, p. 88). New use domains, in all fields, are constantly made possible by advances in computing and the central interest of informatics is to intervene and contribute to the process rather than just observe and describe it. Computing technology changes people’s work and our interest is to augment their skills by the technology rather than replace them with the same (Ehn, 1988). Informatics’ critique of traditional computing research is that it often is an “anthropology of the past” rather than an experimental “archeology of the future” which is our interest (Dahlbom, 1995).

**Work Oriented Design**

A central principle in informatics is that design of computing artifacts and design of its use should take place close to the users (Ehn, 1988). The approach is called participatory design (PD), where ‘users’ and computing experts share the responsibility for designing the technology and the new work place (Bjerknes, 1993). Note that PD is fundamentally different from ‘user participation’ where users serve as passive information suppliers. PD is a process of mutual learning where computing experts learn about the work and users learn about the technology. PD is therefore an approach which highly supports a software use perspective.
There are three different motivations for PD approaches in informatics (Greenbaum, 1993). First, from a pragmatic perspective, those who know the work should participate in improving the same work. Second, from a theoretical perspective, users and experts have limitations in communication skills and therefore need to work closely to gain understanding. Third, the political perspective, people have the right to influence their own work place.

Participatory design have many similarities with soft systems methodology (SSM). SSM is a problem understanding and problem solving methodology, introduced by Checkland (Checkland, 1981), which uses discussion, debate and the development of a series of models as a means to facilitate learning about a problem situation. The methodology evolved as a reaction to the evident shortcomings of traditional hard systems approaches which failed to address the complex softer issues. In the subsequent evolution of SSM, a strong user participation has been a major characteristic. SSM has evolved toward a collaborative approach where 'users' will involve other people in the process of problem handling.

Whereas as PD focus on the current work situation, future workshops is taking PD a step further by approaching the future. FW is a technique for approaching a problematic situation, generating visions about the future, and discussing how the visions can be implemented (Jungk & Mullert, 1987). The core of FW in this research is of course problems and visions concerning education practice as well as problems and visions with computing technology in education. The FW is divided in three phases: the critique phase were current work practise is in focus, the visionary phase were the participants discuss and propose alternatives without consideration of limitations, and the implementation phase were the participants discuss the realistic alternatives and how they can be implemented. A general prerequisite for constitution of FW groups is that all participants should share a problematic situation, desire to change it according to their visions, and have the means to do it. The FW is run by a facilitator who is guiding the participants and ensures active and equal participation, but also makes the group aware of current CT trends. A group of ten persons including the facilitator is an advisable size. All contributions become part of an electronic script. As all tools are for instance wall charts and other tools allowing the participants to explicitly post and discuss each other’s viewpoints and ideas, and very simple prototypes of CT.

**Improve and Enhance Education Practice**

There are several substantial outcomes of future workshops that will improve and enhance education.

First, future workshops are real eye-openers to conservative teachers in that they realize that computing technology is central to the entire shaping and direction of our education. They become aware of how they can use the technology and the awareness brings about the necessary motivation required to start changing the individual teacher's practice. For education students, the future workshop is a creative arena where they have the opportunity to shape their own and their students’ future.

Second, the underlying principle of FW is to approach a problematic situation, generate visions for the future, and discuss how the visions are to be implemented; future workshops are likely to surface innovative and creative, but also realizable computing use domains in the classrooms.

Third, evolvement of ‘teach cases,’ which is an abstract description of an activity that can be supported by, or made possible through the use of a specific computing artifact. A ‘class’ or a ‘course’ consists of a number of activities with specific purposes, such as information searching, presentation, documentation, validation, etc. Each of these activities can be supported by one or many computing technology artifacts, such as e-mail, presentation software, word processors, groupware, etc. It is important to emphasize that teach cases focus on processes, or activities, that take place in education, and on products, that is, computing technology. This means that the content of the activity is subordinate. In contrast to most research and suggestions, the focal point in this research is not the subject taught in the class, but the type of activity that is going on.

Below is a tentative suggestion of two teach cases. It should be emphasized that the two examples are not the result of future workshops, but from my own experience with teaching and reflection over the application of CT to improve and enhance the learning process.

**Example I - ‘Opening Discussion’**

The first example is opening discussion where we have an activity, discussion seminar, and we have a technology, Group Support Systems (GSS). GSS are general-purpose collaborative problem solving tools and usually based on a network of personal computers. All participants in a GSS session can ‘talk at once’ and the session can be followed on each computer and often also on a large public screen. All contributions become part of an electronic script. As all participants have an equal opportunity to contribute, strong personalities will not be dominating the meeting, and the more quiet participant is able to be more active.

For the purpose of discussion, one feature of particular interest is the option of being anonymous. Using this option, the class can discuss more controversial or unpopular issues without the fear of being exposed. Applying GSS in an opening discussion encourage students to participate if they desire to remain anonymous. This is an example of a teach case where computing technology facilitates the necessary conditions. From my own experience, I see many courses where this teach case could have been a very viable point to start a discussion. I do not believe full time anony-
mous students is a good idea, however, I do believe being anonymous in the opening discussion is feasible to surface the important issues no matter the content discussed.

Example II - 'Decision Making'

In the second teach case emphasis is on the decision process. Whereas the first case utilized existing software this case involves the design and implementation of a multimedia tool where a group of students interact with the tool in a decision making task. A scenario is presented to the students and they follow the scenario as it evolves and make decisions related to the scenario. The context for the scenario can be any context where decisions made now will have consequences in the future. For the students, some decisions are possible to regret, but most of them are not, all in line with reality. This type of tool provide the teacher with an opportunity to introduce decision making problems related to the specific subject discussed. Examples are environmental issues, the long term effects of pollution and social programs, such as housing and education.

Concluding Remarks

The motivation for this research is the fact that a large number of schools in Sweden have an advanced infrastructure of computers and networks. However, this infrastructure is poorly utilized by teachers. To change this, it is stated that a traditional solely expert driven approach is likely to fail. A more teacher centered approach, future workshops, is therefore suggested. User participation is a means of reducing resistance to the change process. It is postulated, that close expert and teacher interaction, i.e., future workshops, will result in innovative and creative ideas and design of computing technology use in an education context. These ideas and design will be communicated as good examples of CT use and serve as catalyst for other teachers.

ADULT EDUCATION AND COMMUNICATIONS TECHNOLOGY: SYNTHESIS FOR THE FUTURE

Kurt P. Dudt
Indiana University of Pa.

Gary J. Dean
Indiana U. of Pennsylvania

Curien (1995) states that we are entitled to ask whether the gathering, processing, and dissemination of enormous amounts of information is essential to our well-being. The answer is obvious: we must not only embrace the information age but be able to control its direction and future. Curien's question is underscored by several irreversible processes. First, technology is here to stay. There is no turning back to simpler days of blackboards and flip charts. Second, technology will continue to develop at an increasing rate of change. Third, there will be more applications of technology in all areas of life, including, work, home, and recreation. One result of these processes is that educators must begin to incorporate the use of technology into their practice so that they will not become increasingly marginalized in society. Examples of these processes include the increased uses of personal computing, both at home and in the workplace, the increasing popularity of the Internet, and the increasing uses of technology in entertainment.

Instead of embracing the use of technology many educators and educational institutions appear to resist it. The lecture mode is still dominant in colleges and universities. Public schools continue to be dominated by traditional classroom settings. Adult education often revolves one-on-one instruction and the use of technology is seen as intrusive.

The purpose of this paper is to describe the origins and development of a graduate program in which adult education and communications technology are synthesized. First, the development of adult education and the incorporation of technology into that development is described. Second, recent developments in the use of educational technology is addressed. Third, the conceptual basis for the curriculum is outlined. Fourth, the basis for the new graduate program as defined by a needs assessment is presented. Finally, the curriculum itself is described.

Adult Education and the Use of Technology

Recent years has seen an increasing amount of activity in the field of adult education. Not only has the field grown in terms of its research and literature base but also as a field of practice (Houle, 1991). Adult education is practiced in a wide variety of settings. Apps (1989) provides a framework for describing the many settings. He notes the existence of adult education in several different types of funding situations. First are tax supported institutions such as public schools, colleges and universities, the cooperative extension service, and libraries and museums. Second are nonprofit self supporting agencies and institutions such as religious institutions, health care agencies, community-based agencies, service clubs, voluntary associations, and professional associations. Third are for-profit organizations such as correspondence and proprietary schools, consultants, training in business and industry, and conference centers. The fourth category is described as nonorganized and consists of family and leisure learning that is usually self-directed.

With adult education occurring in so many different arenas, it is not surprising that the use of technology is becoming increasingly important in the field. Technology is being used in several different ways. First, it is being used to enhance instruction in traditional classroom settings; second, it is used as a substitute for traditional classroom instruction and third, it is used to provide distance education opportunities. In the first scenario technology is used to enhance traditional classroom instruction. In this case the use of media such as video, presentation aids (such as overhead projectors), and computer aided presentations are used to supplement the face-to-face instruction. In the second scenario some technologies have been found to be effective in lieu of face-to-face instruction. Examples include the use of computer assisted instruction and guidance (such as programs for career exploration and some training programs) and the more recent applications of interactive multimedia. The third scenario includes the applications of technology to provide for learning opportunities where face-to-face instruction is not possible. Garrison (1989) describes distance education as consisting of three criteria: commun
cation among teachers and students occurring noncontiguously, two way communications, and technology used to mediate the communications process. Garrison's last point is significant as it shows the increasing importance of technology in distance education for adults.

Recent Developments in Communications Technology

There are several recent developments in communications technology which have applications to adult education. First is the development of the personal computer with enough memory to use multimedia allowing for interaction with the computer. No longer is the learner passive—he/she can direct the learning process. The computer can be used with authoring languages, windows, HTML, and other software packages which easy programming. This was not available a few years ago. One application of the personal computer is the use of interactive multimedia which is defined as the computer-controlled integration of text, graphics, still and moving images, animation, sounds, and any other medium where every type of information can be represented, stored, transmitted, and processed digitally (Fluckiger, 1995, p. 5).

According to Clark (1996, p. 4) the Internet is the most comprehensive medium ever developed. She points out that people can communicate easily and inexpensively with others anywhere in the world. In addition, with the new developments of Internet video conferencing, real-time digital audio, and real-time Internet-wide document sharing, the list of potential uses is growing every day (Clark, 1996, p. 4).

The development of computer technology has not outdated the use of more traditional media such as audio, graphics, photography, and video. These media can still be effective educational tools and have their role in classroom and other more nontraditional instructional settings.

Conceptual Basis for the Graduate Program

The graduate program is an attempt to meet the educational needs outlined in the two sections above. Combing instruction in the use of communications technology with a foundation for practice in adult education can help prepare educators and trainers to be fully participatory in the new educational environment. Educators and trainers of adults must be conversant in a number of fields to be fully effective. Traditional graduate programs in adult education have taken the approach of providing process knowledge which is added to a student's existing store of content knowledge. In this approach, graduate students in adult education learn how to teach what they already know. The missing link for most of these graduate programs in adult education is the emphasis on the incorporation of communications technology into the curriculum. This program accepts the process knowledge emphasis, but with a twist. It is acknowledged that the field of training and development is becoming increasingly responsive to two trends: first, there is an increasing use of technology in training, and second, there is an increasing use of generalists as opposed to content experts as trainers.

A second basis for the new program comes from the disciplines of adult education and communications technology themselves. Both are applied fields which have as an emphasis the application of learning principles to educational settings. The commonality between the fields include instructional design, the application of adult learning theory, the integration of the use of technology into classroom instruction, and distance education.

Needs Assessment for the Program

In order to substantiate the need for the new program a two part needs assessment was conducted. The first part addressed the needs of students and the second part addressed the needs of potential employers.

The student needs assessment demonstrated that undergraduate Communications Media students at Indiana University of Pennsylvania had a strong interest in graduate study. One-hundred-seventy-four (84.9%) of those surveyed indicated a moderate to strong interest in pursuing graduate study. This is indicative of the fact that as undergraduate students they learned how to create and develop various technologies, but were not exposed to the educational milieu in which the media are applied. Many of the students perceived that graduate school is an opportunity to expand their career options by obtaining such an education.

A second survey, also of undergraduate Communications Media majors, indicated that 86.4% (n = 32) of the students had a moderate to high interest in the new program that was being proposed. In addition, 81.8% of the same sample indicated a moderate to strong likelihood that they would enroll in the program. Furthermore, 94.5% of the sample stated that they felt the new program presented good career opportunities.

A survey was also sent to employers in western Pennsylvania to determine the extent of employer interest in graduates of the proposed program. Surveys were sent to 200 employers obtained from lists used for internship sites for undergraduate Communications Media students. A 96% (n = 192) response rate was obtained. The following results were obtained: 58.8% (n = 113) stated that they would consider hiring a graduate of the program if they had an opening, 14% (n = 19) indicated a high probability of having an opening in the next year, and 60.9% (n = 117) indicated that they would be willing to host an intern from the program. It should be noted that the number of employers indicating the possibility of an opening is high for the economically depressed area of western Pennsylvania.
These needs assessments demonstrated that there would be a sufficient supply of students for the program as well as employment opportunities for graduates of the program. This laid the foundation for developing the curriculum of the program which is outlined in the next section.

**Adult Education and Communications Technology Curriculum**

Based on all of the information reviewed in preparation of the program proposal including the review of the relevant literature in both adult education and communications technology, the needs assessment, and the expertise of the faculty proposal developers, the following purpose statement for the program was developed:

The purpose of the program is to help students acquire knowledge and skills in theory and research in adult education and in the applications of current and emerging production technologies. Upon completion of the program, students will be able to: Understand and apply the dynamics of adult development and learning theory to the design and implementation of educational programs and media selection and use. Develop needs assessment procedures to make decisions regarding educational programs and media use. Develop goals and objectives for the design of educational material and the selection and use of media. Develop plans of action for educational programs and the use of technology. Select, design, produce, and evaluate target media. Develop formative and summative evaluation procedures for educational programs and media selection and use. Design educational experiences using instructional design and other systematic approaches. Conduct meaningful educational experiences using appropriate adult education methods. Manage and administer educational and media programs and events.

The program consists of a thesis and nonthesis option. The thesis option consists of 36 semester hours and the nonthesis option is 33 semester hours. Following is a description of the core courses in the program:

**The Adult Learner:** A survey course of adult development and learning theory with applications for the design of adult education programs.

**Program and Process Development:** This course addresses the development of educational programs for adults including conducting needs assessments, administering program activities, and program evaluation.

**Organization and Administration:** The following topics are addressed in this course: organization theory, leadership and management issues, and resource acquisition and management.

**Facilitating Adult Learning:** Students learn and practice instructional techniques such as making presentations, group techniques, and conducting classroom instruction.

**Instructional Design and Development:** This course emphasizes the use of instructional design processes to plan and evaluate educational programs.

**Media Production:** Students learn to design and create instructional video programs and slide-tape presentations using computer presentation programs such as Powerpoint.

**Instructional Computing:** This course examines creating of WEB pages, learning to use and apply authoring languages, and exploring the educational applications of the Internet and the World Wide WEB.

**Multimedia Techniques:** Students learn how to integrate and apply text, graphics, images, and sound into educational programs.

**Seminar in Technology and Adult Learning:** This is a capstone course for the program in which the application of technology in adult learning situations is explored. Distance education is an emphasis for this course.

In addition to the courses listed above, students have the opportunity to take up to six credits of electives. An internship option is also available so that students can acquire actual job experience prior to graduation. This program required substantial capital investment prior to implementation. Substantial investments must be made in video technology (e.g., studio equipment, editing equipment, and remote equipment), computer software and technology, and audio recording equipment.

The program is currently in its first year of operation. There are a mixture of students in the program. Some are just out of undergraduate programs and possess limited work experience. Others are returning students who bring substantial professional experience. This mix has been an advantage to the program since students learn from each other. The general impression at this point is that students are excited by the new program and the potential career options open to them.

Computers are allowing teachers from all disciplines to develop project based curriculum that encourages higher order thinking and cultivates classroom community. One no longer needs to be a programmer, scientist, or technician to feel comfortable using computers. Graphical user interfaces, simulation software, the World Wide Web, and intelligent agents have brought the power of computing to a wide range of people working in a myriad of disciplines. Today, the “lessons of computing... have little to do with calculation and rules; instead they concern simulation, navigation, and interaction” (Turkel, 1995, p. 19). Sociologist Sherry Turkel asserts that we are in the midst of a shift from a culture of calculation to a culture of simulation (Turkel, 1995, pp.19-26). For computer-using educators, the shift to a culture of simulation has promoted a hands-on, project-based, or “constructionist” approach to teaching (Papert 1993, pp. 137-156). Instead of being the object of study, computers are used as a powerful tool for enhancing, developing, interpreting and creating content.

This project-based approach facilitates the integration of technology across the disciplines. The Isidore Newman School in New Orleans is currently implementing an ambitious technology plan that includes integrating technology across the K-12 curriculum. In addition to these efforts, Newman has an academic computer department of six computer teachers who teach programming and applications courses in the four school computer labs. This paper focuses on a lesson developed within Newman’s computer department and explores the way the lesson has been adapted to meet the needs of other departments and disciplines.

Background — Technology Implementation in the Newman Curriculum

Newman’s computer department is committed to adding a focus on applications and the Internet to the traditional programming and keyboarding computer curriculum. Focusing on applications and the Internet has created new opportunities and challenges. As the focus of instruction moves away from computers per se, and towards what computers can do, computer teachers have had to develop curriculum that extends beyond the field of computers. Computer applications courses at Newman use technology to address the political, sociological, musical, artistic and literary imaginations of Newman students. Computer teachers are able to explore topics that do not fit neatly within the general curriculum, thereby filling gaps in instruction and exploring nontraditional topics.

Although many topics are covered, department head Dale Smith has placed a strong emphasis on using the applications courses to encourage students to think critically about the social and cultural implications of technological change. In addition to learning to use applications, students grapple with issues specific to individuals entering a culture of simulation at the end of the second millennium. The following lesson was developed as part of my tenth grade applications course. The lesson focuses on Sociology, a discipline that is not traditionally part of the High School curriculum and addresses issues of identity that are specific to the information age. In this case study, the computer department served as a testing ground for a lesson that would later find its way into the history curriculum. Thus, the lesson typifies the Newman Computer Department’s efforts to address nontraditional topics, integrate technology across all the curriculum, and prepare students to live and work in an emerging culture of computer simulation.

Virtual Worlds in Tenth Grade Applications

Multi-user, real-time, interactivity in three-dimensional virtual worlds is now available on the Internet. Access to these worlds is becoming available to a broad range of educators and has the potential to radically change pedagogy. Yesterday’s science fiction is beginning to find a place in today’s classrooms. It is imperative that the next generation of educators be acquainted with the three dimensional frontiers of cyberspace. Before addressing how this technology could be used across the disciplines, I will focus on the opportunities this technology has created for exploring personal identity and social justice as part of the tenth grade applications course. Participants in virtual worlds invent complex and nuanced fictional identities and interact with other people...
without revealing their real life identities. Working in pairs, the students created a sociological profile for their character that included the social categories they felt to be most important. This exercise provoked discussion about race, class, gender, geography, sexual orientation, and age. Students struggled to imagine themselves living a life and inhabiting a body very different than their own. They were challenged to explore unfamiliar perspectives and question their own cultural and moral presuppositions.

Two 15-year old girls decided to become a 9-year-old boy named Mohammed. Mohammed was a precocious little boy who communicated on the Internet from his home in Alaska. Two prep-school boys decided to become a self-professed “redneck” car mechanic. The mechanic often initiated conversations about hunting, fishing, and camping. The cast of characters included a dentist from Boston (unsure about his sexual orientation), a French quarter waitress with a penchant for Voodoo, a Japanese-American film animator working in San Francisco, and an African-American premed student at Stanford University.

Using a Virtual Reality Modeling Language (VRML) browser, my tenth grade students were able to enter 3-D, multi-user worlds and interact with other people under their assumed identities. First, they picked out a 3-D virtual body, called an avatar, that became the visual representation of their character. Then, they created a “public card” that contained information about their character that everyone in the virtual world could access. The body and card express the identity that was elaborated in the sociological profiles. Once the character has a body and a public card, she/he is ready to venture out into social space to interact with others. The students searched the virtual world for other avatars and engaged in lengthy real-time conversations with people from around the world. Students used these interactions to develop, explore, and further elaborate their virtual identities.

Students often had conflicted feelings about their experience in cyberspace. One student described a feeling of freedom “being able to put my identity and problems aside and go inside someone else’s body.” Yet, many students who cast a positive light on the experience could not help but feel “a little guilty” deceiving an “innocent participant.” This feeling was particularly acute when a virtual character was real? He would be so offended.” Another student found that male characters would aggressively seek out conversations with female characters. She noticed that when a “guy knew he was talking to a girl he would definitely treat me differently.” This experience helped her realize “just how prejudiced people can be.” Although each student drew different conclusions from their experiences, they shared one commonality. As fifteen-year old humans, they were all in the process of developing their real life adult identities. Exploring virtual worlds gave them the ability to play with different identities and contemplate the larger social ramifications that identity choices entail.

Virtual Worlds Across the Curriculum

History

It can be difficult for teenagers to understand sociology and psychology because of their limited life experience and the theoretical nature of the disciplines. VRML environments allow students to put abstract disciplines into concrete
practice. The practice of inviting students to participate directly in educational worlds can be used effectively across the curriculum. I am currently working with the chair of the History department to use Virtual Worlds as a tool for exploring American History. His class has engaged in an in-depth study of President Andrew Jackson. In addition to using textbooks and discussions, Dr. Cowett's students conducted research on the Internet and worked with one of Newman's Technology Coordinators to create interactive multimedia presentations about Andrew Jackson.

Using Virtual Worlds allows Dr. Cowett's students to stop studying Andrew Jackson and actually become him. This creates the opportunity for students to shift perspectives and become the object of their study. Students from several sections of American History will take turns using the classroom computers to role play President Jackson as he engages in critical debates with on-line companions. This means that there will be an on-line historical interpreter available on the Internet several hours each day which will serve as a resource for history students and teachers around the world. It will be possible to discuss politics with a virtual Andrew Jackson being role played by the knowledgeable American History students at the Isidore Newman School. Dr. Cowett will receive transcripts of the dialogues in which his students engage, allowing him to evaluate his students learning processes and fine tune his Andrew Jackson curriculum.

**Sciences**

History is certainly not the only discipline that 3-D Virtual Worlds could impact. On the not-so-far-off horizon, Biology teachers will be able to use this technology to navigate 3-D simulations of cells, organisms, or ecosystems. Computer-based alternatives to dissection have already become widespread. Unfortunately, these current simulations replace a 3-D organism with 2-D diagrams. VRML Worlds can solve this problem by modeling organisms in 3-D space. Students will be able to journey into a frog's stomach or travel through a cell's membrane to get a closer look at a mitochondrion. Best of all, students will be able to explore that same frog or cell simultaneously. That means that they can "meet" at the frog's pancreas to discuss enzymes or at the cell's membrane to discuss osmosis. Indeed, Biology teachers will be able to give guided tours through biological entities that were previously represented by flat diagrams in textbooks. In this instance, computer simulation provides more than a humane alternative to dissection. VRML simulations have the potential to allow students to see the invisible, travel through microscopic worlds, and participate in unparalleled distance learning over the Internet.

**Literature, Foreign Language and Beyond**

I can imagine English classes writing and performing collaborative plays in elaborate and globally accessible virtual theaters. Foreign language students could speak French at a sidewalk café in a Virtual Champs Elysee or take a tour of a Spanish Church led by Catalan High School students. Inviting students to participate directly in simulations can be an effective tool in almost any discipline. Indeed, we may soon participate in academic conferences that take place entirely within 3-D cyberspace.

**Conclusion**

Virtual Worlds have allowed students in computer applications courses to explore nontraditional topics (sociology, social justice) and address perplexing issues that face citizens living in a culture of simulation. The technology that facilitated their exploration was first used in the computer department but is spreading to the History department and has the potential to enrich other disciplines as well. This provides one model for how a computer department can be used as a testing lab for ideas that can enrich other disciplines. More importantly, I have attempted to illustrate methods for using computers to help students actively participate in constructing their own knowledge and exploring their personal and moral selves.

jonah@well.corn
Questions: 1. What is the state of educational technologies (by whatever name!) programs in American and Canadian universities? 2. What kinds of undergraduate offerings and requirements are there? 3. What do the graduate programs look like? 4. What markets are being served? 5. What does it take to offer a credible graduate program? 6. What does the future look like?

In the Summer of 1996 we had answers to none of those questions, but, fortunately, one of us was due a sabbatical leave and the other took early retirement, so we were in a position to visit universities and to develop some at least tentative answers. The choice of universities certainly had no scientific basis, and there are important programs that we know of that we missed. Since we traveled in our Cessna T210, weather was, of course, a factor. Some we didn't visit because we had been there before. Others we just couldn't schedule. Nonetheless, we were able to visit 12 universities with active educational technology (or instructional technology, or some other name) programs. They were, in order of our visits, Utah State, Western Washington, Alberta, Michigan State, Indiana, Penn State, Virginia, Georgia, Florida State, Vanderbilt, Houston, and Texas (Austin). The cooperation and courtesy we received from the faculty, staff, and students at each of these universities was extraordinary and refreshing.

We prepared in advance a questionnaire so that we could collect comparable information from each university. In addition, we asked other questions that occurred to us as a result of things we had learned. We report here some of our findings and some observations.

*ET=Educational Technology, IS=Instructional Systems, IT=Instructional Technology, C=&I=Curriculum and Instruction, IST=Instructional Systems Technology, EPsy=Educational Psychology, ED&HD=Education and Human, ID=Instructional Design

Core Graduate Faculty Size and Number of Students

Faculty ranged in size from three full-time core faculty to 10 full-time plus two adjuncts or 9 full-time plus four adjuncts. Master's candidates ranged from 12 to 200+. Ed.S. candidates ranged from none to 28. Doctoral candidates (excluding Western Washington, which does not offer a doctorate) from 3 to 166.

Technologies Requirements for Undergraduates

Most universities require three semester hours in educational technologies for undergraduates, but the requirement ranges from none to 15 hours. It is common to find that graduate teaching assistants are responsible, under faculty direction, for the teaching of undergraduate courses.

Markets Served

Some universities serve only the traditional education market. Some serve predominantly the industry/military market. Several serve both markets approximately equally.

Observations

We aren't prepared to call anything in this section "conclusions", for our data collection was not scientific enough for that, but we feel reasonably confident that these...
"observations" add to the knowledge of educational technologies programs. Some of the observations are derived from findings summarized above, but others are taken from informal data.

1. What is the state of educational technologies programs in the American and Canadian universities? Programs vary greatly in size, theoretical orientation, markets served, and emphases. Nonetheless, we were greatly impressed with the knowledge, enthusiasm, and effectiveness of the faculties and with the quality and enthusiasm of students wherever we went. We frankly observed no weak programs. Of course, there were some practices that we questioned, but we believe that the profession can be very pleased with the present state of graduate programs in educational technologies.

2. What kinds of undergraduate offerings and requirements are there? Almost all of the universities had at least one required course in educational technologies for undergraduates. Two universities had tried having the responsibilities for technologies preparation split among various methods courses on the assumption that the applications would be more immediate. However, faculty from both the universities indicated that the effort was not effective. It seems that faculty in those methods courses had very different competencies from each other in educational technologies and different commitments to technology inclusion in their courses. Further, it was difficult to assure that all areas were included and that there was not inappropriate redundancy. It seems that the most effective approach at present is to have at least one required course in educational technologies for undergraduates, with further application included in other methods courses. Ideally, of course, effective use would be modeled in all courses.

3. What do the graduate programs look like? All of the programs visited except Western Washington offered a doctorate. The educational specialist degree, offered in some universities, was not widely used except at Georgia, where the State requirement for a technologies coordinator in each public school makes the Ed.S. an attractive degree.

The number of credit hours required for the master's and doctoral degrees does not vary greatly, but the amount and kinds of technology courses varies substantially. Some derive theoretical support in such areas as learning/development and measurement/research methodology from other courses and faculty, while some attempt to include that support in technology courses. It is clear that there is no consensus concerning the amount and mix of technical, theoretical, and research preparation.

4. What markets are being served? Although some graduate programs make no attempt to serve any market other than the traditional k-12/higher education market, others serve predominantly the industry/military market. It is common to serve both markets, and the mix is fairly even. In general, and predictably, the industry/military market outbids the education market.

5. What does it take to offer a credible graduate program? We visited some large programs with very substantial resources, but we were particularly interested in what minimums were necessary in order to offer a credible, quality program. Certainly, a program need not be large to be effective, but a certain critical mass seems necessary.

It seems obvious that a program must have administrative support, but a further necessity is consistent administrative support. It takes time to build a program, but it takes almost no time to destroy one. With the rapid turnover in administrators, we have become aware of very strong educational technology programs which have been severely damaged or destroyed by a change in administration. It seems that the only protection a program has from that possibility is to become so strong in terms of community and university support that it is, at least to some degree, immune from the vagaries of administrative change.

The faculty needed to offer a credible program depends upon the market(s) to be served. We believe that either the education or the industry market can be served in a relatively small program, with a core educational technologies faculty of three. Both markets can be served by a faculty of four. In either case, at least one subspecialty should be in instructional design and one should be in networking applications. The education market should have a least one faculty member who concentrates on k-12 applications, while the industry market should have at least one who specializes in business applications. One faculty member should have a technical (programming/analysis/engineering) strength. All of this assumes that the "core" faculty is well supported by strong faculty support in learning/development, measurement/research methodology, and other areas.

Laboratory support, both hardware and software, must be designed specifically for instructional purposes. Open access labs are designed differently for different purposes and do not serve at all well as instructional labs. A separate high-end lab for production purposes is highly desirable.

The program should also have adequate technical support. Faculty, no matter how well qualified, cannot reasonably be expected to use their time that way.

There must be support for graduate students. The ideal support is involvement in instruction/research in the educational technologies program or as development assistants.

6. What does the future look like? It seems clear that there is a substantial and growing industry/military market. The education market, however, is quite mixed. While Georgia, for example, is supporting k-12 educational technologies quite effectively with lottery and other moneys, other places are continuing to cut both k-12 and higher education budgets. For business, funding is called investment; for education, it's "throwing money at the problem."
The quality of students in the programs we visited seems very high, and students seem quite enthusiastic, so it is reasonable to expect the professional area to do well in the sense that we will have good people in charge. The only internal danger that we perceived was an apparent lack of respect in some places for those having differing theoretical orientations. Both of us have most of our professional preparation and experience in the field of reading, and both of us have watched reading damage itself seriously, and damage hundreds of thousands of children in the process, while whole language advocates and direct instruction advocates lobbed bombs at each other from their adopted extreme positions. There is some danger that educational technologies will do the same, as constructivists and systematic instructional designers choose up sides, neither willing to respect the contributions of the other, and both requiring 100% agreement in order to accept others into the chosen camp. Use of aspects from the opposing camp is viewed as heresy, i.e., compromising with evil. It’s a bit disturbing to find that some doctoral students know that they are opposed to a camp, but they don’t know anything about it. Knowing that there’s an enemy, but not even knowing anything about the enemy is what happened to reading. Unless educational technologists can recognize that there are valuable contributions from those with whom we may have disagreements, we could go the way of reading. There are those who seemingly wish to align everyone with one camp or another. Fortunately, there are many who are willing to search for solutions to problems without the constraints of ideological bias. May they prevail.

In general, we are quite impressed with what we have seen. We therefore are pleased to observe that the future of educational technologies is quite bright.

Ken Smith is a professor in Educational Psychology and direct the graduate program in educational technology at the University of Arizona. His address is 13600 N. Como Drive, Tuscon, AZ 85742.

Barbara Smith has taught in both K-12 and higher education and recently retired. Her address is 13600 N. Como Drive, Tuscon, AZ 85742.
This paper discusses the potential uses of distributed Virtual Reality (VR) in education and training. Although a new technology VR has many applications in the near future given the rapid increase in computing technology. In this paper the authors develop a classification system for VR and use it to explore the potential applications of VR and distributed VR. Some state of the art technology in the VR field and related fields is also explored. The potential applications to student and teacher training are examined along with the development problems that must be solved. Two examples, the use of VR in engineering and earth science training are explored in detail.

Virtual reality (VR) is a rapidly developing technology that has many potential applications from entertainment to warfare (see for example Aukstakalnis and Banner, 1992; Rheingold, 1991, and Sims, 1991). One of the most important applications is in training and hence it has direct relevance to both student and teacher training, or will have in the near future, given the current rate of advances in computer technology.

The key ability inherent in VR is the ability of the user to fully visualize a product and integrate, primarily through visual means, a large number of inputs. Until recently a human, a three dimensional being, had to use two dimensional instrumentation to assess and control a three dimensional world. With VR this is no longer the case.

Virtual Reality: Its Principles and Classification

VR is mostly thought of as a pure visual technique. This is not necessarily the case, under it's widest definition Virtual Reality is a method for providing visual, and/or aural and/or tactile inputs which provide an artificial reality for the subject/operator in which relevant information can be displayed and/or manipulated. VR can be used both for display of data and control of the environment or equipment. Control and manipulation of the VR environment can be via manual, visual, tactile or physiological means. In order to understand the types of VR the authors have developed a classification scheme which can be used to understand the type of system required for a given application. Table 1 details this scheme, which will be used later in the paper. As with all schemes there are exceptions to the classification with many potential subclasses, however the classification does at least show the potential complexity of VR systems.

The prime input used by the brain is visual information. Because humans have binocular vision a three-dimensional picture can be created by providing the brain with two overlapping artificial visual images, allowing for depth effects. If correctly presented the brain will process this visual data to produce a Gestalt or artificial or virtual reality. If touch and aural sensations are combined with the visual output then the Gestalt can be further enhanced. If eye and body motion is tracked, then the output of the VR system can be varied to produce a continuous consistent virtual reality. Visual output is mostly commonly provided by helmet mounted CRT’s or LCD displays relayed to the subject/operator’s visual field via infinity focused optics (as shown in Sims, 1991). Any image output must be stabilized in a variety of ways:

(i) Head stabilized for general observation and selection of parts of the Gestalt
(ii) Surrounding stabilized for presentation of real or virtual control systems
(iii) Space stabilized for superposition of VR images on the real world if required.

Aural output can be used to provide a stereo, i.e. position sensitive, sound input to the subject, and in fact one can think of an aural and tactile based system for training of and use by the visually impaired. Further output can be provided via tactile systems, e.g. piezo-electric vibration or even direct electrical simulation of the skin.

All three methods can also be used to control the system, visual by eye motion tracking, aural input by voice control system, and tactile input via body coverings with appropriate sensors. The detailed requirements and methods associated with VR are covered in many publications (for example Aukstakalnis, and Banner, 1992; Rheingold, 1991, and Sims 1991) and will not be dealt with here. Physiological parameters of the subject/operator can also be monitored and affected if required by VR systems.

The classification scheme developed by the authors therefore covers the range of possibilities inherent in VR technology. A class 0 system is included in which visual non-three dimensional output is provided to the subject/operator. This is included to highlight the current common technology used for display of three dimensional data and virtual tours of facilities etc.

**Uses of Virtual Reality and State of the Art Technology**

To paraphrase a saying, the uses for VR are limited by the imagination. Table 2 lists some of the potential and actual uses for VR technology. The table gives the uses, development status (under development or under advanced development to the best of the authors’ knowledge) and whether a distributed (or linked) VR system is a necessity or just desirable. Finally the type of system that may be required for this application is given using the scheme developed above.

*Note: D=Desirable, N=Necessity*

The technology in VR and related areas is continuously advancing and it is impossible to highlight all current developments or even keep abreast of all developments. Four developments which are at the “cutting edge” will be described. The first two “edge” technologies involve display technology, the third storage technology, and the fourth networks. A current or near term technology with respect to data storage and playback will also be described.

One of the problems of VR has been the need for essentially bulky helmets holding the displays. Much work has gone into reducing the size and weight of such systems. Micro Vision, (Aviation Weekly, 1996) has demonstrated prototype monochrome and full-colour displays that shine images directly onto the retina of the eye. The system consists on a low power light source or sources (red, green, blue lasers are used for the colour system) linked by fibre optic to a helmet mounted mirror scanning system which positions the light at a given pixel position. The prototype system can refresh a 640 by 480 pixel image at 60Hz. This rate is high enough for the eye not to see flicker, the human eye being only sensitive to frequencies up to about 30Hz. In addition a 128 element grey scale has been demonstrated along with 40 degree horizontal and 30 vertical field of view.
Recent work (Downing, et al, 1996; Stocksted, 1996) has shown that it may be possible to create real three dimensional images which can walked round and examined, hence eliminating the need for helmet mounted displays. In this work a block of heavy metal fluoride glass is used. The glass contains traces of rare earth elements which emit visible light when exposed to lasers. Three elements are used to produce red, blue and green light.

The image is created by scanning the block with infrared beams at two different wavelengths. Where the beams intersect the combined energy is sufficient to excite the rare earth elements and produce light. The object can therefore be recreated by tracing the outline and contents using a scanning system. Although the light decay time per picture point, or voxel, is fast (a few milliseconds) the lasers can rewrite the image at 30-60Hz and produce to the eye a "continuous" image. There is however much development required before this becomes an available technology.

New storage technologies are starting to emerge which have the potential to store terabits of data in a small space. Nearly all of these rely on organic-based crystals where the optical properties change following exposure to light of given wavelengths. In most cases two lasers are used to change the properties/state of a few molecules and one laser is used to read the state. Such crystals provide the potential to store multiple images, holograms, or massive amounts of data. Packing densities of about 1 Terabit cm\(^{-3}\) are in principle possible. Readout times can also be extremely fast (Kreuzer & Tschudi, 1993).

One of the potential problems in VR is data transmission rates over networks. Optical fibre technology has developed such that within the near future transmission rates of 10 Gigabits sec\(^{-1}\) will be possible over optical networks, (Chan, 1995).

A current or near term technology is the so-called "DVD" CD-ROM (Bell, 1996) where data is written to a multiple layer CD. This technology gives the CD-ROM the capacity to store up to 17 Gigabytes on a single disc with a data rate capacity of 11 Mbits sec\(^{-1}\). Such technologies, given development, are of direct relevance to VR and it's application.

**Distributed Virtual Reality**

A VR system can essentially be stand-alone with a single subject/operator or can be linked via a common database and/or other systems into a distributed VR system. The common database can either be held centrally and modified if required by each system, or local copies can be used with changes highlighted to the other components of the system. A column in Table 2 indicates whether a distributed VR environment/system is required for a particular application. In some applications it is desirable or mandatory. For example in flight training a distributed VR is desirable, but pilots can be trained individually, whilst for other training it is mandatory where, for example, teams of operators interact in command and control of forces. An example where a distributed VR system would be mandatory is in Air Traffic Control where a three-dimensional visualization of air space needs to be accessed and controlled by many operators.

**Virtual Reality in Teaching and Training**

Given the inherent ability of VR to display three or multi-dimensional properties of objects to an operator, the uses in teaching and training are virtually endless. It must, however, be remembered that it is essentially only a display tool and therefore cannot fully substitute for other forms of learning. It is also obvious given the growing importance and development of VR technology that the VR itself should be taught as a subject.

Being a multi-disciplinary subject it can only be taught at a relatively high level. It should however become a mandatory subject in all information technology courses even if minimum time is devoted to it.

VR systems can be used in a variety of ways in teaching and training. For most purposes only a type 0 or 1 system is required. A class 0 or 1 system can be used to demonstrate concepts to a class by using a fixed sequence in which no changes to the VR database occur. For example, the three-dimensional structure of organic molecules in biochemistry can be explored. This type of system can be PC-based with a CD-ROM. Subjects where interaction maybe required will require better technology. An examples of such subjects include CAD/CAM in engineering. One can envision an instructor leading a class through an exercise and then students working on an individual basis on other exercises. With the exception of single class 0 systems used as demonstrators, a distributed VR system is probably essential for use in teaching.

Table 3 below lists a few potential applications for VR in teaching.

Research — 935
Technology Requirements and Developments Required

For basic tutorial type work the basic technology already exists with PCs and CD-ROMs. For more extensive use, lightweight, cheap helmet-type displays need to be available along with the appropriate computer technology.

One of the key problems in the field may be the development of appropriate software. All manufacturers seem to have adopted their own standard in VR, both for software and hardware. Unlike digital image data the authors are not aware of an international standard such as JPEG, MPEG, or TIFF in the field of VR, although basic VR systems can use simple graphics in JPEG and other standards. The following developments are critical in the opinion of the authors to the application of VR in many fields, not just education:

(i) Cheap Displays (<<£1/$1000 a set)  
(ii) Fast Networks (> MBytes sec-1)  
(iii) Standard Protocols  
(iv) Large Data Storage Capacity >>10 Gigabits

Use in Engineering and Earth Sciences

One of the main uses of VR Technology currently is in CAD/CAM in engineering. One of the hardest aspects of CAD/CAM is to appreciate the three-dimensional nature of design, manufacture and use. Hence the recent emphasis on solid modeling and concurrent engineering. It is not difficult to think of many situations where a manipulable three dimensional image of a product or process is of great value to professionals working on the design, manufacture or use of a product.

A VR system of type 0 or I enables the student or user to view a design/model as if in reality, hence reducing the need for changes later on. A VR type I or higher system would allow the student to manipulate a solid model learning easily the three-dimensional interactions between any part of the design. Similarly such a system could be used in principle to view measured inspection and other test data alongside the original design. As mentioned earlier, a distributed VR system would enable a group of students to work together for joint instruction or individually for exercise. A key element of CAD/CAM use has to be the ability to alter the VR database to input changes, new designs, and so on. The VR system would therefore have to have a direct interaction with appropriate design tools to be an effective system.

Many areas in the earth sciences require knowledge on the three or multi-dimensional aspects of a subject. For example, in geology folded rock structures although understandable in two dimensions are best viewed as in “reality”. Similarly in geography, land use and detailed geography are best understood by use of stereo imaging. VR offers the operator/subject the ability to view in three-dimensions and the ability to manipulate such images to view from any viewpoint.

In both engineering and earth sciences much data is multi-parameter dependent. A suitable VR system would enable multi-dimensional analysis to be performed and viewed in an understandable fashion.

Conclusions

Virtual Reality is a rapidly developing field with many potential applications. It has direct application to teaching and training at many levels. Educators should be made aware of the capabilities and limitations of the technology. Distributed systems are required for its effective use in many areas. Virtual Reality should be taught as part of any information technology course.

Acknowledgments

Both authors acknowledge their home universities which have allowed their interests to expand beyond their formal responsibilities into new areas. MRS acknowledges receipt of UK PPARC funding for his post.

Educators in the field of science are actively pursuing avenues for building scientific literacy and reasoning into the classroom through the use of technology. Several authors describe exciting projects involving students from all grade levels, preservice and inservice teachers, and scientists. Schaverien, Sawers, and Sen begin this section with a discussion of an elementary school teacher education program that uses a virtual elementary school classroom to help preservice teachers develop a generative view of science learning rather than the typical transmissive one. Through the experiences of this program, preservice elementary education teachers experience generative learning themselves and build confidence in their ability to facilitate generative science learning by their future students.

A state-wide project for enhancing preservice and inservice teacher training through the use of technology at the elementary and middle school levels is described by O'Haver, Knight, and O'Haver. A wide variety of technology is infused throughout this project. However, the authors stress the need to avoid rushing "too quickly into the technological dream," recommending instead to "move thoughtfully and deliberately, listening to our colleagues and especially to our students, as they join us in the thrill of discovery and learning."

Snyder expands this theme of preservice professional development to the secondary level of education. She examines the development of science literacy in preservice secondary science and math teachers through active, generative learning activities that utilize the internet and computational aspects of a computer.

Generative learning through science and mathematics activities in the elementary school is explored in the next article. The professional development model described by Buss, Zambo, and Wetzel integrates technology into the science and mathematics instruction of an elementary school district. The success of its implementation is particularly promising for the use of technology as a means to reform science and mathematics instruction away from transmissive to generative, authentic instruction and learning.

Coverdale continues this investigation of generative learning experiences by examining a specific case of integrating instructional technology into the science curriculum. The study's elementary teacher used instructional technology to develop students' scientific literacy through an electronic field trip, facilitating scientific inquiry through collaboration with students across the world. The development of this type of "global classroom" that utilizes authentic, technology-rich experiences is in its infancy. Coverdale's qualitative study adds depth and rich contextual understandings of this cutting-edge movement.

Another professional development program that integrates science, math, and technology is described by Bowman and Davis, but at the secondary level. Teachers explore both technology and new forms of teaching that make use of technology. This program has the added element of teacher input and formative evaluation impacting the direction of the workshops and on-going regional inservice agenda.

The theme of technology-enhanced science teacher education programs is brought into close inspection by Kumar and Altschuld. The contextual variables that impact such programs are the focus of their discussion. Using a context-specific model of program evaluation, the authors evaluated an interactive media elementary teacher preparation project of Vanderbilt University. The findings are quite promising in regard to facilitating appropriate understanding of discovery science and reflective teaching through the use of interactive media-based science methods courses.

Another teacher preparation program that emphasizes the use of computers is described by Orlik. This is a program designed to develop future chemistry teacher's understanding of computers, computer applications, internet applications, and their use in the teaching of chemistry. A specific course, "Educational Informatics for Chemists", is described and discussed in the context of countries such as Colombia, where access to software such as Windows is limited.
The final two articles address the area of scientific reasoning. Leddo describes the development of Internet-based intelligent tutoring games that help develop subject-matter understandings through the use of scientific reasoning. A specific game is featured that develops scientific reasoning in the context of solving detective problems in outer space.

A theoretical discussion of modeling student reasoning completes this section. Leman uses a computer application to represent student reasoning as a subset of expert reasoning to solve a problem. As the learner's reasoning grows closer to expert reasoning, new factors are introduced to the model. The purpose of this line of research is to inform the design of tutoring strategies. As this research continues, Leman's findings will be of great interest to those who, like Leddo, are developing computer-based tutoring games and programs.

As can be seen in this brief overview of the articles included in the science section this year, the inclusion of technology in science teacher education is becoming more sophisticated. We are moving from the perspective of using technology as a means to enrich science teacher education programs to one in which technology is an integral, driving force. Our challenge is to continue this growth towards a new perspective and share our findings as effectively as possible so that all science teacher education programs can benefit.

Jacqueline A. Kemper is an Assistant Professor of Elementary Science Education and Coordinator of the Science Education Program at the University of Houston in Houston, Texas. Her interests include early childhood and elementary science education, science teacher education, and the integration of technology into all science education programs. She may be contacted at the Department of Curriculum and Instruction, College of Education, University of Houston, Houston, TX 77024-5872; (713) 743-4947; Fax: (713) 743-4990. E-mail: jkemper@uh.edu
By identifying the diverse meanings learners have for a range of scientific phenomena, science education researchers have contributed significantly to our understanding of learning as active, idiosyncratic and often unpredictable (for example, Osborne & Freyberg, 1985). Such research findings pose critical questions for educators (designing science teaching strategies which will take account of learners' individuality), and for teacher educators (designing teacher education strategies which will assist individual teachers to take account of their students' personal knowledge).

However, in Australia, as elsewhere, many elementary school student-teachers and teachers not only exhibit a low level of confidence in their ability to learn and teach science but they underrate the value of science in classroom curricula (Cobbin, 1989; Speedy, Annice & Fensham, 1989; Whitehead, Symington, Mackay & Vincent, 1993). So, in educating prospective elementary school teachers to teach science, we confront a daunting challenge: to assist student-teachers to develop a repertoire of sophisticated teaching strategies in a discipline in which they lack knowledge and confidence not only with respect to their ability to learn, but also with respect to their ability to teach.

Thus far, science education researchers have responded to this challenge by investigating the development of styles of teaching which take account of the variation in learners' knowledge and which attempt to deal sensitively with student-teachers' and teachers' prior views (for example, Bell, 1993; Schaverien & Cosgrove, 1995; Segal & Cosgrove, 1992). However, these investigations report limited success with respect to these teachers' increasing confidence or their developing ability to teach science in their classrooms. There is continuing concern (for example, Hurd, 1991; White & Klapper, 1994) that although science education research has done much to illuminate learners' knowledge of the world, it has as yet been largely unsuccessful in developing effective ways by which teachers might be helped to exploit that understanding in classrooms.

In our research group, we think we are making progress both in understanding and addressing this apparent lack of articulation between research and practice. We recognise the need to provide workshops for student-teachers and teachers where they can learn science from carefully constructed curricula and where sophisticated teaching strategies can be modelled for them by presenters. However, we also recognise that student-teachers' participation in such workshops, in the absence of children, appears not to be sufficient to enable them to teach science to children in their classrooms in what are often new ways.

In a recent, sustained professional development and research project (Schaverien & Cosgrove, in press), we successfully complemented such workshops with classroom-based mentoring, as teachers attempted to develop innovative styles of science teaching with their own students. The findings of that project suggest that if teachers are to succeed in adopting innovative science teaching approaches in their classrooms, they may well need assistance to resolve deep conflicts between the values underlying their existing practice and those implicit in the innovation they are attempting. In particular, in order to adopt innovative science teaching approaches in that project, teachers needed to be helped to relinquish their view of learning as occurring only by being instructed. Only then could they perceive learning as generative (after Wittrock, 1974; Minsky, 1985; Edelman, 1992 and Plotkin, 1994), as occurring when learners generated ideas and tested them on their value. The support of a mentor appeared to be critical in assisting such relinquishment. Furthermore, that mentor support, with its sustained and frequent conversations between teachers and the mentor, appeared to contribute, by its very nature, to teachers' developing understanding of generative styles of teaching: it allowed them yet another authentic experience (in addition to the science workshops themselves) of learning and teaching generatively.

Such mentored teacher development, though successful, is slow and labour-intensive. It has prompted us to
consider how we might scale up the mentoring process. This paper will begin by describing the Generative Virtual Classroom, our first attempt to scale up that mentoring process by computer mediation, before turning to a brief consideration of further directions for research and development.

The Generative Virtual Classroom: An Attempt to Scale Up the Mentoring Process by Electronic Means

The Generative Virtual Classroom is intended for use by teacher education students, in diverse locations, individually or in small groups. In it, teacher education students can develop their ideas about science learning and teaching from authentic, pre-recorded classroom learning and teaching events. Once logged in, teacher education students are prompted to choose from a set of available digitised videos of pre-recorded classroom learning events. Having selected those they wish to see, they are able to choose one with which to begin. Of course, they may choose to watch it from beginning to end, following the transcripted text track, or to capitalise on the versatility of this medium to replay particular segments. At any point, if the text becomes distracting, it can be hidden from view. Student-teachers are encouraged to stop to record their views about this learning event, first for themselves, as jottings in no particular order on their notepad, and then to organise their ideas, entering them into a community database for themselves and for others to access. In order to enter them into that database, student-teachers are asked to notice and record particular aspects of the learning events they are watching, including:

1. key ideas these children generate;
2. how these children test their ideas - that is, on what basis they keep or discard their ideas;
3. any progression they think they can detect in these children’s ideas during the video excerpt;
4. any distinctive features of these children’s conversations; and
5. any special insights they themselves might have into these learning events, insights which do not fit neatly into any of the four previous categories they have been asked to note.

Our choice of these particular aspects of these learning and teaching events as focuses for student-teachers’ attention is deliberate. Perceiving and attributing salience to children’s generating and testing of their ideas is the basis of a generative view of learning (Schaverien & Cosgrove, 1996); and attending to the development of children’s ideas and the flavour of their conversations over the course of each event ought to help student-teachers to appreciate the subtlety required of teachers if they are to support such learning effectively (Cosgrove, 1995; Cosgrove & Schaverien, 1994, 1996).

As well as generating and recording their views about these children’s learning, student-teachers working in the Generative Virtual Classroom are able to access this community database to search it for their own and for other student-teachers’ views of learning events. They are also able to access pre-recorded narratives and conversations in which these events are interpreted according to a generative view of learning. They can listen to these narratives and conversations in their entirety, following transcripts, or replay segments as they wish.

So, in the Generative Virtual Classroom, student-teachers can observe authentic science learning and teaching events and use them as a basis for theorising about learning and teaching science. They are provoked to make their own ideas about these events explicit and challenged to think deeply about the value of their own and others’ ideas in explaining the learning they see. Such consideration ought to help them to generate a rich variety of ideas about learning and teaching science from which to select ideas of value, from which to develop educationally powerful theories. Such experience ought also to help them to make explicit and to appreciate the progression, over time, in their own views of learning and teaching, of science and of science learning and teaching.

Further Directions for Research and Development

If this process occurs as we anticipate, we expect to be able to discern research evidence that student-teachers are learning generatively in the Generative Virtual Classroom, through electronically mediated conversations. In particular, we expect to be able to confirm empirically that student-teachers are:

1. gradually relinquishing their typically strongly-held theories of learning as occurring only by being instructed, to develop an appreciation of learning as a generative act;
2. developing, over time, a sense of science itself as the progression of ideas by successive, continuing cycles of generation and distinctive (scientific) testing; and
3. recognising such cycles in children’s science learning and appreciating ways in which they might support them by subtle teaching.

The prototype of the Generative Virtual Classroom which is being demonstrated here is in its earliest stage of development. Its form is the result of our decision to use existing, relatively sophisticated applications, rather than to develop a customised package in a lower level authoring language.

At least four factors were influential in this decision. First, whilst the design of the Generative Virtual Classroom has evolved from well-theorised classroom research, we are yet to evaluate the effectiveness of such computer mediation as this in prospective teachers’ learning. By
developing our prototype in this form, we believe we have been able to retain a certain flexibility: we have deferred committing ourselves too early to particular, critical design features, a commitment which would inevitably have closed off options (some of which we cannot yet foresee) which we might wish to take later. Secondly, we valued the capacity to use the Classroom in a distributed way, such that individual student-teachers could own their notepads but contribute to a community database. Thirdly, we were severely limited in the funding of this prototype, and had to opt for a design which would minimise our need to buy in programming expertise. Fourthly, given the technical difficulties (at the time of development) of handling large video files over the Web and of simultaneously, smoothly and transparently using different kinds of text and video files, we opted for a design which would allow us to achieve satisficing (Simon, 1969) if not ideal solutions. In the meantime, we await software developments which might provide nearer technical solutions than those we have been able to achieve in this prototype. Consequently, though we recognise that our prototype may well be a little less polished than it might have been had we taken another decision pathway, we believe that we are now well-placed to evaluate and refine it.

In the coming year, we intend to evaluate and refine this prototype of the Generative Virtual Classroom through trials of it with small groups of teacher education students. We will study the records these student-teachers make in the Generative Virtual Classroom and record conversations with them about science learning and teaching and about the Generative Virtual Classroom itself. As well, we will observe and converse with them in schools during their teaching practicum, in order to document their developing views of learning and teaching in general and of science learning and teaching in particular. Here, we will be looking for any explicit and implicit relationships between these views and these student-teachers' experiences in the Generative Virtual Classroom. In these diverse ways, we hope to be able to evaluate the salience and the effectiveness for these student-teachers of learning about science learning and teaching in the Generative Virtual Classroom. In essence, we will be hoping to answer the following research questions:

1. whether it is possible, by means of the Generative Virtual Classroom, to mediate and support those conversations between teachers and mentors which we know, from our classroom research, to be critical to successful, innovative science teaching;
2. if it is possible by these means, how we might do so better; and
3. if it does not appear to be possible by these means, what the barriers might be and how we might now try to overcome them.

Thus, we will be looking to this investigation to indicate ways of refining the Generative Virtual Classroom itself. Its development so far has been a generative process for us, too; already, even in advance of its evaluation, we can see ways in which we might enrich it further in the short, medium and long term. For example, as well as adding to the set of digitised excerpts from our extensive archive of research videotapes, we would now like to include a range of commentaries on these learning events from children, parents, teachers and researchers, and an expanded set of links to related materials on the Web. We would like to explore the possibilities of capturing student-teachers' views as audio rather than text files and of supporting email and/or chat between student-teachers using the Generative Virtual Classroom in different locations.

As we have attempted to make clear in this paper, we believe that, through the development of such alternative learning and teaching environments as this virtual classroom for teacher education in science, a new and critically important educational research and development agenda is evolving.

This report describes a state-wide project to reform the preparation and support of teachers of mathematics and science for the upper-elementary and middle-school grades in the state of Maryland. The Maryland Collaborative for Teacher Preparation (MCTP) consists of approximately 125 mathematics, science and education faculty from twelve Maryland public four-year and community colleges, 165 undergraduate elementary education majors, and 90 elementary and middle school mathematics and science teachers from the cooperating Maryland county public school systems. The project is supported by a five-year grant from the National Science Foundation’s “Collaboratives for Teacher Preparation” program, beginning in 1993. We are one of 13 such programs nationwide.

Maryland is a state that does not have separate middle-school certification at the present time; most campuses of the state college system offer an undergraduate elementary education degree; and most middle school teachers working in the state have elementary rather than secondary certification. The MCTP is focused on creating a new teacher preparation program, targeted on upper elementary and middle school grades, reflecting our belief that the challenge of reform in science and mathematics education is especially critical at that level and that there is growing support for use of content specialist teachers with interdisciplinary expertise.

Technology for State-wide Communication and Collaboration

Much of the work of the MCTP is the development or reformed science and mathematics content and methods courses and college faculty development. One of our aims is to build, for the first time in Maryland, productive collaborations that would reach across traditional institutional and disciplinary boundaries of the state educational institutions. Because our participants are scattered over the state, we have made considerable use of electronic networking tools to supplement our face-to-face meetings and to reduce the time and expense involved in phone calls, postal mailings, and traveling across the State.

Interactive Video Network

The Interactive Video Network (IVN) is a state-wide compressed-video teleconferencing system that allows project participants all over the state to engage in real-time multi-way video conferencing from specially-equipped rooms located at each state college and research campus. We used this system extensively for meetings in the early phases of our project, but the high demand for IVN time by regularly-scheduled courses and by other organizations has made scheduling very difficult. We now make less use of the IVN facility and more use of email.

Electronic Mail

Email has been very successful in facilitating day-to-day communication throughout the project that would not have been practical in any other way. It is a constant means of communications between the Executive Director, the Principal Investigators, and the Institutional Representatives on each campus site. All of the participating campuses have access to e-mail, and the Academic Information Technology Services at the College Park campus gives free email (UNIX shell) accounts to any teacher or administrator in the state of Maryland, in public or private schools, who request one.

The MCTP Listserv Discussion Groups

In the summer of 1993 we created a listserv discussion group (MDCETP@UMDD.UMD.EDU) that we hoped would facilitate state-wide communication across our campuses. It has proved to be very successful for those who participate. As of Fall, 1996, there were 111 subscribers to the MCTP listserv, including at least one representative from every four- and two-year college in the project. Listserv traffic averages 30 to 40 messages per month (about 2500 lines per month). In addition to the usual administrative announcements of MCTP activities, the list also shares interesting math and science news, resources,
opportunities, and cross-postings from other lists followed by our members.

Based on an analysis of message subjects lines during 1995 and 1996, the most popular subjects of listserv discussion have been: daily class journals from introductory science classes; conceptual assessment questions; faculty development; the development of a "capstone" course; alternatives to lecture; and student attitudes towards new pedagogy; and discussion of specific content issues. Several faculty have posted regular updates on their ongoing MCTP courses - observations, student journals, experiments, student handouts. We continue our efforts to find exciting discussion topics that will stimulate a wider and more substantive participation from the MCTP participants.

A significant aspect of the listserv discussion is that everything is archived automatically by the listserv host computer (this is a standard feature of listservs) and can be accessed after the fact. The MCTP research group uses the listserv archives for research purposes.

The MCTP listserv list is viewed primarily as a faculty participant discussion group, even though students are invited to join. In addition to that list, we have also set up a student listserv list (MCTPINT@UMDD.UMD.EDU) that is intended primarily for student discussion (although faculty are free to join also). So far, the student list has had fewer participants than the faculty list. It is busiest in the summer, when many of our students are at their summer internship sites scattered all over the state and use their list to "check in" regularly. Both of our listserv lists are operated on a autonomous subscription basis.

In addition to the MCTP listservs, an increasing number of MCTP participants subscribe to other listserv lists in their areas of specialization (e.g. National Council of Teachers of Mathematics, Chemical Education, Physics Education, etc.) and actively participate in those forums. MCTP people contribute or answer an average of 12 messages/month on the MDK-12 listserv list (MDK-12@UMDD.UMD.EDU), to which 1000 Maryland K-12 teachers and administrators across the state are subscribed.

**MCTP Web Site**

The start of our project in 1993 coincided with the development of the World Wide Web and the introduction of Mosaic, the first graphical Web browser. The Academic Information Technology Services at College Park set up a Web server and began to offer training in Web site construction. By January of 1995, we were able to set up a World Wide Web site for the MCTP project (the URL is http://www.inform.umd.edu/UMS+State/UMD-Projects/MCTP/WWW/MCTPHomePage.html), to be used both internally to facilitate information sharing within the project and externally as a means of dissemination of project information to the wider community.

In addition to the usual "boilerplate" information on the project goals and structure and lists of participating people, institutions, and courses, we have made an attempt to provide collection of useful "resource" material, including:

- A sampling of course materials from some of our reformed courses
- A collection of selected essays on constructivism and education
- Tutorials on various aspect of instructional technology use
- A pictorial presentation of projects from the Summer Internship program
- A description of and an application form for the Mentor Teacher Workshop
- A database of books, reports, papers, software and other material in our collection
- A large collection of hypertext pointers to "Internet Resources for Science and Mathematics Education", which is used as a starting point for Internet exploration.
- Links to the NSF and to the Web sites of Collaboratives in other states.

The MCTP Web site has been growing steadily and now incorporates over 125 individual "pages" (the equivalent of perhaps 300 or so printed pages). Access data during 1996 show that the use of the MCTP Web site has been increasing steadily over time. In Fall, 1996, the MCTP top menu (home) page was accessed nearly 500 times per month. Other highly popular pages on our Web site include the *Science and Math Internet Resource Collection* (over 700 hits/month) and the Chem 121/122 page (over 600 hits/month), and the *Chemistry Internet Resources* page (over 1000 hits/month). The majority of these hits are from outside the university system, suggesting that the Web site is contributing to our external dissemination efforts.

Direct evidence of the impact of the MCTP's "electronic" visibility outside our own organization are the instances in which external organizations cite MCTP and MCTP-sponsored activities on their own sites. These include the Eisenhower National Clearinghouse, the Virtual Schoolhouse, the BBN Copernicus Project, the Benton Foundation, Oklahoma Partners for Biological Sciences, Columbia University, SUNY Potsdam, Marshall University, and the University of Kentucky, among others. A list of hyperlinks to these organizations is kept on our Web site. There have been at least three documented instances in which MCTP course materials on our Web site have been adapted and used by schools in other states.
The Summer Internship Program

Each summer we organize internship opportunities for our pre-service elementary education students that are carefully structured to give them genuine experience the ways that science and mathematics learning can occur in a variety of research laboratories and informal educational settings. Many of the internship projects have a substantial technology component; for example, some students are involved with educational multimedia CD-ROM development and in developing Web sites for the projects. All interns participate in a two-day workshop at the beginning of the summer that includes training in journaling and electronic communication.

Communication Software Distribution

In an effort to increase the number of MCTP college faculty, project teachers, and mentor teachers who have access to email and to the World Wide Web at home and in their classrooms, we have prepared and distributed floppy diskettes for both Macintosh and Windows that contain the freeware and shareware communication software and detailed step-by-step instructions. The free UNIX shell accounts provided to teachers by the Academic Information Technology Services at College Park allow IP network access via the PPP emulator program called "SLIRP"; our software distribution includes the software needed to utilize this method of access. Recently, commercial Internet Services Providers in the area have begun to offer superior PPP access at modest prices.

Electronic Distribution of Workshop Handouts

To facilitate the dissemination of our technology training efforts, we have converted most of our workshop handout materials to Hypertext Markup Language (HTML) format and have placed them on the Web (http://www.wam.umd.edu/~toh/Handouts.html). These include tutorials on e-mail, Internet exploration, Web site construction, HTML, image processing, classroom multimedia production, finding and evaluating information on the Internet, delivering educational materials on the WWW, and downloading Web sites for local viewing.

Software Lending Library

We maintain a collection of computer software of use in science and mathematics instruction that can be borrowed. Many of the programs are public domain or low-cost shareware packages that can be freely copied and distributed; these have been featured in order to demonstrate what can be done even if extensive funding is not available. Many of these titles can be downloaded from our "downloadable software" page (http://www.inform.umd.edu/UMS+State/UMD-Projects/MCTP/Technology/software.html). We have made an effort to locate software that supports a student-centered, "constructivist" view of learning; thus simulations, student tools, and "construction kit" software is favored over simple tutorials and drill-and-practice.

Technology Events

MCTP participants are active in making technology-related presentations at annual state and national educational technology meetings (e.g. the National Educational Computing Conference; the Maryland Instructional Computer Coordinator Conference, and the Governor's Technology Showcase) and in giving workshops that are attended by teachers, students in our preservice teacher-preparation programs, and college faculty. Topics of these presentations and workshops have included: microcomputer-based laboratory (MBL) experiments; science and mathematics software and CD-ROMs; graphing calculators; World Wide Web; field trip to a local elementary school that is a leader in technology integration; live computer demonstrations of interactive mathematics programs; classroom multimedia production; Web authoring; integrating modern instructional technology into the classroom.

The Fairland Connection

Fairland Elementary School is a suburban public school in Maryland that has been making exemplary application of technology in their curriculum. One of their major accomplishments has been the development of a Web site for the publication of student projects (http://www.wam.umd.edu/~toh/Fairland.html) that has won multiple awards on the national level (O'Haver & O'Haver, 1997). The MCTP hosts the Fairland site on its Web server, provides technological expertise, and uses the school as a field trip site for our pre-service teachers and as a site for in-service training of mentor teachers.
Integration of Technology into Preservice Coursework

Electronic Mail and Use of Internet

All MCTP students are expected to obtain email accounts from their respective campuses. Some students are making extensive use of e-mail and Internet in their courses: keeping electronic journals and emailing them to the instructors each week, finding and using course-related Web sites and other Internet resources, and analyzing data they have collected in laboratory experiments. Most campuses have developed training for students in email and WWW access. One of the campuses has set up a listserv for their own students.

Instructional Software in MCTP Courses

In general, instruction in the use of software as instructional tools is integrated into our content courses, rather than being separated out into a “Computers for Teachers” course.

Microcomputer-Based Laboratories (MBL). The most extensive use of microcomputer-based laboratories has been in introductory physical science courses. Motion detector and temperature probes have been the most widely used. The project has purchased several sets of probes and interfaces to loan to faculty in the project for their courses.

Graphing Calculators. The project has purchased classroom sets of graphing calculators, which have been used in several courses across the Collaborative. We have also purchased two Calculator-Based Laboratory (CBL) systems, which are being used primarily in physical science courses.

Spreadsheets. Several courses are using spreadsheets with students in their MCTP classes, particularly in mathematics and physical science classes, for such purposes as analyzing data from the science laboratory experiments; setting up and solving multi-step word problems dealing with atmospheric pollution (http://www.inform.umd.edu:8080/UMS+State/UMD-Projects/MCTP/Courses/PhysicalScience/ClarisWorks.html), and relating the linear dimensions, surface area, and volume of cylinders constructed from paper.

Discipline-specific Software Packages. In various classes, some of our student use mathematics-oriented software, physics-orientated software (a Newtonian mechanics simulation), statistics-oriented software, chemistry-oriented software, a 3D molecular visualization and animation software package, a computer language well suited for novices and some of the modules from a biology simulations CD-ROM. Some of our faculty have even developed custom instructional software for their classes.

MCTP as a Catalyst for the Promotion of Technology in the Participating Institutions and Schools

Integration of technology requires more that the available of technology and training to use it; it also requires that technology successfully compete for “mind share” with many other concerns of daily school life. Through a persistent utilization of technology in many of our project activities, combined with workshops and site visits to help with installation and application problems, and occasional direct purchase of critical software and hardware, we have encouraged our participating institutions and schools to pay more attention to the technological needs of faculty and students. This effort has payed off in improved access to and utilization of email accounts for faculty, students and mentor teachers, increased access to graphical WWW browsers, and more favorable attitudes of our participants towards technology.

Barriers of Effective Technology Application

As useful as it is in our project, email communications is neither universal nor 100% reliable. A few participants in the MCTP project do not use email regularly. In particular, some of our teacher colleagues do not yet have email accounts and most do not have computers at home, thus making access to email inconvenient. Buying computers for them is beyond what we can expect from the grant at the present time. We continue to work on ways to make email more universal in this project. It takes time to develop the email “habit” of regularly checking and using email routinely. One purely technical problem is that the email systems at the various campuses vary considerably, so that it is difficult to provide instruction that applies universally. The details of printing and saving email, and of attaching files and including pre-written text, is particularly troublesome. Participants must rely on local sources of help for such problems.

Participation on our listserv discussion groups is uneven; most of our college faculty participants are subscribed to the main project list, but relatively few teachers have signed up (subscription is voluntary; the project does not unilaterally subscribe people). As is often observed in such settings, a relatively few active subscribers contribute most of the messages and responses; many other subscribers read but seldom respond or originate messages. However, when asked, even these subscribers say that reading the messages of others is valuable and rewarding; they claim that they are “not ready” to participate actively.

A commonly-voiced objection to participation in listserv discussion groups generally is the fear of getting “too much e-mail”. We usually recommend that people...
who subscribe to several active listserv lists switch to
"digest" mode, a feature of most listserv hosts that
concatenates all the messages for one day into one single
message, greatly reducing the clutter and the intertwining
of messages from different groups.

It has proven difficult to get the instructors of our
various pre-service courses to contribute course materials
for posting on our Web site. The problem is not techno-
logical but rather personal; many instructors do not feel
comfortable contributing their personal materials to such a
"public" forum. A more private project-limited forum
would probably be more acceptable but would not serve
the external dissemination function now served by our
Web site.

The objective of all of this is not to use technology for
its own sake but rather as a tool to help us achieve our
more fundamental goals. In the classroom the important
thing is student learning; to the extent that technology can
enhance learning, then it is a good thing. The most
fundamental problem is defining what really constitutes
good learning. If technology can expand what it means to
learn, then there is the ever-present danger that our own
conceptions of learning, limited by our having been
educated ourselves largely in the older less technological
paradigm, will find it difficult to stretch to encompass a
new kind of learning. For this reason we should not rush to
quickly into the technological dream, but rather move
thoughtfully and deliberately, listening to our colleagues
and especially to our students, as they join us in the thrill
of discovery and learning.

AN EMPHASIS ON SCIENCE LITERACY IN PRESERVICE TEACHER EDUCATION

Jill Snyder
University of New Mexico and Sandia National Labs

Science literacy - which encompasses science, mathematics, and technology - has emerged as a central goal of education as identified by Project 2061, the long-term reform initiative of the American Association for the Advancement of Science. The National Research Council (1995) defines science literacy as “the knowledge and understanding of scientific concepts and processes required for personal decision making, participation in civic and cultural affairs, and economic productivity” (p. 22). According to the National Research Council (NRC), a person that is science literate is expected to be able to form questions and find explanations for everyday occurrences; read, understand, discuss, and evaluate articles of a scientific nature; describe, explain, and predict natural phenomena; be scientifically and technically informed about national and local decisions; and evaluate scientific information, arguments and conclusions based on evidence and the methods used to gather that evidence.

Why is a goal of science literacy for all students, for all Americans, important? The reasons may sound somewhat lofty but their importance cannot be disputed. In Science for All Americans the National Research Council contributed the following argument:

Science, energetically pursued, can provide humanity with the knowledge of the biophysical environment and of social behavior needed to develop effective solutions to its global and local problems; without that knowledge, progress toward a safe world will be unnecessarily handicapped.

By emphasizing and explaining the dependency of living things on each other and on the physical environment, science fosters the kind of intelligent respect for nature that should inform decisions on the uses of technology; without that respect, we are in danger of recklessly destroying our life-support system.

Scientific habits of mind can help people in every walk of life to deal sensibly with problems that often involve evidence, quantitative considerations, logical arguments, and uncertainty; without the ability to think critically and independently, citizens are easy prey to dogmatists, flimflam artists, and purveyors of simple solutions to complex problems. (cited in Rutherford & Ahlgren, 1989, p. xiv)

The council concluded that “the life-enhancing potential of science and technology cannot be realized unless the public in general comes to understand science, mathematics and technology and to acquire scientific habits of mind” (Rutherford & Ahlgren, 1990, p. xiv-xv).

Guiding Principals of the Science and Math Standards

The National Science Education Standards (NRC, 1995) and the Curriculum and Evaluation Standards for School Mathematics (National Council of Teachers of Mathematics (NCTM), 1989) were both written by national committees, made up of teachers, administrators, parents, and the business community for the same purpose: to describe what a quality science and mathematics education, respectively, should look like.

The following principles are the cornerstone of the National Science Education Standards: “science is for all students; learning science is an active process; school science reflects the intellectual and cultural traditions that characterize the practice of contemporary science; improving science education is part of systemic education reform” (NRC, 1995, p. 2).

The National Council of Teachers of Mathematics (1989) set societal goals of mathematically literate workers, lifelong learning, opportunity for all, and an informed electorate. Emphasizing that “educational goals for students must reflect the importance of mathematical
literacy” (pp. 3-4), the NCTM also set these goals for all students: learning to value mathematics; becoming confident in one’s own ability; becoming a mathematical problem solver; learning to communicate mathematically and learning to reason mathematically.

Both math and science standards make the assumption that all students can learn. Learning may take place in different ways, at different rates, and at varying depths, but all students should be encouraged and have the opportunity over a continuous and extended period of time to achieve understanding and confidence backed by experience and knowledge. In addition, all students should participate in challenging and interesting learning environments.

Both standards state that the learning of math and science should be an active, not passive, process with students engaged in problem solving, inquiry, decision making, and communication. Some of the verbs used to describe students doing math and science include investigate, question, explore, communicate, describe, read, write, and test. The National Science Education Standards (NRC, 1995) put a strong emphasis on the inquiry process that involves:

- making observations; posing questions; examining books and other sources of information to see what is already known; planning investigations; reviewing what is already known in light of experimental evidence; using tools to gather, analyze and interpret data; proposing answers, explanations, and predictions; and communicating the results. (p. 23)

Davis and Hersch (1981) claimed that the development of science and technology is a source of new mathematical questions. The NCTM Standards (NCTM, 1989) makes the claim that not only has technology provided tools that make many mathematical activities easier, they have also changed the nature of mathematical questions that can be investigated and answered. The National Science Education Standards (NRC, 1995) expound on the relationship between technology and science, stating that “the need to answer questions in the natural world drives the development of technological products; moreover, technological needs can drive scientific research” (p. 24).

Implications for Math and Science Education

The national committees that wrote the two standards documents recognized that central to the goals of science literacy and mathematical power for all students was the creation of a curriculum and learning environment that nurtured and supported the standards and was significantly different from the current educational environment. Science Teaching Standards (Chapter 3) of the National Science Education Standards and the Professional Standards for Teaching Mathematics were written to provide guidance for those people considered vital to the process of mathematics and science education reform - teachers.

The guidelines set forth in Professional Standards for Teaching Mathematics center around two assumptions: “teachers are key figures in changing the ways in which mathematics is taught and learned in schools” and “such changes require that teachers have long-term support and adequate resources” (NCTM, 1991, p. 2).

The following five assumptions are at the core of the science teaching standards (NRC, 1995):

- The vision of science education described by the Standards requires changes throughout the entire system.
- What students learn is greatly influenced by how they are taught.
- The actions of teachers are deeply influenced by their perceptions of science as an enterprise and as a subject to be taught and learned.
- Student understanding is actively constructed through individual and social processes.
- Actions of teachers are deeply influenced by their understanding of and relationships with students. (p. 28)

Both standards give recognition to Piaget’s theory of constructivism, the theory that “human beings acquire knowledge by building it from the inside instead of internalizing it directly from the environment” (Kamii, 1990, p. 22). This theory supports the idea that children are not given knowledge, but, instead, they form mathematical and scientific concepts, science literacy, as they engage in instructional activities that support a problem solving environment (Yackel, Cobb, Wood, Wheatley, & Merkel, 1990). Both standards stress that teachers need to become more knowledgeable of effective learning and teaching theories and practices, recognizing that these practices may be significantly different from those experienced when teachers were students themselves. This fact underscores the importance of ongoing professional development. And, both standards emphatically state that teachers must be provided with support, encouragement, time, resources, and opportunities to make the changes recommended by the standards.

These changes in the teaching and learning environment represent major shifts in current practices including a shift from:

- supporting competition among individual students to supporting a classroom community characterized by cooperation, respect, and shared responsibility;
- presenting or giving knowledge through lecture and the textbook to guiding students in active inquiry and problem solving;
• memorizing and reciting facts and isolated concepts to providing the opportunity and motivation for discourse, debate, conjecture, and reasoning; and,
• acquiring and memorizing answers/facts to understanding, applying, and making connections among concepts.

Implications for Preservice and Continuing Teacher Education

For successful implementation of the math and science standards in the K-12 community, preservice and inservice teacher education must be well thought out and coordinated. Preservice teachers gain knowledge in their teaching discipline through courses they take in college, many of which are taught in a traditional lecture/demonstration style. They also bring with them the teaching models and learning environments that they participated in while they were K-12 students; again, these experiences are usually more traditional than reflective of the changes recommended in both standards.

One of the most influential experiences that preservice teachers have is their clinical experience, which may consist of a one or two semester internship with a K-12 supervising teacher. This experience should be a time when the teaching and learning theories that students have been exposed to in the university environment meet up with trial and application within the K-12 classroom. It should be a time in which preservice teachers are encouraged and supported in their efforts to try out new ideas, learning theories, and teaching practices. The reality of the situation is that, in many cases, supervising classroom teachers are not selected because their teaching practices reflect the recommendations made by the standards; rather, they are selected because they are willing, for a diverse number of reasons, to participate. Therefore, traditional and, often, non-exemplary teaching practices are reinforced and passed from the supervising teacher to the preservice teacher. This underscores the idea that professional development, knowledge about content, students, and effective teaching practices, should be an ongoing activity for all teachers.

The National Education Science Standards (NRC, 1995) and Professional Standards for Teaching Mathematics (NCTM, 1991) recommend professional development standards for science and math teachers, respectively. Common threads run through both sets of recommendations made by the National Research Council and the National Council of Teachers of Mathematics; a few of these are summarized below:

Professional development for teachers of science requires learning essential science content through the inquiry method. Science learning experiences for teachers must involve teachers in actively investigating phenomena, interpreting results and making sense of findings. Experiences must also introduce teachers to scientific literature, media, and technological resources that build on their science knowledge and their ability to access further knowledge.

Mathematics and mathematics education instructors in preservice and continuing education programs should model good mathematics teaching by creating learning environments that support and encourage mathematical reasoning and discourse, using a variety of tools, such as calculators, computers, and physical and pictorial models.

Professional development for teachers of science requires integrating and applying knowledge of science, learning, teaching pedagogy, and students. Experiences should include inquiry, reflection, interpretation of research, modeling, and guided practice to build understanding and skill in science teaching.

Preservice and continuing education of teachers of mathematics should develop teachers' knowledge of: ways to represent mathematics concepts; instructional resources, including technology; ways to promote discourse and a sense of community; and various means for assessing students' understanding.

Professional development activities for teachers of science must provide opportunities for self and peer reflection on classroom teaching and for feedback about their teaching so that teachers may analyze and apply that feedback to improve their practice. Opportunities for collaboration and the sharing of teaching expertise should also be provided.

Preservice and continuing education of teachers of mathematics should provide opportunities for teachers to examine their assumptions about the nature of mathematics, how it should be taught, and how students learn. They should also have the opportunity to analyze and evaluate the appropriateness and effectiveness of their teaching.

Both standards make recommendations concerning quality preservice and continuing education programs and the teacher's role in professional development. The majority of these recommendations call for teachers to become life-long learners themselves, actively participating in experimentation with alternative approaches and strategies, participating in workshops and content related courses, reading and discussing ideas presented in professional journals, discoursing with colleagues about math/science teaching and learning, designing and evaluating professional development activities, and continually assessing the effectiveness and improvement of the learning environment.

A Preservice Education Course With an Emphasis on Science Literacy

In the Fall of 1996 at the University of New Mexico, a learning environment meant to support and enhance the
science literacy of math and science preservice teachers was provided through a course titled Teaching Reading in the Content Area, a course that was once (but no longer) required for New Mexico state certification. Because the enrollment of science preservice teachers was low for the fall semester, the course was offered to a combined group of math and science teachers.

The instructor, an educational doctoral student and administrator of a technology program, NM Adventures in Supercomputing, saw an opportunity to provide preservice teachers with an experience whose main goal was to develop a conceptual and instructional framework for science literacy that could be transferred to the secondary classroom. The objectives of the course were to: define the meaning and goals of science literacy; create lessons, activities, and projects that meet the goals of science literacy; and become science literate individuals.

The two main activities chosen to enable preservice teachers to meet these objectives were participation in a science/math related Internet project and in a computational science project. The activities involved preservice teachers in actively investigating phenomena, interpreting results and making sense of findings. The activities were also designed to introduce teachers to scientific literature, media, and technological resources that added to their science knowledge and their ability to access further knowledge.

The Internet Project

After searching the Internet, discussing strengths and weaknesses of possible Internet projects, and evaluating their appropriateness for the math/science classroom, preservice teachers chose three group Internet projects from the Global SchoolNet Internet Project Registry (http://199.106.67.200/gsn/proj/index.html).

The objective of group one’s project was to design and construct, using specified materials, the smallest parachute possible which had the longest hang time. Participating as students, the preservice teachers had to build and test their parachute and submit their results to a central site on the Internet to be compared with other students’ results. The goal of group two’s project, titled “A World Community of Old Trees”, was to gather and submit information on trees that are important to people. One of this group’s participants described this as a very open-ended project whose purpose was to analyze the types of information received from such a broad request over the Internet. In group three’s project, “Men and Women of Math and Science”, twenty-four classrooms were chosen to participate. Each participating group was responsible for contributing a set of clues to the identity of a man or woman of math or science to the project host school and for identifying the man or woman whose clues were submitted by another participating school. At the host school, this project was being shared by social studies classes who were creating a timeline for the mathematicians and scientists submitted and English classes who were keeping a log of the project.

At the conclusion of the Internet projects, each preservice teacher described their participation in their project, evaluation of the organization and effectiveness of the project, and possible implementation of the project in a 6-12 grade math or science classroom.

The Computational Science Project

Computational science involves the use of computers to investigate and analyze scientific problems. A key step in the process is to represent the scientific problem by a mathematical model. A computational science project should: involve a scientific application; include a mathematical model; and, make use of a computer to investigate, analyze, and interpret the problem.

The preservice teachers, in teams of three or four, were tasked with: selecting a project question, conducting research on the project topic, choosing a mathematical model to represent the phenomena, designing a computational model which implemented the mathematical model, interpreting their results, and giving a written and oral presentation of their findings. Project topics include: the effect of weather on the expected birth rate for a given geographical area; prediction of future solar eclipses; projected number of AIDS cases in a particular state; and, the effect of various limiting factors on a population that has reached its maximum carrying capacity.

This course provided an environment in which preservice math and science teachers collaborated, integrating mathematics, science and technology - an environment meant to build science literacy.

Recommendations for Professional Development of Math and Science Teachers

“Becoming an effective science teacher is a continuous process that stretches from preservice experiences in undergraduate years to the end of a professional career” (NRC, 1995, p. 55). If current reforms in math and science education are going to filter down into the classroom, substantial changes must be made in professional development. Practicing teachers need to be encouraged, through stipends, advancement in professional career ladders, and/or time support to engage in professional development activities and courses side by side with preservice teachers. As technology enables students to consider new questions and investigate interesting problems, teachers need to learn not only how to use technology tools, but how to effectively integrate them into the curriculum. Preservice and experienced teachers need to have opportunities participate in optimal collaborative environments in which they engage in the same kind of activities the standards
recommend for students, learning, working on real world problems, investigating, interpreting results, learning concepts within an applicable context, and communicating learning in written or verbal form. If learning and intellectual development is to become a lifelong activity of our students, it must first become a lifelong priority of our teachers.

INTEGRATING TECHNOLOGY INTO SCIENCE AND MATHEMATICS INSTRUCTION: A PROFESSIONAL DEVELOPMENT MODEL

Ray R. Buss  
Arizona State University West

Ron Zambo  
Arizona State University West

Keith A. Wetzel  
Arizona State University West

Technology has the potential to change radically science and mathematics instruction in K-8 classrooms. By using computers, multi-media, and telecommunications technology, teachers will be able to present and students will be able to engage in authentic, open-ended problem solving situations in science and mathematics.

Although this potential is substantial, considerable professional development will be required to meet this opportunity. The need for professional development is particularly essential when one considers the issue of incorporating technology into current instructional endeavors. In the present paper, we report on the development and validation of a professional development model for integrating technology into science and mathematics instruction. The professional development model was designed to be aligned with the most recent recommendations for effective professional development and it was funded by a national Eisenhower Grant.

New Science, Mathematics, and Professional Development Standards

Recent advances in mathematics and science teaching expectations as outlined in the National Council of Teachers of Mathematics (NCTM, 1989; 1991); American Association for the Advancement of Science’s Project 2061 (AAAS, 1990) and Benchmarks (AAAS, 1993); and the National Research Council’s (NRC, 1996) National Science Education Standards attest to the reform efforts in science and mathematics that emphasize new instructional approaches. A recurring theme throughout all of these recommendations is the importance of technology in science and mathematics instruction. In particular, technology provides opportunities for students to formulate, investigate, and solve open-ended, authentic problems.

Although these recommendations, especially those related to technology and professional development, are important and will prove to be beneficial to students, inservice teachers are not currently prepared to meet the mandates. For example, recent research summarized in the US Office of Technological Assessment (USOTA, 1995) report indicates that teachers have not been provided with professional development to integrate technology into their instruction. Thus, the focus of the project is on fostering change in teaching science and mathematics as a result of using technology and examining how this change is exhibited in teachers’ beliefs and classroom actions.

Successful Professional Development

Recent research shows that successful professional development takes place over an extended period of time to provide distributed learning and implementation as well as fostering systemic change (Fullan, 1991). Further, Fullan notes successful programs provide training and support for the entire faculty of a school. Male (1994) cogently argues that successful classroom implementation requires: theory, demonstrations of appropriate uses, opportunities for immediate practice and feedback, time to adapt curricula to technology, coaching, and periodic review. Finally, Strudler (1994) suggests that opportunities to be observed and coached are critical in implementing technology in the instructional/learning process.

The Professional Development Model

In the project, Arizona State University West worked collaboratively with Glendale Elementary School District to design and test a comprehensive, professional development model focused on changing the way that science and mathematics are taught in elementary schools by integrating technology into science and mathematics instruction. The comprehensive model has three distinguishing characteristics.

First, the professional development was conducted over an 11-month period, to date, to provide teachers with opportunities distributed over time. The professional development model provided for extended training, demonstrations of use, substantial practice time, immediate
classroom implementation, adaptation of activities to their classrooms, observation, coaching, and review.

Second, instructional pedagogy issues were addressed in each workshop session, as well as issues related to the use of technology in science and mathematics instruction. Workshop instruction was conducted by technology leaders, master teachers with strong technology backgrounds, who developed and provided instruction and demonstration lessons, observed and provided feedback to teachers, and offered technical assistance throughout the project. Other experts in science and mathematics instruction and integration of instruction provided assistance to the technology leaders to ensure that the full array of technology and pedagogy issues were presented.

Third, teacher participants worked in two-member teams, sharing a computer and multi-media set-up, that allowed for mutual support and encouragement. These teams also provided for optimal use of the technology resources.

Method—Implementation of the Model

Forty-two teachers from two elementary schools with high minority enrollments participated in the professional development program that consisted of eighteen 3-hour sessions conducted on a weekly basis after school during the spring of 1995, a 10-day intensive summer session, and 8, 3-hour sessions in Fall of 1995. These workshops were carefully distributed over an extended period of time to allow for assimilation of the information, frequent practice opportunities, and extensive opportunities to implement the techniques and methods in their own classrooms. Consistent with the professional development standards, between each school-year session teachers were asked to reflect on their practice. Additionally, they were provided with opportunities to share successes and challenges at each session.

In addition to learning to use technology, teacher participants were provided with demonstrations and practice in using pedagogical skills necessary to effectively implement instruction that includes technology. For example, managing student use of the computers, cooperative learning techniques to optimize use of resources, and so on were presented and practiced as part of this pedagogical component.

The instructional component of the professional development program focused on providing teachers with information, materials, and skills that could be applied immediately to their classrooms. Topics of the individual sessions included: setting up the hardware including a Apple Macintosh AV computer with display, a laser disc player, and a 27" monitor/receiver; loading software and trouble shooting problems; using word processing, spread sheets, and data bases; using production software such as HyperStudio; using CD-ROMs; using laserdiscs; and so on. Other sessions allowed teachers to investigate using computers: as a means to present problem situations with science and mathematics content, as a resource for student research, as a student tool for science and mathematics presentations, as a tool for performing mathematics explorations, and so on. See Zambo, Wetzel, and Buss (1996) for additional details regarding the training.

During the school-year sessions, instruction in a topic and opportunity for individual practice with feedback was provided. Then teachers were expected to use the newest information/techniques in their classrooms and report at the next session on the successes and challenges they had encountered with the use of the information/material. As the project progressed, in addition to some instruction, participants worked in teams of two or three and designed instructional materials and lessons using the computer set-ups. The summer session provided teams with the opportunity to work on materials that could be integrated into thematic instructional units.

Results—Validation of the Model

Data were collected by several methods. Using a questionnaire, data were collected from the 42 participants at the initial professional development session and after one year of participation in the project. Items included both open-ended questions and Likert-type items. Likert items were rated on a 6-point scale from 1—strongly disagree, 2—disagree, 3—somewhat disagree, 4—somewhat agree, 5—agree, to 6—strongly agree. Items were organized into eight subscales, including: attitudes toward using computers; setting up computers and multimedia (C/MM); trouble shooting C/MM problems; computers in the curriculum; selecting C/MM materials; teaching using C/MM; developing lessons using C/MM; attitudes towards C/MM; and teaching specific topics like spreadsheets, databases, etc. In Table 1, we present several of the subscales and example items that illustrate the nature of the subscales and items.

Additionally, follow-up data were collected through interviews and through a review of the participants' reflections recorded in professional development journals, and logs for computer use. Both quantitative (for Likert-type items) and qualitative methods (for open-ended response items) were used to analyze the data.

Teachers expressed initially low levels of implementation and confidence in their use and ability to teach using C/MM materials. These quantitative data were also supported by qualitative data from teacher journals and use logs. As teachers became more familiar and confident with C/MM technology through instruction and implementation, their classroom use and confidence levels increased.

Importantly, across the one-year time period of the project, six of eight dependent measures—setting up C/MM, trouble shooting C/MM, etc., increased significantly,
all Fs with 1 and 41 degrees of freedom. See Table 2.

These increases in confidence and use of C/MM materials were also noted in their journals and in their computer use logs.

For the majority of these measures, teacher participants gained about one point on the Likert scale over the one-year period. Typically, for those means that revealed significant change over time, the means showed that they moved from a somewhat disagree (3) to a somewhat agree (4) rating or from a somewhat agree (4) to an agree (5) rating. See also the Conclusions section.

Several classroom scenarios illustrate how teachers used C/MM in their classrooms. These classroom scenarios are fairly representative of the types of C/MM classroom applications carried out by teacher participants. For example, in his sixth-grade science class, Mr. A's students explored the circulatory system and its function using lasersdiscs. Students worked in groups of 4-5 to complete the self-guided instructional materials that required them to engage in extensive discourse. Following the small-group work, a whole-class discussion was used to verify and clarify student findings.

Mrs. I., a multi-age, third-fourth-grade teacher, previewed and practiced software for use in her unit on the desert. She then demonstrated to students how to use programs to prepare reports and to present information on deserts to the class. Students used the technology to gather information, create reports and presentations, and to conduct experiments.

Ms. L's third-grade students prepared reports on animals. After previewing the programs and demonstrating their use to her students, students worked at five stations that week for three days. Ms. L. asked her students to make a HyperStudio stack or slide show to present their reports to the class. The students worked in groups of two, took notes, and captured pictures or video for their reports.

Finally, some of the qualitative data suggests the integration of technology into instruction precipitated change in instructional approaches. Teachers more frequently utilized small group work, independent research, and student-directed problem solving as the project progressed. Moreover, data indicated that teachers may be undergoing paradigmatic shifts in their perceptions of science, mathematics, and instruction in those areas.

### Conclusions

Although the participating teachers initially demonstrated minimal computer competency, they were able, within a period of five months, to fully engage their students in fairly sophisticated levels of learning by means of technology. For example, teachers required students to engage in problem identification, research, report generation, and presentations using computers and multi-media which is supported by data from Table 2—Teaching Using C/MM. Moreover, over the course of the one-year period of training provided to date, teachers made substantial gains in their abilities to use technology as an integral part of science and mathematics instruction as confirmed in Table 2—Developing Lessons Using C/MM. As the data in Table 2 illustrate, teacher participants indicated that they as least somewhat agreed or agreed that they could manipulate and/or use technology in their own classrooms to aid science and mathematics instruction. As teachers became more familiar with technology and its implementation, teacher logs demonstrated their own and students' classroom use increased.

Moreover, the classroom scenarios indicate the nature of use and level of sophistication of computer and multimedia use was substantial, given that this was the first year
of a three-year project. In certain classrooms, students used computers and multi-media to gather, organize, synthesize, and present information relevant to the solution of authentic science and mathematics problems. As demonstrated in the scenarios, teachers' requirements of student use varied by grade level, with teachers of older students requiring more sophisticated applications such as HyperStudio. Nevertheless, teachers readily adapted computer and multi-media materials for appropriate grade-level use in their classrooms. Moreover, these adaptations became increasingly evident as teacher participants became more knowledgeable and garnered more expertise in the use of computers and multi-media.

Significantly, the increased utilization of small group work, independent research, and student-directed problem solving provided evidence for changes in classroom instructional culture. Although these changes were modest and only beginning to emerge, they suggest that technology can serve as a means to produce systemic reform of instruction that is more consistent with the new professional standards in science and mathematics.

Given the recent professional organizations' recommendations regarding standards for instruction and professional development, effective models for professional development are clearly warranted. This paper describes both a model and provides evidence of validation of its effectiveness. Based on the results, the present model appears to be useful and has potential for use in other school settings.

While current science policy documents suggest teaching and learning strategies that might lead to students becoming scientifically and technologically literate, little is known about how classroom teachers interpret the documents and how they actually incorporate the use of instructional technology in their teaching for scientific literacy. This paper evolved from a study designed to develop a richer understanding of how one elementary teacher, Ms. Brook (pseudonym), utilized instructional technology to teach for scientific literacy. Using qualitative methodology, I examined the integration of instructional technology into the science curriculum, focusing on how the teacher used instructional technology to advance students' scientific literacy. In this paper, I first provide a theoretical background for scientific and technological literacy. Next, I describe the Flamingowatch electronic fieldtrip and its focus on scientific literacy.

Theoretical Background

Americans live in a society that has become increasingly technological in nature. Apparently straightforward questions such as "Paper or plastic?" force Americans to interact with scientific and technological issues that affect the well-being of their personal lives as well as the health and well-being of the nation as a whole. From the classroom to the workplace, various forms of technology have become more and more integral in peoples' lives. Increasingly, jobs require more advanced skills, including knowledge of how to use technology in the workplace. Workers need to be able to think critically and creatively, make decisions, and solve problems [National Research Council (NRC), 1996]. Thus, it is becoming vital that teachers, students, and the American populace in general achieve a higher level of scientific literacy. The National Science Education Standards define scientific literacy as follows:

Scientific literacy is the knowledge and understanding of scientific concepts and processes required for personal decision making, participation in civic and cultural affairs, and economic productivity. It also includes specific types of abilities. In the National Science Education Standards, the content standards define scientific literacy. (NRC, 1996, p. 22)

This definition of scientific literacy argues that specific knowledge and abilities are needed in order to be scientifically literate. Thus, teaching for scientific literacy is central to science education reform and should be a goal of all schools in America.

Why is scientific literacy important? Science for All Americans [American Association for the Advancement of Science (AAAS), 1990] argues that the world's economic and environmental destiny is dependent on how wisely humans utilize science and technology. Through science, citizens not only can learn how to make decisions about the use of technology, but also assess the applicability and effects of new technologies as they emerge. While many global problems exist as a result of the misuse of technology, the use of technology to generate solutions to problems is vital to the survival of the human species.

The literature on instructional technology is abundant, despite the relatively recent emergence of instructional technology in K-12 schools. Fulton (1993), Viau (1994), Itzkan (1994-95), Max (1994), David (1990), Cuban (1993), Grejda and Smith (1994) and others offer definitions and rationales for technological literacy, and its role in K-12 education. Because of the recent emergence of and rapid expansion of the forms of instructional technology, many in academe link the implementation of instructional technology across the disciplines to the process of school reform. In other words, widespread use of instructional technology in K-12 schools is not the traditional paradigm. Thus, it is useful for researchers to identify and study situations in which instructional technology has moved from the fringe to the center of curricular efforts. In the next section, I describe an example of a technology-rich curriculum project that integrates science and instructional technology.
Electronic Fieldtrip: Flamingowatch

The potential of electronic communication is related to its potential audience: it is worldwide. Where students are given access, they can ignore the walls of the classroom and make direct contact with others across the world for collaborative work and in doing so appreciate the differences in culture and yet the similarity of people (Davis, 1994, p. 643).

This passage is uncanny in the accuracy with which it simultaneously describes the educational power of instructional technology and the ways in which Ms. Brook and her students utilized it in their scientific inquiries. Instructional technologies currently available to teachers and students offer significant potential for supporting active learning and adventurous teaching (Sheingold, 1990).

Flamingowatch was an "electronic fieldtrip" in which students from schools worldwide traveled to the Kenyan savanna in East Africa. For three consecutive days, students viewed an interactive telecast which was broadcast live from Kenya. Following is a description of the technology and science subject matter focus of the project provided in a faxed memo to schools throughout the viewing region:

Delivered to the classroom via TCI Cablevision, and produced by Turner Adventure Learning, this new electronic fieldtrip, FLAMINGOWATCH: NATURAL HISTORY IN THE RIFT VALLEY OF EAST AFRICA, transports students to a region where geologic and climatic forces combine to create an environment singularly hostile to life, yet breathtaking in its biodiversity.

Using two-way interactive cable, fax, and computer modems, students will be able to communicate from their classrooms with historians, scientists, and other students locally and around the country to ask questions and share opinions about Kenya and the annual convergence of three million flamingos in Kenya's Great Rift Valley. In this way, the teachers and Turner Adventure Learning combine a live event with interactive publishing, voice and video interconnects, and a variety of teaching tools that take learning behind the four walls of a classroom.

TCI Cablevision
January 30, 1995

During these three days, students learned about the people of Kenya, the geology, and the flora and fauna of Kenya, paying specific attention to the Great Rift Valley. The fieldtrip broadcasts were hosted by Peggy Knapp of Turner Adventure Learning, and included presentations by and interactions with CNN correspondents and local Kenya experts. Two features separate the electronic fieldtrips from typical use of video programs by schools:
1. the broadcasts were live, in real-time;
2. the broadcasts were interactive--students from schools across the world interacted with the program's experts in the field in Kenya, as well as with each other.

These unique features situated the learning experience for thousands of school children in a real-world context. To support teachers and students on the electronic fieldtrips, Turner Adventure Learning (TAL) provided an extensive curriculum guide which was organized thematically, integrating science curricula with mathematics, geography, literacy, and art.

The Flamingowatch Curriculum Guide

The curriculum guide was supplemented with a series of CNN video clips and an on-line text and graphics library. The interactive portion of the fieldtrip occurred in two forms:
1. students had the opportunity to interact with fieldtrip moderator Peggy Knapp and experts in Kenya in real-time by phoning the TAL number in Kenya;
2. students throughout the world interacted with each other after each broadcast through an electronic forum on America On-line (AOL).

Implementation of the Flamingowatch electronic fieldtrip was complex, requiring much organization of different resources. The resources that supported teachers' planning and organization, as well as provided background information on the subject matter in the curriculum, were the CNN video clips, which focused on the fieldtrip's major curricular themes; a monthly newsletter, which contained updates to all on-line resource material; and a teacher training tape, which oriented teachers to the teaching strategies and resource materials created for Flamingowatch.

One way to represent science curriculum is to integrate the different sciences together [Michigan Department of Education (MDE), 1991]. Another way to represent science curriculum is to integrate science with other subjects (NRC, 1996; Roberts and Kellough, 1996). The Flamingowatch curriculum was interdisciplinary, and organized around the following themes: constancy and change, observation and inquiry, and the independence and interdependence of communities. Each day of the three-day fieldtrip consisted of a one-hour live broadcast from Kenya. The broadcasts served a dual purpose: presenting information related to the curricular themes, and real-time question and answer sessions in which students used school telephones to call in questions to the host, Peggy Knapp. Ms. Knapp answered some of the students' questions and referred some questions to Kenya residents and experts. Other questions were directed to CNN.
correspondents in the field. Following is a brief analysis of the curricular content and subject matter of each fieldtrip.

Day 1
On day one, students explored the geology of the Great Rift Valley, the rich biodiversity found in varying habitats, and how species respond and adapt to a very hostile physical environment.

The theme constancy and change was emphasized. Major topics explored in this theme included:

- volcanism in the Rift Valley;
- the geology of soda lakes;
- geologic processes;
- biodiversity; and
- flora and fauna.

The topics in this theme correlated to three major curriculum connections: earth shaping processes, matter and energy cycles, and systems. In focusing on the physical setting and the living environment, students learned that:

The inhabitants of the soda lakes often live quite literally on the edge. Through drought and flood, tectonic upheaval, and animal and human migrations, the historic ebb and flow of communities within the area presents a fascinating picture of the balancing act that accounts for the survival of a wide variety of species as they respond to this ever-changing environment. (Turner Educational Services, 1995, p. 3)

Day 2
On day two, students focused on the geography of Kenya and the Great Rift Valley. The flamingos of Lake Nakuru were used as a case study of species' adaptations to harsh physical environments. Students also learned about the soda lakes of the Great Rift Valley, examined the culture of the Masai people, pastoral nomads of East Africa, and explored the impact of "ecotourism" on the environment. The theme of observation and inquiry allowed students to ponder the many mysteries that surround the flamingo population of the Great Rift Valley.

Through inquiry activities, students addressed the following questions: Why do these colonies of birds migrate from lake to lake and even sometimes from Africa to Europe? What governs the 'decision' to nest and produce young? Why are they pink and how does this adaptation influence their survival? The topics in this theme correlated to six major curriculum connections: the nature of science, scientific habits of mind, the living environment, adaptations, habitat, and diversity.

Day 3
On day three, students focused on the theme independence and interdependence of species, specifically examining the communities of greater and lesser flamingos inhabiting the shores of the soda lakes. Students learned that: The food chain created around each lake is often fragile and tightly linked so that if one link is broken or weakened, the effects are quickly felt by the entire community. (Turner Educational Services, 1995, p. 5)

Major topics explored in this theme included:

- communities of flamingos;
- food chain/web;
- species adaptations; and
- human influences on the environment.

The topics in this theme correlated to five major curriculum connections: energy transformations, earth shaping processes, interdependence of life, social behavior of organisms, and systems. This overview of the curricular connections in the fieldtrips is consistent with the view of Science for All Americans (AAAS, 1990) and Benchmarks for Science Literacy (AAAS, 1993) that science curricula should be thematic and focus on larger concepts that are interconnected.

Flamingowatch and Scientific Literacy
Scientifically literate students should be able to use, construct, and reflect on scientific knowledge (MDE, 1991). The technology-based Flamingowatch curriculum guide contains many activities, tools, and resources that correspond to the dimensions of scientific literacy described in reform documents such as the Michigan Essential Goals and Objectives for Science Education K-12 (MDE, 1991), and the Benchmarks for Science Literacy (AAAS, 1993). The passage below describes the interdisciplinary nature of Flamingowatch and its design which was framed by the Benchmarks for Science Literacy (AAAS, 1993):

Social studies, science, language arts, problem solving, and study skills objectives are integrated into suggested activities. The underlying structure on which Flamingowatch is based is the Benchmarks for Science Literacy of the American Association for the Advancement of Science, published by Oxford University Press (1993). The content themes, overarching goals of the fieldtrip and all activities focus on competencies outlined in this excellent reference. (Turner Educational Services, 1995, p. 6)

Given that the authors of the Flamingowatch curriculum based their work on the Benchmarks for Science Literacy (AAAS, 1993), one would expect the guide's activities to promote scientific literacy. Document analysis of the Flamingowatch curriculum guide indicates that the
using, constructing, and reflecting on dimensions of scientific literacy (MDE, 1991) are well-represented in the Flamingowatch curriculum guide.

The activities in the Flamingowatch curriculum guide contain several of the dimensions of scientific literacy. These activities are organized on Student Worksheets which the teacher may or may not distribute to students. Many of these worksheets also provide science subject matter in some way. For example, student worksheet T1a - The Big Picture: Constancy and Change provides students a summary paragraph on the science subject matter related to this particular theme. It also provides a list of resources to assist students in learning about the theme, and it provides a Questions for Discussion section. Following are specific questions from this worksheet that correlate to the dimensions of scientific literacy:

1. Describe the forces within the earth that have shaped the Great Rift Valley.

2. Read one or both of the famous stories by Dr. Seuss, Horton Hears a Who, or The Lorax. What do these modern fables have to say? How does it apply to the Great Rift Valley? Explain.

Worksheet T1b - The Big Picture: Observation and Inquiry is similar to worksheet T1a but asks students to compare and contrast, predict, and design in addition to describe and explain. Following are specific questions for discussion illustrating these dimensions of scientific literacy:

1. Compare and contrast the viewpoints of science and magic or ancient religious tradition. What does each viewpoint have to offer human beings? Is each a valid way to observe and seek understanding? (Explain)

2. After reading about the flamingos, visualize or imagine the actual bird, not the plastic figures people use to decorate their lawns. What do you think a flock might look like from an airplane? From under the water? (both questions ask for predictions) Draw quick sketches, preferably appropriately colored, to show each idea. (design)

In addressing the questions in number one above, students would also implicitly be engaging in the habits of mind (AAAS, 1993) dimension of scientific literacy because they would be: evaluating claims and arguments, thinking critically, organizing and expressing ideas.

Conclusion

We do not know how future technologies will effect science curriculum. In this paper, I described how Ms. Brook utilized current instructional technology to effect a technology-rich curriculum. Davis (1994) described the power of telecommunications in allowing students to "ignore the walls of the classroom and make direct contact with others across the world." (p. 643) Flamingowatch epitomized the curricular expansion that Davis (1994) alluded to, and allowed Ms. Brook and her students to pursue scientific inquiry by collaborating with students worldwide.

Flamingowatch is unique among current technology-rich curricula due to its worldwide audience, its three-day real-time fieldtrips, and its interactivity. Students were able to ask questions of the experts in the Kenyan field in real time, communicate with colleagues through America Online immediately after each fieldtrip, and follow the progress of Kenyan school children as they traveled through Kenya's game parks and reserves. With its strong correlation to dimensions of scientific literacy, Flamingowatch's interactivity, interdisciplinary curriculum, and emphasis on research and problem solving could be the type of curriculum that is on the vanguard of the development of global classrooms.

During the last decade, mathematics and science instruction has become a problem of national concern. American businesses and government have made quality mathematics and science education a national priority because they perceive the lack of quality education in these areas as eroding the United States' position as a leader in fields that require a strong background in mathematics and science. In particular they are demanding that schools produce students who can solve contextual problems and think critically. In response to recognized deficiencies in student preparation, the mathematics and science communities have drafted education standards that present new visions for the classroom. The National Council of Teachers of Mathematics (NCTM) Curriculum and Evaluation Standards for School Mathematics (1988) and the National Research Council (NCR) The National Science Education Standards (1996) make recommendations requiring both curricular and pedagogical shifts.

Both mathematics and science Standards advocate instructional methods that encourage students to be active participants in the learning process and that provide students with opportunities to learn mathematics and science by doing them, using the tools and methodology employed by professional mathematicians and scientists. For example, with the aid of a computer or calculator mathematicians/scientists can collect and organize large sets of data, view graphs of complex relationships, and simplify “messy” algebraic expressions. With the use of technology, students can emulate the work of these professionals.

At present, active technology-based visions for mathematics and science classrooms are far from reality in Connecticut and in many other parts of the nation. Several obstacles stand in the way of implementing the new standards in mathematics and science. First, in order to implement the standards properly, teacher must learn to become effective facilitators of active student learning. For teachers brought up in the “lecture followed by paper-and-pencil drill or cookbook lab exercise,” this can be a difficult shift. Furthermore, this skills-oriented style of teaching is not sufficient to prepare Connecticut students for the new types of assessment being implemented by the state or to meet the demands of Connecticut’s modern work force. Similar stories can be told in other states across the nation.

A second obstacle to implementation of the NCTM and Science Standards is teachers’ lack of familiarity with new technologies and with effective technology-based teaching approaches. Many teachers have only recently become aware of the exciting possibilities that technology offers but have not had sufficient professional development opportunities or the availability of equipment to implement new technology-reliant approaches. And still, there are many other teachers who choose not to notice the possibilities offered by technology because they are bound to a teaching style and content that matches their own educational background.

And last but certainly not least, teachers must contend with new content areas, most notably probability and statistics, which have been recommended for increased coverage by both The National Science Education Standards (NCR, 1996) and the NCTM Standards (NCTM, 1988). In particular, The National Science Education Standards states that “all students should develop the abilities necessary to do scientific inquiry” (p. 173), and that “The science program should be coordinated with the mathematics program to enhance the understanding of mathematics in the study of science and to improve student understanding of mathematics” (p. 214) Content Standard 7 of the draft version of the Connecticut Mathematics Framework states: “All students will understand and use basic concepts of probability and statistics to collect, organize, display and analyze data, simulate events, and test hypotheses.” (Connecticut Department of Education, 1995, p. 2)

Many mathematics and science teachers have little or no formal education in statistics. In fact, even those teachers with formal
in statistics have rarely had the opportunity to conduct a personal research project from start to finish. There is clearly a need to provide teachers of both mathematics and science with more background in statistics.

**Our Professional Development Program**

In response to the national needs mirrored at the local level in Connecticut, Eastern Connecticut State University was awarded an Eisenhower Grant, entitled Reshaping Mathematics and Science Instruction: A Statistical and Technological Focus. Key features of the program included:

1. Teaching content in the area of probability and statistics using models of instruction (for example, cooperative learning, laboratory projects, use of writing in the mathematics and science classrooms in accordance with the NCTM and National Science Standards).
2. Using technology as a tool in mathematics and science instruction to support the introduction of real-world problems and exploration projects into the classroom.
3. Fostering collaboration between mathematics and science teachers at the 7-12 grade and college level.
4. Designing an inservice program so that it can, over time, evolve (through teacher input and formative evaluation) to better meet the needs of classroom teachers.
5. Establishing an on-going regional inservice program in mathematics and science.

Components of the program included a summer workshop, fall follow-up sessions, and classroom support. Technology used in the program ranged from low-tech (sticky pads) to high tech (graphic calculators, Computer-Based Laboratory Units [CBL’s], and computers).

This paper will document the needs of Connecticut teachers, detail how we are responding to their needs through professional development activities, and describe the challenges and successes our teachers have faced and continue to face as they work to implement change in their classrooms. We hope that our inservice model might inspire others to adopt similar programs that support change in mathematics and science education.

**Needs of the Teachers**

When we began this program we were determined to help teachers change the way they teach. We felt that using a traditional workshop approach would probably not elicit permanent change. Instead we chose to follow a model that would allow us not only to identify the needs of the teachers before the program, but also to respond to their changing needs (Esterle, Richer, Steven, Myers, & Oppenheimer, 1994). We began developing the program by meeting with interested teachers in April 1995. At this meeting the teachers identified the types of professional development that they felt were needed to help them grow as teachers. As a result of this meeting it was determined that one of the major focuses of our program would be using technology outdoors. A one-week workshop was planned for the summer with four follow-up sessions in the fall. We also decided that the teachers would be provided with direct classroom support from either the project investigators or consultants during the fall and spring of 1995-1996. The teachers seemed most concerned with how to increase their use of technology and statistics techniques by making them an integral part of their curriculum not an add-on. They were also concerned with learning how to use new forms of technology.

**Responding to Teacher Needs**

In developing the week-long summer workshop, attended by 19 area teachers, we carefully considered the concerns and needs of teachers. The primary forms of technology that were used were graphing calculators and Computer-Based Laboratory units (CBL’s). When connected to data collection units, such as ultrasound detectors, CBL’s are capable of inputting data directly into the graphing calculators.

The first two days of the workshop were devoted to learning how to use the graphing calculator and to seeing how it could be used outdoors. We determined tree heights and collected data about water quality and temperature from a nearby lake. Graphing the data helped teachers develop an understanding of how graphing calculators could be included, rather than added into the curriculum. Several teachers remarked on how the short time between collecting and graphing the data would enhance student understanding of graphing. We made sure to include ample time for teacher experimentation throughout these two days.

The second two days of the workshop were devoted to leaning to use the data collection devices and to exploring various computer programs. Except for a few planned presentations on the CBL’s and some “low-tech” statistics, teachers decided which avenues they wished to explore as they sought ways to include graphing and statistics in their classes. At the end of the four-day workshop we asked teachers to decide how they wanted to use their four follow-up sessions and their two days of in-house help from the developers of the workshop.

The teachers decided to combine two of the follow-up sessions into one all-day session on environmental education and to have one follow-up session concentrating on more uses of the CBL’s and student misconceptions and one on alternative assessment. All three of the follow-up sessions were extremely productive. The majority of the teachers decided to begin using their classroom support by having one of the workshop presenters come in and present a lesson to their students. All such presentations were
individualized to suit the curriculum of that particular teacher. Following the initial presentation, some teachers had us come in and assist them in presenting a lesson or had us do presentations on using graphing calculators to other faculty members. Almost all requests for classroom support were centered on using the graphing calculator.

The collaborative means by which we designed the workshop allowed us to adapt the program rapidly so that teacher needs could be effectively addressed. The success of this method can be seen in the extremely positive responses we got from all our teacher questionnaires. One of our teachers went so far as to say that this was the best workshop she had ever attended.

**Challenges**

The challenges found in delivering a highly collaborative workshop include developing a working rapport with the teacher and the increased amount of planning time needed during the delivery of the program. Additional challenges involved the use of "high tech." Despite the amount of time we spent practicing with the equipment, the technology did not always work. We were honest with the teachers about the glitches that did occur and tried to model how to work around such glitches. When the teachers tried using the advanced technology at their schools, they reported that their students were much more patient about technology that didn’t work than they were, but they were still concerned about the loss of valuable instruction time and felt that they needed to develop alternative lesson plans, just in case. They also frequently asked us for technical support and for help in finding trouble-free programs to use with the graphing calculators.

**Successes**

Many of the successes we had with our program are due to the delivery format we chose. By allowing teachers to share their needs and expectations with us, we found that many of the teachers chose to use much of what we had to offer in their classrooms. Two of the school systems that we worked with chose to purchase graphing calculators. Another system had graphing calculators and CBL’s, but the teachers had no idea how to work with them in the classroom. One school system is actively pursuing funding in order to purchase the calculators and CBL’s. All of the teachers involved reported improving their confidence in working with advanced technology. We continue to consult with some of these teachers as they strive to incorporate technology and statistics into their classrooms.

**Conclusions**

To change the delivery of education so that students are allowed to “do” mathematics and science, requires the use of advanced technology and a change in the delivery of instruction. In order for teachers to feel comfortable with these changes, it will take more than the standard “talking head” one- or two-week workshop. Workshops must be changed so that teachers have time to explore both technology and new forms of teaching. They must be allowed time to become familiar with new equipment so that they know the possible pitfalls they face as they try using a graphing calculator. Follow-up sessions are of vital importance so that teachers can expand upon their understanding of how both the new technology and the new teaching techniques. Without trusting teachers with this precious form of time, professional development will often fail to create important and necessary changes in education.

This paper discusses a contextual approach to evaluation of educational technology in teacher education. The study applied a context-specific model of program evaluation (Altschuld & Kumar, 1995) to evaluate Vanderbilt University's National Science Foundation (NSF) funded interactive media teacher education project, "Improving Science Education: A Collaborative Approach to the Preparation of Elementary School Teachers." Technology has gained considerable access to education, and often educators are expected to accept technology on face value with less or no sufficient supportive evidence of its quality, impact and physical and procedural requirements for successful implementation. According to Edmunds "we have a long way to go" (cited in Branscum, 1992, p. 84) before educational technology is integrated into instruction. While technology makes inroads to education, science education is undergoing rapid growth due to proliferation of scientific information and developments in theories of learning and problem solving. These changes have collectively increased the complexity of classroom science instruction.

One of the ways of reforming science instruction would be to revise science teacher education programs with special emphasis being given to the use of technology for classroom instruction. A case in point, interactive videodisk (IVD) technology, has been a center of attention in science education. The use of interactive videodisk technology for teaching methods by Goldman and Barron (1990), and for teaching content by Vitale and Romance (1992) are examples of successful utilization of educational technology in preservice science education. Even though in isolated instances it seems that technology and science education are allied to reform education, there is no guarantee that this alliance will improve preservice teacher learning, leading to improvements in elementary and secondary science classroom instructional practices. A lack of suitable frameworks for evaluating the effectiveness of technology programs in science education is a matter of concern. Most of the existing evaluation models in science education tend to focus on end products, and do not seem to provide a sound basis for comprehensive evaluation efforts with emphasis on contextual and supportive factors (Altschuld & Kumar, 1995).

**Description of a Context-Based Evaluation Model**

Evaluation, primarily of a formative nature, regarding the systematic development of curricula, products, and processes is evident in the writings of Pines (1980) and, to a lesser degree, Small (1988). While the evaluation of developmental steps is prominent in Pines and Small, it was not solely confined to those authors. Welch (1974), Virginia's Standards of Learning-Science (SOL-Science) by Exline (1985), and the Evaluation of a Child-Structured Curriculum by Espejo, Good and Westmeyer (1975) have developmental components. Also it should be noted that the works of Exline (1985), Exline and Tonelson (1987), Welch (1974), and Shell, Horn, and Savers (1986) in one form or another stress contextual evaluation. At the contextual level, Exline (1985) portrays the Standards of Learning (SOL)-Science, as a comprehensive approach to evaluation. One of the noticeable aspects of SOL-Science is the recognition of the need for a "buy in" period for administrators, parents, teachers and other stakeholders. Consequently, six critical support components - administrative support, learning environment, teacher preparation, community involvement, fixed facilities and instructional materials - were identified and must be in place for educational programs to be successful. That is, the quality in science education is a function of the degree to which programs are supported and perceived positively by relevant constituencies.

Welch (1974) emphasized that contextual evaluation would not only be of value in understanding the system but also in determining needs. Over two decades ago, Stufflebeam (1971) suggested incorporating contextual factors in program evaluation. From this point of view, the evaluation model proposed by Altschuld and Kumar...
(1995) recognizes that the life cycle of a program or project in science education is seen as the central core of what is to be evaluated. Since that life cycle exists in a complex mix of social, economic and personal factors, evaluations of large scale science education programs should focus on variables such as organizational climate, evidence that the environment was supportive of change and experimentation, administrative interest in and knowledge of the program, and the availability of resources to enable users to adopt new products and processes. For a description of the evaluation model used in this study, see Altschuld and Kumar (1995).

Procedure

The evaluation of the interactive media teacher education project of Vanderbilt University proceeded as follows. For a description of the Vanderbilt’s interactive media project see Barron, Joesten, Goldman, Hofwolt, Bibring, Holladay, and Sherwood (1993). An in-depth examination of background documents was carried out, looking for major issues and potential questions that would seem to be important for conducting site visits and a contextual evaluation of the project. After document review, the ideas emerging from the documents were distilled into a set of key interview questions for the project staff and students. The content of those interview questions included administrative support, financial resources, physical facilities, understanding and knowledge, availability of resources, fit of the program into the environment, and attitude and enthusiasm. A few examples of questions used in the interview protocols were as follows: “In your judgment, what are or would be the long-term outcomes of the project and the use of interactive media; on students, on the faculty/academic environment?”; “What did you feel that you learned from the interactive media portion of the program? Please be as specific as you can in your answer”; “If another teacher education institution or another area were to adopt a project like this, what specifically would you recommend that they do or consider, and why?” (Kumar & Altschuld, 1996, p. 36-39). The sample selected for interviews consisted of the project director, university administrators, faculty members inside and outside of science education, a school administrator, students currently enrolled in the project-based teacher preparation program at Vanderbilt University, graduates currently teaching in Nashville area schools, a video editor, and a computer programmer.

The interviews took place during 1994-1995 academic year. The evaluators taped all interviews in addition to taking individual notes. Each team member analyzed his interview notes independently. While one team member had tapes transcribed and conducted his analysis from the transcriptions and the notes he had taken, the other member typed interview notes and placed all comments and responses together by question. Hence, by working independently, a degree of independent verification of results was reached. Then, using the following analysis strategy, interview data was examined to create meaning out of the interviews: Coding and the Constant-Comparative Method; Describing the Initial Data Categories; Looking Across the Categories for Emergent Explanatory Themes; and Seeking Verification for the Explanatory Themes (in a second set of interviews conducted approximately six months after the first).

The evaluation study generated two sets of results: Initial Data Categories (IDC); and Emerging Explanatory Themes. The Initial Data Categories contain a class of responses that were consistent and repeated throughout the interviews as identified through individual analyses of data. Points of overlaps and differences were examined and a consensus list of key variables was constructed. An example of several IDCs from one of the interviewed groups is provided below. The following are IDCs from faculty, staff and university administrator interviews: Student learning; Student opportunities to learn; Instruction; Effects upon instructional staff; Institutional effects. The Emergent Explanatory Themes on the other hand are points that span across the Initial Data Categories. They explain connections and ideas, and provide a picture of the overall context of the interactive media project of Vanderbilt University. They are: Administrative support; Osmosis/Permeation of project ideas into the environment; Student perception on campus; Student perception in schools; Technical support; Organizational climate; and Critical Mass (especially in regard to the number of individuals participating in the development of interactive media instructional products).

Evaluative Conclusions

The evaluation study led to the following conclusions. Both current students and former graduates strongly perceived that the interactive media-based science methods courses influenced their understanding of discovery science and reflective teaching, and helped them to integrate content into methodology and teach hands-on science. They also felt that real classroom situations often did not meet their expectations of classrooms portrayed by the project videos.

The project seems to receive considerable administrative support within the university environment both in terms of financial assistance, technical support, motivation and incentives for more faculty involvement throughout the university. The project had permeated from science education into other disciplines. Faculty members outside science education (e.g., social studies education, biology) have adopted the interactive media approaches to teaching.

A nourishing environment is critical for successful development and implementation of innovative ideas that
call for considerable changes away from traditional classroom practices to educational technology-based instruction in preservice education. Vanderbilt University has provided such a favorable environment for the NSF interactive media project in the form of strong administrative support and readily available technical assistance as apparent in the evaluation. The university administration has committed itself to maintain familiarity with the project and to promote project activities. For example, high ranking university officials have taken interest in presenting the project in national forums and to potential funding agencies. Along with the administrators, the faculty members, graduate students and other staff of the interactive hypermedia project were dedicated to the project resulting in a "critical mass" (that, by virtue of size and deep belief in the quality of the innovation, began to impact the overall context, and forced the environment for innovation). Faculty members outside science education began to adopt the innovation in their classes because they felt that the project ideas and materials provided a timely opportunity to improve their teaching practices. In addition, in comparison to the high developmental costs, the project materials are not very expensive, are well organized, and integrate well into established courses in teacher education.

The semistructured interview approach taken in this evaluation of Vanderbilt University's interactive media science teacher education project has shifted the nature of the study from product- to context-based qualitative evaluation of contextual (or environmental) variables. To improve the evaluation, the terms context and "contextual" variable need to be defined in depth. Also, the interviews could have focused a bit more on contextual variables, and some interview questions could have been streamlined. On the other hand, the evaluation reported here helps to clarify the idea that looking at the context of development is necessary to gain a clearer and full picture of large-scale innovative educational technology projects in science education.

Using computers is a way of improving the educational standards of Science and Chemistry teaching. In this respect, different kinds of software make it possible to get better results in instruction compared with traditional methods of education. An important goal of modern education is to develop teachers’ abilities to use computers in their classes. It is known that the quality of teacher preparation is the main cause of all successes and failures in the education. This work is concerned with the description of the course “Educational Informatics for Chemists” which is designed to give to its students a basic knowledge of computer applications in the work of teaching.

The course “Educational Informatics for Chemists” includes five principal modules:
1. Theoretical Aspects of Computer Instruction,
2. Programming Languages,
3. Methods of Software Design,
4. Different Types CAI Software in Chemistry, and
5. Internet Applications in Chemistry Education.

The first part of the course gives the most important information about the theoretical basis for computer instruction. The teaching material and the computer as a modern tool for teaching and learning are the two principal concepts in this part. Students learn methods of structuring and restructuring teaching material which are vital in the process of teaching. The structure of the teaching information for computer course designing must be presented in a systemic form based on a systemic approach (Orlik & Vasco, 1995). This approach is characterized by the transition from cognition of a certain part to the cognition of the whole. In order to develop systematic and scientific thinking in students it is necessary to restructure the content of the new material being studied with the aim of mastering it as an integral system. It is quite important to keep in mind that the modern goal of teaching is to communicate the subject’s structure to the student in the most efficient way.

The computer as a modern teaching tool is almost ideal for this aim. For example, the hypertext approach should be characterized in this part of the course. It is known, that this approach to information is based on the creation of a special kind of data representation, which is defined as a fragmentary text with special links between parts. In this system there is the possibility of checking these links to coordinate and change them (Orlik, 1993a). Students learn that the peculiarity of hypertext is that the information is contained in the form of a network of nodes and links. They can be filled with information of different kinds (e.g. text, graphics, video and sound information). Users have opportunities to create new nodes and links in this structure.

The concept of a computer textbook is important in the first part of the course. The characterization of this concept allows the students to understand many of the drawbacks of textbooks and also of some computer education courses based on the principles of the traditional training. The computer allows the elimination of the fixed nature of the textbook. Modern instructional software provides a facility for restructuring educational material at the request of teacher and student. The representation of the teaching information on the screen can also increase the amount of visually organized educational information.

The second and third parts of the course are dedicated to the characterization of programming languages and methods of the educational software design. Students have opportunities to learn the principles of the algorithmic approach and of the structuring of screen information by studying a basic programming language. They can work out their own short fragment of Computer-Aided Instruction (CAI) programs and this activity allows them to better understand main features of this important work. In this part of the course students can also understand that the new educational software in Chemistry must provide the learner with the following opportunities for optimal educational work:
A. To know the contents of educational information in the main section of the course in a visual schematic form.
B. To be able to transfer from the table of contents to the educational contents of subject.
C. To skip a selected volume of educational information if desired.
D. To return to the section in the educational material that was selected previously.

Another problem of great importance is discussed there - the problem of optimal screen representation. This subject is concerned with the problems of screen design, the psychological aspects of information perception and the correct structuring of visual screen teaching material. It is well known that when working with a computer students get tired sooner to compare to the usual traditional learning. To eliminate such a possibility and to improve the teaching and learning opportunities the screen teaching information must be specially structured. It is necessary to eliminate the boring representation of screen information which is based only on text without illustrations and colors.

In this part of the course students learn a modern approach to computer educational software design. They can understand and evaluate the advantages of graphic and multicolor representations with opportunities for the restructuring of the teaching information compared to the classical screen design.

However, it must be admitted that this traditional approach of screen programming is important for countries such as Colombia, where many educational institutions have the hardware with only MS-DOS opportunities without Microsoft Windows. In this case programming in the classical languages is the way to create educational software and there is a lack of these kinds of CAI programs for the different levels of education (secondary school and University) here.

In the fourth part of the course the students work with different types of CAI software in Chemistry, which can be classified according to the following types:

a. Tutorial and consulting programs.
b. Software for knowledge evaluation.
c. Programs for Chemistry computer simulations.
d. Educational games.

Programs of the above mentioned four types allow students to become aquatinted with examples of CAI based on a highly interactive and visual programming with opportunities for true dialog to take place between the student and the computer. For example, some programs show them dynamic interactive multimedia, which lets students explore the world of Chemistry with their own tutor to help them. Many of these programs stimulate students and offer different kinds of help and tools. In working with simulation programs students learn some thing about this type of man-machine interaction when they can handle models of molecules and experiment in Chemistry by modifying parameters. CAI programs for Chemistry exams show them different approaches for the evaluation and auto-evaluation of their learning. For example, educational games are the kind of the software which increases interest in Chemistry and makes it possible to obtain knowledge and skills in the important topic of Chemistry curricula.

The last part of the course is about the Internet applications for Chemistry Education. Students learn about different opportunities to get the information about Chemistry via Gopher and World Wide Web (WWW), online courses and discussion groups, as well as more information about chemistry curriculums and software. Some new opportunities for distance education in Chemistry are shown to them too.

Different active instruction methods have been used in this course to improve the student’s knowledge. For example, different kinds of schemes that are very useful to reach a better understanding of the theoretical principles and to master key skills (Orlik, 1993b).

Figure 1 represents an example of a scheme of the educational contents designed by the student in the second module of the course. This approach can be an instrument for the generalized perception of abstract notions, and facilitates the formation of systematic knowledge. This leads to a more effective mastering of habits and skills and affects the students creative abilities positively.

The course “Educational Informatics for Chemists” allows students to obtain basic knowledge and skills in one of the interesting and important subjects necessary for the instruction and training of teachers.

Educators wish students had the same interest in learning academic subjects as they do in playing computer games.

Developing computer games that are entertaining, yet educational, pose technical challenges. These include developing a game environment that supports the subject matter being taught, assessing student learning from gameplaying behaviors, and having game events respond to individual student learning needs. The present paper describes work to develop a computer game to teach scientific reasoning that is delivered over the Internet. The game context is to solve detective problems in outer space. Detective work is chosen for its similarity to the scientific method. Assessment of student learning is accomplished by using a rich knowledge representation framework capable of understanding problem solving behavior and by having game characters converse with players to probe their reasoning. The scenes in the game teach different aspects of scientific reasoning. The activities and information present in these scenes are driven by student learning needs.

A Framework for Intelligent Tutoring Games

The goal of our work is to embed high quality instruction in the context of computer games so that students can learn in a fun environment. This presents the challenge of creating games that are as fun as those that would compete for students’ learning time, yet present meaningful instruction. Because our emphasis is on education, we focused on that aspect first and built the game around it.

The first step in our project was to develop a model of scientific knowledge. Since our goal is not simply to present a science curriculum within the context of a computer game but rather to build the same type of thinking skills in students that scientists have, it is important to identify those skills. This will then drive instructional techniques designed to build similar knowledge in students as well as drive the evaluation of how well students have learned that knowledge.

One of the most important points we wanted to emphasize in the game is that science is more than memorizing facts and formulas, even though most students and lay people perceive science as such. In order to accomplish this, we place little emphasis on factual knowledge, but rather on science as a process of inquiry. As such, scientific problem solving is applicable to a wide range of real life problems, even those that we do not normally think of as scientific. Based on discussions with research scientists, we extracted the following process of scientific inquiry.

The process of scientific inquiry begins with a question that needs to be addressed. This could be whether a particular drug is effective in treating a disease, whether a given candidate is likely to win an election, or who committed a crime. The question directs subsequent inquiries, the results of which will be evaluated according to how well they address the question. The generation of a question may be initiated as the result of some event. There may be a body of scientific research that inspires new research questions, there may be a social issue for which legislators want to know public opinion, or there may be a reported crime that needs to be solved.

The second step is to develop a model of the phenomenon in question. Very often, we cannot directly observe the phenomenon we are investigating. Scientists study atoms they cannot “see”; detectives rarely witness the crimes they investigate. As a result, scientific thinkers develop models that represent their best approximation of the phenomenon as they understand it. Often, investigations look for ways to test these models.

The third step is to develop hypotheses that represent possible answers to the question. To be amenable to scientific investigation, these hypotheses must have observable consequences, and the observable consequences of different hypotheses must be different. Hypotheses are typically concretizations of the more abstract models described above. Often in scientific investigations there are natural “null” and “alternative” hypotheses (e.g., the drug has no effect vs. the drug is beneficial). In detective work, the hypotheses could correspond to different suspects being the actual criminal or different objects being the murder weapon.
The fourth step is to collect data or evidence to distinguish among the explanations or hypotheses being considered. This step is a key discriminator between successful and unsuccessful investigators. Effective information gathering requires understanding what types of information discriminate among the hypotheses, and knowing how to collect this information. Especially important is understanding how one can be deceived by information that is carelessly gathered or analyzed. Discriminating information is information that is likely to have very different values under the different hypotheses. (For example, if a drug is effective, more people taking the drug are likely to recover; if the drug is ineffective, people taking the drug are likely not to differ from people not taking the drug.) Scientists may collect data from performing controlled experiments, by conducting surveys, or through observation.

The fifth step is to analyze the data in order to come up with results that would be relevant to the hypotheses under consideration. This requires not only knowledge of the mechanics of analysis methods, but also the ability to select an appropriate analysis method for the problem at hand. Unfortunately, some science classes teach students a catalogue of methods, practicing each on samples of data, but give little instruction or practice in how to decide which method is appropriate or what data should be collected. At this stage it is important to consider whether any of the current hypotheses is consistent with the evidence or whether one must begin a search for new hypotheses.

The final step is drawing conclusions about the hypotheses in the light of the evidence collected. This involves determining which hypotheses are best supported by the evidence and whether that support is strong enough to draw a definite conclusion. It is often the case that we are not 100% certain about our conclusions (e.g., we do not know whether the patient really did get better because of the drug or whether a convicted person really did commit the crime). In those cases, we adopt conventions about the level of uncertainty we are willing to live with in order to accept and act on our conclusions (for example, in science there is the concept of statistical significance; in law, there is the concept of “beyond a reasonable doubt”).

Once we established the concepts we wanted to teach students in the game, we selected a game context. Our goal was to pick something that lent itself well to both a game and the subject matter. We chose solving detective stories in outer space, given the popularity of science fiction among teenagers and the striking parallel between how a scientist thinks and how a detective thinks. Table 1 illustrates this parallel.

<table>
<thead>
<tr>
<th>Scientific Reasoning</th>
<th>Detective Reasoning</th>

<td>Forensics; comparison of clues to</td>
</tr>
<tr>
<td>hypotheses</td>
<td>scenario predictions</td>
</tr>
<tr>
<td>Draw conclusions</td>
<td>“Beyond reasonable doubt”</td>
</tr>
</tbody>
</table>

Based on the above analysis, it is possible to create detective stories that will make teaching points regarding scientific reasoning. For example, one could create stories with multiple suspects to teach students how to gather evidence that will distinguish which is the guilty one. This is analogous to having multiple hypotheses that a scientist must collect data for in order to distinguish which one is likely to be correct (e.g., the patient got better because of the treatment, the patient got better on his own, the patient was never sick). One could manipulate the number of clues or their reliability in order to make teaching points about how it is important to collect sufficient data and how biased data can distort one’s conclusions.

While it is important to create story lines that will be educational, students have made it very clear to us in focus groups that they typically do not like educational software because the fun factor is missing. We asked them what they thought made a fun game. The following is a summary of their input.

Students in the focus groups spontaneously raised the issues of race and gender. Female students complained that most commercial games were male-oriented. They asked for contexts interesting to girls and for female main characters. Minority students (and some white students) asked for non-white main characters. There were two suggestions for handling the issue of the typically male main character. One is to have the game played from the perspective of the main game character’s eyes so that the player never sees the image of the main game character (which presumably is the player). Another suggestion is more creative: to allow the player to create the main game character using a character editor. In this way the main
game character could be male, female, black, white or even another species (e.g., an alien from another planet). This game feature would add variety to the game, which was also desirable. Students also suggested a balance of gender and ethnicity of other game characters, a balance we attempted to strike.

The students identified other elements to make a game more fun. First, they suggested variety across sessions so that players would not be faced with the same scenario each time. Ways to do this included changing the contexts (e.g., different planets), changing the mission (have the player do something different), and making the game more complex.

Students also expressed the desire for novelty and surprise. Surprises are unexpected events that may or may not relate to the main game plot. Students also wanted humor. This includes jokes being told by the game characters, funny antics, and bizarre events.

Students wanted few breaks in the action while they played the game. They expressed strong displeasure with games in which the main action keeps stopping for drill on content matter unrelated to the context of the game. Many said their experience with educational games was primarily of this variety. While any game was clearly preferable to standard classroom instruction, they would never voluntarily play such a game outside of class. Students wanted instruction to flow with the game and be instrumental in moving through the game. Math problems that were too time intensive would detract from the fun. Suggestions for addressing this issue included developing "robot assistants" that perform the actual computations while students engage in the reasoning parts of the problem solving.

Teachers and scientists agreed that the ability to select appropriate methods and interpret results were more important than the ability to perform correct computations. Of course, learning does require intellectual discipline and a certain amount of plain hard work. Striking an appropriate balance between the "work" and "play" aspects of the game is an interesting challenge.

Students were definitely interested in the quality of the graphics and "special effects." Clearly, any computer game that is going to hold students' interest must have good, colorful, creative graphics.

Students virtually unanimously expressed the desire to see some sort of combat/shooting in the game. Even the female students wanted this feature. In fact, when a detective game was chosen as the context, students did not want simply to arrest the criminal—they wanted the chance to shoot it out. It was noted that this type of scene could be used as reinforcement for successfully going through the more "educational" parts of the game.

One game feature that is very important to the students and is present in virtually every commercial computer game is performance feedback. Whether the player is competing for points, promotions, or racing against the clock, these types of feedback motivate students to perform to the best of their ability as well as give them feedback on their progress. In our detective game, performance feedback in the form of promotions: the player progresses from apprentice detective to master detective and in the process solves more complex cases.

Finally, students want the game to be challenging and to become more difficult as they improve. Virtually every commercial computer game has increasing levels of difficulty. This may mean facing "bad guys" at a faster rate or solving more complex problems. Fortunately, this type of game characteristic works especially well in our framework of a detective game that teaches scientific reasoning. The students can progress through more difficult cases requiring more advanced levels of scientific reasoning.

The framework we have presented so far would lead to the creation of an educational computer game that presents a science curriculum in a fun way to students. However, our concept is that the game should tutor the student. By this we mean that the game should continually be assessing the student's level of understanding and evolving the scenarios to meet student learning needs. This is what we mean by the term "intelligent tutoring game".

Assessing a student in an open-ended environment is a challenging process. Current performance assessment faces a similar challenge. With performance assessment, educators receive scoring rubrics that describe different levels of proficiency. The educator then evaluates the students response against the rubric. Unfortunately, this is not suitable for a computer game as the descriptions of the proficiency categories tend to be too imprecise for a computer to match to a student's behavior and the scoring process does not specify the cause of the student's weaknesses. Our goal is to assess the student in such a way as to bolster the instructional process.

This still leaves the challenge of understanding a student's strengths and weaknesses given very open-ended behavior. Because the number of possible action sequences a student can take is prohibitively large, there is no way to encode the "correct" solution path for each case. Rather, we must decide, based on the learning objectives of the case presented to the student, what are the general characteristics of a sound problem solving approach.

For example, if the learning objective is to teach students how to distinguish which of two hypotheses is likely to be correct, then we expect a student to look for evidence that can not only confirm one of the hypotheses but also disconfirm the other (i.e., rule it out). Therefore, the game can monitor which pieces of evidence the student collects and how they relate to the suspects provided. The game should detect whether the student has collected the appropriate evidence regardless of the order in which the
information was collected or the other actions the student took while playing.

It is important to note that simply observing behavior does not, in and of itself, identify the thought process that lead to that behavior. A student may deem a piece of information important for reasons other than those that relate to the teaching objective. A student may omit collecting a piece of information because she does not realize it is available even though she knows that she needs to collect it. Therefore, it is important for the game to be able to determine when these sorts of events are happening. Our solution to this challenge is to have the game characters themselves probe the students as part of their interactions with them. Simple probes such as “who do you think are likely suspects?”, “what evidence are we looking for?”, “why aren’t we picking up that object and having it analyzed?” can shed light into the student’s thought process.

Once the game has determined where the student’s level of proficiency is, it can make decisions on how to evolve the scenarios to enhance student learning. For example, if the student is correctly solving the cases and demonstrating mastery of the learning objectives, she can progress to more difficult cases that embody more challenging learning objectives. On the other hand, if he is failing to meet the learning objectives, the game can offer several forms of remediation. One is to have the game characters themselves offer instruction by making suggestions and offering wisdom, e.g., “Gee, I don’t think we’ve ruled out the possibility that the Martian could have done it.” or “That witness wasn’t very reliable. I don’t think we should believe him.” A second way is to change the stream of events dynamically. For example, if the student fails to rule out that a second suspect could have committed the crime, the game could plant a decisive piece of evidence and literally change the perpetrator to the second suspect. This could be brought to the student’s attention when he makes an arrest. His sergeant may report that another detective searched the second suspect’s house and found the murder weapon and then instruct the student on why it is always important to rule out other suspects, not just get evidence on the one she thinks is guilty.

An Internet-based Intelligent Tutoring Game

A prototype of an intelligent tutoring game has been developed and placed on the World Wide Web (WWW). It can accessed through RDC Publishing’s (a division of Research Development Corporation) home page at http://www.RDCPublishing.com. In the game, the student joins a problem solving team to solve a mystery. The teammates serve as co-problem solvers as well as mentors when the student needs instruction.

The game is written in HyperText Markup Language (HTML). The student views each screen and then clicks a forward or backwards arrow to move forwards or backwards through the story. At several points in the story line, the student is asked to make decisions. These could either be decisions with respect to what path to follow in solving the mystery or to perform quantitative problem solving. The choices the student makes will influence what path the story takes. In the cases where students are asked to solve problems, their answers are used to assess whether they need any remedial instruction. In cases where remedial instruction is provided, students follow a separate branch of instructional activities off the main story line. Upon completion of the remedial activities, they join the main story line in the place they left off. The student then follows the story line to its completion or until additional remediation is needed. By the time the student reaches the end of the story line, s/he will have completed the entire lesson embedded in the story as well as any remediation that was required along the way.

MODELLING STUDENT REASONING IN SCIENCE EDUCATION WITH COMPUTERS: A CONCURRENT COORDINATION

Stéphane Leman  
University of La Réunion

Student model is one central component of Over-the-Shoulder Advisor Systems (OSAS), Intelligent Learning Environment (ILE) and intelligent interface design. This paper tackles the student modelling issue by means of an overlay model: student knowledge is represented as a subset of expert’s knowledge (Carr & Goldstein, 1977). However, departing from the traditional sequential and centralised models, our approach brings to bear on distribution of the learner and expert models and on concurrent interpretation of students’ actions through multiple points of view. On the one hand, learner and expert models are distributed throughout many autonomous agents. Each agent is devoted to one single tiny piece of knowledge (Leman, Giroux and Marcenac, 1995). On the other hand, agents might simultaneously and locally interpret a student action under different viewpoints. Furthermore, agents can communicate and exchange information to assess their conclusions; however, using a distributed overlay model still calls for mechanisms for uncovering implicit reasoning steps from explicit student actions.

After giving a short description of the test-bed expertise, the fundamental issues are discussed:

a. How to represent a student reasoning in a distributed model?

b. How to build the student model at run time?

Modelling Student Reasoning with Agents

Using a Multi-Agent Approach to Model a Student

To illustrate our approach, a sample geometry domain was investigated. In geometry and more generally in problem solving, there are as many correct paths to a solution as there are viewpoints on a problem and a domain. For instance, to build a square with rules and compasses starting from a given line, there are at least three solutions: draw a circle and then three perpendicular lines, draw two circles and two perpendicular lines or draw three circles and only one perpendicular line:

Figure 1. Three different solutions to build a square.

Trying to solve this problem, a student draws several figures and may follow different plans at different times. To undercover the really followed train of thoughts out of the student local actions, we have to consider these plans simultaneously as hypotheses about the student reasoning process until one appears as the good one. To do so, hypotheses are compared to the solutions provided by experts, each one standing as a different viewpoint. A multi-agent approach to student modelling appears as a natural framework to tackle the representation and coordination of multiple solutions as multiple viewpoints, to carve the system according to the locality and wholeness of actions and to consider concurrently various alternatives. As a result, our multi-agent architecture addresses the modelling of both student thought process and student knowledge. It brings up several advantages, in particular for complexity reduction, concurrent examination of multiple viewpoints and real-time evolution.

Agent Types in the System

To build the student model while solving a problem, we need on the one hand a way to look at student’s actions and on the other hand a mechanism able to analyze these actions and to store the results. So two kind of agents have been designed: spies agents observing and reifying student actions, and task agents analyzing actions and building the model.

As framework, an epiphyte information system is used and its current programming platform EpiTalk (Pachet,
Giroux and Paquette, 1994). In our prototype, a student is interacting with a single application providing functions needed to build basic geometric figures as points, lines and circles. Using Epitalk terms, this application constitutes the host. The epiphyte system is the multi-agent system which models the student reasoning processes. The evolving structure of the multi-agent system mirrors the student reasoning process.

Spy Agents. Spies are reactive agents. They do not embody any sort of reasoning. They do not state by their own what is relevant and what is not. They restrict themselves to look at the host, pick up the student actions and transmit this information to interested task agents. Task agents stand at the heart of the system. They are in charge of distributed student modelling.

Spies can be inserted anywhere into the host. But there are many actions that can occur within a host (resize a window, draw a line, etc.) and these are surely not all of relevance for the purpose of teaching geometry. Therefore we must achieve a good balance between an exhaustive spying of student actions, likely to drown relevant information into a noisy flow, and a too succinct one, likely to produce a too gross view on the student cognitive activity.

In our prototype, spies focus their attention on geometric figures a student can trace. For each basic geometric action provided by the interface, a spy agent in charge of detecting it is associated. So all basic geometric actions available to the student are supervised. When a spy detects an action, it first screens the relevant ones to intercept, and if appropriate, then transfers a reification of the action to interested task agents. The reification specifies the action name (Draw-Circle), arguments (with centre (150,200) and radius 50), the time when the action occurred and other information.

Our prototype, both the host and its associated epiphyte system, is implemented in Smalltalk-80. Spies are first inserted into the host. When a student performs an action, it is achieved through message passing. The spy first receives the message, reifies it, sends the reification to task agents and forwards the message to its real destination. The destiny processes the message and sends back result to the spy. The spy registers the results and finally returns the result to the initial sender. In this way, the host behavior is not modified. So required information on student's observable behavior is available, and task agents have to process it.

Task Agents. A multi-agent system analyses the student "primitive geometric" actions in order to infer a distributed model of its reasoning process. Since this analysis is conducted from the viewpoint of the task the student has to perform, we called these agents task agents. To organize and ease student modelling, two kind of task agents are considered:

1. S-agents, addressing static knowledge (knowledge on concepts). In geometry, concepts are the figures (circle, square...) and properties (a square's, edges are equal...) the student should know about. S-agents own tiny pieces of static knowledge on the domain. In achieving its task, a student builds up complex static knowledge out of simpler static knowledge. In the student model, S-agents are used both to model the knowledge compulsory for the task and to check if this knowledge is mastered by the student. This representation scheme bears many advantages for managing new knowledge, forgetting knowledge and reducing complexity. As a result, static knowledge is distributed across the task agents which hold together a part of the student model.

2. D-agents, addressing dynamic knowledge (knowledge on functional aspects of concepts). In geometry, theorems belong to this category. The D-agents hold knowledge used to build new knowledge. A D-agent receives S-agent(s) in input and produces S-agent(s) in output. Again as a result, dynamic knowledge is distributed across the task agents which hold together another part of the student model.

Reasoning Graph

To complete the student model, we need first to know how static and dynamic knowledge are linked and second how these links are mastered by the student. This information is indeed embodied into the structure of the multi-agent system resulting from S-Agents and D-agents. This overall structure acts as what we called a reasoning graph. A reasoning graph is usually hierarchical by nature and may be compared to some sort of plan.

In our test-bed, each solution to a problem is expressed through a reasoning graph. In Figure 2, we give an example of such a graph, the problem being to build the perpendicular median of segment AB:

Figure 2. An example of a reasoning graph.

The reasoning graph describes an expert viewpoint on the problem. To build the perpendicular median of two points A and B, one has to build two circles with centre A (Ca) and B (Cb) respectively, then build two intersection points (J and K) between Ca and Cb, and finally draw the perpendicular median.
Building the Student Model at Run Time

A Distributed Overlay to Model the Student

A distributed overlay algorithm is used to build the student model. Reasoning graphs act as models to overlay. Their associated multi-agent systems reflect the state of the overlay process. Any spied action could be recognized as part of one or many reasoning graphs. Knowledge on the student is distributed across the agents. While modelling, each agent interpret information according to its own more or less local vantage point on the problem to solve. First, spies locally collect raw information and route it to interested agents. As reasoning graphs are hierarchial, leaf agents process it and may send their conclusions to their superiors. So as information sifts up, agents abstract it and the perspective on the student thought process enlarges. Thus, this bottom-up interpretation of the reasoning graph naturally reflects levels of abstraction.

For a given problem, many solutions can exist and many paths can lead to one solution, each path or solution resulting from a different viewpoint on the problem. Modelling a student reasoning process and knowledge becomes far more complicated. The system has to decide which path or solution the student is pursuing. Within our framework, one solution or one path is expressed through one reasoning graph. For instance, suppose our problem is "to build a square starting from two given points". Several solutions are possible and Figure 3 illustrates these three main solutions.

As we have seen before, these three solutions are expressed in three distinct reasoning graphs. At run-time, three multi-agent systems are generated, one for each graph. Each student action is then analyzed concurrently by the three multi-agent systems. Step by step, the chosen solution emerges. Ambiguities are resolved as soon as information becomes available. Even better, a student can follow a rather erratic course, trying one path, abandoning it for another, coming back to the first, and so forth. The multi-agent systems will naturally adapt to and undercover the right one(s) at the right time.

Modelling Students Reasoning

As long as the student follows explicitly step by step the reasoning of the expert, there is no problem. But exercising problem solving abilities, the student soon becomes more knowledgeable, and the OSAS is faced with unexpected sequences of actions.

Is the student wrong? Has the student made a jump in his reasoning process? Has the student found an unrecognized solution? If the student problem solving abilities are improving, the problem is two-fold: first, identify the S-Agents and D-agents that have been by-passed, and second, to model this expertisation behavior.

Recognizing the Master in the Student. We called "expertisation" the recognition and the modelling of this brand-new student behavior. For this purpose, a new type of agent is introduced: R-agent. R-agents model complex reasoning involving multiple S-agents and D-agents. The expertisation may be seen as a reflective operation on knowledge (Smit, 1983). Expertisation acts as a synthesis operation while going from a R-Agent down to S-Agents and D-agents act as an analysis operation.

In our test-bed, for the same example, Figure 3 gives a possible expertisation: a new R-agent (named Med) is created and is represented with only one agent, expressing the reasoning made by a student to build the perpendicular median.

The algorithm proceeds in two steps. At first, if the student has really jumped a sequence of reasoning steps, the system has to establish it and to take it into account. In trying to uncover those steps, the algorithm first tries to get a hand on both ends of the inference chain. So it looks for a higher place in the graph that could be considered as reached by the student. This is equivalent to finding a sub-graph that may be subsumed by an R-agent. Although the research of a sub-graph is known to be NP-complete, this is not actually a hindrance. We actually work with little graphs; the graphs are quite constrained and some properties computable beforehand and heuristic helps controlling the search. When the starting node is received, the algorithm searches for an equivalent path in another
reasoning graph which has been marked as mastered. If such a mastered path exists elsewhere, this is done.

R-Agents as a Way to Represent Reasoning. However if we cannot conclude that all the shunted reasoning process (both concepts and chaining of inferences) is mastered, we then focused on each component, that is S-agents and D-agents. We use a distributed scheme to establish that knowledge modelled by each by-passed agent (X1, X2, ..., Xn) is really mastered. Each by-passed agent is in charge of finding evidence that knowledge is mastered. He gathers opinions of other S, D or R-agents related to the same knowledge than his. For this, he communicates with agents that owns various parts of the student model. Naturally their answer can be various and even contradictory, and so conflicts are possible. To solve conflicts, we use belief factor: Bx. (0 < Bx ≤ 1 represents completely mastered knowledge). Each S-agent and D-agent manages such a belief factor for knowledge. Each agent manages three belief factors Bp, Bg and Br.

Bp is related to the knowledge of the agent taken in isolation. It represents properly belief. It is computed as the mean of the belief in agent X within solutions where it is involved, weighted by the belief of each solution (which corresponds to a classical probabilistic approach)

\[ Bp(X) = \frac{\sum Bg(Xi)Bp(Xi)}{\sum Bg(Xi)} \]  

(1)

Bg is related to the knowledge of the agent but under the scope of the solution that uses it. Bg remains the same for all agents involved in the solution. It's a general belief. It compares the intrinsic value of different solutions. Since solutions differ both in their sources (they are provided by experts of different experience) and their intrinsic value (for instance, some may be more aesthetic).

Br is related to the importance of the agent in a solution. In a reasoning, all the steps are not the same importance. With Br, we distinguish the relative importance of each agent in the same solution.

Once the belief in each agent has been computed, we gather results and attribute belief values for the shunted path. General and relative beliefs are respectively given by (2) and (3) formulae:

\[ Bg(R) = Bg(Xi) \]  

(2)

\[ Br(R) = \sum Br(Xi) \]  

(3)

To attribute properly belief, we balance the belief of each agent Xi by his importance in the current solution. So, we obtain:

\[ Bp(R) = \frac{\sum Br(Xi)Bp(Xi)}{\sum Br(Xi)} \]  

(4)

Then we create a new R-agent with a belief factor with value Bx. Then the brand-new R-agent is introduced in the multi-agent systems and linked to appropriate agents and this R-agent is now a new alternative to solve the problem.

As a tutorial and validation strategy, the creation of an R-agent could be postponed by the presentation of new problems in order to verify that some part of involved knowledge has really been mastered. The important point is that expertisation allows modelling the evolution and the complexity of student knowledge.

Concluding Remarks

We have presented in this paper an original approach to recognize and represent complex student reasoning. A first step consists in a distributed overlay algorithm, while the student follows, step by step, an expert’s reasoning to solve the problem. Expert reasoning are described in reasoning graphs and each node is represented by one agent. When student’s behavior comes close to expert’s behavior, a new agent with new factor of belief is introduced to model his reasoning.

Actually further researches are under investigations in our team. They principally try to answer the following issue: how to design tutoring strategies exploiting a distributed student model?

Over my seven-year tenure as simulation section editor, I have watched this area develop in several important ways. Our simulation builders have tapped the expanding array of technological advances to create a pool of preservice training aids that continues both to expand the scope of simulation applications in teacher education and also to refine the utility of the simulations that are already being used. For example, during the current decade, simulation research and development at the Curry School has yielded an entirely new “breed” of Windows-based simulations that, as described in one of this section’s papers, focus on helping our preservice teachers develop effective lesson-planning skills. Over the same period, our basic teaching skills simulation has evolved into a tool for sensitizing our teachers-in-training to individual learner differences such as gender and ethnicity. Let’s view some of the highlights of the innovations and refinements that are reported by this year’s contributors to the annual’s simulation section.

Rebecca Brent, a long-time colleague from East Carolina University, focuses on a very practical teaching issue—preparing for the opening days of school. Her Simulated Opening of School (SOS) package has been refined extensively over the past five years. As preservice participants complete the most current version, they engage in as many as seven activities whose content ranges from the opening faculty meeting to class enrollments. Rebecca’s soon-to-be published SITE monograph will be most helpful to teacher educators interested in employing SOS in their programs.

Troy Isaak, at Millersville University, used Authorware to create another very practical training tool, the Pine e-mail simulation. Specific modules, by coupling screen displays that simulate the campus network with clear instructions and feedback, help students to learn fundamental e-mail skills ranging from logging on and off the network to saving and deleting messages. The fact that this simulation is replacing all classroom introductory e-mail instruction at the university attests to its training utility.

The third paper illustrates the cooperative efforts of physics and education faculty members to create a simulation particularly helpful to preservice science teachers. From the Universiti Sains Malaysia, Fauziah Suliaman and Ahmad Nurulazam Md. Zain discuss a Pascal program named Walde which is designed to provide preservice science teachers with a clear example of energy conservation. The specific task centers on analyzing the heat transfer process in 12 wall designs.

Emyr Williams, at California State University, Long Beach, has been studying the impact of a multimedia instructional package on undergraduate physical education students’ ability to analyze and diagnose throwlike behaviors. Participant attitudes about the multimedia instruction were positive. Williams speculates that future research may find that multimedia applications in this area are most beneficial when they are used to supplement rather than to replace traditional instruction.

Two Windows-based simulations from the University of Virginia are described. Yu-chu Yeh has developed the Computer Simulation for Teaching Critical Thinking (CS-TCT). This flexible Visual Basic program is designed to increase preservice teachers’ professional knowledge and skills in teaching critical thinking. Activity centers around a lesson in which teacher-participants try out various techniques to increase critical thinking in 12 very diverse students. Extensive feedback is linked to teacher actions. Initial research findings support this tool’s effectiveness in improving participants’ knowledge and skills in this important area of instruction.

In a second paper from the University of Virginia’s Curry School of Education, Amie Sullivan, Yu-chu Yeh, and Harry Strang discuss refinements and continued field testing of the Teaching Decisions (TD) simulation. The current version of this Visual Basic program allows preservice participants to engage in a variety of lesson planning tasks from assigning pupil spatial locations and lesson activities to deciding what the teacher will do during the lesson. As with previous Curry simulations, extensive
post-participation feedback is provided. This paper's most
provocative findings relate to the variations in lesson-
planning patterns that experienced teachers exhibit—
patterns that future preservice teachers will benefit from
studying.

Over the past 27 years, Harold R. Strang has been an
educational psychologist in the Curry School of Education
at the University of Virginia. He teaches courses in human
learning and development. For more than a decade, he,
several colleagues, and a number of graduate students have
been developing and conducting research on computer-
based teaching simulations. Harold Strang is a faculty
member of the Department of Educational Studies in the
Curry School of Education at the University of Virginia,
405 Emmet Street, Charlottesville, VA 22903.
The opening days of school are critical in preparing for a successful school year (Evertson, Emmer, Clements, Sanford, & Worsham, 1989). They can be particularly challenging for beginning teachers, who must teach students a wide range of classroom, playground and cafeteria rules and procedures, plan lessons, perform initial student assessments, attend faculty meetings and in-service workshops, work cooperatively with other teachers to arrange classroom schedules and times for pullout programs, get necessary supplies, make initial contacts with parents, arrange desks and centers, and put up decorations and bulletin boards. Many new teachers are unprepared for this whirlwind of required activity and so must learn to manage it by trial and error.

Simulated Opening of School (SOS), a SITE monograph currently in press, is designed to prepare preservice teachers for the realities of the opening of school. SOS is a role-playing simulation that has been used by over 1200 elementary and middle grades preservice teachers and by eight different instructors during a five-year development period. In SOS, students are assigned as teachers at Alpha Elementary School and work step by step in 3-5 member teams through the first few days of school. The complete simulation takes approximately 8-10 hours of instructional time, but many of the activities can stand alone to provide meaningful one- or two-hour experiences.

Participants in SOS experience two faculty meetings and plan the physical arrangement of their classrooms to provide smooth traffic patterns and optimum learning environments. They anticipate their supply needs for the entire year and arrange to get needed supplies and equipment. While planning lessons for the first two days, they incorporate the development and teaching of rules and procedures, events that are vital to establishing and maintaining an orderly classroom where effective learning can take place. Then they role-play the first day of school, discussing possible events and actions. They learn that the opening of school is a time that calls for flexibility and cooperation with fellow teachers.

SOS is ideal for use in classroom organization and management courses, methods courses with a management component, or curriculum courses. It is immediately applicable to elementary education, but can be modified for middle grades, early childhood, or special education programs. Along with written instructions for the activities, the SOS monograph has accompanying computer files that help create realism within the simulation by enabling teacher educators to personalize all handouts with student names and to modify materials to fit many different classroom settings.

**Activities**

Instructor lesson plans for each of the seven activities in SOS include (1) purpose of the activity, (2) steps needed to prepare for the activity, (3) detailed explanations and directions for each part of the activity, (4) debriefing questions for class discussion, (5) descriptions of written products prepared by participants during the activity, (6) suggested class time, and (7) variations.

**Activity 1: Opening Faculty Meeting**

Preservice teachers frequently have misconceptions about the teacher workday period before the opening of school, believing they will have plenty of uninterrupted time to prepare their rooms and plan lessons. They are also usually unaware of the major role of the principal in influencing the operation of the school and the working climate for the faculty.

During Activity 1 participants take part in a mock faculty meeting for the first teacher workday of the new school year. The “principal,” who may be a former principal in the community or a faculty colleague, conducts the meeting during which participants are given a schedule of activities for the workdays and are confronted with committee assignments, duties before and after school, broken copy machines, and other common aspects of teacher life in an elementary school. They also hear about new district initiatives and are given a motivational speech about the beginning of the school year. Activity 1 stimulates students to think about the role of the principal. They identify possible characteristics of their first principal and strategize ways to work effectively with all types of leaders. Computer files are available for all of the handouts, allowing instructors to personalize duty assignments with
student names and to modify materials to reflect changing initiatives in local schools in which students will complete field work.

**Activity 2: Schedule Construction**

Most preservice teachers have worked in classroom settings where scheduling decisions have already been made before their arrival. They have usually not seen a master schedule for a school or thought about construction of the daily class schedule.

This activity acquaints participants with the constraints of school scheduling as they work with a master schedule, lunch schedule, and time requirements for each content area. A database program allows instructors to personalize the master and lunch schedules with participant names. Each grade level team must consider optimum times for teaching, realistic work periods, and breaks, as they seek to reach agreement on a common schedule for the school day.

**Activity 3: Floor Plans and Supplies**

The purpose of this session is to introduce participants to the types of classroom environments they may face in their first teaching positions. Participants have blank floor plans of their classrooms with variations due to location in the building and the grade level for which the room was designed. They also have lists of the furniture and supplies in their rooms. Some rooms are fully equipped with many supplies appropriate to the assigned level, and others have inadequate or inappropriate supplies. Working in grade-level teams, participants examine the supplies and furniture they have, assess what they need, arrange with fellow teachers to acquire needed supplies, and sketch the arrangement of furniture and desks in their classrooms. Teams also construct a letter to parents about the supplies children should bring to school.

**Activity 4: Lesson Planning**

Most preservice teachers have many experiences with planning individual lessons but almost none with planning for a whole instructional day. The first few days of school pose even more planning challenges because the teacher must set the tone for the classroom and learn about the academic levels and abilities of each student.

This activity acquaints participants with lesson planning for the first two days of school. Participants share ideas about appropriate activities to include in the opening days, including reviewing content from the previous school year, team building, and establishing rules and procedures. They also learn about fire drill procedures and discuss other safety concerns associated with the opening of school.

**Activity 5: First Day of School**

Most preservice teachers have not had an opportunity to experience the opening of school except as students. In Activity 4, participants planned for the first day. Activity 5 allows them to test the feasibility of their plans and to experience the flow of the first day. The instructor systematically goes through the events of the day, posing typical problem situations such as the arrival of a student who speaks no English, a delayed lunch schedule, and a student complaining of a stomach ache. Participants offer individual solutions and generate additional ideas as a group.

**Activity 6: Class Enrollments**

Beginning teachers often accept their first job with little understanding of how teachers are assigned to a school and the impact of enrollment on the individual classroom teacher. During Activity 6, participants meet as a staff to discuss an imbalance in class sizes within the grades. The principal helps participants understand that teacher allotments are made based on enrollment and gives them an opportunity to suggest various strategies for addressing the problem of class size imbalance.

**Activity 7: Reflection and Final Debriefing**

A crucial part of any simulation is debriefing (Christopher & Smith, 1987). Simulations often elicit strong feelings in students as they grapple with unfamiliar and sometimes intimidating situations. In SOS, debriefing takes place individually, in small groups, and in the entire class group. The final activity encourages participants to make sense of the total SOS experience by reflecting on these questions:

- How did you feel during SOS? Did your feelings change as the activities progressed? How?
- What are the most important things you learned during SOS?
- How do you think SOS compares with what will really happen to you during the first few days of school?
- What was it like to work in a team? Do you think real teams will be like this?

In SOS, all the teachers were students in a class and unfamiliar with what was going to happen. What may be different if you are the only new teacher in a school? What might be taken for granted by your principal or other teachers? To whom could you turn for help? What could be improved about SOS as a class simulation? What should definitely stay the same?

**Contents of the Monograph**

The SOS monograph contains:

- A rationale for using SOS, background information on simulations, and suggestions for preparation before beginning the simulation.
- Instructor lesson plans with detailed directions for each of the seven activities.
- Instructions for using diskettes, which are available in PC or Macintosh formats. Text files include a Welcome Back memo from the principal, grade and room assignments, a schedule for the opening teacher work days, master and lunch schedules, a duty roster,
instructions to the leaders of each grade-level team, listings of the contents of each classroom, a memo of fire drill procedures, and memos to teachers on the first day of school and after one week. A database file facilitates the personalization of most handouts with participant names. Graphics files include a school floor plan and blank floor plans for each classroom. Instructions for the principal in Activities 1 and 6.  
- Sample lesson outlines for the first days of school for Grades 1 and 4.  
- Listings of first day problem events for elementary and middle school.  
- Annotated references on the opening of school and classroom management for beginning teachers.

Conclusions  
Simulated Opening of School offers many benefits for the participants. It focuses preservice students' attention on the most important aspects of the opening of school, including classroom preparation, scheduling, and teaching rules and procedures. It includes a wide variety of problematic situations, including getting new students, dealing with anxious parents in kindergarten and first-grade classrooms, being without needed supplies, and making last-minute scheduling decisions and adjustments. By introducing preservice teachers to these simulated situations, SOS prepares them for the real experiences and equips them with many problem-solving strategies. By emphasizing grade-level team work, SOS helps the participants develop skills associated with working in groups, something teachers routinely do. Finally, through debriefing and reflective writing, SOS leads students to take more considered approaches to professional decision-making.

Developing a Customized Pine E-mail Simulation for Student Training

Troy Isaak
Millersville University

During 1994, the university began the process of upgrading the campus network by connecting major buildings with fiber optic cable and installing a dedicated e-mail server. Currently, all academic buildings and office buildings are on-line, and the final phase of wiring all the dormitories is nearing completion. The usage of the university network increased dramatically once the academic buildings that house the student computer labs went on-line. Use of the e-mail system became part of many faculty curricula and assignments, thus necessitating the generation of large numbers of new student network accounts within a short time frame at the beginning of each semester. Also, once students learned that networking and internet facilities were available, many requested an account to correspond with friends at other academic institutions and to stay in touch with family.

To get a new network user account, students were required to take an hour training session for the purpose of learning the fundamentals of the Pine e-mail, the current e-mail system used by the university. However, with the large demand for new user accounts, the classroom training sessions proved to be problematic for several reasons:

1. Training facilities: The computer labs accommodate only 15-20 students at a time, and trainers had to compete with other computer lab uses such as regular classroom instruction.
2. Individual differences: Students in the training sessions had a wide range of skills and background knowledge about technology and the subject.
3. Retention: Practicing the learned networking skills as soon as possible after the training session is essential. Immediate access to the network was often delayed because of class or work schedules, and much of the information was forgotten.
4. Scheduling conflicts: The training sessions were not always offered at convenient times for the new users or at times when the training was needed for class assignments or work.
5. Turnover: Approximately 1900 potential new users enter the university system each year. Accommodating this number through classroom sessions with current resources could not be done.
6. Network instructional staff: The university at present does not support a staff committed to network training. Individuals who are trainers are also responsible for other computing duties.
7. Alternative methods of instruction: Not everyone learns well in large groups. Novice users often feel intimidated and overwhelmed with the new technology. They feel lost in a class situation and require more individual attention and time.

Network Training Solution

The method used to resolve the network training problem was to utilize the technology as a means of delivering the network training on-site when needed by the user. A customized computer simulation of the campus network was developed during the summer of 1996 by the author and a student helper. The simulation provides students with experience in using the campus network before actually logging onto the university system.

The Pine E-mail Simulation

The Pine e-mail simulation was created with Authorware 3.5 and is available for both Windows and Macintosh platforms. The simulation requires about 2 megabytes of hard disk space and runs on a local area network. The network simulation consists of a series of modules that include Creating Your Username, The Internet Address, Logging On/Logging Off, Reading Your Mail, Replying to Messages, Composing Messages, Saving & Deleting Files, and Printing Files. Each module provides users with experiences likely to be encountered when using the network.

The basic screen design for the simulation consists of two parts. The top seventy-five percent of the screen simulates the appearance and functions of the campus
network. The bottom portion of the screen displays instructions and feedback. As students perform networking tasks, their input is evaluated and the feedback is displayed in a feedback frame or box.

Since the simulation is customized for Millersville's University campus network, the design also incorporates the names, phone numbers and e-mail addresses of computer staff where appropriate. For example, messages in the "Reading Your Mail" module contain important information about the system and include information about whom to ask or call concerning networking problems.

Students must complete each module successfully before going on to the next. Upon completion of the simulation, a user agreement form and a verification form are printed. The user agreement form includes university policies and rules governing the use of the campus network. The verification form contains the new username generated from the student's name and identification number, full name, address and phone number. The student signs the form, turns it in to the computer center, and the new user account is generated within two working days. For those who forget how to do any of the basic tasks associated with Pine e-mail, the e-mail simulation also contains a review section. The review does not print a verification form.

Current Status of the Campus Network Simulation

The Windows version of the simulation was installed in three computer labs during September 1996 and tested with approximately 500 students. Student reaction was very positive. The time needed to complete the simulation ranged from forty minutes to two hours and depended largely upon previously acquired computer knowledge and skills.

Because of the success with the initial group of students, all classroom introductory e-mail training sessions were suspended in October 1996 and replaced with the computer simulation. This results in a considerable saving of time for the computer center staff (approximately 120 training sessions per year) which can be put to use in other critical areas.

Currently, plans are underway to make a version for faculty, staff and administration. Since the username generation is done differently, several modules will need to be modified. The time frame for implementation of the new version is the summer of 1997.

Troy Isaak is located in the Stayer Education Center at Millersville University, Millersville, PA 17551

DESIGNING THERMAL OPTIMUM WALL BY SIMULATION FOR ENERGY CONSERVATION

Fauziah Sulaiman
Universiti Sains Malaysia

Ahmad Nurulazam Md. Zain
Universiti Sains Malaysia

With the Malaysian economy undergoing sustained growth of more than eight percent annually for the last eight years, the demand of electricity is increasing and is expected to rise in excess of 10 percent annually. Energy played an important role in the country’s development and with greater industrialization, the demand for energy as a necessary component will continue to expand at a much faster rate than at present. In line with one of the main aims of the World Solar Summit in 1996, there is a need to encourage efficient use of energy in Malaysia to prolong the lifespan of available resources. Rahooja, Hassan, and Saleem (1990) found that heat gained due to conduction and convection into a particular building was 38.15 percent of total heat gained. Energy consumption in buildings could be saved through better designs of walls.

Computers have been used in teaching for about three decades. With the advent of microcomputers in the late 70's, the trend of using computers for instruction has increased. This trend is still continuing as powerful and cheaper microcomputers such as Pentium and Power PCs become more readily available. Computers are currently being used for the teaching of various disciplines such as pure science, applied science, social science, humanities, arts and music, and language.

In the teaching of science, instructional software has been developed mostly for drill and practice and tutorial. More simulation, data collection, and data analysis software needs to be developed to enhance science education and to promote higher-order thinking skills among students. McDaniel, McInerney, and Armstrong (1993) implied that the computer should also be used to meet emerging educational goals which stress cognitive processes. Such a goal can now be met with the new powerful microcomputers.

Simulation software provides students valuable experiences in the classroom or the laboratory. This software illustrates hypothetical or real-life situations which would not be possible through lecture, demonstrations, or experiments, due to time constraints, dangers linked to experiments, or the high cost of equipment. Using such software, students can manipulate the variables and observe the results immediately, and they can repeat the process as often as they wish. Computer simulations can play an important role in encouraging students to 'predict, experiment and explain' so as to better understand science concepts (Champagne, Klopf, & Anderson, 1980). Hence, students can discover how scientifically correct their conceptions of certain phenomena are. Students can become active rather than passive learners.

Choi and Genaro (1987) found that computer-simulated experiments could substitute for traditional laboratory experiments and that students would perform equally well. Moreover, computer-simulated experiments take half the time required for traditional laboratory experiments. In other words, computer-simulated experiments are efficient and cost-effective.

Walde is simulation software based on these theoretical assumptions. This paper will illustrate Walde as an excellent example to preservice science teachers in teaching energy conservation through simulation. Educators in Malaysia as well as in the rest of the world need to be concerned with developing energy-conscious citizens.

Walde

In the process of designing a building, one important consideration is the thermal comfort of the future residents of the building. By minimizing heat flow through the walls, a certain comfortable temperature can be maintained and energy can be conserved. Consequently, less electricity will be used for air conditioning, resulting in greater preservation of resources.

The purpose of this software is to design an optimum thermal wall for energy conservation by considering the comfortable temperature maintained in a particular room. One main factor that contributes to maintaining comfort is heat introduced into the building. Therefore, analyzing the process of heat transfer through the wall becomes very important.
The building materials used in the analysis are the ones commonly employed by engineers and architects. Material and building costs were also analyzed. Additionally, ferrocement and hollow bricks, which are not commonly used as building materials, were analyzed. The outside temperature was assumed to be 32 degrees Celsius, which is the average temperature in Malaysia, and the room temperature was assumed to be 20 degrees Celsius with air conditioning.

A simple iterative numerical method is used in the analysis (Johnson & Riess, 1982). This method generates a sequence of values that converge to the true solution through the use of an initial guess within a certain range. The error of this method is very small and thus gives an acceptable approximation.

A Pascal program called Walde was developed to analyze the heat transfer process in the wall for twelve different designs. Some of the walls were designed with air gaps. The program interactively asks for input parameters such as height and length of the wall, surface area of certain partitions in the wall depending on the particular design, materials used and duration of time for calculation of total costs. The program calculates annual and capital costs, including labor. The cost of air conditioning is taken as MR 0.24 per kW-hr, the normal residential rate.

**Simulation Results**

The results portrayed the effect of using ferrocement as an alternative to the common clay bricks. One of the designs with an air gap seemed to be the best design with its selected materials. A close second is a design which has three layers. From this study, it is found that walls with a certain number of layers provide good insulation and low annual costs. However, the design must also be analyzed to meet aesthetic preference and budget needs. Low annual costs are important, but the capital costs must also be considered. It is also beneficial to add certain metal supports at strategic locations to ensure strength and durability of the wall.

**Conclusion and Discussion**

This study aimed to analyze and design the exterior wall of a building for the purpose of conserving energy used for air-conditioning. Results indicated that heat gained through the walls due to conduction and convection is significant. Therefore in order to improve the thermal efficiency of the house, it is imperative to improve the walls by employing alternative designs and using thermally efficient building materials.

This simulation software could be used by science educators as an excellent example of a simulated experiment to preservice science teachers. Walker and Hess (1984) suggested that simulation can be a useful tool for students and teachers in learning and teaching science. Walde is software that is an economical alternative instead to having students construct walls. Preservice science teachers need to be shown how Walde can be used in teaching heat flow and energy conservation by having a group of two to four students running the simulation. In order to achieve the thermal optimum wall design, students must discuss the possibilities before running the simulation. Students can learn cost-effectiveness in designing the optimum wall. They can compare the annual cost saving that resulted in certain designs by inputting values for height and length of the wall, surface area of certain partitions in the wall, materials used and the duration of simulated time for the calculation of the total cost. This process can be repeated as many times as students wish. Thus, using Walde, students can conduct the experiment as many times as they like. It is cost-effective and will save time for both teachers and students. Moreover, it provides a good example to preservice science teachers on using computers to teach skills, attitudes, and knowledge related to energy conservation.

Fauziah Sulaiman is a lecturer in School of Physics, Universiti Sains Malaysia, 11800 Penang, Malaysia. E-mail: sfauziah@usm.my

Ahmad Nurulazam Md. Zain is an Associate Professor in School of Educational Studies, Universiti Sains Malaysia, 11800 Penang, Malaysia. E-Mail: anmz@usm.my
The ability to observe and to accurately analyze movement skills is fundamental to effective teaching in Physical Education (Barrett, 1979; Kelly, Walkley, & Tarrant, 1988; O’Sullivan, Stroot, Tannehill, & Chou, 1989). Unlike coaches who specialize in sport specific movement forms, physical educators are typically confronted with a large variety of movement forms to analyze and diagnose. Although sport-specific training programs have been successful in developing analytic abilities of preservice physical education teachers (Kniffen, 1985; Halverson, 1987; Rush, 1990; Wilkinson, 1986), the variety of movement forms encountered by physical education teachers, as well as the time available to teach qualitative assessment, precludes a sport-specific approach. Recent skill analysis dissertations completed at The Ohio State University (Johnson, 1990; Matanin, 1993) suggest the potential for a mechanical approach to the analysis of skill (Kreighbaum & Barthels, 1990), otherwise referred to as a performance principle approach.

Theoretically, developing analytic and diagnostic competencies through a performance principle (mechanical analysis) approach would decrease the time required for students to become competent observers. A multimedia approach as opposed to a lecture approach to instruction offers another means by which the time required to acquire mastery of instructional content may be more efficiently (Falk & Carlson, 1991) and flexibly used. Combining the attributes of multimedia instruction, namely the efficient and flexible use of time, along with a performance principle approach to instruction, offers the potential for a time-efficient means of developing analytic and diagnostic competencies.

The purpose of this study therefore was to investigate the effectiveness of a multimedia (laserdisc) performance principle (mechanical analysis) training protocol on subjects’ ability to analyze and diagnose throwlike skills. This study also examined the extent to which subjects’ analytic and diagnostic skills generalized to untrained throwlike movements.

Method

Subjects

Six students enrolled in physical education undergraduate classes volunteered as subjects for this study. Subjects were selected on the criteria that (a) they were able to comply with the schedule requirements for the training program, and (b) they had not taken any undergraduate skill analysis, biomechanics, kinesiology or physics related classes.

Apparatus

A Panasonic SVHS Professional/Industrial Video AG-460 (at a shutter speed of 1/250th of a second) was used to videotape the throwing performances. Two Panasonic AG-7650 video cassette players and a Panasonic AG-750 editing deck were used to edit videotapes. The instructional equipment consisted of a Macintosh Quadra 700 with 20 Mega bytes of Ram and a 350 Mega Byte hard drive, a standard 13" Apple color monitor, a Pioneer Laservision Player LD-V4200, and a 13" Panasonic Video Monitor CT-1331-Y. The instructional modules and probes were developed using Authorware Professional (version 2.0, 1993).

Procedures

Development of the intervention package

The independent variable was developed in the following way: (a) selecting throwlike movements, (b) determining the performance principles for throwlike movements, (c) videotaping the throwlike movements, (d) cataloging the video performances of the throwlike movements, (e) selecting videotape performances for inclusion in the study, and (f) developing the multimedia program.

The throwlike sport movements selected for this study were representative of sport skills taught in middle school physical education classes in Franklin County, Ohio. Six overarm throwlike skills were integrated into the multimedia intervention and main probes (softball, tennis smash, volleyball serve, football, basketball, and javelin). Three
untrained skills were integrated into the generalization probe (badminton smash, soccer javelin throw, and tennis serve). Selection of the applicable performance principles was attained by: (a) determination of the fundamental principles related to all throwlike movements (Kreighbaum & Barthels, 1990), and (b) the presence of these performance principles to varying degrees of significance in all throwlike sport skills taught in middle school physical education curricula. The four performance principles selected were magnitude of force, point of application of force, horizontal direction of force, and vertical direction of force.

Nine middle school (6-8) student performers were selected by their physical education teacher to represent high-, medium-, and low-skilled students from each grade level. Student throwers were videotaped from a side-on angle (90°) throwing from left to right, and from a rear-view angle (180°). To lessen the potential for external distractions (McPherson, 1990) the demonstrators were filmed in front of a plain blue background (Kelly, et al., 1988).

A review of the videotapes of 910 throwlike movements resulted in the elimination of 351 poor quality clips. The 559 remaining videoclips were then classified into five categories: correct performances, and four performance principle error categories (magnitude of force errors, point of application of force errors, horizontal direction of force errors, and vertical direction of force errors). A videotape was then edited to include these videoclips along with an inventory (cross referenced to the original SVHS videos) describing each performance.

The validity of each clip’s inclusion in the study was initially determined by three groups of reviewers. The inclusion criteria were as follows: (Group #1) a middle school physical educator agreed that the performance was representative of throwlike movements at the middle school level; (Group #2) at least three of the four doctoral students concurred with the researcher’s classification of the performance principle error; and (Group #3) a researcher with prior experience in performance principle research agreed with the identification of the performance principle error. After cross referencing reviewers’ feedback, the 215 videoclips that remained were edited from the original SVHS videos to a master tape. This second generation tape (containing 19 minutes of actual footage) was then pressed into a laserdisc.

On receipt of the laserdisc the researcher created an inventory of each throwlike performance using a Hypercard stack. Buttons were created (enabling the researcher to instantly view each clip) for each videoclip performance. These buttons were then placed onto correct performance cards (Hypercard) and four performance principle-specific incorrect performance cards (magnitude of force errors, point of application of force errors, horizontal direction of force errors, and vertical direction of force errors) for both the main and the generalization components of the study. The Hypercard stack categorization process enabled the researcher and a skill-analysis reviewer to compare and contrast performances more effectively. As a consequence of this review process in which performances were viewed at normal, slow and very slow speeds, a framework for the diagnosis of throwlike errors evolved. This framework viewed the throwing action as a sequence of four movement phases (preparation, weight transfer, body rotation, & follow-through) and was based upon motor learning research conducted by Roberton and others (DiRocco & Roberton, 1982; Halverson, Roberton & Langendorfer, 1982; Roberton, 1978). The diagnosis framework for this study required observers to identify the throwing phase in which the first form error occurred. To be diagnosed as a body rotation error, both the preparation and the weight transfer phases would have been flawless. Any arm sequencing errors occurring after the identification of prior flaws would not be categorized as the primary error, as errors in prior sequences would take precedence.

After developing this diagnosis framework, a motor learning reviewer was then asked to confirm the researcher’s and a skill analysis reviewer’s diagnosis of initial phase errors. This process resulted in the exclusion of another 17 clips, i.e. clips where the motor learning reviewer disagreed with the researcher and skill analysis reviewer’s diagnosis. Assignment of the 198 remaining clips to either the probe or module components of the study was determined by chance. Clips were matched according to topographic similarity—e.g., softball throws, where the performance principle error was magnitude of force, were grouped together. From these clusters of similar clips a random selection process was used to determine each clip’s inclusion in the probe or module component of the study.

Instructional Display

Geneva font was used for the instructional displays. The font size varied from 18-20 for the main body of the text and 20-36 for headings. Text background was predominantly white, while the text itself was predominantly black. Occasionally, white text on a black background was used to highlight components of the instruction. Additionally, animated diagrams were incorporated into the modules.

Program Control

The multimedia modules were externally paced with cognitive processing time (Canelos, Dwyer, Taylor, Belland & Baker, 1989). Presentation of the textual information required an approximate reading rate of 300 words per minute. Depending upon the context of the interaction, subjects were either presented with a continue button to progress more quickly to the next screen, or they
were occasionally required to interact a predetermined number of times in order to move on.

After formative testing, it was discovered that the presentation of video from the laserdisc would occasionally freeze. Consequently each screen that included a video presentation had to be programmed to circumvent the freeze problem.

Outline of the Probes
Main and generalization probes consisted of 41 and 33 randomly sequenced videotaped performances respectively. Examples of correct performance, the four types of performance principle errors, and throwing form errors from each of the four throwing phases were included in all probes. Subjects, when presented with a videoclip performance, were required to indicate whether or not the performance was correct or incorrect. If subjects indicated that a performance was correct, the next performance would be presented. If subjects indicated that a performance was incorrect they were then asked to indicate which performance principle was deficient, and which of the four sequential throwing phases first exhibited a form error.

Subject response data were collected by embedding calculations for every possible response that an individual could make (Williams, 1995). For data collection purposes, each videoclip was given an identity number which was embedded into the calculation icon for each performance.

Outline of the Modules
Each performance principle training module included: (a) introductions and definitions, (b) examples of correct performances (both normal image and zoomed image), (c) examples of incorrect performances with a comparison of correctly performed and incorrectly performed phases of the throw, (d) an embedded test with feedback, and (e) a mastery test (80%) to exit. Subject pairs receiving less than 80% on the mastery test were given a review of the instructional content and were then required to retake the test. No specific intervention on the diagnosis of errors was programmed; instead, examples of throwing phase errors were presented in each module.

Prior to data collection, subjects were required to participate in two computer familiarization sessions. The first training session familiarized subjects with the use of the mouse and the keyboard; the second familiarized subjects with a multimedia (laserdisc) mode of instruction.

Research Design
The design used for this study was a multiple baseline (Cooper, Heron, & Heward, 1987) across four performance principles: (a) magnitude of force, (b) point of application of force, (c) horizontal direction of force, and (d) vertical direction of force.

In single subject research, the interpretation of graphic data is achieved by a systematic process of examination known as visual analysis (Cooper, et al., 1987). Visual analysis of data is conducted to answer two questions: (1) whether a consequential behavior change occurred, and (2) to what extent the behavior change can be attributed to the independent variable. Attributing change in behavior to the independent variable is determined by examining data variability, changes in data levels, and data trends.

Subjects completed nine main probes, one generalization probe and four performance principle modules. Probes were used to measure subjects' ability to (a) discriminate correct from incorrect throws, (b) identify performance principle errors, and (c) identify throwing sequence errors. Probes were taken individually by subjects, whereas the instructional modules were completed in pairs. Main probes were administered weekly before and after each intervention. The final main probe was administered in the week following the last instructional module which was then followed by the generalization probe. Sequencing order of clips for each probe was determined by random selection.

Analysis of Data
Two types of data were analyzed for this study—probe scores (single subject design) and subjects' attitudes toward multimedia instruction (questionnaire). Subjects' responses to each probe were saved in a file and subsequently reorganized by identification number for later analysis. To ascertain subjects' attitudes toward multimedia instruction, a questionnaire (Chou, 1990) was administered immediately following completion of the generalization probe.

Results

Major Findings

Discrimination Scores
Although subjects' scores for discriminating between correct and incorrect performance improved after intervention and also generalized to untrained throwlike skills, the baseline discrimination scores were high at the start (66%-93%). (See figure 1.) As a consequence of the review process, the majority of clips included in this study were obviously correct or incorrect. Consequently, the task of discriminating between correct and incorrect skill performance was relatively easy.

Analysis Scores
Baseline scores for correctly determining the main performance principle error for incorrect throws were generally low. An interesting pattern of subject responses occurred immediately following each intervention. Generally subjects attributed performance principle errors to the subject matter (magnitude of force, point of application of force, horizontal direction of force, and vertical direction of force) of the most recently completed instructional module.
For example, immediately after the introduction of the point of application module (second intervention), five of the six subjects' scores for correctly identifying magnitude of force errors (first intervention) decreased while the attribution of errors to the point of application performance principle increased.

Overall subjects' performance principle error detection scores increased for all performance principles; however, the accuracy scores were moderate at best, ranging from 39-58%. Performance principle probe scores varied across the six subjects, and each subject's performance scores varied across the four performance principles. As with Matanin's (1993) study, the inaccurate identification of performance principle errors increased after intervention; however, this inaccurate association of errors to specific performance principles generally decreased as the study progressed. For the generalization probe (throwlike skills not included in the instructional modules), the overall mean generalization scores for each performance principle were close to or above the main post-intervention levels for all performance principles, with the exception of point of application of force which was lower in the generalization probe.

Diagnosis Scores

Similar to Rush's (1990) findings, baseline scores for diagnosing which phase of the throwing sequence (preparation, weight transfer, body rotation, and arm sequence) was incorrectly performed first were low. Without knowledge of the fundamentals of throwlike movements, subjects were unable to diagnose performances prior to instruction. Examples of preparation, weight-transfer, body rotation and arm sequencing errors were integrated into each of the instructional modules. The diagnosis procedure employed in this study required subjects to determine the first phase of a throwing sequence to exhibit form deficiencies. Visual inspection of the data illustrates that the ability to diagnose errors varied across subjects, and each subject's diagnostic proficiency varied from one throwing sequence phase to another. Overall the data indicate that subjects were ineffective in diagnosing throwlike movements.

Data from this study show that overall subjects' generalization probe performance scores were comparable to post-intervention probe mean scores for three of the four performance principles, and all four of the throwing sequence phases. Nevertheless the analysis (performance principle) and diagnosis (throwing sequence) scores for both the main and generalization probes were moderate at best.

Questionnaire

In addition to a Likert type questionnaire (Chou, 1990), subjects were also required to write concluding comments on their multimedia instruction experience. Subjects' attitudes toward the multimedia instruction were positive. Subjects perceived that they had learned the content of the multimedia modules. A portion of subject One's written comments are quoted below.

I thought that learning by multimedia was helpful. I learned a lot of information in a relatively short period of time. I feel as if I am knowledgeable enough now to help others, and pass on the skills that I've learned. (Subject 1.)

Figure 1. Overall discrimination accuracy across probes.
Discussion

Probe scores suggest that subjects failed to master the instructional content presented to them through the specific multimedia instructional format employed in this study. Either the way in which the acquisition of knowledge was assessed and/or the interventions themselves were relatively ineffective. The probe format in this study allowed subjects to select only the one performance principle error (the main error). In hindsight the development of a probe enabling subjects to select in order any performance principle errors they had detected would provide a more complete description of subjects' analytic abilities. Similarly, when diagnosing errors in throwlike movements, the most obvious errors are frequently consequences of earlier errors in the movement sequence. Having subjects initially identify all errors demonstrated by the performer, then recognize the first phase in which these errors occurred, may have provided different results. Although diagnostic skills were incorporated in the modules, direct and sequential interventions developing subjects' abilities to initially detect preparation errors followed by weight transfer, body rotation and then arm sequence interventions errors may prove to be more effectual.

Implications for Physical Education Teacher Educators

Research has indicated that both critical element and performance principle approaches are effective. Physical education teacher education skill analysis researchers may more profitably use multimedia applications to supplement lecture-based instruction as opposed to developing comprehensive multimedia applications to replace it. Using multimedia applications to supplement lecture-based instruction may provide a means to capitalize on the capabilities of technology, while avoiding the time-consuming process of developing comprehensive instructional programs.

Although the lecture time available at the undergraduate level may preclude a critical element sport-specific approach, the development of sport-specific instructional CD-ROMS may provide a practical solution to the development of analytic and diagnostic competencies outside of University-based lecture instruction. For practicing teachers and/or novice coaches, sport or activity specific multimedia based instruction, specifically CD-ROM based programs, may fulfill an instructional need.

The development and quality of materials in the field of physical education teacher education will rely on those within educational institutions and publishing companies affiliated with the field. The time required to develop multimedia instruction is immense. My experience in developing the instructional components for this study leads me to believe that the development of multimedia applications in physical education requires a collaborative team approach. Multimedia development teams comprised of programming specialists, content experts, instructional designers, formative evaluators and film/video experts may potentially decrease the production time required to develop instructional materials and enhance the quality of instruction.

Many studies suggest that effective teaching can significantly improve students' critical thinking (e.g., Ennis, Millman, & Tomko, 1985; Knight, Wexman, & Padron, 1989; Williams, 1987). Professional knowledge (Michelli, Pines, & Oxman-Michelli, 1990) and positive teaching behavior (McBride & Knight, 1993) are crucial to the success of critical-thinking instruction. Since field activities contribute to the acquisition of knowledge and skills (Grossman & Richert, 1988; Ketty & Sellars, 1996), practice in school settings can be invaluable in helping preservice teachers to acquire the knowledge and skills necessary for teaching critical thinking. Implementing this instruction in school settings, however, is often very difficult. Fortunately, computer simulations are beginning to provide an alternative setting for teachers-in-training to become competent cultivators of critical thinkers. Pioneering research in this area, Yu-chu Yeh has developed the Computer Simulation for Teaching Critical Thinking (CS-TCT). CS-TCT training is based on the assumption that teachers, through mindful learning and reflective teaching, will improve their professional knowledge and thus develop effective strategies for teaching critical thinking.

There are two objectives in this study. First, the impact of the CS-TCT simulation on teacher training in critical-thinking instruction will be determined. Second, the relationship among teachers' involvement in the training, change in their professional knowledge, and change in their positive teaching behavior in critical-thinking instruction will be assessed.

The CS-TCT Simulation

CS-TCT participants complete the following four activities: Enter demographic information, teach a lesson, evaluate their students' performance, and review feedback reports. The program-defined students, six boys and six girls, represent three different ethnic groups: African-American, Asian, and Caucasian. They are also preset to vary in motivational level and critical-thinking ability.

The CS-TCT simulation includes the following key features:

1. **Classroom setting.** The program simulates the actions of twelve students in a classroom setting.
2. **Interesting teaching material.** During the simulation, teachers interact with students by presenting important issues in a story.
3. **Broad flexibility.** Teachers can employ many different strategies in interacting with their students.
4. **Mindful learning.** Teachers receive reminders and research-based knowledge designed to promote their acquisition of professional knowledge and skills in teaching critical thinking.
5. **Reflective teaching.** Teachers review profiles in the form of bar charts that are designed to increase self-awareness and to encourage future use of effective teaching behaviors.

Professional Knowledge and Positive Teaching Behavior in Critical-Thinking Instruction

Effective teaching is built on a foundation of professional knowledge (Grossman & Richert, 1988). Two types of professional knowledge are essential for teaching critical thinking: "content knowledge for critical thinking" and "pedagogical content knowledge for critical thinking." Content knowledge for critical thinking involves teachers' understanding the elements of critical thinking, the factors that influence critical thinking, and the relationships among these concepts. Pedagogical content knowledge for critical thinking encompasses teachers' knowledge of available materials and resources for teaching critical thinking, students' understanding of critical thinking, effective strategies for teaching critical thinking, and self-awareness of personal teaching behavior.

Numerous studies have confirmed that teaching behavior profoundly influences students' learning of critical thinking (e.g., Knight et al., 1989; Kolstad, Briggs, & Hughes, 1992; Rice, 1992). Knight et al. (1989) found that teachers' direct instruction in critical thinking
influenced the way in which third- and fourth-grade students selected and applied critical-thinking skills. Three properties of teaching behavior contribute to cultivating critical thinkers. These properties relate to (a) improving students' prior knowledge, (b) promoting students' critical-thinking dispositions, and (c) improving students' critical-thinking skills.

As for the relationship between professional knowledge and teaching behavior, Robinson (1995) found that existing knowledge and experience strongly influenced teachers' development and use of teaching strategies. Increasing teachers' knowledge, therefore, is fundamental for bringing about change in their teaching behavior.

Based on the literature review, the following two hypotheses are proposed:

1. Following a training session, teachers will improve their understanding of professional knowledge pertaining to the teaching of critical thinking, and they will employ more positive teaching behaviors related to critical thinking.
2. Teachers' involvement in the training session will influence their change in professional knowledge and positive teaching behavior for critical thinking; moreover, the teachers' professional-knowledge change will influence their teaching-behavior change.

Method

Participants

The participants included 75 preservice teachers enrolled at the Curry School of Education, University of Virginia. The mean age of the participants was 19.73 (SD = 2.37).

Instruments

The CS-TCT and a 6-point Likert questionnaire, "The Questionnaire of Professional Knowledge for Teaching Critical Thinking" (QPK-TCT), were employed during this research. CS-TCT records provided measures of the teachers' promotion of (1) student critical-thinking dispositions, and (2) student use of critical-thinking skills. The first measure's behavioral components included giving positive feedback, providing cues, and showing physical closeness. The second measure's six behavioral components included allowing time for reflection before requesting an answer, demonstrating examples before employing practice, asking higher-order questions, giving explanations when demonstrating an answer, reviewing the material after the completion of a lesson section, and conducting group discussions. Each behavioral component was scored on a 0 to 1 scale. QPK-TCT measures addressed two aspects of professional knowledge pertaining to teaching critical thinking—"content knowledge for critical thinking" and "pedagogical content knowledge for critical thinking." QPK-TCT response options included "strongly disagree," "disagree," "slightly disagree," "slightly agree," "agree," and "strongly agree."

Procedures

All participants completed the CS-TCT in a computer laboratory. After a brief introduction to the simulation, a QPK-TCT pretest was administered immediately followed by a 15-minute demonstration and practice session. Next, participants engaged in the computer simulation. Finally, participants completed the QPK-TCT posttest.

Experimental design

This study employed a pretest-posttest control group design. Participants were randomly assigned either to an experimental or to a control group. Participants in both groups completed pretests and posttests. Only participants in the experimental group, however, completed the treatment designed to promote the effective teaching of critical thinking. The content of the treatment included five text files of research-based knowledge concerning effective instruction of critical thinking, two teaching profiles of personal performance during the simulation, a review of effective teaching of critical thinking, and several reminders that contributed to mindful learning and reflective teaching.

Statistics

One-way (Group) multivariate analyses of covariance (MANCOVAs) were employed to examine the training effect on the teachers' change in critical-thinking instruction. Group refers to the control and the experimental group, and covariances refer to pretest scores of the dependent variables being tested. Moreover, a path model of structural equations was applied to test the causal relationship of the variables displayed in Figure 2; difference scores were employed to represent the factor scores of the teachers' changes in professional knowledge and positive teaching behavior.

Results

In this study, effectiveness in critical-thinking instruction is defined by professional knowledge pertaining to the teaching of critical thinking and by positive behaviors related to this teaching. Figure 1 displays the mean scores of the professional knowledge and positive teaching behavior for both the control and the experimental group.

The first MANCOVA, which examined the overall CS-TCT training effect on teachers' effectiveness in critical-thinking instruction, yielded a significant group effect (Wilks'λ = .87, p < .01). CS-TCT training yielded a significant improvement in teachers' effectiveness in critical-thinking instruction. Subsequent analyses of covariance (ANCOVAs) yielded significant group effects on both professional-knowledge change ($F(1, 72) = 4.54, p < .05$) and teaching-behavior change ($F(1, 72) = 9.52, p < .01$). The comparisons of least-square means revealed that teachers in the experimental group acquired more profes-
sional knowledge and employed more positive teaching behavior for critical thinking than did teachers in the control group.

Figure 1. Mean scores of professional knowledge and positive teaching behavior for control vs. experimental group

A significant group effect on the teachers' change in professional knowledge pertaining to teaching critical thinking was found, Wilk's $\lambda = .88$, $p < .05$. Subsequent ANCOVAs, however, yielded a significant effect only for the first factor of the professional knowledge—content knowledge for critical thinking, $F(1, 72) = 9.26$, $p < .01$. The least-square means indicated that teachers in the experimental group acquired more content knowledge for teaching critical thinking than did teachers in the control group.

Moreover, the training was found to be effective in increasing the teachers' employment of positive teaching behavior for critical thinking (Wilk's $\lambda = .87$, $p < .01$). Subsequent ANCOVAs yielded significant effects for both types of the teaching behavior, $F(1, 72) = 4.74$, $p < .05$ and $F(1, 72) = 10.98$, $p < .01$, respectively. The least-square means comparisons revealed that teachers in the experimental group employed more positive teaching behavior for promoting students' critical-thinking dispositions as well as for improving students' critical-thinking skills than did teachers in the control group.

In testing the path model of teacher training in critical-thinking instruction (see Figure 2 for the path structure), an analysis of structural equations yielded a non-significant $c^2$ value ($c^2(7, N = 75) = 2.63$, $p = .917$) and satisfactory fit indices (Goodness-of-fit Index = .988, Adjusted Goodness-of-Fit Index = .967, and Root-Mean-Square Residual = .025). These results suggest that the proposed model is a "good-fit" model. An inspection of Figure 2 reveals that (a) the teachers' involvement in the training directly influenced their change in professional knowledge and positive teaching behavior (the loadings are .58 and .46, respectively, $p < .001$); (b) the teachers' change in professional knowledge significantly influenced their change in teaching behavior (the loading is $.28$, $p < .01$), and (c) professional-knowledge change mediated the teachers' involvement in the training and their teaching-behavior change.

Conclusions

CS-TCT training resulted in improving the teachers' effectiveness in critical-thinking instruction, in increasing their professional knowledge about teaching critical thinking, and in enhancing their use of positive teaching behavior during critical-thinking instruction. More specifically, this training yielded an improvement in the teachers' content knowledge about critical thinking and an increase in their use of teaching behavior related to improving both critical-thinking dispositions and skills in their students. While teachers significantly increased their content knowledge about critical thinking, they did not increase their pedagogical knowledge about teaching critical thinking. This finding most likely reflects the fact that pedagogical content knowledge addresses a much broader scope of understanding than simple content knowledge—a scope that involves teachers' responding to students who have different needs in different content areas.

In conclusion, the findings from this study reveal that a computer simulation can be an effective tool for improving teacher instruction in critical thinking. To maximize a simulation's instructional impact, however, fundamental factors such as guided practice, research-based knowledge, and self-awareness must be taken into account. Future research needs to explore the influence of an additional factor, teaching efficacy. Numerous studies have found that teachers' beliefs in their teaching efficacy are associated with their instructional activities and supportive teaching behavior (e.g., Dembo & Gibson, 1985; Housego, 1992). Furthermore, Garcia and Pintrich (1992) concluded that teaching efficacy is fundamental in effective critical-thinking instruction. Such findings strongly suggest that simulation-based training in critical-thinking instruction can produce more lasting effects if it raises teaching efficacy as well as imparting skills and knowledge.
More Involvement: Increased involvement in reading personal teaching profiles, Professional knowledge: change in professional knowledge for teaching critical thinking, PK1: change in personal teaching profiles, PK2: change in professional knowledge for critical thinking, PK3: change in professional knowledge for critical thinking, PK4: change in professional knowledge for critical thinking, PK5: change in professional knowledge for critical thinking.

USING A COMPUTER SIMULATION TO EXPLORE TEACHER LESSON PLANNING

Amie K. Sullivan  
University of Virginia

Yu-chu Yeh  
University of Virginia

Harold R. Strang  
University of Virginia

Computer simulations offer a unique opportunity to research ways to improve teacher education. Over the past fifteen years, Curry Teaching simulations have been used to study preservice teachers’ acquisition of a variety of important professional competencies. Early research focused on fundamental skills such as administering lesson-related feedback and lesson pacing (Strang & Loper, 1985-86). During this period, research addressed teaching domains ranging from preschool (Strang & Meyers, 1987) to elementary education (Strang & Loper, 1983) to special education (Kauffman, J.M., Strang, H.R., & Loper, A.B., 1985). More recent studies have extended Curry simulations’ focus beyond teachers’ use of basic skills to include their more global communication patterns (DeFalco & Strang, 1994) and their sensitivity to individual student learning styles (Strang, Sullivan, & Yeh, 1995). In the most recent research strand, Strang (1996) explored the use of the graphically rich Windows-based Teaching Decisions (TD) simulation to study lesson planning patterns of preservice and inservice teachers. The current study continues research along this strand.

Description of the Planning Simulation

The latest Visual Basic version of the TD Simulation enables participants to conduct a pupil familiarization task and specific lesson planning tasks.

Pupil Familiarization

The familiarization task allows the participant to study key characteristics of the simulation class’ six software-defined pupils before making any planning decisions. Via simple mouse clicks, the participant can link pupil names and pictures to key personality and academic characteristics. Individual pupil note lists can also be easily constructed. These window-lists are immediately accessible during any of the subsequent phases of the lesson planning.

Pupil Spatial Assignments

The spatial assignment task enables the participant to position each pupil in the classroom, to select aids including a blackboard or a computer, and to determine with whom, if anyone, the pupil will work during the lesson. These assignments (or reassignments) are accomplished via click-and-drag actions.

Pupil Activity Assignment

This task enables the participant to assign lesson activities to each pupil or pupil group. A spin button facilitates tapping a master list of 8 activity options to create pupil or group activity assignments. An additional option is also provided for adding participant-authored activities to the list.

Teacher Commitments

This final task allows the participant to decide the amount of time that the teacher plans to spend working with individual pupils, groups of pupils, and the entire class. As with activity assignment, a spin button facilitates the mechanical aspect of this decision-making process.

While the task sequence listed above maps out a logical decision-making path, each participant has complete freedom to move to and from any task at any time during the simulation. Likewise, previous decision-making information (the notes collected on individual pupils or spatial, content or time assignments) is immediately accessible via a single click.

Research Questions

This exploratory study addressed three sets of questions. First, the lesson-planning activities of the two samples of experienced teachers were compared. It is important to note that one sample was drawn from a group of teachers who were beginning an off-grounds master’s program in teacher education; the second was drawn from a group of teachers who were completing the off-grounds program in a different setting. Specific planning differences across the two sites were assessed via a series of analyses of explicit planning variables that included:

1. pupil spatial assignments with the simulated classroom;
2. pupil time allocations assigned to specific lesson activities; and
3. teacher time commitments to individual pupils, to work
groups, and to the entire class.

The second question area addressed the relationship
between the teacher planning variables and major teacher
demographic variables. The third and most important
question area concerned the types of planning patterns that
teachers exhibited during their decision making. The
entire data set was submitted to an analysis that would
reveal whether such patterns existed, and if so, this analysis
would further depict the major characteristics of the
patterns.

Method

Participants

The samples for this exploratory study were drawn from
two groups of experienced teachers enrolled in a University
of Virginia off-grounds master’s program in teacher
education. Classes were held at sites in two metropolitan
areas in central Virginia. These classes typically contain
teachers from all grade levels who vary widely in teaching
experience. During the summer of 1996, 53 students
completed the lesson-planning simulation as a laboratory
requirement in a learning and development course. Site A
participants included 17 female and 5 male students who
were beginning their graduate program in education; site B
participants included 28 female and 3 male students who
were completing the program. The participants displayed
from 1 year to 29 years of teaching experience (M = 8.12,
SD = 6.74).

Procedures

The class at each site was introduced to the lesson-
planning task through a brief verbal explanation linked to
clear visual depictions of upcoming activities displayed by
an LCD projection unit. Next, groups of from 10 to 12
participants cycled through available computer work
stations at 90 minute intervals. Each participant first
completed a simple keyboard registration process and then
reviewed simulation navigation instructions. The partici-
 pant, assuming the role of a fifth-grade teacher, proceeded
to complete the task of becoming familiar with individual
pupils and the specific decision-making activities that
comprised three lesson-planning tasks. The participant
controlled both the task sequence and the amount of time
devoted to each task. During the navigation process, major
lesson-planning actions were stored in a sequential data file
for future analysis. After completing the tasks, the
participant clicked an Exit button to finish the simulation.
Completion times ranged from 30 to 60 minutes. A short
individual debriefing immediately followed the completion
of the planning simulation. After all participants at a site
had completed the simulation, they received a 30-minute
group debriefing during which the entire class’ collective
results were viewed and discussed.

Statistical Analyses

A number of statistical tests were employed to address
the three sets of research questions.

Site Differences

T-tests assessed group differences on three spatial
assignment variables: computer assignments, blackboard
assignments, and group assignments. A 2(site) by 4(activity
type) loglinear model tested the interaction between the
two sites and the four activity types. In this analysis, site
designated the two teacher cohorts, and content type
referred to four activity categories derived from Bloom’s
taxonomy of the cognitive domain (Woolfolk, 1993).
These categories included knowledge, comprehension,
application, and analysis-synthesis. Individual activity cell
frequencies represented the number of teachers whose
most-employed activity was defined by the cell’s descriptor.
A 2(site) by 3(teacher commitment) loglinear model
tested the interaction between the two sites and four teacher
time commitment measures. Individual cell frequencies
represented the number of teachers whose most-employed
time commitment was to individual pupils, to groups of
pupils, or to the entire class.

Planning-demographic Variables Relationships

Pearson correlation analyses were employed to explore
the relationships between three demographic variables and
the major simulation-generated planning variables.
Demographic variables included gender, teaching-grade
level, and years of teaching experience. Planning variables
included the three spatial assignment measures, allocation
measures for the four activity categories, and allocation
measures for teacher commitments to helping individual
pupils, groups of pupils, and the entire class.

Global Planning Patterns

Cluster analyses were performed on the entire data set
to identify variable patterns that broadly defined how
teachers approached the lesson planning task.

Results

Results obtained from analyses of group differences
revealed that teachers at site B (where participants were
completing the program) assigned more of their pupils to
work with each other than teachers at site A (where
participants were beginning the program), t(51) = -3.01, p
< .01. No significant site differences emerged from t-tests
applied to variables that defined teachers’ use of black-
boards or computers, t(51) = .09 and .87, respectively, ns.

Regarding activity assignments, the loglinear model
analysis yielded a significant group by lesson activity
interaction effect, c^2(3, N = 53) = 14.97, p < .01. For site
A, the analysis of simple main effects did not yield a
significant difference, c^2(3, N = 53) = 6.73, ns. For site B,
however, an analyses of simple main effects revealed a
significant difference in teacher frequencies across the four
activity categories, $c^2(3, N = 53) = 12.52, p < .01$. Teacher count was high in application activity and low in comprehension activity. No significant differences resulted when site comparisons were made across each of the four activity categories.

Regarding teacher commitments, the loglinear model analysis yielded a significant site by commitment interaction effect, $c^2(2, N = 52) = 20.23, p < .01$. For both sites, analyses of simple main effects revealed a significant difference in teacher commitment frequencies across the four categories, $c^2s(2, N = 52) = 27.91$ and $9.17$, respectively, $ps < .01$. For site A, teacher count was higher for individual pupil commitments than for group or class commitments. For site B, teacher count was higher for individual pupil and group commitments than for class commitments. Further analysis revealed a significant site difference for teacher class commitment, $c^2(2, N = 52) = 8.07, p < .01$. Teacher count was lower on this variable for site A participants than for site B participants.

Only one significant relationship emerged when the 10 lesson-planning variables were compared with the three demographic variables. Female teachers were more likely than male teachers to assign pupils to computer stations, $r(51) = .30, p < .05$.

Relating to questions pertaining to lesson-planning patterns, the results of cluster analyses yielded three distinct groups. The 3 teachers comprising the first group had relatively long teaching careers, were relatively low in assigning pupils to work together, and were relatively high in committing themselves to interact with the entire class. The 32 teachers comprising the second group had relatively short teaching careers and were relatively high in committing themselves to interact with groups of pupils. The 14 teachers comprising the third group were relatively high in both assigning pupils to work together and in committing themselves to work with individual pupils.

**Discussion**

Several interesting conclusions can be derived from the results of this exploratory study. First, it appears that teachers in the two target sites differed in their approach to the planning simulation. Teachers at site B (those completing the graduate program) stressed more cooperative pupil interactions and showed a more distinct activity assignment pattern and more complex teacher-time commitment assignments than did teachers at site A (those beginning the program). These group differences may merely reflect site conditions, or they may suggest that experiences within the master's program influenced the teachers' attitudes concerning the importance of cooperative learning, application-based activities, and personal involvement at all levels of student interaction.

Distinct patterns emerged from the cluster analysis even though this statistic was applied to only a few preliminary variables. Teaching experience and four decision-making variables defined the three clusters. The first and smallest cluster included participants with relatively long teaching careers who gravitated toward committing their time to the whole class and tended to de-emphasize the importance of pupils working together. The second and largest cluster included participants with relatively short teaching careers who preferred to work with groups of pupils. The third cluster included participants who emphasized cooperative learning while providing teacher help to individual pupils.

The strength of the results justifies the continuation of this research strand. We are particularly interested in better understanding the variations in strategies that experienced teachers employ in their lesson planning. Discovering additional variables for inclusion in cluster analyses is a first step toward achieving this goal. An initial viewing of the data files of individual participants produced several promising additions to the current pool of variables. These additions included teachers' note-taking behavior, use of classroom equipment, and activity authoring.

In conclusion, the results of the current study provide important insights into the way that experienced teachers plan lessons. To add clarity to the current strategic profiles, however, not only must additional variables be added to the existing pool, but the study must be replicated with a variety of teacher cohorts. The information we learn about successful lesson planning from our experienced teachers will become part of the feedback that our preservice teachers will receive as they continue, during the TD simulation assignment, to develop their own personal planning strategies.
