A Time Series Design, Change-Over-Time study was used to determine the usefulness of four tasks in distinguishing maturational factors and neurological characteristics of eight boys, ages 6-12, who were diagnosed neurologically impaired. Results indicate that the tasks are characterized by use of regular art materials, interest to the subjects, ability to be replicated, and allowance for expression and visuo-motor enhancement. Data on three other measures: resistance to adaptation, sensitivity to maturation, and sensitivity to neurological impairment, were collected, but are not discussed in this paper. This study has relevance to art therapists whose work is to measure the effects of treatment with heterogeneous patient populations.

A crucial issue for art therapists is finding the most effective therapeutic method for individualized patient treatment. Unlike psychologists, art therapists must confront the veracity of their methodology through small samples and heterogeneous clients. Large sample statistical findings are very difficult to attain. For many years, narrative case studies have been the dominant form for demonstrating the effectiveness of art therapy. Additionally, many art therapists use assessment procedures to determine the current functioning of the client before treatment.

Over the past 20 years, numerous assessment and evaluation tools, both quantitative and qualitative, have been developed by and for art therapists (e.g., Burns & Kaufman, 1972; Ulman, 1975; Kwiatkowska, 1978; Hays & Lyons, 1981; Wilson & Wilson, 1981; Mijekovic & Irvine, 1982; Kramer & Schehr, 1983; Silver, 1988, 1990; Cohen, Hammer & Singer, 1988; Malchiodi, 1990).

Many assessments designed by art therapists are one-session, one-activity procedures and are used to evaluate the status of the client. These assessment procedures are not repeated once treatment begins. Instead, the art work of the client is closely monitored for indicators of change in the client's disposition. Occasionally, assessments are used both before (pre-test) and after (post-test) treatment, to demonstrate change resulting from intervention: post-treatment assessments are seldom administered. The practice of administering periodic assessments during the treatment period is even less frequent.

Despite the gains in objective reporting made through assessment, many of the drawbacks of case studies identified by Rosal (1989) persist in assessment procedures. Independent and dependent variables are not described, and most assessment procedures developed by art therapists have not been tested on a large population. A recent informal survey of assessment use in child art therapy (Mills & Goodwin, 1991) indicates that a wide range of assessment procedures are used by art therapists. The majority of assessments listed, however, rely on qualitative reporting processes, thus limiting replication and generalization of results. Assessment can demonstrate the outcomes of art therapy, but it does not address the need to measure therapeutic gains during the treatment period.

All therapists ask themselves how much of their
intervention entered into the growth, or lack of growth, of their clients. If treatment is long term, the problem of distinguishing between normal maturation and intervention can be even more elusive, especially in work with children. Assessment does not address the need to measure therapeutic gains during the treatment period. It does not specify which interventions were effective and when the effects occurred.

The time-series design, an alternative to the case study narrative and pre-treatment assessment, is a plausible approach to determine the effects of treatment. Time-series research grew out of behavioral psychology which has advocated its use since the late sixties (Kratchowill, 1979). The feature common to all time-series design in the study of groups or individuals is time. Time periods vary, but may be long enough to be considered a longitudinal study.

Additionally, time-series designs emphasize "repeated measurement under baseline and intervention conditions" (Kratchowill, 1978, p. 8). The client’s behavior is observed at phase one of the study. When treatment or alternative treatment is introduced, the effects of the treatment on the client’s behavior are noted (Rosal, 1989).

The time-series design is considered to be an empirical procedure particularly suited for use with an individual subject or "small group, over time, with the introduction of some intervention into the data series, and with subsequent monitoring of the series to examine effects" (Rush & Kratchowill, 1981, p. 59). Designed to examine individual variability, it allows the clinician "to establish a degree of functional relation between independent and dependent variables..." (Rush & Kratchowill, p. 60), to monitor the introduction of specific variables and to gauge its effect upon the individual.

It is suited to use with heterogeneous client populations. Data can be evaluated through visual and/or statistical procedures. "Visual analysis consists of judging graphic data under different conditions of the experiment" (Rush & Kratchowill, p. 63). In this case, the evaluation criteria must be quite stringent if the procedure is to have potential for success.

The single case experimental design-time series paradigm is also uniquely suited for use "in natural settings where data collection procedures necessary for true experimental designs were not feasible" (Kratchowill, 1978, p. 8). For example, it can be used in work with geriatric clients, borderline patients, and autistic children. It is characterized by repeated measurement under baseline and intervention conditions, and avoids the use of between group and between individuals comparisons. The design may be a simple ABAB format, or any combination, with intervention introduced at random or regular intervals. "A" stands for the baseline condition, and "B" indicates the intervals of intervention conditions. For example, a regular intervention interval is coded ABAB; an irregular intervention interval is coded ABBABA. Or, treatment may precede alternative treatment or intervention: BA.

Using a single subject research, time-series change-over-time model to demonstrate changes within the process of therapy, the clinician can control alternative approaches to treatment. Like the case study and assessment tools, it is used to evaluate change. The difference is that the demonstration is pre-planned, and comparatively more controlled and often quantitatively measured. Evaluation of the intervention is done during treatment, not only at the beginning or end of treatment, as in assessment. The time-series paradigm is used when the same subject is tested repeatedly. This model is compatible with art therapy because art therapists work with individuals or small groups over a period of several to many sessions, are able to pre-plan intervention, and have quantitative measures available to use when desired.

Purpose of Study

The purpose of this study was to use a modified time-series, single subject, change-over-time design to test a battery of tasks over a six-month period or longer. The tasks were designed for use with neurologically impaired children and administered on a pre-planned monthly schedule. It was hypothesized that the changes in artwork, quantitatively measured, would be due only to maturation, not to treatment intervention.

This study was designed to establish the effectiveness of the research design and methodology, and to establish the effectiveness of the task battery in seven areas. Four areas of non-quantitative measures are discussed in this paper—the tasks should: (1) use common art materials, (2) sustain the client interest, (3) allow replication, and (4) enable the child to work expressively or enhance visuo-motor skills. Three measures, which were quantitative, were tested: (5) resistance to adaptation, (6) sensitivity to characteristics of maturation, and (7) sensitivity to characteristics of neurological impairment; these will be discussed in a future paper.
Method

Subjects

The subjects were eight boys, ages 6-12, diagnosed neurologically impaired. All were enrolled in a private school in a rural section of the Northeast. The school is explicitly for neurologically impaired and emotionally disturbed children who could not be served by their public schools. All children enrolled in the school were of average or above average intelligence and none had physically handicapping conditions.

Subjects were selected by their classroom teacher on the basis of who might profit from individual art sessions, who might be able to make good use of art materials, and whose parents would be inclined to approve of their child’s participation.

The age range of 6-12 years was divided as follows: age six = 1; age eight = 2; age nine = 2; age ten = 2; and age twelve = 1.

Family constellations varied from intact families to several which were single parent families. Socio-economic status ranged from professional (e.g., college professors) to blue collar and middle class. All children lived within a one-hour bus ride from the school in neighborhoods which ranged from urban to suburban. Children attended school on a daily basis.

One of the reasons for selecting a time-series single subject design was to accommodate the differences between children. These included a range of age, socio-economic levels, family configurations, and emotional and neurological conditions of each child. The heterogeneity of the group within the larger framework of the diagnostic category was therefore a desirable factor in this research. All subjects attended all six months of planned sessions.

Materials

Four assessment tools, plus the Bender-Visual-Motor Gestalt Test, comprised the task battery. The Bender was administered only once at the beginning of the time series. The other four tasks were administered monthly.

Each child produced six sets of the following tasks, excluding the Bender:

Bender-Visual-Motor Gestalt Test (BVMG) (Bender, 1938): The Bender is a set of nine designs, one on each card. The child is asked to copy each design onto a sheet of 8¾” × 11” white paper using pencil. He is then asked to reproduce the designs from memory.

Rey-Osterreith Complex Figure Test (CFT) (Taylor, 1959): Each subject was requested to make one copy of this test, using pencil on 8½” × 11” paper. After a few minutes, a memory drawing of the same was requested.

Human-Figure-In-Action Drawing (HFIA): Subjects were asked to create a drawing of themselves or another person in action (Figure 1). 8½” × 11” paper, pencil or colored magic markers were used. This could be from memory, fantasy, or imagination.

Story-Sequence Drawing (SSD): Using pencil or colored magic markers and 8½” × 11” paper, each subject was requested to draw a story with a beginning, middle, and an end (Figure 2). It was to be sequential, and drawn within four-six frames or steps.

Clay Human or Animal: Each subject was asked to make at least one figure, using a ¼ pound stick of plasticene/oil-based clay (Figure 3).

Rational for Selection of Tests and Tasks

Lezak (1983) states: “Constructional performance combines perceptual activity with motor response and always has a spatial component. . . . The integral role of the visuo-perceptual functions in constructional activity becomes evident when persons with more than very mild perceptual disabilities experience some difficulty on constructional tasks” (p. 382).

Constructional performance is affected by location of lesion. For example:

“Patients with right hemisphere damage tend to take a piecemeal, fragmented approach, losing the overall gestalt of the construction task. They may neglect the left side of the construction or—occasionally—pile up items (lines in a drawing, blocks or puzzle pieces) on the left . . . (they) do not benefit from having a model. Patients with left-sided lesions may get the overall proportions and the overall idea of the construction correct, but they tend to lose details and generally turn out a shabby production” (Lezak, 1983, pp. 382-383).

The selection of tests and tasks was critical for this study. Each test or task was selected to meet seven criteria: (1) Art materials. Materials chosen need to be commonly used in art therapy treatment; their familiarity and non-technical nature should allow for maximum opportunities for expression. (2) Interest, challenge and success. Subjects were asked to attempt each task six times. Therefore, the tasks had to hold sufficient interest. (3) Replication. Tasks were repeated six times using exactly the same directions. Exactly the same procedures were to be
Fig. 1. Human-Figure-in-Action Drawing. Brian, age 9: "Terra fermies looking over a hill."

Fig. 2. Story-Sequence Drawing. Andrew, age 10: "A man drives his dune buggy over a hill and falls into the ocean. He is rescued by a ship. He says to the Captain: 'Thanks, pal.'"
followed every time with each subject to ensure uniformity from session to session. (4) Opportunities for both expressive exploration of themes and enhancement of visuo-motor skills. The tasks needed to include open-ended directives, allowing the child to explore themes from current life, fantasies, or memories. The structured task should allow the child to engage in a predictable, and therefore safe, activity which challenges his visuo-motor skills. The three quantitative measures were: (5) Resistance to adaptation. Tasks need to be resistant to learning from repeated exposure which could lead to adaptation, or mastery of the task. (6) Sensitivity to maturation. Tasks need to be sensitive to developmental changes in the subjects' art work which resulted from normal maturation. (7) Sensitivity to characteristics of neurological impairment. Tasks need to be sensitive to perceptual impairment and locus of lesions of both the left and right hemispheres.

The structured tasks, the BVMG and the Complex Figure Test, were selected because of their appropriateness for use with neurologically impaired populations. These tasks would serve as a guide or screen to consider the semi-structured tasks, the Story-Sequence Drawing (SSD), Human-Figure-In-Action (HFIA), and Clay Figure.

The Bender Visual-Motor Gestalt test is highly sensitive to characteristics of neurological impairment and is scored based on a developmental scale developed by Koppitz (1963). It is useful with children ages 5-10 and adults. The developmental scoring can differentiate between distortions “which primarily reflect immaturity or perceptual malfunctioning, and those which are not related to age or perception but which reflect emotional factors and attitudes” (Lezak, 1983, p. 5).

There are two phases of the test: copy and recall. The literature shows a reasonably high degree of consistency, over time, of the performance and scoring of the tests (Lezak, 1983).

Koppitz, testing children with brain injury, concluded that the Bender VM Gestalt could be of “considerable help in diagnosing Minimal Brain Injury (MBD), but it is not possible to determine the etiology of MBD from children’s Bender Test records” (Koppitz, 1975, p. 72). She, therefore, recommended using it with other tests for diagnostic purposes. Clinically, although there were wide differences from child to child, she noted that general characteristics are often found in the tests of the MBD child:

- a lag in visual-motor integration (that is, there was a significant immaturity in the drawings of the MBD when compared to the normal child)
- marked discrepancy between IQ score and Bender test scores
- a significant number of rotations.

Adaptation to the test was not a factor in the choice of this test since it was administered once. It was found to be challenging and stressful to the subjects, and therefore not repeated after the first administration.

The Rey-Osterreith Complex Figure Test (CFT) was selected to “investigate both perceptual organization and visual memory in brain-damaged subjects” (Lezak, 1976, p. 321). This was the original intent of Rey (1941), who designed the CFT. Osterreith (1944) standardized the procedure, using 230 normal children ages 4-15, and 60 adults ages 16-60, plus “two groups of children with learning and adjustment problems (and) a small number of behaviorally disturbed adults, 43 who had sustained traumatic brain injury and a few patients with endogenous brain disease” (Lezak, 1983, p. 395).
Taylor (1959) states that:

Children with old injuries (to the central nervous system) often show perceptual difficulties from early childhood on. The precepts which they retain are frequently distorted and poorly differentiated. Children who have developed normally up to a certain point before the injury may have retained some well structured spatial concept even though they no longer can elaborate new ones with ease (p. 396).

The Rey-Osterreith Complex Figure Test, when used with brain-injured children, often results in distorted, primitive or concretized reproductions (Taylor, 1959). Taylor suggests that more intensive study of the test's usefulness with atypical children is needed. Most errors were expected to be in organization of perceptual material in the design.

The test is made up of two subtests: copy and memory tests. In normal children, the memory drawing often nearly duplicates the flat copy drawing, but shows better organization. Brain-injured children draw poorly from memory, possibly due to an inability to coordinate previously perceived isolated details. Failure to integrate details into a larger structure means they are not easily remembered. This requires extra effort from a child who has all too often experienced failure (Taylor, 1959).

For use with neurologically impaired children in this study, the task, as originally designed, was modified. Rather than request the subject to copy the design, using a pre-arranged sequence of colored pencils, the child was simply asked to use a #2 pencil to copy the figure onto an 8½" x 11" paper. Similarly, he was offered only the #2 pencil to draw the figure from memory.

As in the original study, the steps taken to complete the copy and memory portions of the test were of interest. The errors at each step are also important sources of information about the child's perceptual strategies. A scoring system developed by Taylor (1959), adapted from Osterreith, was used to assess the drawings.

For brain-injured subjects, one would look for a wider discrepancy between copy and memory scores than is found in normal populations. This is evidence of a fragmented or piecemeal approach to copying, dealing with smaller visual units and building up the figure, bit by bit. Other characteristics include omissions, perseveration, repetition of elements which had been copied, and a design element placed in a more familiar representation, e.g., making the circle with three dots into a face (Lezak, 1983).

Few subjects in the present study were able to draw the design from memory. Specific clusters of approaches to drawing the design were noted. In general, a brain-injured subject often begins by drawing the large central rectangle and details within it (left hemisphere damage). Or, he or she might approach the task by beginning with a detail and adding the remaining details in relation to the large rectangle (right hemisphere damage) (Lezak, 1983).

Scoring of this test has not been standardized on a large sample. However, it was felt that the data gathered during this study might be useful to other research which made use of this test. Approaches to drawing the Complex Figure Test might also bear a relationship to the three semi-structured tasks in the present study. Finally, similarities and differences could be studied between the Complex Figure Test and the Bender Visuo-Motor Gestalt Test.

Standard verbal directions are used, thereby insuring that the test could be repeated exactly. The remaining criteria, adaptation and interest to the subjects have not previously been tested. Therefore, new findings were possible on these two measures.

The Human-Figure-In-Action Drawing (HFI) is designed for this study, based upon the Harris revision of the Goodenough Draw-a-Man test (Harris, 1963), the Kopitz Human-Figure-Drawing (HFD) test (Kopitz, 1968), and the Burns and Kaufman Kinetic-Family-Drawing (KFD) test (1972).

The purpose of this task is to collect, on a regular schedule, samples of the subject's rendering of the human figure. The human figure is a sensitive indicator of body image and of the child's sense of self. Kopitz indicates that human figure drawings are very useful as part of the test battery for assessing brain-injured subjects (Kopitz, 1968).

The subject is asked to draw the figure in action "doing something" to tap into his memory and imagination, and to elicit a result having greater affective quality.

The Goodenough-Harris scoring system (Harris, 1963) measures intellectual maturation in the child (Lezak, 1983). The Kopitz scoring system is sensitive to characteristics of brain injury and emotional factors. Both scales are developmental and are appropriate for use with children ages 5-12.

With respect to brain injury, Kopitz (1968) found that there are eleven Developmental Items on HFDs which

"... may have implications for brain injury at one or more age levels. These items were:

Omission of body (age 6 and up),
Omission of pupils (age 7 and up),
Omission of neck (age 10 and up).
Omission of two dimensional arms (stick arms) (age 7 and up).
Arms not pointing downward (arms horizontal or up) (age 10 and up)
Arms incorrectly attached at shoulder (age 9 and up).
Omission of hands (age 6 and up),
Incorrect number of fingers (age 7 and up),
Omission of two dimensions on legs (stick legs) (age 8 and up).
Less than two pieces of clothing (age 7 and up),
Less than four pieces of clothing (age 12 and up)” (Koppitz, 1968, p. 175).

Koppitz was also able to isolate eight emotional indicators which
“... were found to occur more often in the HFDs of the brain-injured boys than on drawings of the Control Subjects. These were: Poor integration of parts of figure (ages 7-12), Gross asymmetry of limbs (ages 6 and 7 and up), Figure slanting by 15 degrees or more (ages 7, 10, 11), Transparencies (ages 7-12), Omission of body (age 6), Omission of neck (ages 10-12), Tiny figure, less than 2" in height (ages 6-8, 11-12), Hands cut off” (1968, p. 176).

According to Koppitz,
The first six of these Emotional Indicators reflect immaturity, poor integrative capacity, impulsiveness, and instability, all of which are so characteristic of so many of the brain-injured children. The last two of the Emotional Indicators seem to reflect above all the brain-injured child's poor self-concept and his feelings of inadequacy and helplessness” (Koppitz, 1968, p. 176).

She cautions, however, against making a diagnostic judgment using only these items as criteria.

To further elicit emotional factors in the development of the subjects used in the present study, the children are given a choice of using either a #2 pencil or colored markers. The mode of color usage, realism of color, and affective use of color potentially could be tapped through this revision.

Ability to replicate the directions and scoring is ensured by standard verbal directions and quantitative scoring. Adaptation is scored on a developmental scale, since the human figure is often drawn by children. This, however, needs further testing as does the criteria about interest to the subjects.

_Story-Sequence Drawing (SSD)._ In this task, the subject is asked to draw an episode containing at least four stages (a beginning, two middle stages and an end). He can use either pencil or colored markers to draw all stages on one 8½" × 11" paper or on separate papers.

This task is adapted for this study from an unpublished task developed by Kramer and is similar to one developed by Wilson and Wilson (1981).

Wilson and Wilson (1981) state:
“... (of) children who were able to tell stories (often this is not achieved before the age of five or so) (Botvin, 1976), few were unable or unwilling to draw a story in the six frames—and sometimes as few as one frame or as many as twelve—it was the amazing variety of ways with which they chose to examine the most basic of life’s themes that we found most exciting” (Wilson & Wilson, 1981, p. 75).

Although their research was conducted in the United States, Japan, Finland, Egypt, Australia and New Guinea, it was not conducted with neurologically impaired children. Their findings indicate four major themes: "slice of life," development (plants, birds growing up/dying), natural process (day-night, calm-storm), and a trial (test of strength, struggle, success, combat). They summarize: "Story drawings generally provide for a fuller, more complex and consequential mirror of an individual's conception of the four realities (common reality, archetypical reality, normative reality, and prophetic reality—see Kreitler & Kreitler, 1972, p. 70) than can be achieved by single images" (Wilson & Wilson, 1981, p. 79).

If the child chooses to use color, it enhances the emotional tone of the story. Degrees of consistency of theme, style, and tone are evident from session to session, and with respect to the other tasks within each session.

The study tested categories of maturation, neurological impairment, and subject's degree of interest.

To determine whether this test can be replicated, verbal directions and both quantitative and qualitative scoring are used. Resistance to adaptation was also tested.

_The Clay Figure_, the final task, was the only three-dimensional task required of each subject. It is intended to tap into the child's ability to model a human or an animal. This task is necessary for purposes of assessing and confirming the developmental stage of the child. Younger children tend to work in an analytic style, often making a pancake figure, while older children use a synthetic style, and produce upright figures (Lowenfeld, 1957; Golomb, 1974).
Consistency or lack of consistency between this material which invited regression and the more cognitive controlled pencil might provide information about the child's emotional development. Sometimes three-dimensional work elicits items in subject matter and more or fewer details, or attention to detail other than that elicited by two-dimensional work. The clay medium gives additional information about subjects whose perceptual deficiencies were subtle.

The works of Golomb (1974) and Lowenfeld (1957) were used to assess the sensitivity to maturation, the developmental level of the child, and the changes which took place over time.

The subjects were allowed to work in the clay in either a flat or an upright position. The pieces could be modeled using either the analytic or the synthetic method. The analytic method seems to be useful where a lot of detail is preferred. The synthetic method gives a more solid form, which can reflect body experiences and activate knowledge (Golomb, 1974). The analytic method is useful if only a vague form concept is available to the child. He needs to watch what he is doing in order to represent the object in mind. This may have some relationship to neurological impairment, when taken in context with other tasks.

Quantitative scoring and consistent verbal directions ensured that the task would be presented exactly the same way each time. Resistance to adaptation is to be determined by this study.

**Procedure**

Each of eight boys, diagnosed as having neurological impairment, were individually tested over a six-month period. A quiet room within the school was used at various hours during the school day. Sessions took place on two consecutive or two alternate days of one week per month. Length of sessions were from one-half to one hour with variations determined by the child's interest span, working style, and schedule. Verbal instructions for each task were given. The sequence of each task during the session was recorded, as were comments and behavior of the child.

A word needs to be said about the sequence of the tasks. As with any diagnostic procedure, the researcher, who was also the examiner, found that in each session the sequence of the tasks had to be adjusted to the particular child. Some subjects began with the Complex Figure Test, a structured task, and moved to the semi-structured tasks. Other subjects preferred to do the opposite. The quality or validity of the products did not appear to suffer from this flexibility in session strategy.

In each session, the examiner allowed the child to choose where he would sit. This varied from directly across from the examiner to the request that the examiner move to a distant part of the room. Seating positions are usually standardized for most testing procedures. To elicit the child's cooperation and best efforts the researcher found that highly sensitive subjects and highly distractible subjects required variations in the usual testing procedure.

At the first session, the examiner introduced herself and invited the subject to sit anywhere he wished within the classroom. The examiner explained that they would have two art sessions together that week, and that both would come back next month for two more art sessions. The sessions included copying tasks, some free drawing tasks and one clay task. The subject could do each of the activities once over the two-day period. Ample materials (paper, pencils, markers and clay) were visible to the child. Design cards were hidden from the child's view until they were used.

The Bender Visual-Motor Gestalt Test was administered first, on the initial day of the six-month period. The directions are: A sheet of 8½" × 11" white paper and three pencils with erasers are placed in front of the child. The examiner says: "I've got nine of these altogether (hold up the pack of cards with the back facing the subject). I'm going to show them to you one at a time and your job is (or 'you are') to copy them as exactly as you can. Here you go." (Lezak, 1983, p. 387). Place the card in front of the subject with the length running horizontally to him. When he finishes the drawing, the second card is placed on top of the first. Continue this way until completion. (If the child draws the design very large, and needs additional paper, supply them without comment). Usually one piece of paper is sufficient (Lezak, 1983). After a brief rest, the examiner invites the child to draw all the designs from memory. "Now I'd like you to draw all the designs you can remember on this sheet of paper."

This was followed by an invitation to do another copy task or free drawing or work in clay. Instructions for the Rey-Osterreith Complex Figure Test are: A sheet of white 8½" × 11" paper is placed horizontally in front of the child. Fresh pencils are offered. The figure is presented so its length is horizontal to the subject's horizontal plane. The examiner says: "Look at this drawing and try to copy it as well as you can. Try to make sure that you do not forget anything" (Taylor, 1959, p. 396). After the
child is finished copying, the figure is removed and
the examiner engages the child in light conversation
for about three minutes. The child is then told: "I'd
like you to draw that same design again, but without
looking at the card." Often this is difficult for young
children. The examiner closely watches the perform-
ance. She notes the sequence by drawing the image
and numbering the sequence of the units or uses a
copy of the design and numbers the sequence of the
units. Arrows are drawn to indicate the direction
each line is drawn.

For the Human-Figure-In-Action, the child is
given a fresh sheet of 8½" × 11" paper, fresh pencils
and a box of eight colored markers. He is instructed:
"You can use pencil or markers to draw a picture of a
person doing something. This can be a drawing of
yourself doing something you like to do, or of a
friend, or of an imaginary person."

Directions for the Story-Sequence are: a sheet
of white 8½" × 11" paper, several pencils and a box
of eight colored markers are placed in front of the
child. The examiner says: "I'd like you to think of a
story. The story should have a beginning, middle
and an end. When you have thought of a story, I'd
like you to draw each part of the story. You can use
one paper, and divide it into boxes (demonstrate), or
you can use several sheets of paper."

Some children verbally organize their story by
telling it to the examiner before drawing, while
other children begin drawing almost at once. Very
confused children may need to be encouraged to tell
the story out loud, and, with the examiner's as-
tistance, decide what to illustrate.

For the Clay Figure directions a stick of plas-
ticene is placed in front of the child on a cardboard
base, 9" × 12". The examiner says: "Use this clay to
make a human figure. It can be a boy or girl or man
or woman, or an animal. You can use all the clay for
one figure or break it into pieces and make several
figures." Only one stick of plasticene is allowed for
each subject.

Each child is allowed to choose the order in
which tasks are completed. Tasks not attempted on
the first day of the two-day session are presented on
the second day.

This procedure was repeated each time, except
that the BVMG was not administered after the first
day of the period. At the end of each two-day ses-
sion, the examiner explained that she would take
pictures of the subject's work and she would return
the work on her next visit. After the last session of
the series, she returned the artwork to the subject's
classroom teacher.

Observations and Discussion

The purpose of this study was to establish a bat-
tery of tasks for use with neurologically impaired
children over a period of six months. The task bat-
tery included both structured and semi-structured
activities. Seven criteria were identified as essential
characteristics of each task. A quantitative analysis of
the results was not obtained for this section of the
study; that data will appear in a future paper.

(1) Use of art materials. All tasks used art mate-
rials: pencil, markers, paper and clay. As stated
above, children experienced these as regular art ses-
sions using regular art materials.

(2) Interest. The task battery proved to be of
much interest to all eight subjects. Each subject ea-
gerly looked forward to each session, and attendance
was perfect. Subjects prized their art work and
looked forward to taking it home. Most subjects
were confused and disappointed that they could not
attend sessions weekly, following a schedule similar
to that used for their art classes. This suggests that
the boys experienced the sessions as regular art pe-
riods, not as testing sessions. They accepted that the
examiner could come to the school only on a
monthly basis. No one task was preferred over an-
other, although the order in which tasks were com-
pleted varied according to the child's choice.

(3) Replication. Directions and materials for
each task were easily repeated each session. The
only variation necessary was for the memory subtest
of the Complex Figure Test. In this test the exa-
miner offered the opportunity to draw from memory,
but did not require reluctant subjects to attempt this
section of the test.

Several subjects wished to rotate the Complex
Figure Test card to a vertical position. This was
gently, but firmly discouraged. Typically, there were
changes in size of the design and strategies for draw-
ing the design. Many subjects placed the drawing in
different parts of the paper, corners, for instance.
This was particularly interesting when the quadrant
selected corresponded to that chosen for the
Human-Figure-In-Action drawing.

The number of sheets of paper used in the
Story-Sequence Drawing varied from subject to sub-
ject, and session to session. Subjects told stories of
various lengths and complexity.

(4) Allows for expressive work or enhances
visuo-motor skills. The Complex Figure Test chal-
gened most subjects, stimulating the need to ob-
serve, organize and graphically reproduce the figure.
Similarly, organizational skills were necessary to express ideas in the figure drawing, clay and story. These last three tasks allowed room for free choice of themes and style of expression, from cartoon characters to attempts at representation. The non-technical materials were very familiar to the children, and needed no period of mastery which might inhibit expressiveness.

(5) Adaptation. While subjects remembered tasks from month to month, only one subject repeated the same Story-Sequence each time. All other subjects produced new products each time. Only the Complex Figure Test offered an opportunity for learning, but the Figure was so complex, it offered little chance for mastery.

(6) Maturation. Scoring for the Complex Figure Test, Human-Figure-In-Action, the Story-Sequence Drawing and Clay Figure are based on developmental scales. All tasks were structured to be sensitive to allow for variations in visuo-motor skill, interest, attention span and frustration tolerance of the age levels 6-12 years. In a time-series design, the subject's products and performance are measured against his own previous performance.

(7) Sensitivity to neurological impairment and locus of lesion. Quantitative data on this criteria will be reported in the second part of this report.

Other factors contributed to the success of the task battery. The balance between structured and semi-structured tasks provided enough choice for each subject within the sessions. This was particularly important for those subjects who needed to move from a stressful task to one which made fewer demands. This varied with each subject, with the Complex Figure Test difficult for some, and the Figure-In-Action difficult for others. The variety of materials provided opportunities for choices, as did allowing the children to choose the sequence of tasks.

The variety of tasks allowed for the exploration of many or few ideas, changes in themes or the use of one theme. There was enough diversity to hold the children's interest over the six-month period. The Complex Figure Test remained challenging to all subjects, despite repeated administrations.

The study was not without flaws. One of the major problems was that the six-month period was too short. When looking for potentially dominant trends in the child's development, the tasks need to be highly sensitive to small changes as indicators of change or maturation. Since much of the material brought to each session could be influenced by events in the child's life at home or school, it would have been desirable to keep records of the events throughout the testing period. This might have provided clues to changes in themes, choice of materials or frustration tolerance.

Conclusions and Recommendations

This study suggests that a single subject time-series design for a change-over-time study can be a valuable and useful research tool for art therapists. It can be used with a heterogeneous population of neurologically impaired boys. A task battery of structured and semi-structured activities can sustain the interest of subjects over a six-month period, and the tasks are resistant to adaptation. This is a valid method of conducting research, and has particular application to clinical settings where art therapists work with individuals over medium to long periods.

The time-series design can be used to test the effectiveness of therapeutic intervention within the treatment period. Using the task battery as a dependent variable, we can gauge the effects of different art materials. For instance, water-based clay may be substituted for oil-based clay to gauge regression and recovery from regression, or black paper and white pencil may be substituted to gauge the effect on visual organization (Uhlin & Dickson, 1970; May, 1978; St. John, 1979).

Empirical study of the client during treatment is still necessary. The time-series design appears to be a useful addition to our methods of treatment evaluation. It is hoped that this study will stimulate interest in the time-series design not only for neurologically impaired populations, but also for any population treated by art therapists.

Art Therapy and Self-Esteem

Michael Franklin, M.A., A.T.R., Director, Art Therapy Program School of Art, Bowling Green State University, Bowling Green, OH.

Abstract

The impact of creating art and how this process relates to the elevation of self-esteem is often taken for granted by professionals in both art therapy and other fields. While there is little doubt concerning the validity of this relationship, there does seem to be a lack of research and a lack of understanding concerning this issue. All too often the subject of self-esteem is loosely defined, resulting in an oversimplified view of its meaning. This paper discusses ideas from literature on self-esteem that relate to both the art making process and overall treatment goals targeted in an art therapy setting. The art component of art therapy is stressed throughout since it is believed that an isomorphic relationship exists between specific features of self-esteem and this central component of our work.

Curiously enough, as a specific topic of research self-esteem has received minimal attention in the art therapy literature. Art therapists intuitively observe that a strong connection exists between art therapy, the art making process and self-esteem, but few have attempted to describe these relationships in detail. All too often art therapists seem to take it for granted that producing art is good for us and that it automatically contributes to various therapeutic goals such as the elevation of self-esteem. However, when asked to clarify these beliefs, people often struggle to define their terms. In short, there is more to the subject of self-esteem than convenient intuitive explanations.

Given the likelihood that the majority of mental health treatment facilities would almost always target self-esteem as a major goal of treatment, it is important to identify how art therapy can contribute to this universal clinical topic. Also, self-esteem issues permeate every aspect of society and go well beyond the boundaries of the clinical setting. Investigating and solving the nation's most prominent social problems almost always, in part, boil down to a discussion on the subject of self-esteem. Concern about self-esteem is growing, particularly in states like California where a massive endeavor is underway to study and implement self-esteem strategies to promote social change (Mecca, Smelser & Vasconcellos, 1989).

The ideas described in this paper will address the relationship that exists between self-esteem, creating art, and art therapy. Examining the connections between these themes will hopefully set in motion further dialogue and research on this topic.

Definitions of Self-Esteem

Endless definitions surface when investigating the meaning of self-esteem. The subject is easily complicated due to the many ideas contained within this two-word title. To begin with, the term "self" has multiple interpretations, each valuable, but potentially different from the other. There is the true and false self outlined by Winnicott (1965). Jung described the central importance of the self archetype (Campbell, 1971). Kohut (1977) and other authors (Berger, 1987) have yet another viewpoint on the subject. Rather than focus on libidinal drives, they adopted the term "self object" which referred to functions that augment the development of a sense of self (Berger, 1987).

Other definitions emerge when cultural perspectives of self are considered. For example, Eastern viewpoints often conceptualize the abstraction of self in totally different terms from Western authors (Fontana, 1987; Marsella, Devos & Hsu, 1985). Purkey and Schmidt (1987) define self as the summation
of a multi-dimensional system consisting of various learned beliefs, covering the total range of personal perceptions and self-evaluations. These viewpoints are perceived as truths that ultimately define the meaning of personal existence and personality structure.

Self-esteem is perhaps the most familiar subject within the umbrella topic of the self-concept. Whereas self-concept is equated with identity, self-esteem refers to self evaluation and is often understood as a strong appreciation of oneself. Thus, trusting in personal abilities and developing an attitude of self-worth is at the core of an elevated sense of self-esteem.

Researchers generally agree that self-esteem equates with personally generated evaluations of worthiness (Coopersmith, 1967). These self-appraisals can take many forms ranging from transitory to enduring. It is the well-anchored, enduring sense of belief in one's unique personal qualities that therapists hope to buttress and solidify. In general, self-esteem is viewed as a condensation of self-evaluative processes that define a sense of personal worth.

The formation of self-esteem has several sources. Making sense out of how others perceive us and value our contributions is one; for example, harsh external appraisals can create a damaged internal sense of self-worth. Observations from others of actual behavior versus personal interpretations of behavior can cause distortions in the perception of personal worthiness. Add to these factors the ingredients of social class, race and culture and the equation grows in terms of contributing factors to the formation of self-esteem.

Descriptions of self-esteem are easy to come by; however, explaining it continues to challenge researchers. Jackson (1984) describes the inherent problems associated with methods often employed in psychological research. All too often empirical research reduces personal meaning into fragments for study. Jackson strongly favors the interviewing format as a research model since it makes an effort not to reduce or distort the subjective experiences of another. Offering individuals the opportunity to tell their own stories within a carefully structured format lessens the chances for distortion of the original message. Although there are merits to this procedure, of course, there are also shortcomings. For example, observer bias could easily influence the information compiled.

According to Knapp (1973) and Coller (1971) most research instruments used to study self-esteem fall into combinations of the following four categories: behavioral trace reports, direct observations, projective techniques, and self-reports. Each has its merits and limitations. The procedure that Jackson advocates, in essence, is aligned with the work already carried out by most art therapists. When creating art one can not help but look inward and participate in decision making that is targeted at the resolution of various emotional and cognitive processes. Since projection and the subjective experience occupy a central role in the creation of art, and art therapists usually process the content of client art work through the interviewing procedures that Jackson describes, art therapy can become a forum in which to study self-esteem.

The Metaphor of Creating Art and Self-Esteem

Many authors who write about art therapy describe terms that relate to the subject of self-esteem. Landgarten (1981) talks about art as evidence of an assertive self-directed act. Rhyne (1973) describes the Gestalt art experience as allowing for the discovery of what makes people unique. Wadeson (1980) refers to art therapy as a "doing" form of therapy that activates creative potential. Rubin (1984) mentions how art serves as a concretization of the internal self. It is a way for people to say "me" or "I" or "I do" or "I can do" (p. 193). Erikson (1979) has reflected on the therapeutic merits of art materials and how they offer self-integrating experiences. Both Ulman (1975) and Kramer (1958, 1971) discuss the therapeutic opportunities for healthy self-involvement offered by active engagement with the art making process.

Additionally, there are many similarities between the topics of the art making process and life's processes. The unformed materials, much like the notion of the tabula rasa, begin to take shape as the artist engages in a decision-making process that documents change. To work with art materials is to transform their physical and symbolic potential. Thus, art may be considered a simultaneous process of reformulating the self through the active formation of an object.

Also, the art making process may be compared with the stages of human development. Working from the infancy of the empty page to the adulthood of the final product allows for the exploration of clinical and developmental themes from several perspectives. The first relates to the physical evolution of a work of art and how it parallels developmental models of growth. Another perspective can be ob-
ART THERAPY AND SELF ESTEEM

served when unresolved issues from the past surface during specific stages of the creative process, thus presenting a tangible means to confront those issues. Active participation in the balancing of tensions that naturally surface during this process facilitates self transformation.

Lastly, there is the opportunity to conceive, incubate and birth an idea towards conception through art making. These forces and how they operate have been discussed by various artists. For example, Paul Klee referred to art as a metaphor of the “creation.” He saw an analogy between the laws governing universal processes in nature and how these same processes are reproduced in the artist (Grohmann, 1987). In addition to Klee, Max Ernst, while painting, felt as if he was a witness to a birth that he had created (Winner, 1982).

Self-Esteem, Empowerment and Art

Lack of self-empowerment is often present in the lives of people with a fragile sense of self-esteem. One of the major strategies often employed when dealing with self-esteem is helping people to become assertive and gain a sense of power over their lives (Mecca, Smelser, & Vasconcellos, 1989). Allowing clients to create their own images and participate in their unfolding contributes to the theme of empowerment. This is especially true when we consider how art objects can serve as a worthy substitute for the missing or absent “real thing” (Arneheim, 1980, p. 249).

When the process of making art is completed, a product exists that is unique and one of a kind. Refining that which did not exist before, and will never exist in that exact same form again, validates and empowers the uniqueness of the person. Making an object out of an idea puts a powerful tool in the hands of a person who feels fragile and unworthy (Regelski, 1973). Objectifying subjective experiences creates a climate where the darkest internal events can be given form, contemplated, and eventually understood (Langer, 1964).

Art can become a safe place where the old self can be confronted and the new self rehearsed. Participating in this process, in spite of the personal pathology encountered, gives rise to a sense of accomplishment that can be affirmed by the environment (viewer), other (art therapist), and self. The narcissistic gratification that is experienced provides steam to pursue further efforts in spite of the injurious views of the self that are encountered (Kramer, 1971). In essence we are rewarded by the visual gift that we create for ourselves (Rhyne, 1973).

Art making provides the possibility to explore with clients how they value themselves by observing what is invested of themselves in their art work and how they respond to it. Confrontation with these attitudes provides a context in which to change them. People are in the unique position when in the art therapy room to experiment, to make mistakes that eventually transcend these previously held viewpoints. Within the safety of the therapeutic environment and the forgiving qualities of the materials, failures can be experienced and eventually tolerated. Readjusting perceptions of external and internal criticisms is possible due to the many safe opportunities to visually form and contain conflicts. The materials communicate reliability and possibility, while the art therapist conveys empathy, tolerance and acceptance.

Altering the many harsh internal assessments which in part are based upon perceived failures and ultimately replacing them with a new perspective is a major component of an effort to elevate self-esteem. Also, the art making process appears to be accessible to a variety of age groups and populations. It is also compatible with a high degree of pathology and people who are fragile in this area can usually participate on some level (Kramer, 1971).

Coopersmith (1967) mentions that self-esteem implies characteristics such as the ability to direct behavior, make decisions and take risks. In essence, he is describing behavior that constitutes the art making process. Goals of treatment in therapy almost always include enhancing the capacity for self mastery, individuation, empowerment, assertiveness, and participation within social support systems (Mecca, Smelser & Vasconcellos, 1989). These goals for psychotherapy mentioned typify the art making process and permeate all facets of the art therapy process. Individuation is also enhanced as one sorts out issues of self, ultimately encouraging self empowerment through the visual formation of emotionally loaded material. To create something and ultimately confront that creation, even if it represents traumatic material, allows one to reabsorb the event in a restructured form. Viewing these self-directed visual solutions demonstrates that internal chaos can be formed and redefined often without overwhelming the client. Self mastery, empowerment and assertiveness become possible as the ego recognizes victory over once elusive and frightening internal forces.

In addition to these events, audience response
becomes a crucial and integral part of this process as well. Group members or staff can offer feedback; involvement of this type results in opportunities for social support and peer acknowledgement.

Self-Esteem and Relationships

Relationships, perhaps the primary area where self-esteem issues would manifest, can also be addressed through the metaphor of art. The subject of relationships is quite potent when we consider how programmed our culture is to expect immediate gratification when involved with interpersonal encounters. Between anticipating polished images to appear on drawing paper as quickly as they do on television and the inclination to change relationships as quickly as we change TV channels, youth in particular are influenced to expect unreasonable results. A double bind exists when youth feel pressured to construct personal imagery as polished as printed or electronic media. The result of such encounters produces inevitable confrontations that expose personal inadequacies and unrealistic expectations.

Additionally, dysfunctional relationships also impact self-esteem. Oates and Forrest (1985) observed that abusive parents often came from dysfunctional backgrounds, avoided other people to discuss problems with, had poor regard for their partners, abused their young and shared the major contributing factor of low self-esteem. Similarly, Oates, Forrest, and Peacock (1985) matched 37 abused children with the same number of non-abused children and found there to be a significantly low self-concept, reduced ambition, and fewer friends amongst the abused children. Self-esteem, the much needed “social vaccine,” is often absent in the appropriate doses from the social structure of our culture (Mecca, Smelser & Vasconcellos, 1989). Relationships are certain to suffer, and in many cases are destined to fail when self-esteem is damaged.

While it is too much to ask that art therapy fix these societal problems, it is not beyond the scope of our field to address them. The theme of relationships, on a metaphorical level, permeates all dimensions of the art therapy process. Within the metaphor of art, rehearsal of relationship building skills can be subtly exercised between art therapist, client, materials, product and audience. Simultaneous triadic interactions (Figure 1) engage these themes in such a way that allows for safe encounters with art products and people. Relationships are formed with the art therapist, the materials, the evolution of the art object, and the viewer concurrently.

Personal vulnerabilities will naturally affect both the metaphoric theme of relationships within the art process as well as interactions with the therapist. Pride and shame, two primary emotions currently associated with self-esteem, often dictate the terms of any fragile relationship (Mecca, Smelser & Vasconcellos, 1989). Pride equates with high self-esteem and shame with low self-esteem. Perceiving oneself in negative terms creates a context for shame to grow. Unacknowledged shame almost always evolves into anger and, ultimately, rage and violence. The mask of anger skillfully covers the felt shame. Strategies to manage anger and acknowledge shame, both strongly avoided emotions, are key elements in developing self-esteem (Lewis, 1971).

Allowing for hidden shame to be seen in the context of the art work fosters safe encounters with a potentially painful subject. Through art, safe psychic and physical distancing from the visual manifestations of shame is available to the client. As the client responds to each new art production, old patterns can be redefined and new attitudes developed which can eventually lead to a sense of personal worthiness.

Comfort in making choices can also be enhanced. Clients often express their inability to choose, feeling a paralysis of will. When sitting with clients in sessions I often count to myself the many decisions that went into their art work. Once finished, we both count the many choices that had to be made. Perceived weaknesses around the theme of making decisions are gently confronted, demonstrating their power to choose. Witnessing these themes through the challenge of the art making can then be generalized to other areas of daily living and eventually incorporated into the clients’ internal resources and personal strategies.

Clinical Encounters With Art and Self-Esteem

I have witnessed repeatedly the growth enhancing possibilities inherent in the process of creating art, both in myself and with clients. Growth, as it relates to self-esteem, is usually used to define features of success and triumph. However, failure and struggle also often contribute a great deal to art work and the development of self-esteem and personal growth. The hard work and the degree of self-confrontation involved in the art making process places unusual demands on all facets of the personality (Kramer, 1971).

Internal assessments concerning choices and de-
ART THERAPY AND SELF ESTEEM

Fig. 1
cisions coexist with the eventual external assessments from viewer and audience. To create art is to exist in a transparent state. The self is eventually externalized through visual imagery for an audience to respond. The continuum of acceptance and rejection becomes an inescapable feature of all art work, thus creating inevitable repercussions for self-esteem issues. In short, the process invites endless opportunities for a string of encounters with success and failure, acceptance and rejection.

From a personal perspective I know several artists who have given up their work due to the pressure of their efforts to confront their visions. Clients are susceptible to the same pressures as the working artist, although it is not always apparent. They also struggle with constant self-evaluations and audience assessments. When working with clients I have found that one of my most indispensable tools as an art therapist has been my identity as an artist. It is through this lens that I can truly empathize with clients during their visual struggles to form their pain or passion (Franklin, 1990). Just like learning to become a therapist involves personal experiences in therapy as a client, so too does becoming an art therapist involve consistent encounters with art materials and their possibilities.

Case Example

Tim was a sophomore in college with a history of poor grades who struggled with relationships. He was still dealing with his anger and confusion around a turbulent divorce during his teenage years. In addition to his family problems, Tim also had difficulty with his studies due to dyslexia and problems organizing visual/spacial relationships on a printed page. All of these emotionally loaded issues developed into severe feelings of anxiety that greatly affected his school work and social life. As his grades fell in college and certain friendships began to dissolve, he decided to seek out therapeutic services at a counseling center. Traditional verbal psychotherapy was tried, but never really succeeded in meeting his needs. A couple of therapists were consulted, each finding Tim to be an unmotivated client. Between his many no-shows and what appeared to be a lack of motivation for treatment, art therapy was suggested.

I heard about his resistance, but as always, wondered how much was due to the client and how much was due to the therapist. It seemed important that I meet him at his model of the world (how he constructs meaning out of his experiences). I interviewed him during our first session about his various interests, talents, and beliefs, in short, his strengths. For the most part he denied any special abilities, except for his love of the flute. This was pertinent information since an understanding of self-esteem is usually arrived at by perceiving a synthesis of the many activities that a person participates in. One could be an average cook, excellent athlete, poor student, etc., weigh all of these experiences together, and come up with a general evaluation of personal worthiness (Coopersmith, 1967). Tim was clear that he felt inadequate in several areas, however, not with the flute. Here was my in or point of entry—the flute provided us with a context that was familiar and valued by him. If we were to be successful, then I would have to meet him through his source of pride. Balancing the pride with what often feels to be overwhelming shame, creates a forum for integrating these strongly felt paradoxical experiences. The language of the flute was to support our search.

Themes were selected each week that Tim felt strongly about; most centered around personal and family relationships. He was invited to create a musical composition which focused on each theme. Once finished Tim was then asked to make a drawing based on each flute composition. The results were astonishing. During our sessions he would play his flute compositions filling the space of the therapy room and beyond with his music. The overall quiet that regulated each of the therapy sessions was complemented by his gifted melodies.

Tim was excited at the results he was finally experiencing. By addressing his dominant auditory and visual senses and communicating through his familiar vocabulary of music, Tim started to make meaningful connections. Finding power in his ability to formulate his experiences through music and art, Tim began to experience his feelings and organize his thoughts in new ways. The pleasure of playing the flute allowed him to find strength and cross over into those hurtful areas of pain and doubt. Discovering new ways to restructure old perceptions, Tim began to develop a growing sense of confidence. Empowered by these evolving perceptions, Tim also had new tools to take charge of his life. He still had difficulties with family and personal relationships; however, he now had a new way of looking at their meaning and listening to their impact.

Conclusion

Creating art is hard work that takes courage. The shadow of failure always accompanies one along
ART THERAPY AND SELF ESTEEM

the way—there are no guarantees. Through the metaphor of visual art, art therapists offer a variety of processes that are isomorphic with basic life struggles and challenges. Therefore, careful thinking about the entire art making process should be a tireless pursuit that engages all art therapists. Focusing on the points highlighted in this article is especially relevant to the practice of art therapy. Although it is difficult to prove, researchers feel that self-esteem is a significant precondition for creative work (Coopersmith, 1967). In order to participate in the art process, self-esteem, in some measure, must be present. As art therapists we need to grasp the subject of self-esteem beyond intuitive beliefs. By understanding the nature and development of self-esteem we can enhance it in our clients, in part, by offering the rich metaphor of art. Given the magnitude of self-esteem in therapy and our unique vantage point as art therapists, there is much that we can offer to this universal clinical topic.

This article is dedicated to the memory of Elinor Ulman.

Brief Reports

Gender Differences in Drawings: A Study of Self-Images, Autonomous Subjects, and Relationships

Abstract

This paper reports a study of gender differences in drawings by 261 school children responding to a projective drawing task. Their responses are examined for concepts of self-sufficiency or connectedness with others in an attempt to find answers to three questions: Do children tend to identify with the subjects of their drawings by choosing principal subjects of the same gender as themselves? Do boys tend to represent autonomous subjects in their drawings? And, do girls tend to represent subjects interacting with others?

Drawings and titles are examined first for the genders of their principal subjects, comparing them with the genders of the children who chose them. Also, the drawings are examined for subjects acting alone or independently, and for subjects interacting with others.

A previous study by the author found significant differences in drawings by males and females across four age groups: third graders, high school seniors, adults, and the elderly. The men and boys in the sample tended to portray the world as threatening and their principal subjects were portrayed as fighting back and overcoming dangers. The women and girls, however, received nearly identical scores for the principal subjects and environments they portrayed (Silver, 1987).

The present study is an attempt to amplify and clarify the previous findings by addressing one of the four age groups, children primarily 8-9 years of age, and asking the following three questions:

1. In responding to a drawing task, do children tend to identify with the subjects of their drawings by choosing principal subjects of the same gender as themselves?

   It is often assumed that children and adults represent themselves, directly or indirectly, when responding to projective drawing tests. To obtain quantitative information about the degree to which principal subjects represent self-images, drawings by 261 children were examined, comparing their genders with the genders of the subjects they choose, and taking into account the subjects of sentences and the use of pronouns.

2. Do boys tend to represent autonomous subjects in their drawings?

   Autonomous subjects are defined as people or animals who act independently and appear self-sufficient. They may be the only subject of a drawing or appear indifferent to other subjects. In the previous study, the subjects portrayed by boys tended to live in threatening environments, but managed to escape from dangers, as illustrated in Figure 1. Scored on a rating scale ranging from 1 point (strongly negative) to 7 points (strongly positive), the mean score of their principal subjects was 4.1; environments, 2.9.

3. Do girls tend to represent subjects interacting with others?
GENDER DIFFERENCES IN DRAWINGS

Although the subjects portrayed by girls in the previous study also lived in threatening environments, they tended to interact with other subjects, but not escape, as shown in Figure 2. The mean score of their principal subjects was 2.8, environments, 2.9*.

Gilligan, Ward, and Taylor (1988) find gender-related perspectives for organizing thoughts and feelings in two modes of moral judgment: the feminine mode based on concepts of care and responsibility to others and the masculine mode based on concepts of detachment and self-sufficiency. Different ways of viewing the world yield different ways of perceiving and solving problems. In our culture, the ideal of childhood development is seen from the masculine perspective, equating maturity with self-sufficiency and equating deficiency or immaturity with interdependence. These authors challenge the male ideal, suggesting a concept of morality centered on care and responsiveness to others. From the feminine perspective, there are no relationships between concepts of self and of morality as evident in the relationships of self to others. It is observed that woman’s sense of self is built around connections with others, and loss of connection is experienced as a loss of self (Miller, 1976).

Procedures

The present study examines responses to a drawing task for concepts of self-sufficiency or con-

Subjects

Subjects for this study included 261 children, 145 boys and 116 girls, ages 7 to 10, selected from eight elementary schools. Previously, these children had responded to the Silver Drawing Test when it was administered to children and adults in order to develop normative data and determine test reliabi-

ty. In the present study, responses to the Drawing from Imagination subtest by children in the second, third and fourth grades were reexamined for gender differences. The second graders were 7-8 years old; third graders, 8-9 years old; and fourth graders, 9-10 years old; most of the children in this study were between 8 and 9 years of age.

The schools included suburban public schools in New Jersey, Nebraska, Pennsylvania, and Ontario, Canada, as well as four schools in low to middle class neighborhoods in New York. New York schools included two suburban public schools, an urban public school and an urban parochial school.

Results

As shown in Tables II and III, a majority of the children drew pictures about subjects of the same gender as themselves, the boys tending to draw pictures about male subjects and the girls, female subjects. In the drawings by girls, 63% of the principal subjects were female, 10% male. In the drawings by boys, 59% of the principal subjects were male, 6% female. To determine whether these differences were significant, the chi square test was used. Results indicate that gender differences were significant at the .001 level of probability.

Among those who chose subjects of the opposite sex, all but four seem to identify with, or empathize with, these subjects. These four children drew fantasies about adults. In the two fantasies by boys, women appeared ridiculous as well as menacing, who threaten small animals with knives. In the two drawings by girls, one man was portrayed as a cruel scientist and the other man’s behavior was ambiguous.

2. Drawings About Autonomous Subjects

Of the 261 children in the sample, fewer than half drew pictures about autonomous subjects. Although boys outnumber girls (46% boys, 37% girls), the differences between genders were not significant.

As shown in Tables IV and V, both genders had more positive than negative associations with autonomous subjects: 70% of the girls and 72% of the boys associated autonomous subjects with pleasurable experiences; 14% of the girls and 9% of the boys associated them with unpleasant experiences. The greatest difference between genders was found in drawings about autonomous subjects who appeared actively engaged in pleasurable activities, characterized by the score of 5 points. Here the boys outnumbered the girls—28% compared with 14%.

Examples of drawings about autonomous subjects are shown in Figures 4 to 6.

**Fig. 5** By Kenny, "1. I am sitting and watching TV. 2. I bought [sic] soda and popcorn. 3. I took [off my] cap and sweater."

Kenny's use of the first person singular confirms that his subject represents himself. His boy is not just passively enjoying TV; he is actively self-sufficient, having bought a snack and made himself at home in his comfortable room. a strongly positive association with an autonomous subject. Score: 5 points.

**Fig. 6** By Billy, "The boy and the knife [sic]" Billy's association is with death and suicide. Score: 1 point.

**Fig. 7** "The Man with the Knife," by Ted. Assaultive and life-threatening relationship. Score: 1 point.
Fig. 8 "The girl was watching TV and playing a game but the brother came in and changed the station," by Minna. Unfriendly and stressful. Score: 2 points.

Fig. 9 "I love my pets (dog and cat)," by Danielle. Loving. Score: 5 points.

Fig. 10 "The cat who tried to save the rat," by Anthony. Caring in a dangerous world. Score: 5 points.
3. Drawings About Relationships

Of the 261 children in this sample, more than half drew pictures about people or animals interacting with other subjects, or implied relationships with others. Although girls outnumbered boys in drawing about relationships (63% girls, 54% boys), these differences were not significant. Again, there is a 75% probability that this is due to chance.

In the emotional content of these drawings, boys outnumber girls almost four to one, in drawing fantasies about life-threatening or violently assaultive relationships, characterized by the score of 1 point (19% boys, 5% girls), as shown in Tables VI and VII. Girls outnumbered boys, however, in portraying unfriendly or hostile relationships, scored 2 points (40% girls, 28% boys).

Examples of such drawings are shown in Figures 7 to 10.

In examining drawings about positive relationships, we find that girls outnumbered boys (girls 45%, boys 31%), but if we break down positive relationships into friendly relationships (4 points) and caring or loving relationships (5 points), there was little difference between genders in drawings scored 5 points (girls 16%, boys 14%) and girls outnumbered boys in scoring 4 points (girls 29%, boys 17%).

Discussion

The findings of this study support the assumption that children who respond to projective drawing tasks tend to identify themselves with the principal subjects of their drawings. Results indicate that most of the 261 children in the sample drew pictures about subjects the same gender as themselves to a degree that is a statistically highly significant at the .001 level of probability.

In addition to subjects the same gender as themselves, 27% of the girls and 36% of the boys chose animal subjects which also may serve to represent self-concepts. Since there was no opportunity to ask the children to discuss their drawings, the drawings about animal principal subjects were eliminated from statistical evaluations.

Also eliminated was the finding that most of the children who chose principal subjects of the opposite sex seemed to identify with or empathize with these subjects. Although 10% of the girls and 6% of the boys chose principal subjects of the opposite sex, only four children failed to represent these subjects sympathetically.

The drawings about autonomous principal subjects do not show significant differences between genders. Although the proportion of boys who represented autonomous subjects (46%) did exceed the proportion of girls who represent autonomous principal subjects (37%), this did not occur to a degree which is statistically significant.

It is interesting to note, however, that proportionally twice as many boys as girls drew pictures about autonomous subjects actively enjoying themselves: 28% of the boys and 14% of the girls drew pictures about self-sufficient subjects engaged in pleasurable activities. This finding parallels Gilligan's observation that detachment and its attendant egocentrism are associated with the masculine mode.

In drawings about relationships, again no significant difference between genders was found. Although the proportion of girls who represented relationships (63%) did exceed the proportion of boys who represented relationships (54%), this difference was not statistically significant.

When we examined the emotional characteristics of relationships portrayed, we found that 15 boys (19%) and only 4 girls (5%) drew pictures about violently assaultive relationships. Although the proportion of girls who portrayed friendly or pleasurable relationships exceeds the proportion of boys, there was virtually no difference between genders in portraying loving or caring relationships (girls 16%, boys 14%). Some of the boys associated caring relationships with living in a dangerous world while all of the girls associated caring relationships with living in a pleasant world, indicating another possible difference between genders.

The number of respondents in these rating scale categories were much too few to expect to find significant differences. It is hoped, however, that future studies with larger populations will amplify and clarify these findings.

Is There a "Late Style" of Art?
Line Use in Human Figure Drawing by Elderly People

Susan Evans Spaniol, A.T.R., Newton, MA.

Abstract

A great deal has been written about the artistic development of the maturing child; however, research in artistic development ends abruptly with adolescence. Scant mention is made in the literature of artistic transitions after adolescence, although the research on adult development in general has been growing exponentially over the past several decades.

The purpose of this pilot study was to investigate whether a distinct phase of artistic development evolves in late adulthood. Since artistic activity was a vast and complex area, this investigation was limited to a narrow, but exemplary aspect of the visual arts: line use in human figure drawings. The medium of drawing was selected because it is perhaps the most universal and immediate of the visual art forms. Similarly, the human figure was selected because it is thought to be the most frequently drawn of all subjects. Line use was singled out for study because it is the most simple and basic element of drawing, yet also one of the most variable.

This research was inspired by the relatively recent postulation of a distinct phase of artistic development positioned at the end of the lifespan of many great visual artists (Arnhem, 1986; Clark, 1981; Munsterberg, 1983). Termed the Late Style by Arnhem, this stage is described as qualitatively different from the preceding phase of middle adulthood, suggesting continuity of artistic development across the lifespan of people deeply engaged in the visual arts. According to Arnhem, the last stage of life is distinguished by contemplation, introspection and transcendence. As the aging person redirects attention inward, concern shifts from natural appearances to "underlying essentials." Looseness of style characterizes their art works, as similarities become more important than differences, objects lose their distinctness and the surface becomes diffuse.

Evidence supporting a hypothesis of a distinct artistic style in old age must demonstrate the universality of artistic development during old age. To analyze line use, it is necessary to subdivide it into its various components, including width, pressure, variability and length. Drawings by the elderly must be compared to those by younger people of all ages. This research study was designed as a beginning step in investigating the possibility of a distinct phase of artistic development in old age.

Methodology

A total of 227 subjects ranging in age from 3 to 80 years were selected to represent the decades of life from early childhood through late adulthood. The oldest group of subjects, ages 61 and above, were drawn from a special university-based study group for retired adults. Of 24 elderly persons participating, 20 were female.

The test administered was a drawing completion task consisting of several simple lines that suggest two figures facing one another (Figure 1). This task was designed to provide structure to untrained people who might otherwise feel intimidated by a blank piece of paper. Subjects were asked to identify only their age, sex and art training, if any. They were informed that the purpose of the drawing task was to examine how people draw at various ages.

The test was scored by four judges working independently without reference to information about individual subjects. The judges were selected for their expertise in art education and experience in looking at drawings. Specific criteria used on the scoring sheets were developed from other studies in which they had been successful measures of drawing skills (Burton, 1981). Classifications of lines were: continuous; broken and heavy; broken and soft; modulated (thick and thin); contour broken; and shading used for color, space, texture or mood. Categories were scored as present or absent by individual judges. In the final compilation of the data, an item was scored as present when there was agree-
IS THERE A LATE STYLE OF ART?

Fig. 1 DRAWING COMPLETION TEST

ment between three or more judges. Results are presented in terms of percentages representing ratios between the frequency of specific characteristics occurring in drawings by various age groups and the total number of drawings in those samples; plus or minus 10% is assumed to be significant for the purposes of this study.

Results

The results of this pilot study are equivocal in supporting the hypothesis of a distinct phase of artistic development on the basis of the analysis of line use in human figure drawing. The data describe changes in various aspects of line use across the lifespan (Figure 2). However, the statistics are not powerful enough to support a stage theory of late artistic development.

Changes in the use of continuous and broken lines suggest the possibility of the Late Age Style which Arnheim and others have observed. Analysis of the use of a continuous line indicates a fairly steady decline that seems to accelerate in old age. Conversely, analysis of the occurrence of a soft broken line shows a continuous increase until old age, when its use appears to accelerate markedly. Analysis of the heavy broken line is more ambiguous. Although its use generally follows a U-shaped curve, increasing until middle age and declining thereafter, the data suggest an accelerated decrease following middle age. The evolution of other aspects of line across the lifespan appears to be less significant. The use of a modulated line is rare across the entire lifespan, with only 10 examples out of a sample of 227, and none after age 40. Use of line as shading also occurs only ten times in the entire sample. The only use of line for shading that has potential significance is texture, which shows a marked increase in old age, although its use is infrequent. An attempt to analyze complexity as defined by multiple types of line use in a given sample indicated no significant differences across the lifespan.

Of all the linear qualities, continuity and soft broken lines show the widest range across the lifespan. Continuous lines are employed by 87% of all children under age 10, but only 21% of senior adults. While there is a 76% difference between the scores of the youngest and oldest subjects, the range of scores between the other five age groups differ by only 16%. Use of the broken soft line is almost a precise complement of continuous line use, being employed by only 3% of children through age 10, yet used by 19% of all older adults. Similarly, these scores also represent a difference of 76%, while the range of scores between them differs by only 15%. Scores for the broken heavy line approximately follow a U-shaped pattern, with least frequent use during childhood and old age. While the complementary nature of the patterns for continuous and soft broken lines suggest an inverse relationship, they do not seem to represent a continuum. Differences at the extreme age groups for each type of line use may indicate the existence of stages that are qualitatively different from those in between.

Conclusions

This pilot study demonstrated changes in line use during the later years of adult life. However, it did not discriminate whether the apparent development represents the effects of physical and mental decline, a qualitatively different stage of artistic development, or some combination of both.

The drawings of untrained persons as well as professional artists exhibit an increasing looseness of definition and decreasing differentiation between objects. During old age, broken lines predominate, boundaries dissolve and surface patterns become relatively homogeneous for artist and nonprofessional as well. The literature on the Late Style acknowledges the emotional and physical decline due to aging, yet it also attributes the style to the culmination of a lifetime of experience and wisdom (Arnheim, 1986;
Clark; 1981; Munsterberg, 1983). The art of these masters is described as a distillation of visual appearances intended to suggest underlying laws rather than to portray natural reality (Arnheim, 1986). Conventions are frequently cast aside and rationality is often devalued. Instead of studying outward forms, the artist looks inside his or herself for meaning and relies on intuition for guidance.

Unlike the artist, who often remains productive and creative throughout the lifespan, the ordinary person generally becomes less contributing, imaginative and flexible with age (Gaines, 1975). By definition, physical deterioration accompanies aging. Personality tests describe general emotional and intellectual deterioration as well, suggesting cognitive constriction, emotional instability, reduced impulse control and slowed responsibility (Panek, Wagner & Kennedy-Zwergel, 1983). The increased looseness and decreased differentiation described by the test results may certainly be attributed in part to this physical, mental and emotional decline. Whether the Late Style of untrained persons may be related to psychosocial changes as well remains to be documented.

Reflections: To Hell and Halfway Back

Introduction

This paper reflects the unusual ability of a patient to articulate her struggle with her illness and journey back to health. Amy tells us what she knew and what she has learned in the therapeutic process. The record of this personal journey is followed by a postscript written by the therapist. It is illustrated with some of Amy’s drawings produced during the therapeutic process. The drawings were selected by both of us.

“God, grant me the Serenity to accept the things that I cannot change, the Courage to change the things that I can, and the Wisdom to know the difference.”

The words to the Serenity Prayer, stated above, are framed on a plaque beside my bed. They are the last words I see before I go to bed and the first ones I see when I wake up. The Serenity Prayer, written by a recovering alcoholic, is the fundamental guide that all recovering addicts (alcoholics, gamblers, drug and food abusers) adhere to. Since all people who suffer from an addiction need to change basic behaviors and attitudes, the Serenity Prayer offers a viable direction to take while striving towards recovery.

*Editor’s note: Although it is the policy of Art Therapy to withhold client names, Ms. Hendel and Dr. Levick gave permission in this instance.

My parents got divorced when I was two years old. My grandmother has Alzheimer’s disease. My best friend for twelve years, my dachshund, Buster, died in my arms after a long and debilitating illness. These are things that I cannot change; I have no other alternative than to accept them. But there are things in my life that I can change, things that with a little courage and a lot of help, I can learn to deal with in a healthier, more productive fashion.

I am bulimarexic. I have had an eating disorder for the past six and a half years. For five of those years, I was a severely underweight anorexic. For the past year and a half, I have vacillated between anorectic and bulimic behaviors. The trip has been painful. I have journeyed to hell and back. Fortunately, in the last six months, I have gathered the strength and found the help to guide myself towards recovery. It has taken over six years, but finally, I see “light at the end of the tunnel.”

Because “knowing” is important to me, I learned that anorexia, or anorexia nervosa as it is formally known, is defined as the voluntary starvation resulting in a minimum loss of fifteen percent body weight. Bulimia, or bulimarexia, is defined as periodic binge eating followed by some form of purging, such as self-induced vomiting, use of laxatives or diuretics, strict dieting or fasting, or vigorous exercise.

My eating disorder activated in the summer of 1985, shortly after I graduated from Brandeis University. During that period, I was experiencing a great deal of anxiety regarding the direction I wished
to pursue in terms of a career. For the first time in my life, I was no longer protected within a safe and sheltered environment (like I had at Brandeis and like I had in high school). I began to isolate myself. I accepted an unstimulating job doing phone solicitation from my house. Most of my friends from college had already moved away and I felt lonely and confused. The only human contact I had was with my neighbor, Lenny. Although he was twenty years older than me, I turned to him for companionship.

Around that time, my dog (Buster) was diagnosed with terminal cancer. The news devastated me. Buster was not “just” a dog. He was my true joy in life; he was my rock, my ’raison d’etre.’ When he became ill, I felt I had to make the rest of his life as comfortable as possible. I rarely left his side. I put every ounce of energy I had into taking care of him.

In August of 1985, I had a short bout with the flu and I lost three pounds. At 5’6” and 125 lbs., I was by no means overweight. But when I saw how easy losing weight could be, I became obsessed. I began exercising for several hours a day. I stopped eating protein; then I stopped eating complex carbohydrates. Shortly thereafter, I stopped eating dairy products. Within one year’s time, my diet consisted of Diet Coke, Trident Gum, and broccoli. I lost my period; I developed a heart murmur, and according to a doctor who treated me several years later, I caused irreparable damage to my internal organs.

**Diary Entry—January 3, 1986**

“How can I explain my eating disorder? I wish I knew. I continue to waste away, knowing damn well that I am hurting my body and jeopardizing my health. I look terrible; I feel terrible. None of my clothes fit. My eyes are sunken in. When I look in the mirror, a jaundiced, gaunt creature stares back at me. There are mornings when just getting out of bed uses every ounce of strength I have . . .

Yet, when it comes time to eat, when I finally allow my body to refuel, my good intentions peter out. I offer it some veggies, maybe a little fruit. But anything that is fatty or high caloric must stay away. They are taboo. To put such things in my body is grotesque and repulsive.

I know I need to gain weight. And I know I need to gain it soon. But for some reason, all the knowledge in the world doesn’t help when it comes down to actually eating. All kinds of thoughts race through my head: tonight I won’t eat anything but tomorrow I’ll have something as soon as I get up . . . If I don’t eat anything now, then tomorrow I won’t have to exercise as hard . . . If I skip eating the apple tonight then tomorrow I can have an extra piece of gum . . . Rationalization becomes a self-induced doctrine. Every time I try and help myself, I decide to start tomorrow. The only problem with that is, tomorrow never comes.”

On December 5, 1987 (a Sunday evening), Buster died in my arms. He had been in a coma for four days, and if his condition had not improved by Monday, December 6, I would have had him put to sleep. Luckily, I had already prearranged his funeral the month before. I had located and bought a plot for him in a pet cemetery in Foxborough, Massachusetts. On December 6, at precisely 10:30 A.M., I threw the last bits of dirt on Buster’s grave. At the time, I weighed 82 lbs.

Four days after I buried Buster, I packed my things and moved to Florida. Because of all the weight I had lost, I was extremely sensitive to the cold weather and my body craved some warmth. Lenny also wanted to relocate, so we drove down to Miami together. Right before we left, my mother called me from Connecticut to ask why I was making such a drastic change.

**Mom:** “I understand it’s difficult for you to stay in Waltham, but why don’t you come back to New London, instead. Your room is still here for you.”

**Me:** “I’m cold.”

**Mom:** “That’s a pretty strange reason to move 1500 miles away.”

**Me:** “Right now, I’m wearing three sweaters, the heat is on full blast, and I’m still freezing. I need to go where it’s warm and sunny.”

Although my family was aware that I had a problem, they had no idea just how sick I was. Besides being grotesquely thin, I was hopelessly suicidal. It had been over a year since I had seen anyone in my family and I was doing my best to make sure it was a while before I saw them again. On my drive down to Florida, I remember literally praying that the change of scenery would help rejuvenate me. Lenny had already found adjoining apartments for us in a cheap rental complex in North Miami. He also assured me that I’d be able to find a support group to help me with my eating disorder.

After I got to Florida and settled into my apartment, the first thing I did was find a psychiatrist. A local hospital gave me the name of a doctor who was supposedly the top psychiatrist in the area. When I reached his office, a secretary had me fill out some forms. Within minutes, a short man with elevator shoes came in and escorted me into his dimly lit, extremely cold room.

**Dr.** “Why are you here?”
Me: "Well, I recently lost my dog and I feel suicidal. I think I’m anorexic."

Dr.: "What makes you think that?"

Me: "Well, for one, I’m afraid to eat. For two, I’ve lost about forty pounds in the last two years."

Dr.: "Yes, you are rather skinny. It’s hard to tell with all the layers of clothing you’re wearing."

Me: "I’m cold."

Dr.: "I think we should put you on Nardil. It’s an anti-depressant and it should help increase your appetite. If you don’t feel any better in, let’s say three month’s time, call me and we’ll try something else."

The doctor handed me a bill for three hundred dollars and showed me to the door. As I waited for the elevator, I remember wondering whether jumping off the sixth floor was high enough to do the job.

After this experience, I saw three other psychiatrists, two of whom were eating disorder specialists. Each one gave me a prescription for a different drug and told me to come back in three months. Needless to say, I felt discouraged. In the meantime, I tried private therapy. I tried group therapy. I tried Prozac. I tried Overeater’s Anonymous meetings. I tried marijuana. I tried attending lectures. I tried vodka and tonics.

On December 5, 1989, I hit rock bottom. The only thing that I had learned about eating disorders since moving to Florida was that they were a very big business. That morning, as I was holding a bottle of sleeping pills, an advertisement for an eating disorder hospital scrolled over my television screen. I jotted down the address and got into my car. Three hours later, I was admitted.

Insurance companies rarely accept clients with pre-existing conditions. As a result, my coverage was minimal. The hospital that admitted me recommended a three month stay, but my insurance company only agreed to pay for five weeks. If I wanted to stay the extra seven weeks, it would have cost me approximately $36,000 out of my pocket. That, of course, was impossible.

In the hospital, I learned some useful things about eating disorders. I learned about control issues, about stress reduction, about dysfunctional families. I learned how dangerous starvation is to the body. To help me gain weight, the hospital put me on a 2,500 calorie a day regimen; I was not permitted to exercise. But as I was gaining the weight, I was secretly planning to go on a severe diet as soon as I left the hospital. I did not like the fact that my personal freedom was taken away, even though that was precisely what the program’s primary goal was.

Unfortunately, during my fifth and final week of hospitalization, a bulimic girl named Ann became my roommate. Every night, she spent hours trying to convince me that the only way I would be able to stop gaining so much weight was to purge.

Ann: "Why bother getting depressed over all the food that they’re making you eat? Just do what I do: eat whatever you want, whenever you want. Then, just as quickly as it goes down, bring it right back up."

Me: "Throwing up is disgusting. I’d rather not eat at all."

Ann: "Amy, think about the past few years of your life. Think about all the hunger pangs, all the days of being weak and listless. Don’t you miss eating candy and cookies and chocolate? Don’t you miss going out to dinner and spending time with friends?"

The day my insurance lapsed, I left the hospital and went back to my apartment to give it a try. I spent three consecutive days locked in my room doing nothing but eating and throwing up. When I finally came out for air, I could not handle it; I retreated back in. Eventually, what started out as an experiment turned into a nine month affair. I was totally out of control. Lenny tried to find another hospital program, but I rejected the offer. I had absolutely no faith that things would get any better. I had exhausted every possible avenue of treatment and I was getting worse.

Diary Entry—February 14, 1990

"I can’t stand this anymore. I have eaten more in the past three hours than I used to eat in a whole year! My heart is beating so hard I think it’s going to come out of my chest. My hands and legs are twitching. My mind is racing with thoughts of suicide, sleeping pills, machetes. All of that chocolate and pizza and cake . . . Fortunately, I threw up the ice cream. I wish I could throw up more but I can’t get out of this chair right now.

God, what am I going to do? I feel so helpless, so lost. Nothing feels good to me. I have nothing to look forward to. The only thing I ever loved died in my arms. What the hell is left for me in this screwed up world? I hate it. Take me, God. Put me out of my misery. PLEASE! I just can’t take this anymore!!!"

Several weeks after I left the hospital, my family (my parents, their respective spouses, and my two brothers) flew down from New England to visit me. Because I had gained so much weight, they all as-
sumed I was “cured.” What a joke! The old adage “appearances are deceiving” could not have been more appropriate. Since coming out of the hospital, I had lost all ability to manage my time. I could barely spend five minutes productively, let alone twenty-four hours. Although I looked fine, I was suffering tremendously.

While visiting, my mother and her husband decided that they wanted to rent a condominium in Florida for the rest of the winter months. That winter, my mother met Dr. Myra Levick, an art therapist who worked extensively with patients suffering from depression, addictions, and eating disorders. My mother told Dr. Levick about me and asked if she could introduce the two of us. Dr. Levick explained that she had recently retired, but occasionally, she would treat a person from her home on an outpatient basis. She gave my mother her card, telling her to have me call to make an appointment.

My mother called me six times that week, each time beginning the conversation with “Have you called Dr. Levick yet?” I decided that I could not take her nagging anymore, so I made the call. I had seen six therapists since moving to Florida; one more could not hurt. I made an appointment to meet with Dr. Levick the following Monday evening.

When I arrived at her house and rang the doorbell, a man wearing a Philadelphia Eagles’ sweatshirt answered the door. He introduced himself as Myra’s husband. He told me that Myra would be right with me and he escorted me into her office. The first thing I saw upon entering the room was a wall lined with diplomas. A large bookcase was built against the far wall of the office. There were books by Freud, by Jung, by Erikson. There were about fifty books on art therapy alone. As I was noting all of her books, I heard movement in the next room so I quickly sat down on the black leather couch that was adjacent to the desk I assumed was Myra’s. When the door opened, a short, slender woman came in and introduced herself as Dr. Myra Levick.

Myra began our meeting by informing me of the length of each session. The fee was expected at the end of each session. We were to meet once a week and if I needed to cancel or change an appointment, she expected a call twenty-four hours in advance. Sessions involved, 1) a discussion of current issues and moods, 2) a mental voyage down memory lane, and 3) a drawing to help discover things that were not easily revealed verbally.

Our first meeting was strictly informational. Myra wanted to know the history of my family, the dynamics of my eating disorder, and my current living situation. At the end of the hour, she asked me to follow her out onto the porch. There, she had previously prepared a table with a pad, pastels, crayons, and magic markers. She then asked me to draw a picture (using any marker I wanted) of my family.

When I was finished, Myra told me that we would start our next session by evaluating my drawing. Driving home that evening, I remember thinking how interesting it was that I drew myself so much tinier than I drew the rest of my family. I also remember how difficult it had been to decide whether or not my mother’s husband belonged in the picture. He has been married to my mother for over ten years and I’ve never felt comfortable including him in my family.

At our next session, Myra listened to my observations, and then began to list her own. She pointed out the sour expressions I painted on each face. She pointed out that my oldest brother was the only one who had most of the proper extremities attached to his body. I explained that he is the only well-adjusted member of our family. She also showed me how alike I drew the bodies on both the men and the women. This, she suggested, might reveal confusion over sexual identities. By the time Myra was through analyzing my drawing, I was astounded! She knew more about my past by that one drawing than other therapists had gleaned after months of therapy. I left that meeting feeling optimistic. Finally, someone could read through all of my “bullshit.”

I have been seeing Myra for over nine months. Through intense, emotional revelations, combined with drawings of my family, my moods, and my relationships, I have made enormous strides in understanding how and why I have an eating disorder. Myra and I do not discuss food. We do not discuss diets. We talk about feelings, about self-esteem, about self-preservation.

My eating disorder is the result of a troubled childhood. Not only was I raised in a dysfunctional family, but I grew up blaming myself for my family’s chaos. I felt a tremendous amount of rage towards my parents. I was angry at my mother for raising three children in a hostile and cold home environment. I was angry at my father for abandoning his family when I was only two years old. I have spent a lifetime searching for the warmth and compassion that I missed out on as a child. It is obvious that my overwhelming (and bizarre) attachment to Buster evolved from a need to receive and give love in an otherwise “loveless” environment. It is also obvious
to me that my involvement with Lenny was primarily an attempt to replace the father figure I never had.

An eating disorder is a coping mechanism. It is a highly destructive form of self-punishment. Although everybody who develops anorexia or bulimia has a unique set of circumstances with unique reactions, all share at least one thing: a complete immersion of the self into a ritualistic and often, masochistic world. As I stated earlier, "knowing" is important to me so I turned to Myra for an explanation regarding how art therapy is used to treat people with eating disorders (and other addictions). She described art therapy as a nonverbal form of psychotherapy using the patient's graphic productions as a means of communication. For her, the format of examining a patient's drawings is used in the same way that the analyst and patient examine dream work.

In Myra's experience with treating anorexia and bulimia, she finds that her form of treatment helps explore the etiology as well as the symptoms and manifestations of the disorder. She said that she has found that most anorexics and bulimics are highly intelligent and will do a great deal of rationalization to explain and describe their disorder. The nonverbal form of therapy cuts through obsessive and repetitive verbalization. The drawings help explore and reveal precipitating factors and incidents that lead to an exacerbation of the symptoms. Drawings reveal specific aspects of a relationship that a patient often denies or avoids in verbal discussions.

Myra insisted that every patient she treats must be monitored by a medical physician. She told me that the recovery process depends on how much the patient is willing to give up in terms of secondary gain, like attention from the family or as an excuse for not participating in normal activity. She believes that symptoms can be put in remission, but that a person must learn to be his or her own therapist, tuning into specific familiar behaviors that might lead to a renewal of symptoms.

I accept the fact that an eating disorder is a manifestation of frustration, anger and deprivation. It is usually the result of a dysfunctional family. By understanding past traumas, a person can forgive him/herself and eventually learn to forgive others. For the past six and a half years, I have taken a painful extended from "life." I have trapped myself in a world filled with severe isolation, self-abuse, and self-hate. By going to therapy, I have given myself the chance to move back into the world and have some sort of decent life. I know I still have a long way to go, but I am just now beginning to understand how I have masked my identity with an eating disorder, how I have used it to cover up the pain and sadness of my past. I still struggle with food. Perhaps I always will. But I now have a sense of my own self-worth. I finally believe that I deserve the chance to experience joy, and pleasure, and love.

Diary Entry—March 11, 1991

"Last night, I flipped through my photo album of Buster. What a magnificent dog he was! So majestic, so debonair. I still miss him intensely. There isn't a day that goes by that I don't think about the way he frolicked through the snow, the way he cuddled up in my arms and licked my face. But now, I'm working on a new photo album. I'm putting together pictures of Sami (when he was a kitten), of the beautiful palm trees, of New Year's Eve with a few of my neighbors. One day, I'm going to look back at all my pictures. Instead of crying about what was, I'm going to smile at what is. One day, and it will be soon, I'm going to hold my head up high and instead of cursing at God for taking, I'm going to thank Him for giving. One day . . . One day . . ."

Postscript

You have read the personal account of a patient's struggle with a debilitating eating disorder, bulimarexia. What follows is a discussion of some of her drawings produced during the art therapy sessions. The selection of these drawings, a joint effort, is based on their reflection of and impact on the therapeutic process.

In her paper, Amy reported the different things I pointed out in her very first drawing, her family (Figure 1). In that meeting, I didn't say that she placed herself between her two brothers, with her father on one side and her mother and her husband on the other. She drew the parent figures in black, with her brothers drawn in blue and herself drawn in bright red. Everyone, except herself, is footless and attached to the bottom of the page. She has feet and is not grounded. The image suggested to me that she was suspended in space between the two families, her father's and her mother's. The need to explore this theme further led to sessions with her parents, siblings and her new sister-in-law. These meetings provided important information about the early family structure when the children were small. Amy has little memory about this period. Not surprisingly, her brothers also had very selective memories about their early childhoods. During the treatment sessions, her mother and father were not only cooperative and supportive, but corroborated the
chaotic period during the dissolution of the marriage and the resulting behavior of the children.

Figure 2, produced a month later, was drawn in response to my request to depict herself in a situation with her mother, in Connecticut, and her father, in Florida. She drew herself driving the car. Her father was placed on the right, and her mother and mother’s husband were drawn on the left. While somewhat isolated in both drawings, she converses with her father, but uses earphones to shut out her mother and mother’s husband. This theme was explored during subsequent sessions while she prepared to visit her mother’s home and attend her brother’s wedding.

During this time Amy rigidly adhered to an exercise program that, she said, allowed her to eat “a certain amount of food.” She developed a skin rash that she feared was from the chlorine in the pool. The amount of swimming she could do would be limited, if this was true. I suggested that she try to draw these feelings: “let it go on paper.” Figure 3, she said, was the anger she felt at “not being able to keep up with her rituals.” I asked her to follow through with this thought in another drawing. She drew the television, popcorn, book, visiting friend, lying in bed, telephone—all of the things she could not allow herself to do until she swam for a certain length of time. Then she promptly crossed them out (Figure 4). These were the first images in which Amy allowed herself some real freedom of expression without losing control.

Six months into therapy, Amy registered for college courses. While waiting for them to begin, she began to express her loneliness verbally and pictorially. She said she felt like a whale, and that she had gained 20 pounds. (This was not true—she had actually gained about six to seven pounds.) Using a lot of bright colors and the whole paper, she drew a whale beached and dying. This contradicted the depression she claimed. The whale, I pointed out, was reaching for the nearby water. Water represented life for it. I asked her to draw what she would like to be. She drew a dolphin jumping in the water (Figure 5). These drawings reflected more stability and energy through the grounding of the two forms and a more expansive use of space and color. Future goals
were discussed which were more realistic and more optimistic than previously. She conceded, intellectually, that her eating disorder was a symptom of early childhood traumas and that she did have the ability to intellectually control her pathological responses. She agreed to plan future sessions, first with her mother and then with her father. These would provide more information about her early development.

Figure 6, produced two weeks later, is a drawing of herself with her family on the right and, on the left herself in relation to the world. She acknowledged that while she was still very separate from the family, she is “as much a person as they are.” But, in relationship to the world she is no more than a dot. It was at this point that she began to see the relationships among her early traumatic experience of parents’ separation and divorce, the traumatic loss of the dog she loved and cared for, and her withdrawal from friends and environment at the onset of her illness.

The visits from her parents were helpful and productive, as were those that followed with her two brothers and sister-in-law. Early childhood and pre-illness periods were explored in depth. Figure 7 depicts Amy and her two close girl friends during her days at college. The full, grounded, clearly female figures show not only how Amy felt about herself while in college, but how she was beginning to feel about herself again.

As described in Amy’s personal account, the treatment approach used was based on psychoanalytic constructs. My goal was to help her retrace her development and to explore and understand those early traumas and precipitating factors that contributed to her illness. In the process, I appealed to her intellectual ability and ego strengths. As she learned how to modify and control her ritualistic eating behaviors, she would be able to move into the real world again. Regular medical checkups and supervision of sleeping medication were required. As long as her test results indicated that she was in good health, and she could maintain her school schedule, there was no discussion of her eating habits.

Amy completed the three courses in which she was enrolled, earning good grades. Her reflections on her illness and therapy were written as a final assignment for one of these courses, and were recommended for publication by her professor and peers.

Her relationships with her parents and family members are gratifying to all of them. She is currently employed by one brother and exploring possibilities for school and continued work. The destructive relationship with Lenny has been terminated, and Amy is socially active with her neighbors and family. Physically, she has gained 50 pounds, and is now average weight for her height. She feels good about the way she looks. She has resumed menstruation regularly during the last three months after a cessation of six years. She has not engaged in binging or purging for two months.

Amy is not “all the way back.” But, she has worked very hard in therapy and continues to do so.
Reviews

Creating Mandalas
for Insight, Healing and Self-Expression

Reviewed by Elizabeth (Liz) Ratcliffe, M.S., M.F.C.C., A.T.R., Book Editor.

Every once in a while a book appears which, right away, becomes a "classic" in its field. Until it gets into print, we don't realize how much it has been needed, because there has been nothing available to remind us that there is a gap in the existing literature. Such a book is Susanne F. Fincher’s Creating Mandalas, published in paperback by Shambhala, 1991. The subtitle: For Insight, Healing and Self-Expression, suggests that personal benefit can be derived from this easily read volume. And Ms. Fincher, who discovered the healing power of creating mandalas, following the death of a child and a painful divorce, tells us that her personal recovery and subsequent fifteen-year study of the history and traditions of the mandala in many cultures, have been the impetus for this book. My reading of the work has persuaded me that besides being invaluable as a personal inspiration and resource, it may well become the single most useful professional reference for creating mandalas with clients, students or laypeople interested in knowing more about this ancient and mysterious circle form.

The word "mandala" comes from ancient Sanskrit, and was introduced to Western psychology by psychiatrist Carl Jung in the first part of this century. In Jung’s medical internship at the Burgholzli Psychiatric Hospital in Zurich, he had been intrigued by his observation that frenzied schizophrenic patients would often create self-soothing by drawing circle forms. Later after his traumatic break with Freud and his own midlife breakdown, he himself found the power of self-healing by repeatedly drawing mandalas. He writes, “I sketched every morning in a notebook a small circular drawing... which seemed to correspond to my inner situation at the time... Only gradually did I discover what the mandala really is:... the Self, the wholeness of personality, which if all goes well is harmonious.” (p. 18).

Very early in history human beings discovered what seems to have served as the spiritual focusing power of circle forms. In prehistoric rock carvings from every continent we see the designs. Wherever they occur in art, architectural monuments, rituals and symbolic references, the circle seems to represent universal human consciousness. Sacred creation myths based on the idea of the circle occur in traditions of ancient Europe, Africa, the South Pacific and the American Indians.

Fincher says, “Ancient mandalas carved in many places around the world suggest an awe of the sun and moon. These circular heavenly bodies could have served our ancestors as natural symbols, shaping consciousness and assisting human beings to de-
velop their thinking beyond purely instinctual levels.” (p. 3). Descriptions of much prehistoric lore supply a rich and scholarly background for the author’s presentation of the usefulness of making mandalas in today’s world. Robert A. Johnson, Jungian analyst and author, states in his Foreword to her book, “Never before has mankind been in such need of the healing power of the mandala as at present. Our fractured disintegrating world cries for that cohesive force which is the great power of mandala.” Ancient Tibetan mandalas, whether in sandpainting or “thangka” form, still serve Buddhist religious practice as a visual aid to meditation, and entrance into deep spiritual trance.

Fincher’s section on creating and interpreting mandalas draws on the psychological theories of Jung, Neumann, Von Franz, Edinger, Rhoda Kellogg and Joan Kellogg. She credits Joan Kellogg with the precise instructions for beginning mandala work—kinds of art materials, setting, relaxation techniques for preparation, dating each work and ordering sequence, and finally—affixing a spontaneous title. Interpretation includes careful recording of colors (and associations), listing shapes and numbers of repeated forms (and associations), and cross-referencing personal associations of color, shape and number with the spontaneous title. From this process there begins to emerge a pattern of meaning. Keeping a journal of the process becomes an invaluable part of the healing journey, which as in sandplay or dream work, takes its meaning from the sequential process rather than from any single mandala.

Chapters on color, color systems, and forms and numbers, give precise attention to these elements. In clear and direct format Fincher shares her widely researched information so that the reader has easy access to the author’s rich encyclopedia of ancient and modern sources. Yet, as a contemporary scholar and experienced art therapist, she also carefully instructs the reader always to value personal preferred associations above general or historic facts. I especially appreciated this honoring of the individual. For I have come to be suspicious of theories that claim absolute answers in the increasingly complex field of human psychology. I applaud such statements as, “The color associations in this chapter are given only to stimulate your thinking about the colors in your mandala. These are not the ‘right’ meanings.” (p. 34) And, “This chapter has been an attempt to show that colors in mandalas have another layer of meaning determined by their relationships to one another . . . (and) are not intended as hard and fast rules.” (p. 90). The author has included sixteen beautiful color prints illustrating patient and other mandalas.

The chapter on numbers and forms, liberally sprinkled with sketches and drawings, provided for me one of my favorite reads, for its content provides a detailed compendium of archetypal lore. Of this vast wealth of collected source material Ms. Fincher says, “I have woven together traditional symbolism from religious liturgy, psychology and mythology . . . . This information can help you amplify the meaning of your own symbols” (p. 93). Numbers and forms are assigned several possible meanings, often contradictory in nature. For instance, ONE can stand for the single individual, or it can stand just as well for all that is potential; EIGHT represents stability and harmony as well as the divine instigator of endless change. The BULL symbolizes both the feminine (with its two crescent moon horns), and the powerful masculine god (whose below thunders across the angry sky). The DOG can represent the faithful friend, and in another context bestiality.

Two final chapters are given over to the Great Round of mandala forms (the twelve stages of egoself development, or individuation) drawing on Joan Kellogg’s work of the archetypal mandala series, and telling some personal stories of people whose lives have been profoundly affected by working with mandalas.

In Susanne Fincher’s book Creating Mandalas we, as art therapists, find few final absolute answers about how to live our inner and outer lives, but many suggested possibilities about how to understand and guide our complex human selves through troubled waters. As ancient Chinese scholars (and contemporary students) of the I Ching, use their intuition for matching the pattern of the thrown yarrow stalks with the wisdom of the hexagrams, so can readers and practitioners of this richly rewarding book seek relief, understanding and healing for the world-weary soul of their clients and themselves.
Guidelines for Submissions

All submissions will be acknowledged upon receipt by the AATA National Office. *Art Therapy* uses a blind peer review procedure for full-length articles and brief reports; final decisions regarding publication are made by the reviewers and the Editor. Decisions regarding submissions to other sections are made by the Editor, Associate Editor and special section editors.

The following are guidelines for developing and submitting a manuscript. Manuscripts that do not conform to these guidelines will be returned to the author without review.

**Manuscript Categories**

1. **Full-length Articles.** Full-length articles may focus on the theory, practice and research in art therapy or related areas. Manuscripts must include an abstract of approximately 75-125 words summarizing the major point of the article.
2. **Brief Reports.** Short articles which focus on the results of research are appropriate for this section. Manuscripts should include information on the research design, methodology and results; an abstract of approximately 75-125 words should also be included.
3. **Viewpoints.** Short articles focusing on personal experiences, poetry or original art may be submitted to this section.
4. **Book Reviews.** Reviews of books of interest to art therapists may be submitted at any time. Books which authors wish to have considered for review may be sent directly to the AATA National Office at the address listed above.
5. **Film/Video Reviews.** Reviews of media (films or videotapes) may be submitted at any time. Media which producers wish to have considered for review may be sent directly to the AATA National Office at the address listed above.
6. **Comments.** Brief comments on articles published in *Art Therapy*, issues critical to the profession and practice of art therapy, or letters to the Editor may be submitted to this section and should conform to the style of all other submissions.

**Other Requirements**

1. Send five (5) clear copies of each manuscript to Cathy A. Malchiodi, A.T.R., Editor, *Art Therapy: Journal of the American Art Therapy Association*, c/o AATA, Inc., 1202 Allanson Road, Mundelein, Illinois 60060. Neither AATA nor the Editor can be responsible for submissions sent to any other address.
2. Only original articles that are not under consideration by another periodical or publisher are acceptable.
3. Manuscripts must be typewritten on 8½" × 11" white paper with margins of at least an inch. The body of the paper, references, tables and quotations must be double-spaced.
5. An abstract of 75-125 words must be included with full-length articles and brief reports.
6. Please avoid footnotes wherever possible.
7. A cover sheet should be prepared to include the full name(s) and degree(s) of the author(s), professional affiliations, and the return mailing address of the author to whom correspondence can be sent. Authors’ names, positions, titles and places of employment should not appear in the body of the paper to assure anonymity and to facilitate blind review.
8. Use tables sparingly and type them on separate pages. Refer to the APA *Publication Manual* for style of tabular presentations. All tables, charts or diagrams must be legible and able to withstand reduction.
9. Photographs must be at least 5" × 7" and black and white glossy prints, preferably with high contrast. Xerox copies of illustrations or art expressions are not acceptable for publication. Figure numbers and captions should be noted on the back of photographs; captions must be typed and submitted on a separate sheet of paper. Please refer to figures in the text as Figure 1, Figure 2, etc.
10. Lengthy quotations (300 words or more from one source) or reproduction of works of art (this does not include client art expressions, which is addressed below) require written permission from the copyright holder for reproduction. Adaptation of tables or figures from copyrighted sources also requires approval. It is the author's responsibility to secure such permissions; a copy of the copyright holder's written permission must be provided to the Editor immediately upon acceptance of the article for publication.
11. Client/patient confidentiality must be protected in the title, abstract, text, photos, illustrations and other accompanying material. Proper releases for use of client art expressions and other client information must be obtained and kept on file by the author.
12. It is expected that any manuscript accepted for publication in *Art Therapy* will go through at least one revision before publication. If authors have prepared their manuscripts on either an IBM, IBM-compatible or Macintosh computer, upon acceptance, they can send a 3.5" diskette containing an electronic copy of the manuscript to the AATA office. This will help speed processing, editing and publication.

**Note:** Authors bear full responsibility for the accuracy of all references, quotations and materials accompanying their manuscripts.
ATTENTION AUTHORS

In order to help us process your submission more quickly, please complete the following information and attach one copy to your manuscript:

Name: ____________________________________________________________

Degrees/Credentials: ___________________________________________________________________

Address: ______________________________________________________________________________

Phone #: ________________________________ work ________________________________ home

Type of Submission (check one):

   ___ Article
   ___ Brief Report
   ___ Viewpoints
   ___ Book Review
   ___ Film/Video Review

Title of Submission: ____________________________________________________________________

Checklist:

   ___ Five copies, typewritten on 8½” × 11” paper.
   ___ Abstract of 75-125 words (for articles and brief reports only).
   ___ Detachable cover sheet with author(s) name(s), affiliation, degrees and credentials.
   ___ Appropriate release forms obtained for use of client art expressions and client information. (You do not need to send these with your submission, but you must have them on file.)

THE ORGANIZATION

The American Art Therapy Association (AATA), a non-profit organization founded in 1969, is a national association which represents a membership of approximately 3500 professionals and students. It is governed and directed by a nine-member Board elected by the membership. The AATA has established standards for art therapy education, registration and practice. AATA committees actively work on governmental affairs, clinical issues and professional development. The AATA’s dedication to continuing education and research is demonstrated through annual national and regional conferences, publications, films and awards.

MEMBER BENEFITS

Individual members receive

Publications
- Art Therapy, the official journal of the AATA.
- The quarterly AATA Newsletter.
- Substantial discounts on AATA publications such as Annual Conference Proceedings, other professional journals, films, and membership directory.
- Free AATA literature, such as Educational Programs List, Art Therapy Media List, and Standards of Practice.
- Mailings of professional interest.

Services
- Insurance, including professional liability, major medical, life and disability
- Access to national experts in art therapy

AATA Conferences
- Discounts on registration fees to AATA national and regional conferences.

Nationwide Advocacy
- Governmental affairs activities including Congressional review and monitoring
- State legislative and regulatory activities
- Promotion of recognition and reimbursement of art therapists by third-party payers.
- National liaison with related professional organizations for recognition and promotion of the profession of art therapy

Professional Standards
- Development of model job and licensure laws
- Development and implementation of national guidelines for approval of Master’s Degree and training programs in art therapy.
- Development and implementation of nationally recognized Standards of Registration of Professional Art Therapists.

GENERAL MEMBERSHIP APPLICATIONS

1. The membership year is the calendar year January 1st through December 31st.
2. Contributing, Associate and Student applicants for NEW MEMBERSHIP ONLY: Please follow the chart below when submitting membership application.

Applications received between
Jan. 1st and May 31st—Full dues payment.
June 1st and Sept 30th—Half year dues plus $5.00 payment; membership will expire Dec. 31st of same year.
Oct. 1st and Dec. 31st—Full dues payment; membership for the remainder of current year and the next full year through Dec. 31st.

3. Professional Member applicants must meet Criteria for Professional Membership. Formal application with documentation is submitted to the Membership Chair for approval.
4. AATA Membership and AATA Registration (A.T.R.) each have a separate application procedure. Registration is bestowed only the Standards Committee.
5. National AATA membership is required for Chapter Membership. Please contact the AATA office for information on AATA Chapters.

CATEGORIES AND FEES

PROFESSIONAL—by application only; such members may vote, hold office and serve on committees.

Credentialed Professional Member: Individuals who have been dually approved for Professional Membership and Registration (A.T.R.) by the AATA, dues are $90 per year.

Active Professional Member: Individuals who have completed professional training in art therapy, dues are $75 per year.

CONTRIBUTING—Individuals, organizations, institutions or foundations which contribute annually to the AATA. Such members may not vote, hold office or serve on committees. Dues are $100 per year.

ASSOCIATE—Individuals interested in the therapeutic use of art who support the purposes and objectives of the AATA. Such members may not vote, hold office or serve on committees, Dues are $75 per year.

STUDENT—Individuals who do not meet the qualifications of Professional Membership and are currently taking coursework in art therapy or related fields. Requires a current statement from the institution of learning indicating full-time status and coursework content. Student members may not vote or hold office but may serve on the Student Subcommittee of Membership. Dues are $35 per year.
STATEMENT OF PURPOSE: Art Therapy: Journal of the American Art Therapy Association is the official journal of the AATA, Inc. The purpose of the Journal is to advance the understanding of how visual art functions in the treatment, education, development, and enrichment of people. The Journal provides a scholarly forum for divergent points of view on art therapy and strives to present a broad spectrum of ideas in therapy, practice, professional issues and research. An emphasis is placed on the use of the visual arts in therapy, but articles in related disciplines of interest to art therapists will be considered for publication.

ART THERAPY: JOURNAL OF THE AMERICAN ART THERAPY ASSOCIATION (ISSN 36-3180580) is published quarterly by the AATA, Inc., 1202 Allanson Road, Mundelein, Illinois, U.S.A., 60060. Telephone (708) 949-6064; FAX (708) 566-4580. Non-members may subscribe at the following annual rates: $35 (U.S.) and $56 (Foreign); institutions: $50 (U.S.) and $70 (Foreign). AATA members receive the journal as a benefit of membership.

Single issues: For price and ordering information, call or write to AATA, Inc., 1202 Allanson Road, Mundelein, IL, 60060 (708) 949-6064.

This journal is abstracted in: Psychological Abstracts, INNOVATIONS & RESEARCH, Art Bibliographies Current Titles and Art Bibliographies Modern

Advertising: Please see advertising rates listed elsewhere in this journal or contact the American Art Therapy Association, Inc., 1202 Allanson Road, Mundelein, Illinois 60060 (708) 949-6064. The publication of any advertisement by the AATA, Inc. is not an endorsement of the advertiser or of the products or services advertised. The AATA, Inc. is not responsible for any claims made in an advertisement.

Authorization to copy: No part of this publication may be reproduced, stored in a retrieval system or transmitted in any form or by any means, electronic, electrostatic, magnetic tape, photocopying, recording or otherwise, without permission in writing from the copyright holder.

Change of Address: Notices should be sent at least six weeks in advance to AATA, Inc. Subscribers should notify the post office that they will guarantee forwarding postage. Undelivered copies resulting from address changes will not be replaced, but single issues may be purchased at the single issue price.

Video Review: Imagery and Grief Work: Healing the Memory

About the Cover: "Burning Desire," 22" H x 19" W x 6" D, translucent orange alabaster, by Robert Wolf, M.P.S., A.T.R., art therapist, psychoanalyst, photographer, and sculptor; Associate Professor, College of New Rochelle, Editorial Board Member, Art Therapy. About the piece, Mr. Wolf says: "My professional sculpting experience has provided a synthesis of the artist and the therapist within me."
Editorial

Art and Loss

Cathy A. Malchiodi, M.A., A.T.R., Editor

In this issue, Ellen Speert opens her paper on the use of art therapy with perinatal loss by stating that, "Art therapy is a modality well suited to the needs of grieving women." Most art therapists would also agree that art expression is well suited to the therapeutic needs of anyone who has experienced a loss. Additionally, it has been observed by others outside the field of art therapy that the desire to self-express through an artform is often heightened at times of mourning (Peckham, 1965; Hatcher, 1985). Hatcher (1985) describes this phenomenon from an anthropological standpoint:

Whatever the theoretical explanation, it is clear that art somehow helps human beings cope with the trauma of death. Beauty and art forms have been part of funeral ceremonies since Neandertal times. This universal human problem is met everywhere with symbolic solutions to satisfy the mind and aesthetic solutions to release the emotions (pp. 106-107).

Judith Rubin (1980) presents a similar perspective through personal observation:

On walking through the woods near our vacation cottage, I recently came across a self-directed use of art as a way of coping with an overwhelming event. A rural man—a laborer—had carved a powerful totem-like sculpture out of a tree trunk, as part of his mourning process following the tragic death of his young wife. His explanation of the impulse was that he "had to do something," and that the activity of creating the carving had seemed just right, perhaps filling the void left by his loss (p. 6).

The idea that art making can be helpful in processing a loss is certainly not new. In one sense, humankind may have developed art to alleviate or contain feelings of anxiety, fear, crisis, and threat (Johnson, 1987) as well as to make important events such as death "special" through the creation of visual imagery (Dissanayake, 1988). Within our professional field, art therapists have investigated the specific use of art expression in therapy with those clients who have experienced a loss (Simon, 1981; Junge, 1985; Case, 1987; Rayner & McIntyre, 1987, to name a few). Others have used art expression to help those who are seriously or terminally ill face issues surrounding their own death and to express feelings (Perkins, 1976; Fleming, 1983; Jeppson, 1983; Cotton, 1985; Minar, Erdmann, Kapitan, Richter-Loesl, & Vance, 1991, to name a few). Like Speert, these art therapists consistently observe the power and potential of art to help identify, cope with, and/or heal the pain experienced during the process of recovery from loss.

Many clinicians have acknowledged art expression as a way to work through the grief process. Art (as well as creative writing, poetry or other art forms) seems to appear spontaneously in the attempt to express the deep suffering one experiences when confronted with a significant loss. Kubler-Ross (1969; 1981), who brought discussion of the process of bereavement into the mainstream, devoted a chapter of one of her books on death and dying to the use of drawings made at a significant time (see Furth,
1981). Other authors in the field of death, dying, and grief remark that expressive arts are helpful to processing a loss (Schneider, 1984, for example), although comments about why the arts are important are less specific.

Additionally, art products made at times of facing a significant loss also seem to have special meanings and content. It has been observed that art expression reveals an "inner" knowledge of impending death for the dying. British psychotherapist Susan Bach (1966; 1975; 1990) has accomplished a significant amount of research in this area, particularly with terminally ill children; both Bernie Siegel (1986) and Gregg Furth (1988) have relied heavily on Bach's research in their use of art expression with the terminally ill. Bach's work has mainly focused on the relationship between the body (soma) and the soul (psyche) in children's drawings. She has noted that visual characteristics such as the numbers of objects in a drawing, color values, and direction of movement in drawings can indicate both recovery from illness as well as downward trends in physical health. For example, according to Bach, the predominant values of colors used by a child with a life-threatening illness give direct information on prognosis.

Bach is well-known among those who are of a Jungian bent for her quadrant theory of drawing analysis, which is discussed in her early work (1966; 1975) and her more recent publication, Life Paints Its Own Span (1990). She has developed and tested the idea of dividing a drawing into four distinct quadrants, each of which is considered to represent an aspect of the self. For example, Bach associates the lower left quadrant with negative aspects and, therefore, with downward trends in physical health; objects in this quadrant or movement in the direction of the lower left part of a drawing may be predictive of increasingly poor health or lack of response to medical intervention. However, despite her years of data collection, Bach remains conservative in her use of the quadrant theory and cautions that professionals must also consider other elements such as color, movement, and content.

Art therapists have explored the hypotheses presented by Bach in their work with the terminally ill. Perkins (1976) conducted a preliminary study of the drawings of life-threatened children between the ages of 3 and 12 with life-threatening illnesses; the majority of these children had some form of cancer and a prognosis that was poor. She noted that death anxiety exists fairly consistently, manifesting itself in symbols "suggesting a generalized threat to the child's security" (p. 12). Perkins also used Bach's guidelines (the quadrant theory) for looking at the compositional structure of the drawings. The results of her study indicated that children with serious life-threatening illnesses demonstrated an awareness of death in the colors, symbols, and composition they chose. These findings from Perkins' small sample of children seemed to concur with those of Bach's; others have also explored Bach's concepts, arriving at similar observations (Cotton, 1985; Malchiodi, 1991).

When reading the work of Susan Bach, the transpersonal aspects of the use of art expression in therapy become clearly apparent. For example, the "soul window" has been mentioned by Bach (1966), Perkins (1976), and Cotton (1985); this term refers to a small, often round window that is placed under the eaves of a house. According to Swiss folklore, the soul of a person leaves the home through this opening. Another example which demonstrates transpersonal aspects is the association of the upper left quadrant as an area through which the spirit "goes out of life." Bach, Perkins, and Cotton have documented the depiction of paths going from right to upper left and the appearance of the setting sun in this quadrant, both predictive of impending death.

Clearly, the idea of "going out of life" through a particular space in the drawing and the term "soul window" are two concepts that have deep spiritual meaning and derivation. There are many other images which have strong connection to the spiritual realm, some more universal and some personal to the creator. When art expression is used to access the inner life of the individual who is grieving a loss of the self or loss of another, the realm of the transpersonal is inevitably touched. Profoundly spiritual imagery may emerge in client work at times of crises involving the resolution of a loss.

The first time I was struck by this phenomenon was as an art therapy intern working with a group of adolescents in an alternative program in a public school system. A 13-year-old girl in the group struggled for months with the death of her grandfather; she was extremely guilt-ridden and confused about his death because, at the time of his passing, she was not allowed to see him and speak to him one last time. Several months after the loss she came to an individual therapy session and reported that she had had a wonderful dream the previous night. I asked her to draw or paint the dream, describing as best she could what she thought the most important or memorable part was. She painted Figure 1, depicting her grandfather in the center on a large throne-
ART AND LOSS

Fig. 1. "My Dream of Grandfather" by girl, 13 years; watercolor, 8½" × 11".

Fig. 2. "Act of Remembrance: Quilt for Ken"; mixed media including photos, transparencies, color Xerox, paint, silk habutae; 24" × 24".
like chair and herself as the person just to the right of him. She included many other people whom she indicated were various important family members.

What was most significant to her in this dream was the fact that she had the opportunity to speak with her grandfather and to hear that he remembered her and considered her to be a very important granddaughter whom he greatly missed. The part that she thought was most unusual was the ending of the dream: a reindeer came to take her grandfather away from the family to another place. Although this seemed strange, she said she was also greatly comforted by it, feeling a sense of relief when this happened in the dream.

Being a novice in my work at this point I had no real understanding of the meaning of the reindeer or the true importance of this dream in the transpersonal realm of healing a loss. Later, as I began to explore symbols, I found several references that helped me to understand the connection of the reindeer to the death of the grandfather and the beginning of the girl's emotional recovery from the loss. For example, the reindeer is a herd animal which humans have followed, or been guided by, over the centuries; in the girl's dream, the reindeer comes to take the grandfather away to another place. Also, the term "rein" is thought to signify the forces of life and the relationship of the soul to the body; to cut the "reins" is symbolically equivalent to dying (Cirlot, 1962).

This case example demonstrates that art expression is not only a way to connect with that which is lost on a transpersonal level, but also a way to remember or commensurate what has been lost. Art has often been made in memory of someone who is lost or departed. In some sense, all art expression may serve as an act of remembrance.

In times of grief many have turned to creating visual memorials to remember, record, and immortalize someone who has died. The AIDS Quilt is a powerful example of this need. When confronted with my own loss of my cousin to AIDS, I found myself deeply drawn to this process in a very personal way (Figure 2). The only way to work out his death was to create the patchwork of events that intertwined our lives, although these memories had become bittersweet with the ending of his life.

The process of creating the quilt was a long one, not unlike the process of completing my own grieving; it took me several months to complete the 12 squares which went into the final piece. It involved many hours of looking through old photo albums, collecting images, and talking to relatives to further illuminate the history of our relationship. I spent a great deal of time writing in my journal and exploring my own feelings and fears about death and dying. Finally, after all the squares were complete, there was the final process of carefully stitching the pieces together and quilting the spaces around them.

This process obviously evokes the ideas of traditional practices of quilting as a commemorative art form, however it also demonstrates the need for creating or experiencing meaningful rituals to deal with loss. The most well-known ritual involving death is the funeral where the bereaved are allowed a public forum to express grief and celebrate the life of the deceased. But rituals can also be specially constructed to address the specific needs of the bereaved. Boegel and van Morising (1991) powerfully describe the personal use of ritual involving movement, objects, and mementos in the "Carla Performance" in response to the death of a loved one. In a discussion of this piece, Gantt (1991) suggests that the art therapist can assist the grieving person in the development of an appropriate ritual, shaped by the client for his/her own situation.

There is also a certain amount of ritual in the telling of a story about an art expression: it is now known that telling others our stories in times of stress or loss can be health-giving and anxiety-reducing. Pennebaker (1990) has established that the telling of painful events is key to successful recovery, both physically and emotionally. Speert importantly observes that art making within a group context can involve both isolation in the process of creation and eventual connectedness to others through the sharing of the product. Others can respond to the product and share common symbols concerning their own losses with the group.

One of the most powerful aspects of art expression in processing loss is the ability to address fear through the art process. Loss of any kind sets up a deluge of diverse feelings—anger, depression, guilt, anxiety, and for many, fear. Once into the process, there is no fear when drawing or painting or constructing. After all, just confronting that blank paper or the untouched materials or clay can be the most courageous of acts when one is in extreme psychic pain. As 28-year-old Dori Hauri (cited in Dreibuss-Kattan, 1982) writes:

When I paint, I feel less pain. I am still aware of my approaching death, but it loses its tangibility; the thought is not pointed any longer, nor is it blunt. It just exists. I feel that the painting is inside me like a
freshly sown plant and its fruit can grow. With my paintings I can oppose my illness. (p. 51)

Lastly, although some individuals can confront and work through many of the conflictual issues of bereavement through art forms on their own, Rita Simon (1981), British art therapist, notes that the “companionship and security of a therapeutic relationship” (p. 135) is necessary to successfully process a loss. The individual who is grieving and working through a loss through art expression needs a responsible witness and guide to illuminate the process and to give the appropriate and knowledgeable response to that which is expressed in visual form. In some cases, this training in both the areas of graphic communication and human emotion may be critical, such as in identifying the individual who is so troubled by loss as to consider taking his/her own life. As professionals in the field of art therapy, our knowledge about visual form, the art-making process, and the psyche is essential in assisting the individual who wishes to explore and work through the pain of loss in visual art.

This article is dedicated to the memory of Merritt Riordan, who died in May of 1992, and to his family Anne, Mike, and Stacia Riordan and Chris Pecock.

Supervision and the Issue of Case Management

The traditional framework for art therapy supervision includes a discussion of theory and practice, metaphor and process, media and expression, projection and interpretation, and other issues to assist the art therapy intern to better achieve clients’ goals set during the session. Many variations and special problems will arise with each person and each population engaged in treatment. All will be considered in the supervisory hour. None of these issues is foreign to our educational policies and are foundations for the supervisor/supervisee work.

However, one clinical difficulty is often ignored or purposely avoided by many art therapy training programs. Case management is the piece left out of our education in many instances. The argument is made that case management is best taught within the practicum by the clinical supervisor on site, an employee of the facility. I agree that this solution is workable if the clinic or hospital is a teaching agency and pays attention to the students’ need for assistance. My concern is with the many instances when the clients’ needs have been poorly handled because the instruction needed to provide them with information, or active help, has not been forthcoming.

Emotional stress is not an uncommon reaction for an intern entering a practicum. Responsibility for treatment and first-hand encounters with the wide range of human troubles appropriately causes heightened anxiety. However, additional tension which is engendered by the necessities of coping with both clinical issues and case management can be reduced by helping the student anticipate the realities of the mental health world at this time of economic cutbacks, increased crime, and abusive behaviors. Far from the creative and satisfying experiences of engaging a client in the art therapy process, exploring material and experimenting with positive change, is the experience of reporting to Children’s Services the abusive activity of an adult to a child. We have to face that a good part of the practicum will not involve using inventive media to introduce movement intrapsychically—rather, it will involve using the telephone and filling out forms to satisfy legal and ethical standards.

For example, does the intern know how to proceed when the clients’ art product indicates that abusive behaviors are “secretly” going on in the home? Does s/he pursue more art tasks hoping to gain clear evidence or does s/he confront the family or child verbally with her suspicions? Has the intern been briefed how to proceed with reporting to the proper authorities? Is the art product seen as confidential, privileged communication of therapy or legal evidence that may be subpoenaed? When suicidal symbols emerge in the art expression where does the intern turn for help? Are needed hospitalization procedures clearly understood? If there is no sure reason to commit, does the student know how to insure around the clock protection for the patient in their home? When these crises come about has the student been advised how to precisely document all aspects of the clinical emergency in a manner that protects the intern from possible legal action? These issues only touch on some of the many situations that call for student involvement outside the focus of art therapy treatment.

We teach with pride that art therapy expressions provide a clinical tool which leads to a better understanding of the client’s world. However, when the message conveyed in the art calls for immediate protective action, the therapist must deal with the larger system as it is defined legally by the state.

I don’t think that this dilemma necessarily defeats the pleasure and excitement that our students feel as they learn to be professionals, but it seems to me that the idealism that they bring to the practicum could be protected if we warn them ahead about some grim realities. I have yet to have a student share with me joy and inspiration over the task of filling out a Medi-Cal form for the State.

We should give serious thought to how the socio-economic issues of our time impact the curriculum and the supervision of today’s student/interns. Perhaps in some areas this is not a major problem, but those who live in California, New York, Chicago,
or in the pockets of troubled areas in our country, I venture to say that our students are involved for a large percentage of their training in case management. Even if they try to avoid the problem or feel distressed by having to take on these duties, they are there.

To me, the conflict is real: art therapy thinking and case management thinking only overlap to a small degree. We have the responsibility to teach all aspects of treatment. If that is unrealistic, as I believe it is, we must address the situation and clearly define who will educate our interns when the need arises in the area of case management.

Response to Survey of Assessment Use with Children

I am currently teaching the course, "Treatment Planning in the Creative Arts," in Lesley College's Expressive Therapy Program. In our readings I included the article published in Art Therapy, "An Informal Survey of Assessment Use in Child Art Therapy" (Mills, A., & Goodwin, R., 1992). In our class of 23 students, we looked at the wide variety of assessment procedures available to art therapists, ranging from projective drawing tests used by the clinical psychologist, standardized art therapy measures such as the Diagnostic Drawing Series and loosely structured sessions that respond to client initiatives. As a mid-term assignment, the students wrote a paper based on an assessment of their choice at their internship site. They were free to follow or modify existing procedures, to invent their own and/or to encourage their clients' spontaneous art activity.

In reviewing the students' assessment procedures it was fascinating to discover how similar their approaches were to the art therapists surveyed by Mills and Goodwin (1992). Like the art therapists in that survey, the students showed a great diversity in their choices of assessments. Many modified standard assessments to adapt them to their specific sites and populations. Others freely invented their own procedures. Those who used standard procedures did so in a variety of ways. Students who used the DDS obtained much information useful to their teams and some suggested modifications. Those who used the standardized House-Tree-Person seemed to be least satisfied.

The choices and attitudes of this class of Expressive Therapy graduate students provide support to the findings of Mills and Goodwin (1992) that art therapists often prefer to modify existing techniques or create their own.

Newton, MA

Special Notes

THE WHITE HOUSE
May 21, 1992
Dear Ms. Malchiodi,

How thoughtful of you to send a copy of Art Therapy: Journal of the American Art Therapy Association.

The goal of disseminating information on art therapy looks like a worthy one. I am sure that those who deal with mental health services are grateful for this enrichment and breadth of helpful strategies for working with people who are emotionally disturbed. Thank you so for thinking of me and for sharing.

With best wishes.

 Warmly,

Barbara Bush

June 25, 1992

Cathy Malchiodi, A.T.R.
Editor, Art Therapy
5 AATA, Inc.
1202 Allanson Road
Mundelein, Illinois 60060

Dear Cathy,

Just received your first issue of Art Therapy and wanted to send my congratulations and best wishes on the new look, layout, and organization. I know the gigantic effort involved in a major makeover as well as the large consumption of time in editorial duties—and simply wanted to send my highest congratulations to you and the good folks involved in the production.

Sincerely,

Thomas A. Hatfield,
Executive Director
The National Art Education Association, Reston, VA
The Use of Art Therapy Following Perinatal Death

Ellen Speert, M.Ed., A.T.R., Encinitas, CA

Abstract

Art therapy is a modality well suited to the needs of grieving women. During the bereavement period following a miscarriage, stillbirth, or abortion, complex emotional responses are often difficult to verbalize, leaving grieving women isolated and confused. This paper presents information on perinatal death and the usefulness of group art therapy as an intervention within the framework of the new psychology of women. Client art expressions illustrate how women have used art therapy to work through their grief and move toward a deeper sense of personal empowerment and connection with other women.

For years, the issues of the death of a baby due to miscarriage, stillbirth, or abortion surfaced in numerous art therapy groups which the author facilitated. Due to the frequency of this occurrence, a four-part, one-day workshop to specifically address perinatal death through art therapy was developed. Each part of the workshop was designed to address the various phases of the grief cycle. Simple art materials were used to: provide a spontaneous art expression as a graphic, metaphoric representation of the self; symbolically explore personal loss; work with the theme of reclaiming "the girl within," and express connection and wholeness through creating group art expressions.

Perinatal Loss

Each year in the United States about 33,000 babies are stillborn (about one in 100) according to the National Center for Health Statistics. According to Friedman (1982), stillbirth occurs at the rate of 12.6 in 1000. A much higher percentage (about one in 10 pregnancies) ends in miscarriage and an unknown number in abortion.

Despite the large number of perinatal deaths, the mother's need for mourning often goes unmet (DeFrain, 1986). Perinatal death brings together two of the most emotional of human experiences: birth and death. Although women come together in the joy of the former, they are often left isolated in the grief of the latter. Friends and family generally feel uncomfortable and ill-equipped to address the subject, leaving the woman alone in her grieving. Furthermore, the mother may be left in "medical limbo" as her obstetrician views her/his job as finished and the pediatrician has no infant to attend (Peppers, 1980). Common medical and lay responses include: "You can have another one," "It's a freak of nature," and "It's nature's way of getting rid of defects." Doctors and nurses may further distance themselves from the emotional reality of this loss of a life by referring to the baby as the "product of conception," a sanitized term to go along with the medical procedures following miscarriage or abortion. These responses overlook the woman's need to grieve her loss and may inadvertently increase her sense of isolation.

With the suppression of grief, the mourning process is prolonged and may trigger compounding emotional problems. In addition to symptoms seen during bereavement (sadness, anger, depression, emptiness, and blaming), the mother often experiences guilt inadequacy and a sense that the perinatal death reflects her failure as a parent. There may also be serious behavioral ramifications including sleep disturbance, suicidal thoughts, marital turmoil, increased rate of divorce, substance abuse, family violence, and overprotection of surviving children (DeFrain, 1986). Also, with perinatal death there are no shared life experiences or memories, so a woman is left with a sense of unreality, further disconnecting her from others.

Physical symptoms are also present and are similar to those experienced following the death of an
adult. However, women often speak of deep physical pain, aching arms and/or chest during the months following the perinatal loss. These symptoms differ in some respects from those experienced following the death of an older person.

The Psychology of Women and Perinatal Loss

Even if a woman who has experienced a perinatal death is in therapy during the time of loss, traditional psychological constructs may not meet her needs. During the last decade, women have begun to study the ways in which their own psychology differs from that of men. Historically, men were not only the ones to construct the theories of human development, but they also served as the only subjects studied. It is perhaps because of this limited research population that Freud (1938), Erikson (1950), and Levinson (1978) all saw life as a struggle toward achievement and separation. It was assumed that when female clients did not mature along these lines they were deficient and, by definition, abnormal. Hancock (1989) writes that Freud assessed psychological development of the male by his separation from his mother and “thus the concept of development in terms of male norms and female deficiencies and pronounces women inferior in maturity” (p. 230). For this reason it was generally believed that the measurement for psychological and emotional maturity rested on the degree of separation and individuation one achieved.

Stiver (1991) points out "that the inflexible application to female development of a concept derived from male development, without sufficient attention to the quality and nature of women's experience, leads to a significant misunderstanding of women” (p. 86). Stiver, along with Jordan, Kaplan, Miller, Surrey and others at the Stone Center at Wellesley College, have brought to light new perspectives concerning the psychology of women. As a result, affiliation and connectedness are now considered important components of female maturity (Jordan, Kaplan, Miller, Stiver, & Surrey, 1991). Their perspectives redefine what constitutes psychological health, taking into consideration the unique aspects of female growth and development.

Surrey (1991), in what she calls the "self-in-relation model of development," postulates a female-centered theory of maturation. She traces the development of identity through specific relational networks and uses the term "relationship differentiation" in place of separation-individuation. Surrey uses the concept of differentiation in the sense of an embryonic cell becoming more highly developed. She states that "this is a process that encompasses increasing levels of complexity, choice, fluidity and articulation within the context of human relationship" (p. 60). Thus, development of relationships is central to female maturation and identity.

Surrey's concept is of particular importance in understanding women who are grieving a perinatal loss. This loss severs relational connection and cuts down the sense of choice, fluidity and articulation. Fortunately, these very qualities may be enhanced and nurtured within the art therapy process.

Specific Uses of Art Therapy with Perinatal Loss

Carol Gilligan (1982) observes that a woman's identity is threatened by separation. Art expressions created at the time of perinatal loss, and for months afterwards, often graphically express a lost sense of self. Figure 1 is an example of this lost sense of self, a collage figure with the head removed and arms outstretched. The creator stated that "it feels like I'm reaching for something or someone, like I need to connect." Thus, in creating this figure, the woman could express her loss and, in seeing similar symbols created by others, reduce her sense of isolation.

With the loss of a fetus, clients express a sense of being cut off from their own bodies (Figure 2). This woman, whose mother took diethylnitrosomine (DES) while trying to conceive her, now finds herself unable to carry a baby to term and has had repeated miscarriages. She shows graphically the blocks she has in experiencing a sense of her own body. Due to the visual and kinesthetic richness of color, texture, scent, and sound, clients' senses are often stimulated. They frequently feel more connection to their bodies through the process of pounding, tearing, painting, and gluing.

Because women tend to fuse their sense of identity with intimacy and connectedness, their assessment of self is measured by the standard of their relationships. Miller (1976) observes that a woman's sense of self becomes very much organized around being able to make, and then maintain, affiliations and relationships. . . . Disruption of connections is perceived not as just a loss of a relationship, but as something closer to a total loss of self” (p. 83). This is expressed in the repeated hand-print motifs (Figure 3) as women speak of not only being unable to touch their babies, but also of not feeling real themselves. The hand symbolically says, "this is me." Several cli-
ents also told of making impressions of their stillborn babies' hands to create a tangible object to preserve.

A woman who has lost her fetus naturally experiences a feeling of confusion over her loss. Art expression provides her with containment for this often chaotic outpouring (Figure 4). For example, the tearing of paper and flinging of paint provides an avenue of release while simultaneously structuring the chaos. Background paper had been placed inside a large tray which served to contain and give a tangible boundary to the flood of emotion.

In contrast, feelings of depletion and isolation are expressed. Many women speak of feeling lonely, isolated, and empty and use the art to fill this internal void. Surrey (1991) observes that "if the connection feels severed, there can be a sense of deadness, blackness, and even terror: some have described this experience as a 'black hole'" (p. 172). Figures 5-7 illustrate the working through of emptiness and vulnerability. A clay body was ripped open and brightly colored tissue pieces were first placed inside the womb/wound, then removed and later were again placed inside. As this woman worked through her loss, she felt a need to cover and protect her clay self using dryer lint and the shredded tissues from her tears. She also added "a brain to help understand it all." Finally, removing the protective blanket and acknowledging the pain as part of herself, she used the tissues to surround rather than cover herself.

Lost babies are created over and over again in a wide variety of media (Figures 8 & 9). Clay, plasticine, and cloth can have soothing qualities, due to their tactile richness and the ability to form an object which can be held. With the art product, there can be a feeling of connectedness to the lost babies, keeping them a part of the woman's life. The women in the perinatal loss groups often speak of the need to have a tangible and lasting part of their lost child. One woman stated that the plasticine baby (Figure 8) which she now keeps in a visible place at home helps to say to others, "You might not be dealing with it (the stillborn baby), but I am."

As previously stated, for many women there is not only a need to be in a relationship in order to experience a complete sense of self, but they may also need to feel competent and in control. The death of a fetus may create a feeling of incompetence and loss of control which can be addressed through art therapy. Because of the contained, concrete quality of art making in a structured, therapeutic context, women are able to take risks, practice new behaviors, gain control, and develop a sense of mastery. The art product may then be placed at a distance and viewed more objectively. Although alone in the art making, the woman has allies in reviewing the art expression and can try out new ideas with the encouragement of others in the group. For example, the various changes the artist made in the sculpture (Figures 5-7) provided her with a greater sense of control.

Art expressions often reveal rage (Figure 10); clay, as a resistive medium, is helpful in releasing this rage. The outpouring of anger may be a response to the unfairness of life, a woman's feeling of incompetence, her inability to control what has happened within her own body, the lack of sensitive medical response, or other frustrations. After creating the piece, the woman stated, "I am pushing myself up out of the block and screaming. "The block is styrofoam, which she stated is, "fake and cold, but the clay is warm and real... my rage is helping me push out."

Clay is also effective in relieving some of the pain in the chest and arms which mothers complain of following a stillbirth. With the force necessary to form clay, clients reduce the somatic component of their pain directly through body movement. Arms are now productively active rather than passive, at least during the session. Additionally, women speak of experiencing greater energy and less depression during art making, despite the sad content of their work.

Hancock (1989) observes women's needs to meet "the culture's expectation of the perfect weight, the perfect curl, the perfect makeup, the perfect orgasm, perfect childbirth, perfect children..." The demand for perfection is yoked to that for nurturance in the ideal of perfect nurturance that drives us all" (pp. 187-188). The creative process provides the opportunity to express a woman's authentic self, lifting the layer of external, social expectations for perfection and conformity to roles. Art making allows the grieving woman to focus inward and to express and release emotions that family, friends and others have been unable to accept.

Lastly, the loss of a fetus is often experienced as the loss of the (procreative self. This shift in the sense of self from full and creative (as during a wanted pregnancy) to loss of the creative potential may mirror an earlier loss of confidence.

**iller (1976), Gilligan (1982), and Hancock (1989) have studied the diminished sense of autonomy and self-confidence during normal female adolescent development. Hancock (1989) discovered that confident, self-assured nine-year-old girls often became conformist, hesitant and self-doubting only a
few years later. Something in society gives females the message that creativity and confidence is no longer to be trusted or valued after age 12 or 13. Hancock refers to this creative, confident individual as the "girl within."

The creative process can enhance self-esteem and revive a personal sense of purpose. Art making may symbolically rekindle this "spark" as women again see themselves having the capacity to create. The creative process can renew the "girl within" while simultaneously working through the grief process.

Loss → Creativity Workshop: Techniques

In the workshops conducted by the author, simple art materials are introduced first. One of several warm ups is presented: wet paper and paint technique (finding an image to develop out of paint dropped on wet paper), wrapping up paper and developing an image out of the fold lines, or simply finding an image to develop out of a scribble. During this warm up there is often talking, sometimes even laughter. This may be due to the newness or awkwardness of the art making, as many clients state they have not made art since grade school.

Next a process is used which the author developed. First, each woman is asked to tear a shape to represent herself from a color that feels right for her. Fadeless paper is provided because of its wonderful colors and the deckel edge produced when torn. Second, she chooses a color to represent her loss and tears it into an appropriate shape. Third, she uses rubber cement or glue stick to attach these, in their appropriate relationship, onto an 18" × 24" piece of white cardboard or heavy paper. Lastly, she draws with oil pastels what is needed to bring comfort, wholeness, or peace to the torn-paper images.

During this process the room is silent, in contrast to the warm up which preceded it. Women often comment later that they had forgotten they were in a group and that they felt totally alone as they worked. The group then spends as long as is needed talking about the process and product.

The third phase of the workshop is designed to focus on the creative "girl within." Each woman talks of a time when she felt free to explore and express herself. An individual collage is then created by each participant using a variety of materials such as feathers, cloth, glitter, nature objects, tissue, paint, etc. The wide selection of art materials encourages exploration and evokes early feelings of creativity and freedom.

After talking about these individual collages, a group mural is assigned, incorporating each woman's sense of her own child within. This process puts the women in connection with others in the group. There is often a visual interconnection of symbols and lines, and the process is far from silent. By this stage in the workshop, the women have established connection and intimacy with others in the group.

Art making, by the nature of its two-step process of expression and reflection, allows both the isolation of internal focus and the connectedness with others. As the visual symbols of loss are shared with others in the group, they also promote deeper self-understanding as well as connection.

Summary

The creative experience of using the art for self exploration during the time of traumatic loss provides a tremendous opportunity for growth. It is the author's experience that connection (the female voice of "we" rather than the male voice "I") is a critical factor in the shift to a sense of empowerment and eventual growth. The trauma of a fetal death may be healed by a new sense of relatedness both with others as well as with the self.

Miller (1976) states that there is the "... absolute necessity of, and absolute existence in human beings of, the potential for both cooperation and creativity... the intense personal creating that we each must do all through life. Everyone repeatedly has to break through to a new vision if he is to keep living" (p. 44). Indeed, clients demonstrate these elements of cooperation, creativity and the re-creation of their personal vision by struggling with the art media. Through this work each woman fashions a stronger identity.

Perhaps female clients can be better served by framing interventions and the entire structure of their treatment in terms of a relationship model, supporting connection rather than autonomy. As Surrey (1991) observes, "the joining of visions and voices creates something new, an enlarged vision... thus the sense of connection and participation in something larger than oneself does not diminish, but rather heighten the sense of personal power and understanding" (p. 172). This author increasingly utilizes the workshop and group format of treatment in place of individual therapy. As Kohut's view of treatment is to help patients feel that "the sustaining echo of empathic resonance is indeed available in the world" (1984, p. 78), so this writer finds the group therapy format provides more reflective sur-
THE USE OF ART THERAPY

faces to both contain and mirror each women’s experience of loss and validate her sense of self. The echo, in this way, can be heard not only through the therapist and the artwork, but through the other group participants. The feminist psychological approach of mutual empowerment and connection continues to be studied at the Stone Center (Jordan et al. 1991), and further research based on this work is needed on group art therapy models.

The Loss → Creativity Workshop is designed to stimulate a deeper, more personal response in working with women experiencing perinatal death. As Johnson (1989) writes of our role as therapists that we “are constrained by the greater value our society places on control versus empathy, external versus internal concerns, managing versus caring... In this sense our struggle is part of a larger, even more important struggle, not merely that of the women’s movement, but supporting the values women have come to represent” (p. 236). These feminine values of empathy and connectedness are enhanced by the process of creating art together in a group format.

Further support for the group therapy approach comes from DeFrain (1991), who has spent many years observing and working with families suffering perinatal loss. He states, “The death of a baby is clearly not an individual loss... though individual treatment is often warranted, we believe that in most cases it would be wise to encourage group solutions to many of the dilemmas the death imposes” (p. 229).

As health professionals, art therapists must support the need to express and creatively transform the issues of grief and loss with our clients to prevent some of the psychological, sociological and behavioral problems resulting from unresolved grief. We must not shy away from connecting with this pain and loss. As we are learning from the new psychology of women, a sense of connection is an essential part of addressing the needs of grieving women, particularly those experiencing the unique trauma of perinatal loss.

Research Approaches Within Master's Level Art Therapy Training Programs

Debra Linessch, M.A., A.T.R., M.F.C.C., Los Angeles, CA

Abstract

A research project was conducted as a preliminary exploration of the attitudes and approaches toward research within Master's level art therapy training programs. The results of a questionnaire that was sent out to the research methodology instructors of graduate programs in art therapy are discussed. Comparative information regarding the ways in which the research process is prioritized, conceptualized and taught within different training approaches is offered by the author.

The constellation of issues that surrounds the teaching of art therapy research methodologies is a growing concern to art therapy education. Consequently, an investigation was begun into the ways in which Master's level art therapy training programs integrate research components. The focus was on concerns inherent in the process of research and the approaches utilized by programs to teach and integrate research with the program. This paper outlines the research procedure utilized, presents a summary of the results and discusses patterns that emerged from the data.

This project was based on the following three assumptions, or presuppositions, affecting process of inquiry:

1. Within the field of art therapy, a tension has existed between systematic rigor and creative research. This has affected both scholarly process and the teaching of research methodology.

2. Students may enter art therapy training programs with the bias that research is both quantitative and a foreign, incomprehensible experience.

3. The expanding scope of research methodologies offers art therapists new opportunities to engage in research that can be compatible with art therapy methodology.

Research has been only infrequently debated in the art therapy literature (Junge, 1989; Kwiatowska, 1978; McNiff, 1986; Rosal, 1989; Rubin, 1984; Wadeson, 1980). In the earliest of the writings that discuss methodological approaches, Kwiatowska (1978) articulates the prevailing attitude that careful observations and systematic organization could support solid research conclusions based on the art work produced in art therapy. Questioning the behavioral science approach, Wadeson (1980) addresses the complexity of art therapy research and emphasizes the need to refine and modify existing behavioral science research methods, perhaps even invent new ones. Rubin (1984) adds to the discussion, pointing out the unique problems in doing art therapy research and suggests alternate methodologies that might offer more compatible approaches. McNiff (1986) expands this discussion in his text on art therapy education, suggesting non-traditional forms of research that could best support and relate to the essentially creative character of the art therapy process. In an interesting published dialogue, Junge (1989) and Rosal (1989) share their disparate views regarding future directions for art therapy research. Although Rosal (1989) argues for an emphasis on single case research and Junge (1989) argues for expansion of methodological approach, in many ways they are in agreement, expressing the important idea that the field of art therapy needs to evolve methodologies of scholarship that are consistent with its methodologies of clinical practice. Nowhere in the literature, however, was there discussion of how art therapy research was being taught in training programs.
RESEARCH APPROACHES

Procedure

A questionnaire was sent out to all Master's level art therapy training programs listed in the American Art Therapy Association's Art Therapy Education Program List (AATA, 1990). The questionnaire was designed to provide art therapy educators with an opportunity to portray the format and philosophy of their approach to research. The questionnaires were mailed to the individual designated by the program as the instructor of the research methodology course. A follow-up letter was sent shortly thereafter and telephone calls were used to pursue those individuals who did not respond.

Once the questionnaires were returned, the data was approached systematically, and thematic categories were developed to organize and understand the information. Although the research was essentially quantitative in approach, an attempt was made to integrate an open-ended approach to the data. As a result, despite categorical treatment of the survey results, the sequence was based on one outlined in Taylor and Bogdan (1984). Introduction to Qualitative Research Methods. (pp. 130-144). Attempting to treat the questionnaires as qualitative text, themes were tracked, hunches, interpretations and ideas were followed, typologies constructed, concepts and theoretical propositions developed and data viewed contextually. This mix of methodologies was a major deterrent throughout the data analysis and interpretation, and became a major limitation in this study.

Results

A large number (25/52) of the questionnaires were returned. This high response rate (78%) may suggest that art therapy educators were eager to take advantage of this opportunity to discuss research within their graduate training programs.

Goals

Table 1 presents a summary of the answers regarding the programs' goals for their required research project. The most frequent response to the question about goals was an answer combining mastery in area of concentration (A) and synthesis of studies and clinical experience (B). This may reflect the widely held opinion that the research component of a Master's level training program supports the acquisition of clinical skills.

Professional contribution to the field (C) was of secondary importance and attainment of scientifically sound research skills (E) seemed to be important to fewer instructors, notably within those programs attached to medical or research institutions. Two respondents who selected (E) questioned the word "scientifically," implying that sound research skills, but not necessarily scientific ones, can be a goal. Innovation and creativity in research design (D) was generally held to be a very high expectation at the Masters level, but was included by many as a goal.

Two interesting additions (write-ins) added to the data. The first, "to attain artistically sound research goals," represented the request for new ways of understanding art therapy research. The second, "to examine the vicissitudes of the clinical experience," seemed to offer further support for the belief that research is understood primarily as a resource for the development of clinical skills.

Relative Value of Research Within Training

Table 2 presents the results of a question asking for relative ratings of research compared to other components in Masters level art therapy training programs. Respondents typically had strong opinions about this question and used the form to express their values about research. As indicated in the chart, most programs rated research second to the clinical or practicum experience, although several attested to a desire to move in the direction of increased attention to the research component. No respondents indicated that research was more

importance than clinical experience. Only one program felt strongly that research was much less important than all other aspects of its program.

The data indicate that research is less important than practicum and academics, but there is less consensus about its priority over personal growth and the studio art process. It is interesting that the largest discrepancy in opinion occurs in the relative rating between research and the studio art process. This may be one of the indicators of the perceived tension between creativity and research scholarship.

### Research Methods Introduced

Table 3 presents the research approaches introduced to art therapy Master's level students. The returned questionnaires indicated that most of the programs provide overviews of the main categories of traditional research, particularly case study, descriptive and quasi-experimental. Interestingly, several include at least an introduction into alternative research approaches, particularly phenomenological and ethnographic.

Table 4 presents a summary of responses to a question regarding the ways in which these methodologies are introduced to the students. The data reveal a diversity of approaches. Nine programs indicated they had developed a research methodology class specifically for their program, and seven of these discussed ways in which they had designed this to be uniquely compatible with the art therapy process. However, it appears that instruction in research methodologies is often embedded in other courses, i.e., assessment courses, case study courses, etc. Typically in programs attached to medical or research institutes, art therapy students study research methodology in other human service departments, sometimes by program requirements, sometimes as an elective.

Although research methodology classes were typically described as one semester long, the length of time given to students to complete their research projects varied from one semester to two years. Thirteen programs indicated that completion of the required research project took approximately one academic year. The most frequently (18/25 respondents) mentioned way of providing ongoing support for the student engaged in research was a combination of semester long seminars and individual tutorials. Only one program claimed the structure of a research committee and extra faculty thesis advisors.

Research Options Offered

When asked about what kinds of research the students were actually doing (as opposed to what kinds of research they were learning about), the respondents presented a slightly different profile; most students engaged in either case study or quasi-experimental research. Table 5 presents a summary of the programs’ responses.

It is important to mention that the list of approaches offered as options in this section of the questionnaire was developed from the programs’ own curriculum descriptions. It was thought that these categories, offered in the language of those who would be responding to the questionnaire, would be most easily comprehended. However, problems emerged as it became clear that respondents were utilizing different definitions of the research approaches in their responses.

In response to the question, the case study was repeatedly the research method of choice. Although empirical/quantitative projects were mentioned as frequently (18), these approaches typically had a smaller percentage of the program’s students participating in them. Irrespective of whether the program rated research as a priority or not, the case study repeatedly was the research approach in which the majority of students were engaged (ranging from 40% to 100% of students). Many programs indicated that at least some of their students were involved in empirical research projects, typically programs associated with medical or research institutions.

*Specific options mentioned one time:
- qualitative, hermeneutic
- art historically based research
- various kinds of clinical experiences
- exploration of indepth media applications
- single case study designs
- oral examination
- spiritual and personal development
- theoretical reviews
- student ideas making significant contribution
- grant
- published journal article
In contrast, one respondent displayed a strong preference for the quasi-experimental single case study indicating that 90% of their students used this particular methodology to design their research projects. Also, nine programs included research options that are not typically understood as research in other human service training programs, i.e., clinical program development, audio-visual projects, extra clinical experience, spiritual and personal development, and grant writing. Two programs indicated that the research options available to their students were in a state of flux, in one case shifting toward new evolving paradigms and in a second case, encouraging more scientific empirical research.

Encouragement for Presentation/Publication

When asked if they encouraged formal presentation or publication of student research, all but one of the respondents replied in the affirmative. The implication here seems to be strong support for fostering student participation in the dialogues and scholarly discussions of our field.

Expression of Concerns

This category of results reflects the fact that respondents frequently added their own narrative comments. In an attempt to accurately portray the flavor of these comments the content is categorized and summarized and conveys some of the passion, interest, delight and anger that was expressed. Two respondents expressed concerns with the questionnaire itself, describing it as “overly black and white” and “limiting the inquiry to the behavioral/science bias/perspective.” In many ways respondents expressed their belief that the manner in which research education is integrated within art therapy training programs is complicated and needs to be considered, discussed and debated. The written concerns ranged from diverse opinions regarding research philosophy:

Is art therapy at the M.A. level a terminal degree? (and) should the in-depth question of M.A. research be in part dependent upon answering this question?

The purpose of the research training is to help students become more questioning and insightful clinicians.

We discourage research study at the M.A. level and focus on clinical training.

I believe that most M.A. programs do not really teach research.

Our base goal is the inclusion of the artistic tradition in research/scholarship.

We are encouraging more empirical/quantitative (work).

Research is conducted on many levels throughout the program.

Plans are underway to design a course in research which would be taught by art therapists who are doing or have done research in art therapy.

Discussion

The questionnaire suggested a profile of the diversity of approaches used to educate art therapy trainees in the research process. Although the respondents were generally in agreement about clinical training having priority in Master’s level programs, there seemed to be differences of opinion about the relative value of research instruction. Two dissimilar emphases emerged: one, strong and clear, that described the research component of training programs as support for clinical development and the other, weaker and much less cohesive, that described the research component of training programs as an important endeavor on its own. This suggests that there is an escalating need to reconsider the role of research within our training institutions.

The questionnaires also suggested an interesting profile of the ways in which art therapy students are introduced to and engage in the research process. The data indicated that trainees typically receive an overview of traditional research approaches, but that this instruction rarely correlated with the actual research endeavors they design. The data repeatedly suggested the following scenario: although introduced to many research methodologies, the art therapy student found the case study most compatible with the creative psychotherapeutic process in which s/he is immersed. This is a tentative speculation based on the patterns that emerged in the data, but severely limited by the questionnaire design which did not adequately provide clear definitions for the research categories.

Although a growing number of programs have already designed or are in the process of designing specific instruction in art therapy research, overall the questionnaires reflected a lack of specific methodologies for art therapy research. This suggests that art therapy educators may benefit from some exploration of the kinds of inquiry processes that emerge from our own field.

This study was essentially limited by the very struggles which motivated it. As described in the in-
RESEARCH APPROACHES

Introduction, my own presuppositions about research in the field of art therapy point to a disciplinary inclination toward qualitative methodologies. Yet the methodologies that support this research were predominantly quantitative in both philosophy and tools of inquiry. The lack of consistency between data gathering (quantitative) and data analysis (qualitative) did not enrich, but rather limited the endeavor. Consequently, the research potential that a statistical analysis of the survey might have yielded was hampered by not using an appropriately sensitive tool for the textual analysis. In effect, a mix of methodologies and a general lack of expertise about the inquiry process limited this study.

It became apparent throughout the data analysis that different programs have developed very different resolutions to the complex interplay between clinical training, creativity, and scholarship. In some situations, these resolutions have become stances or postures, i.e., to minimize research, to make research more empirical or to isolate one particular research methodology.

It is my belief that a wide range of research methodologies offers exciting opportunities for art therapy inquiry. Such a range will allow art therapists to maintain a fundamental commitment to the creative process while engaging in rigorous scholarly work. Also, a spectrum of approaches will enable art therapy educators to introduce a variety of methodologies that will be compatible with creative needs and with the ongoing scholarly needs of our field.

Conclusion

Much more work needs to be done in support of the questions that were preliminarily addressed in this research project. Questions about research scholarship in our field and within our training institutions are complex. The diversity of opinion regarding the goals, values and methodologies of Master’s level art therapy research became apparent throughout the process of this research project. It seems imperative that those of us who are concerned about art therapy research within our field acknowledge the complexity of the issues and utilize the diversity for growth rather than rigid divisiveness.

Call for Submissions to Art Therapy

Art Therapy: Journal of the American Art Therapy Association is currently seeking submissions in the form of full-length articles and brief reports on theoretical, methodological, and research for two special theme issues:

1. Art and Medicine. Articles may focus on the use of art expression in the assessment or treatment of physical disease; theoretical, ethical, or practical issues in the application of art expression in a medical setting or with physical illness; original research in medical art therapy.

2. Professionalism in Art Therapy. Articles may focus on current professional issues in the field of art therapy such as, but not limited to, licensure, credentialing, job development and governmental affairs. Theoretical, historical, methodological, or research articles focusing on these themes will be considered.

Submissions must adhere to the “Guidelines for Submission” which are outlined in Art Therapy; please review these guidelines carefully because manuscripts which do not meet these guidelines will be returned to authors without review.

DEADLINE for submission of manuscripts is December 15th, 1992. Please send manuscripts to:

Brief Reports

Art Therapy with Adult Female Incest Survivors

Carolyn S. Waller, M.A., Hyde Park, Utah

Abstract

“Very little systematic research has compared different types of treatment for adult victims of sexual assault” (Resick & Schnicke, 1990, p. 458). Art therapy research in the treatment of sexual abuse has mainly been concerned with the content of art expressions produced by clients (Spring, 1984; Ticen, 1990). Therefore, comparative studies of art therapy and group verbal therapy have the potential of aiding therapists in treating this population.

Fifteen adult female incest survivors participated in this study which employed a control group and two experimental groups. Participants rated the significance of the curative factors of catharsis, cohesion, and insight in their treatment. The results of this study indicate that group art therapy, using a series of structured tasks, increased the value assigned to each of these curative factors.

Reports of successful programs for treating sexual assault victims have been published, but few are empirically based. One exception is a study carried out by Roth, Dye and Lebowitz (1989) on the effectiveness of group psychotherapy intervention with adult women who were assault victims. The treatment of adult female incest survivors is equally lacking in controlled studies although numerous authors have described treatment models for clients from this population (Courtois, 1988, Sgroi, 1988, 1989, Spring, 1990; Ticen, 1990). Research concerning incest has concentrated on prevalence or symptomatology (Briere & Runtz, 1988; Bryer, Nelson, Miller & Krol, 1987; Herman, Russell & Trocki, 1986; Russell, 1986) in an attempt to predict the aftereffects of sexual abuse by a family member (Lindberg & Distad, 1985). Herman and Schatzow (1984) developed an empirically based, time-limited group treatment for women who had a history of incestuous abuse. However, few studies have compared different therapeutic modalities (Roth, Dye & Lebowitz, 1989).

Research into the use of art therapy with sexual abuse has been concerned with the elements included in the art produced by clients and patients (Spring, 1985; Ticen, 1990), but the process of art therapy and clients’ responses to this modality have been neglected. This study compared verbal group therapy and group art therapy in the treatment of adult female incest survivors. The Curative Climate Instrument (Fuhriman, Drescher, Hanson, Henrie & Rybicki, 1986) was used to determine the participants’ ratings of the curative factors of catharsis, cohesion, and insight as helpful in their therapy.

Method

A total of 15 adult female incest survivors took part in this study. The control group consisted of three women who participated in eight weekly individual psychotherapy sessions during the study. Two experimental groups of incest survivors met for eight weeks in 90 minutes sessions. A group of seven women using only verbal techniques and an art therapy group of five women that used the process of drawing, painting and verbal processing. Both experi-
mental groups addressed issues common to women who have been sexually abused: social isolation, betrayal, lack of trust, guilt, shame, anger, and wish to confront the perpetrator or care giver.

Participants completed a demographic questionnaire at the beginning of the study. After two weeks and eight weeks all participants completed The Curative Climate Instrument (Fuhriman, 1986). This instrument is a 14-item, five-point Likert Scale that measures subjects' ratings of the curative factors of catharsis, cohesion, and insight as significant in their treatment. It was developed by Fuhriman based on Yalom's Q Sort (1975).

The Kruskal-Wallis one-way analysis of variance by ranks was used to compare the control and experimental groups' ratings of these factors at the end of the second and eighth weeks. The Sandler's A-Statistic was used to determine changes in each group's ratings of the subscales after the six-week period. In both statistical methods, p<.05 was considered significant.

Results

Mean ages for the groups range from 32-38, an indication that the negative aftereffects of incest are present in these women's lives years after the abuse occurred. The mean number of years of abuse duration were 9.61 and 10.1 respectively for the verbal and art therapy groups. However, these numbers may be inaccurate due to participants' repression of memories or understanding of the term abuse.

Hypothesis 1 stated that art therapy will increase the value of insight in adult female incest survivors. Women in the art therapy group increased their value of insight after eight weeks. (Sandler's A = .215, DF = 4, p<.005).

The art therapy group increased its value of insight significantly over the six-week interval between testings. There was little change in either the control or the verbal group's rating of this curative factor (see Figure 1).

Hypothesis 2 stated that art therapy will increase the value of catharsis in adult female incest survivors. Participants in the art therapy group valued catharsis more after eight weeks. (Sandler's A = .282, DF = 4, p<.025).

The art therapy group increased its value of catharsis significantly over the six-week interval between testings. The control group's value of catharsis remained unchanged and the verbal group increased its value of catharsis after eight weeks of therapy (see Figure 2).

Hypothesis 3 stated that art therapy will increase the value of cohesion during the course of therapy. Cohesion was valued more after eight weeks by participants in the art therapy group. (Sandler's A = .261, DF = 4, p<.025).

The art therapy group showed a significant increase in its valuing of the cohesion factor after eight weeks in therapy. The control group increased its value of cohesion while the verbal therapy group decreased its value of the same factor (see Figure 3).

Hypothesis 4 stated that the art therapy group would value insight more than either the control or the verbal group after eight weeks. This hypothesis was not accepted. Although the data showed a trend, it was not at a significant level (see Figure 1).

Discussion

Two important limitations must be noted concerning this study: the small sample size and the method used to recruit participants for the verbal group. It was not feasible to have large numbers of participants in either of the experimental groups if participants were to experience optimum therapeutic results. Adequate time for participants to engage in discussion and interaction with therapists and other group members was a major consideration in structuring the groups. Recruiting clients from mental health agencies rather than advertising for subjects limited the number of prospective participants for this study, but prevented the inclusion of women who were in crisis. The decision to recruit in this manner was based on ethical considerations of the possible risks to participants and insured the availability of emergency therapeutic services to participants in the event of severe emotional distress.

The verbal group was an ongoing open group that had been meeting for two years. Some of the participants had been members of this group for two years and others for only a short time. It is possible that the length of time in the group prior to the study was a factor in the clients' ratings of the curative factors. In contrast, the art therapy group participants met for the first time when the research began.

Art therapy used with a group of adult female incest survivors increased their value of catharsis, cohesion, and insight as curative factors in their treatment. Experiencing these factors may have caused them to value them higher, even when clients have not consciously put a name to those factors. In the art therapy group catharsis was performed in two ways: through the use of the art medium and through the verbalizations of strong and long repressed emotions. Cohesion may come about
through the sharing of art materials as well as the sharing of common problems and experiences. The knowledge that another woman shares a similar history may be cause for bringing about closeness in members of a therapy group. Insight into the origins and present effects of serious problems can be accelerated by sharing the insights of another woman with a similar problem. Examining a problem becomes a concrete event through the visual expression of the problem, its possible solutions, and feedback from others whom the person has grown to trust.

Art therapy group participants commented that the art product, or paper on which they drew, acted as some sort of buffer or barrier between themselves and the world. This barrier can be lowered or raised at will by the artists depending on how threatening the contents are to them. Persons and animals can be disguised, symbols whose meanings are unknown to others can be used in complete safety. They can deny the interpretations of others, erase, paint over, tear or fold, and put away any material which is too affect laden for that moment. Several of the women stated that talking during the process of artmaking seemed to give them ideas for changing their drawings by the use of either additional media or colors.

Sharing of materials by therapists and group members can be an important part of trust and cohesion building in a group. Requesting additional supplies by participants may have been a way of testing both the therapist and other members of the group at the beginning of this study. Some women were continually giving up supplies to others even when they were using that particular crayon, pencil, or pair of scissors. These same women reported being “caregivers” and “rescuers” in their lives outside the group. The women who asked for supplies or ideas for drawings often spoke of needing more emotional support from family and friends than they were willing or able to provide. Caring for each other through the sharing of materials seemed to mirror the verbal support evident in the conversations.

Freedom in the use of art materials may reinforce to clients that they are trusted to have good judgment. It may also encourage the clients to feel free to express themselves in other unique ways with less fear of criticism or negative results. This is contrary to what the incest survivors have usually learned in their families of origin. The women talked about strict rules surrounding their use of art materials when they were children. Participants were reassured that they were allowed to work in any way they chose as long as everyone was safe.
INCEST SURVIVORS

Clients in both of the experimental groups were constantly urged to find the connection between past adaptive behavior and the maladaptive behavior used in their present lives to deal with the memories and effects of abuse. It appears that the opportunity to draw a situation and see it in some concrete form allows a client to examine the causes and effects more directly than when using words. The artwork can also serve as a prompter to clients in keeping the discussion focused on the discussion topic.

Group art therapy is cost-effective because several clients can be treated at the same time. It also provides a more democratic forum where clients may participate at the same moment and on their own level during the art-making part of the sessions (Liebmann, 1985). The art therapy group creates a safe place for clients who do not trust words or hide behind them. Incest victims were often lied to, threatened, and misled with words from their abusers and family members. The clients in art therapy report that the use of art feels safer as a medium of communication.

Conclusion

The results of this study suggest that a structured series of art therapy interventions can be useful in the treatment of the long-term effects of incest in adult women in out-patient group therapy. Appreciation and valuing of the curative factors of insight, catharsis, and cohesion may be enhanced thus preventing premature termination of therapy when only catharsis has been achieved. Further research can aid clinicians in formulating additional treatment interventions and understanding more about how the process of art therapy functions.

Art Captures the Impact of the Los Angeles Crisis

Jane Walter, M.A.

On April 29 of this year, long-standing unresolved frustrations, angers, and inter-racial tensions erupted into violence, fire setting, and rioting in the city of Los Angeles and across the nation. Triggered by the court decision concerning the police handling of Rodney King, protest and unlawful and destructive actions were set in motion. Involvement in the crisis was brought home to every citizen in a more personal way than ever before. Most of us were overwhelmed and traumatized by the unbelievable actions of the police seen in the countless TV reviews of the Rodney King beating video. When the riots began, the media gave 24-hour exposure on every channel and brought into every home the fires, looting and the angry despair of the crowds. Criminal and outraged reactions, positive and negative actions by citizens, deeds of bravery and cowardice were all before our eyes for four days and nights of curfew and restricted activity. However one judges this extraordinary event, what is undeniable is that everyone felt as though they were on the frontline of this revolution.

We therapists were particularly disturbed by the feelings of emotional stress, helplessness and confusion experienced by our clients. For example, children were encouraged to loot with their parents, and those who did not saw others gain desired goods in this manner. The conflicting messages and the fear of danger and violence were beyond the life experience of the young and evoked old terrors and despair from the elderly.

Words cannot express the impact of the images evoked by this crisis: the fires, the mobs, the beatings, the angry faces of the crowds. For a fortunate few, the opportunity to place these images and find some words that helped make some of the stress more manageable was provided by the art therapists and art teachers in the schools and in the clinics. In addition, the city responded to volunteers who came into the community and offered some workshops and time for expressive arts. The need still continues and the interest in the art healing process has not been forgotten. Although as always, there is the denial and repression of a large system that has turned away from long-term resolution of the heart of the problem.

A selection of drawings done by children and adults after the L.A. riots is offered along with brief commentaries by each therapist.

Shirley Riley, M.A., A.T.R., M.F.C.T.,
Private Practice, Los Angeles, CA

Figure 1 is a drawing by a 50-year-old woman who suffered many days of serious depression and dissociative reaction, when the riots evoked in her the feelings of attack, fear and lack of security that paralleled similar feelings experienced in her youth. For her, red is rage and green is abandonment, hence, the fire and burning houses were experienced on an external and internal level.
ART CAPTURES THE IMPACT

Mindy Newborn, Graduate Intern, Poseidon School, West Los Angeles, CA

Figure 2 was drawn by a 14-year-old Black/Hispanic boy. He has spent most of his life in juvenile hall and foster homes. Both his parents have been in and out of jail for as long as he can remember. He has expressed his anger at being a poor Black male in a White society in which he feels victimized.

The day after the L.A. riots the boy was extremely angry because, he said, “I wanted to go looting, but my aunt wouldn’t let me.” He was also angry about the police and their violent reaction toward African Americans in Los Angeles. He was asked to do a drawing about how he was feeling about the riots. Without hesitation, he drew a road leading to a burning city; on one side of the road there are signs warning, “At this point turn back.” and “Welcome to L.A.” In the distance is South Central L.A. burning with people running away. The other half of the page is Beverly Hills; there are no fires burning and many armed police are guarding the area. He put himself in the center of the page on top of a sign warning, “Risky.” He explained that, “the rich people in Beverly Hills get protected by the police just because they’re White and rich, even though their buildings weren’t on fire. The poor minorities in South Central get no help from the police while all their buildings burn down.”

There was a disgusted resignation and a sadness in his voice as he spoke about the riots. When I asked him about the Black first rising out of the burned building, he responded by saying, “We’re fighting back. Just wait.”

Figure 3, the box’s collage of a child floating through the sky, responds to his feelings of helplessness during the riots. When I asked him how that child might feel, he replied, “scared and alone.”

All of his drawings about the riots indicate feelings of isolation and sadness.

Figure 4 illustrates the work of an 18-year-old White male who has experienced physical and sexual abuse from the time he was three. He was placed in foster homes from the age of four and has been in and out of juvenile hall. He is extremely verbal and responded to the riots with feelings of outrage and anger directed toward the police. He was very proud of being able to get away with looting merchandise from some stores in Los Angeles during the riots. He said, “I looted because it was a chance to get a hold of things that I never get a chance to get a hold of. It had nothing to do with Rodney King. It was about, “let’s get what we can get and get out.”” His drawing (Figure 4) shows Hollywood before and after the riots. His depiction of “During” shows his experience of looting at a Radio Shack, fires raging and blunt written descriptions of death and destruction. He said, “I feel hurt by it (the riots) but I also feel good because people were striking back.”

Yoko Takasumi, LCSW, A.T.R., Regional Program Director, El Nido Services, Los Angeles, CA

Figures 5 through 10 were drawn by adolescent girls during a crisis intervention session at Gardena Rilley High School, a part of L.A. Unified Schools for pregnant minors. The teacher reported that these girls did not have much to say when she attempted to talk to them that morning; however, given the opportunity to express their feelings and impressions through images, they were able to express themselves dramatically. The art also stimulated verbal expression and discussion in the group. The students were asked to draw their impression of the crisis, including what they saw and how they felt. When they were finished, they were asked to title their drawings.

Figure 5, “Simi Valley vs. LA” drawn by an 18-year-old expresses her disbelief and anger over the “not guilty” verdict for the Rodney King case. She also commented that because everyone was looting, it almost seemed O.K. to steal. The group related to her feelings of confusion and her mistrust of the justice and police systems. Some offered the explanation that they believed that the jurors were bribed.

Figure 6, created by a 17-year-old girl, is a composite of images which impressed her the most about the whole crisis. “There were fires and lootings everywhere. The news crew was busy televising. All the markets in South Central LA were destroyed.” A White truck driver was beaten brutally by Black gang members and became a representative of racially oriented violence. On the upper left corner is an image of Rodney King who spoke on television pleading for peace. His words, “Can we get along” serves as the title.

Figure 7 titled “Corner of Western & Florence,” drawn by another 17-year-old girl, focuses on the same man who was beaten. The brutality and lack of response from the law enforcement officers frightened her.
Fig. 1

Nothing is safe!!!

Fig. 2

Fig. 3

Fig. 4
Figure 8. drawn by a 16-year-old student, makes a distinct statement about what it was like for people depending on welfare checks and food stamps. The government checks were not delivered on time because of the disruption of the postal service. When a few check-cashing businesses reopened after the riot, everyone rushed to cash their desperately needed checks. The result was a big crowd and long lines. This picture reminded some group members of the feelings of panic they experienced while standing in long lines in markets miles away from their homes.

Figure 9, titled “Black Community is Now Burnt. Reconstruction Begins: We All Learn,” was drawn by a 16-year-old girl. The police vehicle arrives too late and trash and money are scattered about a ruined building while more fires are burning in the background. Her imagery does not match her cognitive awareness of beginning reconstruction efforts. The group talked about how some store owners offered the looters whatever they wanted in exchange for protecting the building.

Figures 10 and 11 are samples from a second grade orthopedically handicapped class at 153rd Street School in Gardena. Most of the children in the class suffer from neurological damage and are functioning below grade level. The teacher was very relieved when art intervention was offered to deal specifically with the riot because she was unsure of how to help the children talk about their feelings. The children were asked to draw what they saw or how they felt about the unrest.

A 7-year-old boy saw the fire at the mall when he went to Burger King with his uncle (Figure 10). He kept repeating, “This is fire burning, y’all.” He did not stop until the entire mall was filled with the color of fire as if he needed to discharge anxious energy. He finished off with the blue, which he said was water.

Figure 11 is done by another 7-year-old from the handicapped class. He pictured the blackened figure as the bad man who sets the house on fire, and himself as crying with tears. He kept laying colors heavily for a long time, unlike his usual simple
drawings with happy stories. The layers of color may have reflected his layers of anxiety.

This population of vulnerable children tended to personalize the trauma more readily than others, tending to internalize external events. Both of the boys imagined themselves as being in the fire. Art was helpful in this circumstance in externalizing their fears and separating their feelings from reality.

Jane Walter, M.A., Didi Hirsch
Community Mental Health Center,
West Los Angeles, CA

Both Figures 12 and 13 were drawn in a community mental health center during the time of the uprising. This culturally diversified clinic experi-
ART CAPTURES THE IMPACT

enced its share of the devastating effects of the riot's turmoil, looting, smoke-filled skies and tensions. One client, on her way to the clinic, was terrorized by a mob while they entered her bus with baseball bats, breaking windows and wounding a passenger. The damage and violence spread far beyond the inner cities; the tension and fear were experienced by all of Southern California.

Figure 12 was drawn by an art therapy group of adult clients in an outpatient community support setting for the chronically mentally ill, during day three of the uprising. Typically, this population experiences great difficulties joining with one another through art. The residual symptoms of their illnesses and side effects of medications are often evidenced in withdrawal, rigid defenses and disconnected thought processes which impede their abilities to link feeling states to internal and external stimuli.

This group drawing reflects the degree of anxiety felt over the riots; this otherwise detached and withdrawn group attempted to bind together in a supportive circle of hands in order to provide comfort and create a safe place and to make sense of all that was happening in their lives. Words were later added to the art experience and stimulated a discussion about the riots. One group member finished the group by verbalizing, “It’s too bad that everyone can’t come to the same conclusion about what our communities need to do.”

Figure 13 was drawn on the sixth day after the riots during a children’s group treatment program. This culturally diverse group was comprised of boys, ages 10 to 12, experiencing behavioral difficulties related predominately to attention deficit, hyperactive disorders, and oppositional defiance.

The group of boys was directed to “draw how the city should be rebuilt after the riots.” The children took the directive one step further by offering solutions as to how the city could prevent future incidents of this nature from occurring. All group members unanimously agreed that City Hall was the most important building in the drawing. They reported, “It should be there to help people with problems and for keeping the peace.” Another group member retorted, “City Hall should also allow people to come anytime during business hours to discuss the problems they are having in their communities.” Lastly, a boy commented, “Yeah, but City Hall also needs to listen and do something about the problems before riots happen again.”

Postscript—Shirley Riley, A.T.R.

My motivation for gathering these examples of crisis-art expressions was based on my continued amazement and respect for the impact of artwork from clients who normally have great difficulty in communicating their inner experiences. Through clinical contact and supervision, I observed how successfully my colleagues utilized the value of the image during times of crisis. It seemed important to me to share these drawings with art therapists outside of our sadly torn community of Los Angeles. It brings to mind the many other crises that have impacted the people with whom we work which have been more clearly understood when seen through their eyes in their art. If we art therapists ever need confirmation of how important our services are in the therapeutic world, moments like these reconfirm the unique contribution we make to our field.

The Well-Being Journal: Drawing Upon Your Inner Power to Heal Yourself

xii + 155 pp., paperback, $10.95. ISBN 0-87877-141-7

Reviewed by Elizabeth Ratcliffe, M.S., M.F.C.C., A.T.R., Book Editor

I recommend Lucia Capachchine's Well-Being Journal to people who seek self-renewal and are willing to take the time to nurture themselves by going through its pages. This book is appropriate for use by both individuals and groups.

What I had intended to be a critical reading of the book in preparation for this professional review became a personal experiencing of it when physical problems overtook me this Spring. I was debilitated by an unexpected operation for a detached retina followed by a grade 11 sprained ankle. With upper and lower extremities essentially useless, my sense of well-being took a nose dive into the enforced expanse of immobilized time and house-bound space.

Although I had no unused journal books on hand, plenty of 8½ × 11 loose paper, craypas and felt pens provided tools for a test run of Capachchine’s process. I supplemented my reading through active involvement with her chapter suggestions. Gradually, colorful pages of non-dominant-hand chicken scratched drawings and writings began to replace eye patches, ace bandages and crutches in the bedroom's clutter. Focusing on The Well-Being Journal’s sequential exercises, my attention shifted from the depressing confines of sick bay to the alive inner world of my unconscious. This reminded me that my body might be telling me something useful. The message is familiar to those overtaken suddenly by illness: SLOW DOWN AND PAY ATTENTION TO THE NEEDS OF YOUR BODY. EMOTIONS, AND YOUR SPIRIT.

The single most rewarding experiential exercise in Capachchine’s journal turned out to be the “dialogic” alternate-hand work. Although by nature highly intuitive, my family of origin bestowed upon me a tendency to favor reasonableness over feelings. It appeared that when my nondominant left hand began to “create answers” to my dominant right hand’s questions, surprising inner wisdom was revealed which could begin to enlarge my universe by adding or uncovering new dimensions and potentials. Creating these dialogues together with their accompanying drawings gave me a profound sense of discovery and excitement. The frustrations of having to cope with physical problems receded into a quieter place involving acceptance and building nursing chores into my daily life.

Instead of feeling frustrated by my incapacities, I could begin to see positive value in my current state. Out of my childlike pictures and alternate hand dialogues there emerged, like secret codes from invisible ink, constructive positive messages about my ability to take charge of what was happening to me. What had originally promised to be only an exercise in reading and critiquing someone else’s self-help book had turned into a personal experience of self-healing and growth. Paraphrasing M. P. Follett's Creative Experience in Marion Milner’s 1950s classic On Not Being Able to Paint, concepts by themselves mean nothing until they are knitted into the structure of my being, and this can only be done through my own activity. By putting into practice...
Capacchione's admonition regarding *The Well-Being Journal*, "It works only if you use it" (p. 19). I had found a working tool to reaccess my own well-being. Although my use and appreciation of *The Well-Being Journal* grew out of my having been physically incapacitated during the time I had planned to read and review it, many other motivations exist for exploring its contents. Useful information and creative exercises supply assistance for readers interested in such things as eating patterns, body-mapping, food and moods, efficient use of time, problems with relationships, and remembering and recording dreams as tools for inner healing.

Of the seven chapters in the book, only three specifically concern themselves with the physical body. In the first the author presents her philosophical and psychological background for writing this book. In Chapters Two, Three, and Four body awareness, image and self-care are her concern. The last three chapters focus on relaxation and recreation, supportive relationships, and healing from the inner self. The final 15 pages are devoted to an appendix titled, "Finding a Health Professional," and a detailed bibliography and discography. The bibliography, divided into categories such as "Body/Mind," "Healing, Massage and Bodywork," "Diet, Nutrition and Weight Control," and "Male and Female," consists only of books published up to 1989.

Noticing this reminded me how many new volumes dealing with self-care and holistic health have been published in the 1990s. Since 1979, when Capacchione published her first book, *The Creative Journal: The Art of Finding Yourself*, she has produced five other journals. They focus on different aspects of creativity as an agent of healing and are intended for various populations. As a consumer as well as an art therapist and psychotherapist, I am grateful to Lucia Capacchione for her contributions to the growing body of literature in a rapidly growing field now entitled psychoneuroimmunology.

**Art, Culture, and Ethnicity**

Reviewed by **Howard McConeghey**, Ed.D., A.T.R., Professor Emeritus, University of New Mexico, Albuquerque, New Mexico

Of the 20 chapters in this book, more than half concern a single ethnic group: African-Americans. This may be the result of the greater amount of resource material readily available on Black art and aesthetics, and of the political emphasis on civil rights and African-Americans in the United States. Nonetheless, it is a disappointment to this reviewer that as late as 1990 no chapters are devoted to Hispanic or Asian minority groups, and only two chapters concern Native Americans: Northwest Coastal Indians and an Eskimo village in Southwest Alaska. No other Native American groups are represented.

The book, written by and for art educators, may be of little interest to art therapists except the possibility of ethnic, cultural, and aesthetic differences. These may suggest differences in the psyche of various ethnic groups and therefore the need for unique therapeutic approaches.

This review is organized according to chapters with similar or related themes, rather than the chronological order of presentation in the book. The Black aesthetic is the primary focus of the book, and several chapters speak directly to this question.

by Adriene Walker Hoard, presents research suggesting there is a certain rhythmical, flowing quality which is composed not only by solid forms, but also by the voids between forms. In the visual arts this rhythm is similar to the syncopated musical beat in jazz which fills in the tones in and around the main beats. In addition to this rhythm of solids and voids the Black aesthetic includes a depth of feeling and physical responsiveness to affective stimuli and, referring to the work of Fouda (1988), a “deep-felt cooperative consciousness” (p. 157). She says this is an ancestral group experience. Hoard surmises that at the base of Black aesthetic lies “an instinctual response to form” (p. 157), thus suggesting a relationship between visual structure and ethnicity.

To test this hypothesis, Hoard presents a research study in which “90 non-objective or abstract paintings collated to isolate the stylistic attribute of visual structure” (p. 159), were presented to adults both formally trained and untrained in the visual arts. The results of the study suggest corroboration with the hypothesis of cultural Gestalt.

Chapter Four, by Pamela Gill Franklin and Patricia Sturh, presents a similar study of Black people’s responses to paintings by Black artists Jacob Lawrence and Faith Ringgold. Participants were asked to indicate the degree to which the paintings reflected the Black experience. Value was placed on those works which conveyed social and political concerns.

An historical background begins Robert L. Adams “Alain Locke Revived: The Reconsideration of an Aesthetic.” Locke (1886-1954), a Black philosopher and prime mover in the Harlem Renaissance, was spokesperson for a “New Negro Formulation” of racial values. It charted a strategy for achieving freedom through the arts for the African-American. Locke believed that art can be a tool for advancing Black social causes. According to Adams, five aesthetic tenants were central to Locke’s views. Artists should:

1. employ propaganda in their art;
2. know that African art is the fountainhead source of modern art;
3. not be restricted to racial subject matter;
4. employ the particular and the universal;
5. have rootage in a cultural soil (p. 233).

Two chapters later, we encounter Oscar Logan’s ‘Concepts and Values of Black and White Instruc-
tors Affecting the Transmission of the Black Visual Aesthetic in Historically Black Colleges and Universities.” Logan suggests that Black art can be distinguished by an interdependent triad consisting of Black Culture, Black Aesthetic, and Black Art. These refer to various attitudes and styles of contemporary Black artists. The Black Art Movement (activists), a part of the group of Black Culture, emphasizes propaganda, particularly in subject matter. Mainstream artists belong to the group called Black Aesthetic. They conform to international stylistic trends (mostly non-objective). Blackstream artists (Trans-African), considered to be a part of the Black Art Movement, use symbols, colors and techniques of African art, but with generally accepted aesthetic standards.

Logan’s study indicated “race had a lot to do with how instructors rated most of the value statements” about Black aesthetic issues, “and, to a lesser degree, their ability to identify the artists’ works” (p. 263). The statements were drawn from five categories which supposedly shape the Black aesthetic: 1) historical perspective; 2) call and response; 3) improvisation; 4) representational balance; and 5) balance intensity in color.

While focusing on the Black historical culture, Murry Normal Depillars emphasizes the importance of the image in “Multiculturalism in Visual Arts Education: Are America’s Educational Institutions Ready for Multiculturalism?” “Art is not passive,” he tells us (p. 115). He quotes Lerone Bennett Jr. concerning the “image-situation”:

It acts because it is the image which is the ground of man’s acts. This is a point of enormous importance, for men act out of their images. They respond not to the situation but to the situation transformed by the images they carry in their minds. In short, they respond to the image-situation, to the ideas they have in themselves in the situations (p. 115).

Depillars suggests that Black culture was dominant in the world before classical Greek and Roman cultures developed, and that this fact has been distorted by the white Greco-Roman tradition. He propounds the theory that the Egyptian civilization and the Egyptian Pharaohs were Black. Imhotep, called the “Father of Medicine,” was, it’s a respected builder, magician, philosopher, astronomer, and physician (p. 122). “The Greeks worshipped Imhotep, and roughly 2500 years after his death,
changed his name to Asklepios" (p. 122). Since Greek ascendency a "Dis-Africanization" has replaced the original perspective.

Likewise, in "Linking the Legacy: Approaches to the Teaching of African and American Art," Paulette Spruiel-Fleming presents the same historic perspective: the Black world is the true initiator of the "Western" civilization. This position is "flaunted before the eyes" of Afro-Americans today (Diop, 1974, p. xiv). Fleming urges that this African-American cultural experience be communicated to Americans, who have been significantly influenced by several centuries of negative information. This is the task, she says, of global multicultural art education.

Eugene Grigsby calls this negative information the "White Ghetto." "Afro-American Culture and the White Ghetto" defines a mental attitude of white people who are unaware of the rich African-American culture that surrounds them.

"The Depiction of Black Imagery among the World's Masterpieces in Art" by Lee A. Ransaw, gives substance to this claim. Of 30,000 paintings in the Louvre, fewer than 50 include Black figures. With 20,000 in the National Gallery of London, fewer than 30 paintings depict Black figures. And in the Metropolitan Museum of Art, only 23 paintings depict Black figures. Blacks, in these paintings, are usually seen as kind and gentle servants. The clearest summary of this survey is that Blacks have been observed with friendly eyes by European masters, but not with too much respect.

Turning to multiculturalism and multicultural education, Judith Mariahazy presents Ralph Smith's four categories of multicultural art educators. Exegetal multiculturalists "interpret foreign cultures on the basis of their own personal viewpoints primarily to criticize the society of which they are members" (p. 193). Dogmatic multiculturalists maintain that their own culture is superior. Agnostic multiculturalists are interested in "exotic artifacts," but have only shallow interest in other judgments based on their own cultural values. Dialectical multiculturalists avoid any judgments based on their own cultural values and are willing to learn from alien cultural traditions. "Multiculturalism and Art Education" does include a very short mention of Native Americans and Mexican Americans, but the focus is on Blacks.

Carmen Armstrong, in "Teaching Art in a Multicultural/Multietnic Society" believes that art teachers need to reconsider the pervasive mainstream notions of formalism that differ from other systems of organization. She urges the art educator to reconsider the prevailing Greco-Roman aesthetic if they are to become "more sensitive to the culturally diverse value systems operating in art and possible culturally based semantic barriers to student receptivity" (p. 97).

The book opens with "Teaching Art to Disadvantaged Black Students: Strategies for a Learning Style." Leo F. Twiggs stresses that teaching art as an extension of life experiences may be the only value in an otherwise hostile and alien environment. To achieve this, teachers must begin to perceive art as an humanistic endeavor. Creativity and innovation must be encouraged rather than promoting "tried and proven methods" (p. 8).

Similarly, Mary Stokrocki, in "A Portrait of a Black Teacher of Preadolescents in the Inner City: A Qualitative Description," suggests that the primary goals of art education are to relate art to students' everyday life and heritage, and to improve their inner confidence and comprehension.

An Eskimo village school is described by Joanne Kurz Guilfoil. Implications for the study of other cross-cultural settings are suggested, such as, cooperative planning to include ethnic representatives, and soliciting student opinions.

Ester Page Hill decries a "Shattered Fantasy: Minority Access to Careers in Art Education." She finds that the most critical barrier to access to careers in art education is financial.

Art therapists may be particularly interested in cultural and racial issues of the family. However, "The Minority Family as a Mediator for Their Children's Art and Academic Education." offers nothing new for art therapists or art educators.

W. Lambert Brittain studied the developmental stages in the drawings of children from New York and compared them to drawings by Aboriginal children in Australia. While he found little difference in the drawings of four and five year olds, in children over six years old the difference in baseline usage provided a striking contrast between the two groups. The Aboriginal children almost never employed a baseline.

"Ancestry and Aristocracy; Indigenous Art of the Northwest Coast" is an interesting discussion by Barbara Loeb of the art and culture of that region. No specific reference is made to multicultural education.

Can technology be used in education to address cultural and racial issues? In "Art and Culture in a Technological Society" Vesta A. H. Daniel's main point is that:
What artists can garner from artificial intelligence, such as computer science, is how to share more effectively (and efficiently) the mysterious nature of art, the effect of experience on sensibilities, and the evidence that culturally, temporally, and geographically distant and ostensibly different societies may be advancing toward significantly similar conclusions (p. 95).

She appears to be opposing the idea of ethnic diversity because technology, particularly the computer, offers the possibility of cross-referencing data from art history and anthropology on a global scale. This would allow essential rudimentary aspects of art and aesthetics of the various cultures of the world, she says, to be considered on a broader base—"intuitive, spiritual, mystic, and unspoken"—to be presented (presumably via computer data) in formats that can be shared by greater numbers of individuals from differing cultures (p. 86). The high road to expanding a world-view and sharing a system of knowledge that "suits the needs of the current social-cultural situation," lies, she says, in harnessing the use of technological tools (pp. 94-95).

Art therapists, . . . assume, would be less willing to accept Daniel's concern for "official knowledge" or a system of knowledge because of a deep concern of the idiosyncratic aspect of the unique individual psyche. This reviewer believes that art educators should have the same concern.

Another chapter which suggests assimilation rather than cultural and aesthetic difference is by Bradley Smith. Titled "Assimilation: Learning How to Learn the Beauty of It All" it is the most extreme example of the chief weakness noticed throughout the book: generalities and Romantic simplification. Smith's chapter is filled with grandiose sentimentalism. While it is poetic, it is sentimentally so. An example of the truisms presented in this short (five pages) chapter will clarify my point. Smith asks, "Teachers of the world—What should we be cognizant of as we toss the pebble of awareness into the pond of focus and cause ripples of transformation and change?" (p. 247). He proceeds to offer three "tools of learning how to learn." First "we must in truth recognize the unintellectuality and unperceptiveness of too many human beings from the four corners of the globe" (p. 242). Second "we must bring world issues to a point of concentration with the microscopic visionary of the 'greatest dreamers of all time'" (p. 243).

"The third tool of learning how to learn," he says, "is the most exciting and most difficult to achieve. It is a search for a new tomorrow, after researching the best and worse (sic) of an unacceptable today" (p. 243). Change. Smith admits, causes friction. "However, friction does not have to come in the form of war; it can come in the form of love, just as fission may result in new life" (p. 243).

The final chapter, "A Chronological Minority Bibliography," is a listing of articles on the subject in the National Art Education journal, Art Education, since its beginning in 1951.

While there is considerable information in this book, it could hardly be said to break new ground or to present a full and courageous view of Art, Culture, and Ethnicity in the late 20th century.

SPECIAL ANNOUNCEMENT

Art Therapy is pleased to announce that the publication, INNOVATIONS & RESEARCH in Clinical Services, Community Support, and Rehabilitation, will be including our journal in their abstracting services, beginning with Vol. 9, No. 1. INNOVATIONS & RESEARCH is published by the National Alliance for the Mentally Ill (NAMI) and the Center for Psychiatric Rehabilitation. NAMI is a family advocacy and support organization of over 135,000 members nationally, with an additional 10,000 associate members. The Center for Psychiatric Rehabilitation is a research, training, and consultation center co-funded by the National Institute of Mental Health and the National Institute on Disability and Rehabilitation Research.

Publication of abstracts from Art Therapy in INNOVATIONS & RESEARCH will bring our journal to the attention of researchers, mental health professionals, librarians, students, and consumers. Art Therapy is extremely pleased to be invited to participate in this valuable resource.

Reviewed by Patricia St. John, Ed.D., A.T.R.

Myra Levick has written a one-of-a-kind book about art therapy for parents and teachers. Based on her book for professionals (They Couldn’t Talk and So They Drew, 1983), this volume is intended to guide those “who are primarily involved in caring for children” (p. 9) into a portion of the art therapist’s complex practice.

This book does not claim to transform parents and teachers into art therapists; it does assist the reader in knowing when to seek professional help. Dr. Levick begins with a statement of the problem: children do not always tell us when they are troubled. With less highly developed verbal skills, their artwork can alert us to their emotional needs. Their emotional needs change as children develop. Likewise, characteristics of drawings change. Grief for help may take the form of a change from the child’s typical behavior and typical drawing style.

Dr. Levick organizes her book into two major sections: the first section includes preliminary information about children’s drawings, including 10 “common warning signals” (p. 17). At this point, she lays out her theory of art psychotherapy (p. 46), and how to “inspire creative expression” (p. 62). The second section, Chapters Four through Eight, provides a detailed, profusely illustrated discussion of normal child development observed through behavior and artwork. Within each chapter she points out “warning signals” common to each age level from numerous cases out of her own practice. Child development and psychoanalytic theories are skillfully interwoven with assessment and treatment plans.

An example of Levick engaging her lay readers is her analysis of the drawing of a troubled child. A small house is drawn by a five-and-one-half-year-old boy. The house looks typical for such drawings, but Levick alerts us to clues that indicate the house is atypical. The usual chimney with smoke is missing; there are no people or other objects. The house appears to be “floating.” These are warning signals “for someone to stop and pay attention” (p. 12). Discussed in a later chapter are the clues to recognizing these signals and how to interpret them. In several other case presentations, Levick demonstrates artfully how to gather information from family and teachers. Involved are the careful assessment of drawings and extensive talks with the children. The techniques of the trained professional reveal there is no magic to understanding these drawings.

The most valuable chapters are those that explore child development in artwork, emotionally and socially. Understanding typical child development is prerequisite to identifying the atypical. Delinated are four typical stages/sequences. The first is the Babble/Scribble lasting from 18 months to two-and-one-half years. Second is Word-Shape which occurs typically at about two-and-one-half to four years, followed by the Sentence-Picture Stage/Sequence at four to seven years. The final stage of childhood, Fact-Fantasy, appears at about seven to 11 years. All age groupings are approximate. Each stage/sequence has its own specific characteristics, its own “warning signals” and appropriate methods for understanding the child within that stage/sequence.

For example, by age five, during the Sentence-Picture Stage/Sequence, children are making recognizable drawings. Some objects may have “realistic” coloring. Typically, a baseline hugs the bottom of the page. Children progressively notice differences between boys and girls, and identify with mommies or daddies. Drawings can reflect feelings about family members and the child. Sometimes this is repre-
sented symbolically, "... three related objects in drawings are one of the ways a child symbolizes a mother/father/child relationship..." (p. 114). In the instance of one boy, Daddy is symbolized by a complete drawing of a clown, while the child's representation of himself is incomplete. "Clowns are awesome—they do all kinds of amazing tricks that make children laugh and cry and even feel scared. Around this age fathers can also be awesome, especially when little boys are trying to be like them" (p. 114). Warning signals at this stage may include lack of a baseline, failure to represent people, and omission of the distinction between male and female figures.

In another case, Levick describes a very shy adopted child who was in therapy. At home, he was made to draw by his mother, who was often critical of his drawings. Through careful intervention, Levick established a therapeutic relationship with the child, and found that he was having trouble adjusting to a new country. She also determined that he was intellectually bright, ruling out developmental delay. The reader had already seen his house drawing on page 12. The house reflected his emotional state: lonely, isolated and depressed. After consultation, the parents agreed to enter therapy to learn how to help him grow emotionally.

This excellent book has its flaws. Levick makes a distinction between the art therapist and art psychotherapist by distinguishing between two schools of thought: "Art as therapy" and "Art in therapy" (p. 29). Art as therapy (read art therapist), she explains, "assumes that the very act of creating something artistic is healing" (p. 29). Art in therapy (read art psychotherapist) has goals which are "very similar to the goals of psychoanalysts who encourage patients to discuss dreams and childhood memories... helping the artist become aware of all the parts of the image, and of the thoughts and feelings that produced that image" (p. 30). She briefly, and almost offhandedly, acknowledges that a third group uses both approaches, depending on the needs of the client. It is apparent that she identifies herself as an "art psychotherapist." There is a not so subtle implication that the art psychotherapist is superior and is therefore similar to a psychoanalyst. There is no description of how art therapists work. Ironically, she does not maintain strict use of these terms throughout the book. This false dichotomy can be confusing to the reader. The incorrect impression given is that the art psychotherapist is more rigorously trained than the "regular" art therapist.

A minor quibble is that although Levick encourages parents and teachers to allow children to produce spontaneous artwork, she does include some examples of directed artwork. It is not clear why a directive approach is warranted or what might be the difference between directed and spontaneous artwork. On the positive side, she points out concisely when parental intervention is indicated. For example, parents might be useful in assisting groups to identify a topic for a mural or other group project.

Other detractions may have more to do with the publisher rather than the author. Levick gives many more examples than are illustrated. On occasion the reader must visualize the artwork. Undoubtedly, inclusion of all the artwork would have been too costly for the publisher. However, this reviewer was frustrated by not having the artwork at hand. One can imagine the resulting confusion for the untrained parent or teacher for whom the book was conceived. The same concern relates to the total lack of color illustrations. Color can be a key element in identifying warning signals.

Despite these criticisms, this is a very valuable book. It may be written for teachers and parents, but should be on the shelf of every art therapist (or psychotherapist, if you like). Levick's methodology, her careful probing and pragmatic interventions are thoughtful and thought-provoking. The very simplicity of her methods is deceptive. This is art therapy in the hands of a very experienced professional. Parents and teachers reading this provocative book will discover that art can be the open sesame in deciphering the mysteries of child behavior.

Imagery and Grief Work: Healing the Memory

Mary S. Cerny, Ph.D.

Reviewed by James J. Consoli, M.A., A.T.R., N.C.C., Film and Video Editor, and Instructor, Eastern Virginia Medical School Graduate Art Therapy Program, Norfolk, VA.

For all sad words of tongue or pen,
The saddest are these:
It might have been.

John Greenleaf Whittier, 1856

Dr. Cerny willingly makes an intuitive leap with this video. She demonstrates the effectiveness of imagery work in addressing conflicting issues of grief by using imagery to tap a deeper level—the unconscious or preconscious. She explains how a person may know that he or she is not responsible for a loved one’s death, yet may feel guilty, and how it is at that deeper level that effective treatment needs to occur. She describes the process and presents a live session with a young woman suffering from unresolved grief following the untimely deaths of her sister and father. Five years after the initial imagery intervention, Cerny had the unique opportunity to conduct a follow-up interview to assess its benefits.

The process Cerny incorporates is very similar to the work of Annes A. Sheik, Ph.D., of the American Imagery Institute in Milwaukee, Wisconsin. In this method, the imagery work is created internally only, not in a two or three dimensional form, and often without employing hypnotic induction techniques. The client is discouraged from maintaining eye contact with the therapist. In the video session the client is asked to close her eyes, and to form a picture in her mind of a specific image, her deceased father. She is asked to describe the image and encouraged to confront related conflicts.

Cerny cautions the viewer not to push the client too fast. It may be premature to encourage the client

152 1278
to work with imagery immediately or to say goodbye to someone before dealing with unresolved anger. Cerny quotes Horowitz (1983), who cautions: "Image formation is one kind of thinking, a mode that is close to emotion. A psychotherapist listens for image experiences, but any exclusive focus on image formation is an unbalanced approach."

Although I was attracted by the casualness and informality of Cerny's style, I perceived a need for a more disciplined approach. My concerns center on certain interventions she used while her client was in the trance-like state. For example, when the client said she felt scared, Cerny responded by saying, "Why are you scared?" This invites an intellectual response, not the initial goal when using imagery intervention.

Another more potentially damaging intervention includes imagery of the client's father, whose history included alcoholism and abusive behavior. The client did not feel close to him. In an attempt to resolve the conflict between them, Cerny stated: "He is coming over to you and giving you a big hug... Does that feel good to you?" Grimacing, the client replies, "Not really."

This last example demonstrates that resolution needs to come from within the client. Otherwise, the solutions are contaminated by the therapist's "germs." This type of intervention is analogous to psychological surgery, during which the client is quite vulnerable and less protected. Destructive inflections and further trauma can occur in the name of therapy. Therefore, by incorporating what Groves (1989) calls "clean language," the therapist, while keeping all surgical instruments sterilized, empowers the client to resolve conflicts independently.

In general, this video provides a very good example of how internal imagery can be used in therapy. The video's production quality is adequate for the consumer market it serves. Typical of Menninger video productions, packaging is professional. The discussion guide is an excellent resource. The content of the video is a challenge to all art therapists to explore further the realm of imagery work, without art materials.

As we continue to address issues of our professional identity, we need to explore imagery beyond the art room. Imagery and therapy include much of our identity and function as art therapists. Who, then, is more qualified?

CALL FOR PAPERS

2nd ANNUAL ART THERAPY CONFERENCE
“ART, CREATIVITY AND HEALTH”
University of Utah Conferences and Institutes

The University of Utah Conferences and Institutes invites program proposals for the 1993 Art Therapy Conference. “Art, Creativity and Health,” to be held in Park City, Utah on June 18-20, 1993. Proposals must be made according to the guidelines listed below.

CATEGORIES

Paper: Oral presentation of written material on theoretical, methodological, or research topics related to the conference theme.

Workshop: Experiential format designed to engage participants in a technique or method to gain mastery over material covered.

GUIDELINES FOR SUBMISSION

1. All proposals must be typed (single spaced) and must describe the scope, nature and content of the presentation. It should also contain goals and objectives as well as references to relevant literature. The proposal should be no longer than one page in length (approximately 250 words).

2. A separate reference list should accompany each proposal; this list should contain the citations for all references made in the text of the proposal.

3. The title of the proposal should not exceed 12 words.

4. A 50-word abstract should accompany the proposal; this abstract may be used to describe the presentation in conference materials.

5. All proposals must include the presenter’s name, degrees, address, and phone number on a separate sheet. Please indicate which type of format (paper or workshop), the level of presentation (basic, intermediate, or advanced) and the number of participants (no limit or state specific number).

6. Please submit five (5) clear copies of all materials.

7. Proposals which do not meet these guidelines will automatically be disqualified.

DEADLINE FOR SUBMISSION:

Postmarked no later than December 5, 1992.

Send all material to:
1993 Program Committee
Art, Creativity and Health Conference
Conferences and Institutes
University of Utah/2174 Annex Building
Salt Lake City, Utah 84112

($2.90 postage for above)
THE ORGANIZATION

The American Art Therapy Association, Inc. (AATA), a non-profit organization founded in 1969, is a national association which represents a membership of approximately 3500 professionals and students. It is governed and directed by a nine-member Board elected by the membership. The AATA has established standards for art therapy education, registration and practice; AATA committees actively work on governmental affairs, clinical issues and professional development. The AATA’s dedication to continuing education and research is demonstrated through annual national and regional conferences, publications, films and awards.

Purpose:

● The progressive development of the therapeutic use of art.

● The advancement of standards of practice, ethical standards, education and research.

● The provision of professional communication and exchange with colleagues.

● The provision of legislative efforts to promote and improve the status of professional practice.

● The promotion of the field of art therapy through the dissemination of public information.

Chapters:

Affiliate Chapters of the AATA have been established throughout the U.S. Chapters conduct meetings and activities in an effort to promote the field of art therapy on a local level. Chapters provide a forum for addressing professional issues as well as a network of people working toward common goals. Information and support for Chapter members is passed on from the AATA Assembly of Affiliate Chapters to the local level.

You must be a national member to become a Chapter member. Information on locating the chapter nearest you is available from the AATA office.

MEMBER BENEFITS

Individual members receive:

Publications

● Art Therapy, the official journal of the AATA

● The quarterly AATA Newsletter

● Substantial discounts on AATA publications such as Annual Conference Proceedings, other professional journals, films, and membership directory

● Free AATA literature, such as Educational Programs List, Art Therapy Media List, and Standards of Practice

● Mailings of professional interest

Services

● Insurance, including professional liability, major medical, life and disability

● Access to national experts in art therapy

AATA Conferences

● Discounts on registration fees to AATA national and regional conferences

Nationwide Advocacy

● Governmental affairs activities including Congressional review and monitoring

● State legislative and regulatory activities

● Promotion of recognition and reimbursement of art therapists by third-party payors

● National liaison with related professional organizations for recognition and promotion of the profession of art therapy

Professional Standards

● Development of model job and licensure laws

● Development and implementation of national guidelines for approval of Master’s Degree and training programs in art therapy

● Development and implementation of nationally recognized Standards of Registration of Professional Art Therapists

GENERAL MEMBERSHIP APPLICATIONS

1. The membership year is the calendar year, January 1 through December 31.

2. Contributing, Associate and Student applicants for NEW MEMBERSHIP ONLY: Please follow the chart below when submitting membership application.

Applications received between:

Jan. 1 and May 31: Full dues payment.
Membership expires Dec. 31 of same year.

June 1 and Sept. 30: Half year’s dues plus 50% payment. Membership expires Dec. 31 of same year.

Oct. 1 and Dec. 31: Full dues payment. Membership valid for remainder of current year and next full year.

3. Professional Member applicants must meet Criteria for Professional Membership. Formal application with documentation is submitted to Membership Chair for approval.

4. AATA Membership and AATA Registration (A.T.R.) each have a separate application procedure. Registration is bestowed only by the Standards Committee.

5. National AATA membership required for Chapter Membership. Please contact AATA office for information on AATA Chapters.

CATEGORIES AND FEES

PROFESSIONAL - by application only. Such members may vote, hold office, and serve on committees.

● Credentialled Professional Member: Individuals who have been dually approved for Professional Membership and Registration (A.T.R.) by AATA; dues are $80 per year.

● Active Professional Member: Individuals who have completed professional training in art therapy. Dues are $75 per year

CONTRIBUTING: Individuals, organizations, institutions or foundations which contribute annually to AATA. Such members may vote, hold office or serve on committees. Annual dues are $100.

ASSOCIATE: Individuals interested in the therapeutic use of art who support the purposes and objectives of AATA. Such members may not vote, hold office or serve on committees. Annual dues are $75.

STUDENT: Individuals who do not meet the qualifications of Professional Membership and are currently taking coursework in art therapy or related fields. Requires a current statement from the institution indicating full-time status and coursework content. Student members may not vote, hold office but may serve on Student Subcommittee of Membership. Annual dues are $35.

PAYABLE IN U.S. DOLLARS
MAKE CHECK PAYABLE TO: AATA

American Art Therapy Association
1202 Allanson Road
Mundelein, IL 60060
Guidelines for Submissions

All submissions will be acknowledged upon receipt by the AATA National Office. Art Therapy uses a blind peer review procedure for full-length articles and brief reports; final decisions regarding publication are made by the reviewers and the Editor. Decisions regarding submissions to other sections are made by the Editor, Associate Editor and special section editors.

The following are guidelines for developing and submitting a manuscript. Manuscripts that do not conform to these guidelines will be returned to the author without review.

Manuscript Categories

1. Full-length Articles. Full-length articles may focus on the theory, practice and research in art therapy or related areas. Manuscripts must include an abstract of approximately 75-125 words summarizing the major point of the article.
2. Brief Reports. Short articles which focus on the results of research are appropriate for this section. Manuscripts should include information on the research design, methodology and results; an abstract of approximately 75-125 words should also be included.
3. Viewpoints. Short articles focusing on personal experiences, poetry or original art may be submitted to this section.
4. Book Reviews. Reviews of books of interest to art therapists may be submitted at any time. Books which authors wish to have considered for review may be sent directly to the AATA National Office at the address listed above.
5. Film/Video Reviews. Reviews of media (films or videotapes) may be submitted at any time. Media which producers wish to have considered for review may be sent directly to the AATA National Office at the address listed above.
6. Comments. Brief comments on articles published in Art Therapy, issues critical to the profession and practice of art therapy, or letters to the Editor may be submitted to this section and should conform to the style of all other submissions.

Other Requirements

1. Send five (5) clear copies of each manuscript to Cathy A. Malchiodi, A.T.R., Editor, Art Therapy: Journal of the American Art Therapy Association, c/o AATA, Inc., 1202 Allison Road, Mundelein, Illinois 60060. Neither AATA nor the Editor can be responsible for submissions sent to any other address.
2. Only original articles that are not under consideration by another periodical or publisher are acceptable.
3. Manuscripts must be typewritten on 8½” x 11” white paper with margins of at least an inch. The body of the paper, references, tables and quotations must be double-spaced.
5. An abstract of 75-125 words must be included with full-length articles and brief reports.
6. Please avoid footnotes wherever possible.
7. A cover sheet should be prepared to include the full name(s) and degree(s) of the author(s), professional affiliations, and the return mailing address of the author to whom correspondence can be sent. Authors' names, positions, titles and places of employment should not appear in the body of the paper to assure anonymity and to facilitate blind review.
8. Use tables sparingly and type them on separate pages. Refer to the APA Publication Manual for style of tabular presentations. All tables, charts or diagrams must be legible and able to withstand reduction.
9. Photographs must be at least 5” x 7” and black and white glossy prints, preferably with high contrast. Xerox copies of illustrations or art expressions are not acceptable for publication. Figure numbers and captions should be noted on the back of photographs, captions must be typed and submitted on a separate sheet of paper. Please refer to figures in the text as Figure 1, Figure 2, etc.
10. Lengthy quotations (300 words or more from one source) or reproduction of works of art (this does not include client art expressions, which is addressed below) require written permission from the copyright holder for reproduction. Adaptation of tables or figures from copyrighted sources also requires approval. It is the author's responsibility to secure such permissions; a copy of the copyright holder's written permission must be provided to the Editor immediately upon acceptance of the article for publication.
11. Client/patient confidentiality must be protected in the title, abstract, text, photos, illustrations and other accompanying material. Proper releases for use of client art expressions and other client information must be obtained and kept on file by the author.
12. It is expected that any manuscript accepted for publication in Art Therapy will go through at least one revision before publication. If authors have prepared their manuscripts on either an IBM, IBM-compatible or Macintosh computer, upon acceptance, they can send a 3.5” diskette containing an electronic copy of the manuscript to the AATA office. This will help speed processing, editing and publication.

Note: Authors bear full responsibility for the accuracy of all references, quotations and materials accompanying their manuscripts.
ATTENTION AUTHORS

In order to help us process your submission more quickly, please complete the following information and attach one copy to your manuscript:

Name: ____________________________________________

Degrees/Credentials: ____________________________________________

Address: ____________________________________________

Phone #: work ____________________________________________ home ____________________________________________

Type of Submission (check one):

___ Article

___ Brief Report

___ Viewpoints

___ Book Review

___ Film/Video Review

Title of Submission: ____________________________________________

_________________________________________________________________

Checklist:

___ Five copies, typewritten on 8½” × 11” paper.

___ Abstract of 75-125 words (for articles and brief reports only).

___ Detachable cover sheet with author(s) name(s), affiliation, degrees and credentials.

___ Appropriate release forms obtained for use of client art expressions and client information. (You do not need to send these with your submission, but you must have them on file.)

Author’s signature ____________________________________________ Date __________

Please send completed form with submission to: Editor, Art Therapy: Journal of the American Art Therapy Association, c/o AATA, Inc., 1202 Allanson Road, Mundelein, Illinois 60060.

Healer

NOVEMBER 4 - 8, 1992
THE RIVIERA
LAS VEGAS, NEVADA

This year’s Conference will feature:

• Day-long preconference courses with graduate credit option
• Keynote speaker John MacGregor, Ph.D., author of The Discovery of the Art of the Insane
• 120 presentations on a wide variety of art therapy topics, such as: special populations, abuse, spirituality and the arts therapies, professional issues, and assessment
• Experiential workshops
• New Masters Supervision Groups
• Special events

AATA members will receive additional information and full registration packages by mail. Other interested parties should contact:

AATA, Inc.
1202 Allanson Road
Mundelein, IL 60060
708-949-6064
ART THERAPY is published quarterly by the American Art Therapy Association. Members of AATA receive the journal as a membership benefit. Non-members may subscribe at the following annual rates: Individuals $35 (US); $56 (Foreign); Institutions: $50 (US); $70 (Foreign). A discount of 10% is available for 10 copy minimum orders. Single copies are available at $9 member; $16 non-member. Printed in the U.S.

Make checks payable to AATA and return with application to:
American Art Therapy Association, 1202 Allanson Road, Mundelein, IL 60060

Please enter my subscription for 1992. Enclosed is my check, payable to AATA, for $35.

THE ARTS IN PSYCHOTHERAPY

An international Journal

Editor-in-Chief:
David Read Johnson, PhD, RDT
Associate Clinical Professor, Department of Psychiatry, Yale University; Clinical Psychologist, Veterans Administration Medical Center, West Spring Street, West Haven, CT 06515, USA

THE ARTS IN PSYCHOTHERAPY is a quarterly, international journal for professionals in the fields of mental health and education. The journal publishes articles (including illustrations) by art, dance/movement, music, poetry and drama psychotherapists, as well as psychiatrists and psychologists, that reflect the theory and practice of these disciplines. There are no restrictions on philosophical orientation or application.

SPECIAL RATES AVAILABLE FOR MEMBERS OF QUALIFYING SOCIETIES!
Members of qualifying societies can receive a discount on one-year Professional subscriptions to the THE ARTS IN PSYCHOTHERAPY. Please write for further information.

Editors welcome original manuscripts. Submit papers in triplicate to: Managing Editor, Sylvia Halpern, 20 Ridgecrest East, Scarsdale, NY 10583

SUBSCRIPTION INFORMATION
ISSN: 0197-4556
Volume 17, 1990
Published 4 issues per annum
Annual Institution Subscription Rate (1990) US$130.00
Two-year Institution Rate (1990/91) US$247.00
Professional Rate (1990) US$ 40.00
Student Rate (1990) US$ 16.00
STATEMENT OF PURPOSE: Art Therapy: Journal of the American Art Therapy Association is the official journal of the AATA, Inc. The purpose of the journal is to advance the understanding of how visual art functions in the treatment, education, development and enrichment of people. The journal provides a scholarly forum for divergent points of view on art therapy and strives to present a broad spectrum of ideas in theory, practice, professional issues and research. An emphasis is placed on the use of the visual arts in therapy, but articles in related disciplines of interest to art therapists will be considered for publication.

ART THERAPY: JOURNAL OF THE AMERICAN ART THERAPY ASSOCIATION (ISSN 0742-1656) is published quarterly by the AATA, Inc., 1202 Allanson Road, Mundelein, Illinois, U.S.A. 60060. Telephone (708) 949-6064; FAX (708) 566-4580. Non-members may subscribe at the following annual rates: $35 (U.S.) and $55 (Foreign); Institutions: $50 (U.S.) and $70 (Foreign). AATA members receive the journal as a benefit of membership.

Single Issues: For price and ordering information, call or write to AATA, Inc., 1202 Allanson Road, Mundelein, IL 60060 (708) 949-6064.

This journal is abstracted in: Psychological Abstracts, INNOVATIONS & RESEARCH, Art Bibliographies Current Titles and Art Bibliographies Modern.

Advertising: Please see advertising rates listed elsewhere in this journal or contact the American Art Therapy Association, Inc., 1202 Allanson Road, Mundelein, Illinois 60060 (708) 949-6064. The publication of any advertisement by the AATA, Inc., is not an endorsement of the advertiser or of the products or services advertised. The AATA, Inc., is not responsible for any claims made in an advertisement.

Authorization to copy: No part of this publication may be reproduced, stored in a retrieval system or transmitted in any form or by any means, electronic, electrostatic, magnetic tape, photocopying, recording or otherwise, without permission in writing from the copyright holder.

Change of Address: Notices should be sent at least six weeks in advance to AATA, Inc. Subscribers should notify the post office that they will guarantee forwarding postage. Undelivered copies resulting from address changes will not be replaced, but single issues may be purchased at the single issue price.

About the Cover: “Uneasy Sleep,” 15” x 12”, oil on sheet metal mounted on wood, by Edith Kramer, A.T.R. About the piece, Ms. Kramer says, “The painting is one of a series of paintings on sheet metal based on colored pencil drawings done while riding the New York subways. The paintings on metal are part of an extensive group of drawings, paintings, collages and sculptures representing various aspects of the New York subways.”

Introduction to Special Issue: Biological and Anthropological Bases of Art Expression

Cathy A. Malchiodi, M.A., A.T.R., Editor

In Shadows of Forgotten Ancestors: A Search for Who We Are, Carl Sagan and Ann Druyan (1992) critically examine the connections between humans and other species and ask the question, "What does it mean to be human?" By reviewing what we know about the origins of life and evolution, the authors reflect on some of the fundamental questions of human existence. They also carefully consider many characteristics thought to be the sole domain of humankind, finding that there are strong overlaps in both human and animal characteristics.

In the realm of the arts, Sagan and Druyan briefly touch on the notion that art, dance and music traditionally are thought to be uniquely human activities; however, among animals, there are strong indications that this is not completely true. For example, the authors cite the bower birds' decoration of their nests, chimpanzees' pleasure in drumming and gibbons' gratification in song. Morris's seminal studies of the chimpanzee Congo (1958a; 1958b; 1961; 1962), Beach, Fouts and Fouts (1984) and their work with chimpanzees, and the research of art therapists David Henley and Barbara Ann Levy in this issue, all demonstrate that this aspect of cultural life may not be solely limited to our species.

My first real exposure to the idea of a biological basis of art expression occurred several years ago when I was given a copy of Desmond Morris's The Biology of Art (1962) which describes his study of picture-making in apes and its relationship to human art. In 1953, Morris became acquainted with Schiller's (1951) work with chimpanzee drawings and, as a consequence, was determined to continue this work with apes. He eventually was able to study nearly four hundred drawings and paintings by Congo, a chimpanzee at London Zoo. As a result, Morris recorded the picture-making behavior of Congo and other primates for many years, comparing similarities to human art making (also see Morris, 1958a; 1958b, 1961).

At the time of Morris's study, Congo's art expressions became the subject of great public interest in England and a television program featured the chimp's paintings, including an actual demonstration of his skills. Eventually, a two-chimp show of paintings by both Congo and a second painting chimp, Betsy, was held at the Institute of Contemporary Arts in London in 1957. Morris (1962) recounts the skepticism that many expressed upon seeing an exhibition of chimpanzee paintings held at a London art gallery:

The average Englishman loves animals and hates abstract art. It is not surprising therefore that an animal which paints abstract pictures produces a rather irritating mental conflict. Should one praise the animal or curse the pictures?
The press, along with many of the visitors to the exhibition, took one extremist view or the other. The pictures were either viciously attacked as an insult to human dignity, or wildly praised as heralding a new art form. A few discerning eyes saw them for what they were—a series of unique documents, records of a new and biological approach to art. (p. 13)

According to Morris, human art has been examined in the past from one of several reference points—prehistoric and prehistoric art, folk art of so-called primitive peoples, the art expressions of the mentally insane, and children’s developmental processes. In no one of these categories are the biological principles of picture-making adequately established. For this reason, Morris’s study of the work of Congo and other great apes focused on the development of biological principles of art expression. As a result of his work with primates, Morris determined six biological principles which he believed could be universally applied to both humans and apes or, as he put it, to “everyone from Leonardo to Congo” (1962, p. 158).

In addition to the idea that art making may have biological roots, there is another question related to this theme that may intrigue art therapists—is art making a necessity to life itself? To respond to this question, by special arrangement with the National Art Education Association, we are able to bring you the 1991 keynote address, “Art for Life’s Sake,” by noted scholar Ellen Dissanayake. Dissanayake’s ideas are both intriguing and challenging because the biological and anthropological aspects of art expression and art making are central to her conceptual base, as well as psychological and art historical underpinnings. She attempts to look at art in the broadest possible perspective—one she refers to as “paleoanthropsychobiological” or “species-centered.” The guiding premise of this view is that art is “a fundamental human species characteristic” and is “a normal and necessary behavior.”

Dissanayake’s thoughts on the role of art making in human life will likely have great appeal to art therapists who believe that art making is an essential and accessible experience to all individuals. But other issues raised in this edition of Art Therapy may challenge you to reconsider some fundamental principles of our field or, at the very least, view picture-making from a different perspective. Before you dismiss the fact that chimpanzees, apes, monkeys, elephants, and dolphins have only a laughable relationship to the picture-making activities of human-kind, give some serious thought to how strong our biological connections are to these species and how compelling our own similarities are to our animal relatives. To fully understand and accept these relationships may, as Sagan and Drúyan point out, be important to our understanding of our own species, and perhaps the ultimate survival of our human selves.

Response to Book Review

As a founding member of the Association of Teachers of Mandala Assessment, Inc., I read with great interest Elizabeth Ratcliffe’s review (Vol. 9, No. 2) of Suzanne Fincher’s book, Creating Mandalas for Insight, Healing, and Self-expression. This book is indeed a valuable contribution to the field of art therapy as a reference book on the mandala. Fincher credits many sources, her primary one being art therapist Joan Kellogg, with whom she studied in the 1970s and whose insights, she acknowledges, opened up the possibilities of the mandala for her. Fincher’s material, particularly on creating and interpreting the mandala and on colors and forms, is an elaboration of the information taught by Joan Kellogg in her training courses in mandala assessment. She also expands upon Kellogg’s work by investigating additional forms and the significance of numbers in the mandala. Although Fincher presents this material in a clear, organized format and has contributed insights from other authors (in addition to the ones Kellogg cites in her work), there are serious oversights.

A classic, it may be, as Ms. Ratcliffe suggests; however, it is a flawed classic. In the beginning of the chapter, “The Great Round of Mandala Forms,” Fincher gives Kellogg full credit for developing the system for identifying archetypal stages in a cyclical pattern, which has been the essence of Kellogg’s life work. Fincher goes on to explain in detail twelve of the archetypal stages of the great round, but is guilty of one major omission: she does not include stage 0, an important stage which Kellogg included in the second edition (1984) of her book, Mandalas: Path of Beauty. Fincher’s bibliography refers only to the first version of Kellogg’s work (1978). Stage 0 is an integral part of Kellogg’s theory. Prior to her discovery of it, her description of stage 1 incorporated many aspects of stage 0, thus making stage 1 complex and difficult to understand. Fincher presents this outdated material from fourteen years ago.

If Fincher takes it upon herself to write about someone else’s work, she has a responsibility to do her homework and reference her source’s most recent material. She has done a disservice not only to Joan Kellogg, but to all students of the mandala who may not be aware of Kellogg’s fully evolved theory. I still recommend Fincher’s book as useful, especially her thorough review of various color theories. However, I do want to emphasize that if people wish to understand Kellogg’s theory they should go directly to the source (MARI® Course in Mandala Assessment or Kellogg’s book) rather than rely on Fincher’s poorly researched rendition thereof.

Carol T. Cox, M.A, A.T.R.
Art for Life’s Sake

Ellen Dissanayake, New York City, NY

I don’t know which is greater—the pleasure, honor, or privilege of being invited to address the members of the NAEA. I hope that the title of my lecture, “Art for Life’s Sake,”—like the question of the title of my book, What Is Art For?—will stimulate you to think about art in a new way, as well as to appreciate why thinking about art in a new way is important.

I intend to give a brief history of Western art—not the usual “art history” of the practice of art but rather a history of the Western idea of art—and then present my own view of art for life’s sake. This arises from an unfamiliar perspective, one that is so different, in fact, that it doesn’t have a name. In order to call it something, I have occasionally called it “palaeoanthropo-pychobiological”—an adjective that is quite literally stunning—to suggest several things. First, that the idea of art encompasses all of human history (i.e., as far back as the Palaeolithic or even earlier); second, that it include all human societies (i.e., is anthropological or cross-cultural); and third, that it accounts for the fact that art is a psychological or emotional need and has psychological or emotional effects. Most people would probably agree that their personal “idea of art” includes all these things, but I will show you that as presently practiced and taught in the West, art is a conceptual ragbag or casserole full of the most incompatible and confusing notions.

My palaeoanthropo-pychobiological view is that in order to include human history, human cultures, and human psychology, art must be viewed as an inherent universal (or biological) trait of the human species, as normal and natural as language, sex, sociability, aggression, or any of the other characteristics of human nature.

Before beginning, I would like to tell you how I came to develop this view, why it came to seem mandatory. While a graduate student in art history, while writing my thesis on 19th-century French symbolist art, I had the unexpected opportunity to travel to Sri Lanka, the small island nation off the southern tip of India, formerly known as Ceylon. Eventually I returned there to live and married a Sri Lankan man. For 15 years I lived abroad, and during that time also spent a year in Nigeria, two and a half years in Papua, New Guinea, and three months in India. Living in non-Western countries permits, indeed demands that you look afresh at all the cultural truths and beliefs that you have grown up with and taken for granted. Among these of course was my idea of art.

Living in another culture also makes you realize that different as other people’s beliefs may be from one’s own, we are all still recognizably people—and so you wonder what is universal. My way of approaching these questions came to be biological or evolutionary—looking at all humans as members of one species and then thinking of art as a kind of behavior that developed as they evolved, to help them survive. It took many years of reading and thinking and writing to address the different aspects of this approach. I am still finding new paths to follow and new things to incorporate. In 1988 I published a book, What Is Art For?, that set out my general ideas, and a second book which is called Homo Aestheticus: Where Art Comes from and Why (1992). I think these ideas have revolutionary implications for how we as a society think of art. Indeed, one of the major insights to come from my studies was just how peculiar our Western concept of art is—unprecedented in human history, and I think it is extremely important to understand this in order to see why a new view of art is required.

Editor’s note: Ellen Dissanayake earned her B.A. in Humanities from Washington State University and has her M.A. in Art History from the University of Maryland. In 1977, she received a grant from the Guggenheim Foundation to pursue research at Oxford University on the evolutionary significance of art. She has recently received a Fulbright Lecturing/Research Fellowship to continue her studies in Sri Lanka.

Dissanayake’s work has been significantly influenced by the years she has spent in such places as Sri Lanka, India, New Guinea, and Nigeria. Currently, she lives in New York City where she is a lecturer for the New School of Social Research. She has published two books, What Is Art For? and Homo Aestheticus (which is reviewed in this issue of Art Therapy).
Thus I will first outline how our peculiar or anomalous Western concept or idea of art has developed over the past two centuries, before setting out my palaeoanthropological view of the human species, a species that deserves to be called aestheticus or artistic as much as it deserves to be called sapiens or wise.

Development of the Western Concept of (Fine) Art

It is true that we can read about the word and concept “art” in early treatises from Greek and medieval times. But it must be realized that these are translations and that the authors may not have meant the same thing by the word “art” as we do. In fact, Plato did not discuss “art,” but rather beauty, poetry, and imagnemaking; Aristotle dealt with poetry and tragedy. They used a word, technē, which we have translated as “art,” but this word was applied equally to fishing, chariotdriving, and other mundane activities. It meant “having a correct understanding of the principles involved,” rather as we understand the “art” of salmon cookery or of motorcycle maintenance.

In medieval times, the arts were in the service of religion, as they have always been, but were not regarded “aesthetically,” if this means separately from their revelation of the Divine. Renaissance artists gradually replaced God-centered with man-centered concerns, but their works continued to portray a recognizable world, whether actual or ideal, and the “art” was in accurately representing that subject matter, using craftsmanlike standards of beauty, harmony, and excellence.

The eighteenth century is recognized today as having been a focal point in which a number of social and intellectual trends came together. intertwined and influenced one another, and eventually became in combination and intensity what is now called “modernity.” Among these trends I will mention—and I hope you will forgive the rather breathtaking oversimplification—five important and unprecedented changes. (1) A gradual secularization of society, whose aim became life, liberty and the pursuit of happiness for individuals rather than acquiescence to a humanly unknowable Divine plan. (2) The rise of science which not only fostered questioning and dissent but made possible the development of technology and industrialization. (3) The social or interpersonal changes that resulted as the emotional and affective ties of feudal and kin loyalty were replaced by instrumental relationships based on the exchange of money. (4) an emphasis on reason as the best means for understanding and controlling the matters of life. and (5) the great political revolutions in America and France with their subsequent division of society into workers and bourgeoisie and gradual weakening of the nobility and clergy.

What we now call “the Romantic Rebellion” was a reaction to the goods and evils inherent in these great changes. For example, while individualism became possible and people could be freed from tradition, custom and authority, they also became more alienated from their work and from other people. New possibilities for thought and experience were accompanied by an unprecedented loss of certainty and security about one’s place in the world. New comforts and conveniences arose, but people also became more regimented in their work and gradually removed from the world of nature. While reason and critical analysis encouraged objectivity and fairness, earlier visionary and mythopoetic modes of thought were devalued, being nonlogical, although their expression in communally shared traditional practices had given great emotional satisfaction.

To artists, as to everyone, the new order brought both liberation and insecurity. As the nineteenth century advanced, their primary patrons were no longer the Church and the court. Instead it became necessary to please the public—multiform, faceless, swayed as today by hype and novelty—in what was to become an art market. Aspiring artists no longer were apprenticed in a guild system, but learned what standards were acceptable from newly-established national academies and collections in national museums. Private dealers and galleries appeared to intercede between artists and the public. Professional critics who wrote for newspapers and newly-established magazines of art contributed to the new milieu as did schools of art and scholars of art who established their field as a sequential and developing history of particular works of art that every well-educated person should know. The words or concepts of “art,” “genius,” “creativity” and “imagination” took on their modern meanings.

Modernism: Art as Ideology

Included in the many new approaches and subjects that 18th century thinkers turned their attention to was a subject that came to be called “aesthetics”—a concern with elucidating principles such as taste and beauty that govern all the arts and indeed make them not simply paintings or statues but examples of (fine) “art.”
As the subject developed over the next century, a startling and influential idea took hold that, like the concept of "art," was unprecedented. This was that there is a special frame of mind for appreciating works of art—a "disinterested" attitude that is separate from one's own personal interest in the object, its utility, or its social or religious ramifications. The work of art became a world-in-itself, made solely or primarily as an occasion for this kind of detached aesthetic experience, which was considered to be one of the highest forms of mental activity.

"Disinterest" implied that viewers could appreciate any art, even the artwork of eras or cultures far removed from their own, whether or not they understood the meaning the works had for the people who made and used them. In this sense, art was "universal." Another corollary was that works of art in themselves, apart from their subject matter, gave a special kind of knowledge—a knowledge which, with the waning of religious belief, often took on the spiritual authority once restricted to the Church. Still another was the idea of art for art's sake (or even life for art's sake), suggesting that art had no purpose but to "be" and to provide opportunities for enjoying an aesthetic experience that was its own reward, and that one could have no higher calling than to open oneself to these heightened moments.

As paintings became less and less like mirrors held up to nature, so that viewers could no longer decipher or naively admire them, critics as mediators increasingly had to explain to the public what made an artwork good or bad and even what a work "meant." In England, in the early decades of the twentieth century, Clive Bell and Roger Fry were extremely influential as they invoked "formalist" criteria for appreciating the puzzling new work of Post-Impressionists such as Cézanne, or the Cubists—work that could not be understood with the serviceable old standards (that anyone could recognize) of beauty of conception, nobility of subject matter, representational accuracy, or communication of valued truths. Art had become if not a religion, an ideology whose principles were articulated by and for the few who had leisure and education enough to acquire them.

In the mid-twentieth century, more elaborate and abstract formalist standards were developed in America by critics like Clement Greenberg and Harold Rosenberg in order to justify abstract expressionism, a school of painting that confronted sensibilities and challenged what had previously been acceptable as art. "Flatness," "purity," and "picture plane" became the verbal tokens of the transcendent meanings viewers were told they could find in the skeins and blobs and washes of paint. Because these values were not easily apparent to the untutored observer, appreciating art became more than ever an elite activity, requiring an apprenticeship and dedication not unlike that of the artist. Never in question was the "high" art assumption that works of art—no matter how strange they looked or unskilled they seemed to be—were conduits of transcendent meaning, of truths from the unconscious, expressions or revelations of universal human concerns that the artist was uniquely endowed to apprehend and transmit.

As the "isms" proliferated and art became more esoteric and outrageous, the role of the critic became not only helpful but integral to the reception of works of art. Looking back, it seems inevitable that an "institutional" theory of art arose to explain what art is. As formulated by philosophers of art like George Dickie and Arthur Danto (who were describing what was the case, not advocating or defending it), an artworld (one word) composed of critics, dealers, gallery owners, museum directors, curators, art magazine editors, and so forth, was the source of conferring the status "work of art" onto objects. What artists made were "candidates for appreciation," and if the artworld bought and sold them, wrote about them, displayed them, they were thereby validated as "art"—not before.

Implicit in this account is a recognition that what is said (or written) about a work is not only necessary to its being art, but is indeed perhaps more important than the work itself. There is no appreciation of art without interpretation. We can tell that a pile of stones or stack of gray felt in a museum is different from a pile of stones on the pavement near a construction site or a stack of felt in a carpet store because those in the museum are viewed through a lens of knowledge of their place in a tradition. "To see something as art at all," proclaimed Danto, "demands nothing less than this, an atmosphere of artistic theory, a knowledge of the history of art." In this view, there are no naive artists or naive art. Today's artists can both explain the theories behind the works that are to be seen in museums and galleries and place their own works in these traditions.

**Postmodernism: Art as Interpretation**

The assumption that interpretation is indispensable to appreciating and even identifying artworks...
has opened a Pandora's box that is now called "postmodernism," a point of view that calls into question two centuries of assumptions about the elite and special nature of art. While the term "postmodern" is used (and abused) as indiscriminately as "modern" was before, postmodernists are united in repudiating the "high" art (or modernist) view I have just described. They stress that theirs is not just one more "ism" or movement but rather a declaration of the end of all isms and movements. Theirs is a radical change of consciousness, they claim, that challenges the entire "modernist" ideology.

Rather than assuming that art reflects a unique and privileged kind of knowledge, postmodernists point out that any "truth" or "reality" is only a point of view—a "representation" that comes to us mediated and conditioned by our language, our social institutions, the assumptions that characterize individuals as members of a nation, a race, a gender, a class, a profession, a religious body, a particular historical period. Artists, just like everybody else, do not see the work in any singularly privileged or objectively truthful way, but rather—like everybody—interpret it according to their individual and cultural sensibilities. What has been enshrined as "high" art is then to the postmodernist view a canon of works that represent the worldview of elite, Western European, white males. Hence "taste" and "beauty" and "art for art's sake" are constructions that express class interests. To claim that one can appreciate works from alien cultures is an imperialistic act of appropriation—molding them to one's own standards while blatantly dismissing or ignoring the standards of their makers and users. Art is not universal, but conceptually constructed by individuals whose perceptions are necessarily limited and parochial.

Finding that modernist aesthetics masked chauvinistic, authoritarian, and repressive attitudes towards uneducated, non-Establishment and non-Western people, and towards women, postmodernist artists have thus set out deliberately to subvert or "problematize" the old "high" art standards, often parodying or otherwise flattening them. For example, enduring "timeless" works of art are replaced by intermittent or impermanent works that have to be activated by the spectator or cease to exist when the performance is over. Or, challenging the aura of exclusiveness and religiosity of the museum, art is created on the street, in remote deserts, or found in humble or trivial objects and materials. Postmodernist artists deny the integrity of individual arts by using hybrid mediums—sculptures made of painted canvas, or paintings made of words and numbers.

The uniqueness, authority, ideality and originality of high art is challenged by borrowing (copying, photographing or otherwise appropriating) images from past art to be used in new works, or by making many repetitions or reproductions of an image or construction. Pastiche and collage are popular postmodern media in which works are composed of fragments that have no apparent relation to one another except for their juxtaposition.

Although the art praised by postmodern critics is puzzling, if not shocking and offensive, the social problems and cultural predicaments it reflects cannot be denied. The works and ideas that are called postmodernist can be lamented or ignored, but like modernism's works and ideas, they certainly reflect the society that spawned them. After the political calamities and barbarisms of the twentieth century, the Enlightenment and Victorian faith in human intelligence and goodness or in the progress and perfectibility of human existence seem as antiquated and untenable as medieval theology. Socialism and, more recently, other underclass movements have challenged pretensions to achieving objective, universal justice, law, and morality—as have the recurrent scandals at the very heart of government. After Freud it is hard to believe that objective rationality alone could drive human affairs, a hope also laid to rest more mundanely by the success of glossy advertisements that effectively persuade us to overspend on ever new and tantalizing non-necessities. Relativity theory in physics at least suggests the theme of relativity elsewhere. The polluting fungoid spread of the automobile and its concrete accoutrements of freeway and parking lot over city and landscape, not to mention other even worse environmental ills, certainly calls into question the wisdom of human technological domination over nature. The proliferation of images in advertisement and on television makes all events—from an exciting new dentifrice or room freshener to a fire in the Bronx, a missile attack on Tel Aviv, Johnny Carson's monologue, a famine in Africa, the Super Bowl, or an earthquake in Peru—appear equally real (or unreal), occurring as they do in succession, compressed in time and space and significance. The postmodernists' exposure of the rigid, exclusive and self-satisfied attitudes that often lay behind the rhetoric of modernist ideology is, in large measure, welcome, as is their preparing the way for the liberation and democratization of art.

But I find postmodernist aesthetics troubled and inadequate when it proclaims that there are a multiplicity of individual realities that are infinitely interpretable and equally worthy of aesthetic presentation.
and regard. The question arises: if everything is equally valuable, is anything worth doing? Is sprawling promiscuity really an improvement on narrow elitism? Is absolute relativism a more credible position than absolute authority? Postmodernism abandons the crumbling edifice of modernist authority for an equally uninhabitable and esoteric antistructure of relativism, cynicism, and nihilism that I claim does not have to be the inevitable outcome of the matter.

Art for Life's Sake

One way to begin to understand and resolve the perplexing contradictions, inadequacies, and confusions of both modernist and postmodernist aesthetics is, I believe, by considering art in the broadest possible perspective—the palaeoanthropo-psychobiological view that I mentioned—as a universal need and propensity of the human species.

Let me now jettison that tongue-twisting phrase and introduce a synonym, "species-centered." As medieval society and art was God-centered, that of the Renaissance man-centered, and ours perhaps best described as profit- or commodity-centered, I hope that a more human future society and art will be species-centered—that is, will regard all humans as alike in having the same fundamental needs.

For my purposes here with you as art educators, I would like to point out that one of the most striking features of human societies throughout history and across the globe is a prodigious involvement with the arts. Even nomadic people without permanent dwellings and with few material possessions usually have elaborate poetic language or dance styles; more settled people generally decorate their dwellings, objects of daily or ritual use, or themselves. There is no known society that does not practice at least one of what in the West we call "the arts," and in many groups art-making is among their most important endeavors.

I find it significant that the word "art" acquired its modern meaning and its existence as a concept as the arts themselves became practiced and appreciated by fewer and fewer members of society. In small scale, unspecialized, premortem societies, individuals can generally make and do everything that is needed for their livelihood. There, while there is no abstract concept of "art," everyone may be an artist—decorating their bodies and possessions, dancing, singing, versifying, performing—even when some persons are acknowledged as being more talented or skillful than others. In these technologically simpler societies, the arts are invariably and inseparably part of ritual ceremonies that articulate, express, and reinforce a group's deepest beliefs and concerns. As the vehicle for group meaning and a galvanizer of group oneness, art-conjoined with ritual is essential to group survival—quite literally art for life's sake.

In a highly-specialized society like ours, the arts are also specialties and may exist for their own sake apart from ritual or any other purpose. This separation, peculiar only to modernized or "advanced" societies, makes art a problem. Art's heritage of specialization and self-proclaimed irrelevance permits it to be dismissed by school and governmental budget-makers as a "frill," while its aura of sanctity and privilege remains as a reproach to those whose upbringing has not included exposure to "fine" arts. Dismissal, ignorance, irrelevance, and exclusivity of art are all artifacts of our own peculiar cultural predicament and not inherent in arts anywhere else.

The species-centered view of art combines modernism's proclamation that art is of supreme value and a source for heightened personal experience with postmodernism's insistence that it belongs to everyone and is potentially all around us. It does this by thinking of artmaking and experiencing as a human behavior. Let me explain.

In the evolution of the human species, not only did we gradually acquire certain characteristic physical and physiological adaptations—such as upright posture, an opposable thumb, relative hairlessness, a nine-month gestation period—but behavioral adaptations as well. Even though we no longer live in a hunter-gatherer milieu, these behavioral predispositions still characterize us as a species in their high degree of development and interrelatedness: tendencies to be sociable, to acquire and use language, to make and use tools, to impose conceptual order to attempt to control or regularize the forces of nature, to join with our close associates in mutual endeavor. Among these tendencies, I claim, is also the behavior or propensity to "make special." Particularly things that one cares deeply about or activities whose outcome has strong personal significance.

Something that is "special" is different from the mundane, the everyday, the ordinary. It is extraordinary. Now all animals can tell the difference between the ordinary or routine and the extraordinary or unusual. They would not survive if they were oblivious to the snapping twig or sudden shadow that means a predator may be nearby. But when joined with the other abilities that evolving humans
had—inelligence, resourcefulness, emotional and mental complexity, the ability to plan ahead—the “special” could take on a significance that was more than simply alertness to possible danger.

We have to speculate about how early this propensity to recognize specialness arose, but it was at least 250,000 years ago—more than ten times earlier than the cave paintings that are usually called the “beginning of art”—in Homo erectus and early Homo sapiens.

The crucial factor for claiming the beginning of a behavior of art, I believe, would have been the ability not just to recognize that something is special, but deliberately to set out to make something special. This also seems to have occurred at least 250,000 years ago. In a number of sites from that long ago, and thereafter, pieces of red coloring material have been found, far from the areas in which they naturally occur. It is thought that these were brought to be used for coloring and marking such things as bodies and utensils (which would have of course perished without trace), as people continue to do today—to make them special. There is also evidence of cranial deformation as early as 70,000 B.C. and toothfilling and tooth decoration were also practiced. These may not seem like “art” but they do show the wish to use form and color to “make special.”

I suggest that to our ancestors it was essential not only to make good tools—spears and arrows for the hunt—but to make sure they worked by making them and the activities that were concerned with them special. In hunting societies that we know of today, behavior made special (or “controlled” behavior) is as much a part of preparation for the hunt as readying spears or arrows. Before the hunt, hunters may fast, pray, bathe, obey food or sex taboos, participate in special rituals, wear special adornment.

This control of their behavior and emotions can be interpreted as a way of vicariously demonstrating the control they desire in order to successfully achieve their goal. And although “behavior made special” need not be aesthetic or artistic, when one exerts control, takes pains, and uses care and contrivance to do one’s best, the result is generally what is called artistic or aesthetic.

Along with control of one’s behavior—making it special by shaping or elaborating it—would go making important tools and implements special, showing one’s investment in their working properly, one’s regard for their importance. Weapons and tools would be prime candidates for being made special.

It is in ritual ceremonies where one sees the arts most profusely in traditional societies and where I believe the nascent tendency to make special would have had the opportunity to diversify and flourish. Ritual ceremonies are group efforts to control the important things that people care deeply about—not only acquiring food but averting evil, curing illness, securing safety and prosperity, and resolving conflict. While rituals are unique in form and content in each society, they occur in response to strikingly similar circumstances—times of uncertainty, often of transition between one material or social state and another (e.g., plenty and want; disease and health; childhood and sexual maturity: unmarried and married; life and death).

I believe it is no accident that the arts are found prodigiously in ceremonial rituals and the paraphernalia associated with these ceremonies. In fact, I claim that the shaping and elaborating of behavior and of the material world that we today call the arts were necessary to the performance of ritual ceremonies. First, they made the ceremonies pleasurable so that people wanted to do them and would continue to do them, and they also made them compelling and memorable so that they “worked.” The group participation in a common endeavor and the communally-shared emotion would strengthen the general cooperation and feeling of affiliation that was essential for small bands of people to survive in a violent, unpredictable world.

One can then say that to begin with art was not for its own sake at all, but for the sake of the performance of ritual ceremonies. What was important to the survival of early human society is not that decorating bodies or dancing in imitation of an ostrich would bring rain or create more game—although the group members certainly would have thought that was what they were doing. Rather it was the emotional bonding of the participants that gave the ceremonies survival value. The making special, the touching of or entering an extraordinary realm that making special encouraged and allowed, the unifying self-transcendent emotions that were called forth, demonstrated the like-mindedness, the oneness of the group so they would work together in confidence and unity. As human life evolved and became more complex, ceremonies and arts would become more complex as well. They would be used to assist the transmission of group tradition and information, as John Pfeiffer has so brilliantly shown in his book, The Creativity Explosion, which deals with the emergence of Stone Age art.

For these reasons—unification, passing on cul-
cultural knowledge—individuals in human societies where ceremonies were performed would survive better and leave more off-spring than those who did not. And being crucial and intrinsic to ritual ceremonies, the arts were crucial and intrinsic to human survival—art for life’s sake.

To think of art as a behavior of making special is truly a change of paradigm. Usually art refers to objects—paintings, pictures, dances, musical compositions, works of art that are the result of artistic behavior. Or the appellation “art” is given to objects that possess some quality—of beauty, harmony, excellence—and denied to those that do not. Yet if art is regarded as a behavior, making things special, emphasis shifts from the object or quality or commodity to the activity (the making or doing and appreciating), as we see in premodern societies where the object is essentially an occasion for or an accoutrement to ceremonial participation.

“Making special” is a fundamental human proclivity or need. We can see it in such simple things as when we cook special meals and wear special garb for important occasions, and find special ways of saying important things. Ritual ceremonies are occasions when everyday life is shaped and embellished to become more than ordinary. What artists do, in their specialized and often driven way, is an exaggeration of what ordinary people also do, naturally and with enjoyment—transform the ordinary into the extra-ordinary. Looked at in this way, art, as making the things one cares about special, shaping and elaborating the ordinary to make it more than ordinary, is fundamental to everyone and, as in traditional societies, deserves to be acknowledged as normal—encouraged and developed.

To suggest that art is more common and widespread than has usually been supposed does not have to mean that all standards fly out the window and anything goes. (Indeed, even with the idea that art is uncommon and rare, that has already happened.) Nor does it imply that it is trivial and careless. To make something special, after all, generally implies taking care and doing one’s best so as to produce a result that is—to a greater or lesser extent—accessible, striking, resonant, and satisfying to those who take the time to appreciate it. This is what should be meant when we say that via art, experience is heightened, elevated, made more memorable and significant. Thus everything is not equally meaningful or valid. The reasons that we find a work accessible, striking, resonant, and satisfying are biologically endowed as well as culturally acquired. They are not merely a matter of playful and shifting interpretations.

Although “Art” as a concept seems to have been born of and sustained by a commercial society, is therefore only roughly two centuries old, and hence is relative, even discardable, it should not be forgotten that the arts have always been with us. So have ideas of beauty, sublimity, and transcendence, along with the verities of the human condition: love, death, memory, suffering, loss, desire, reprieve, and hope. These have been the subject matter of and occasion for the arts throughout human history, and it is a grievous lapse when contemporary thought assumes that because art is contingent and dependent on “a particular social context” that abiding human concerns and the arts that have immemorially been their accompaniment and embodiment are themselves only contingent and dependent.

The species-centered view of art I have developed here claims that there is valid and intrinsic association between what humans have always found to be important, and certain ways—called the arts—that they have found to manifest, reinforce, and grasp this importance. That the arts in postmodern society do not do this, at least to the extent that they do in premodern societies, is not because of some deficiency or insubstantiality of an abstract concept but because their makers inhabit a world—unprecedented in human history—in which these abiding concerns are more often than not artificially disguised, denied, trivialized, or banished.

Adopting the species-centered view of art allows us personally to better appreciate the continuity of ourselves and our artmaking with nature. Art is not confined to a small coterie of geniuses, visionaries, cranks, and charlatans—indistinguishable from one another—but is instead a fundamental human species characteristic that demands and deserves to be promoted and nourished. Art-like activities exist in all societies and all walks of life.

If you are to carry one idea away from my talk I hope it will be this: art is a normal and necessary behavior of human beings that like talking, exercising, playing, working, socializing, learning, loving and nurturing should be encouraged and developed in everyone.

Editor’s note: Art Therapy would like to thank the author and the National Art Education Association for permission to reprint this article. The article originally appeared in What is Art For? Keynote Addresses of the 1991 NAEA Convention, Karen Lee Carroll (Ed.). pp. 15-26.
Commentary

Linda Gant, Ph.D., A.T.R.

Ellen Dissanayake’s meticulous scholarship and careful thinking [I refer here to her two books as well (Dissanayake, 1988; 1992)] can teach us several important lessons. Perhaps the first and most sobering one is that art therapists must be humble about the claims we make as to what art and, by extension, art therapy, is and what it does for people unless and until we can claim command of such a body of literature and experience as she has.

Second, we should recognize that her “species-centered” emphasis provides a keystone to what ultimately could be an over-arching theory of art making far more encompassing than psychodynamic theory. Such a synthesis could tie together the work of Langer, Cassirer, Arieti, Freud, Jung, Dewey, and Kramer with Dissanayake’s “palaeoanthropo-psychobiological” approach to provide a diachronic and synchronic perspective on the importance of the arts as the embodiment of human affective experience. My hope is that this admixture would provide solid reasons for the philosophical promotion and financial support of the arts with special populations as well as in the educational system.

Third, Dissanayake’s mastery of anthropological and historical ideas should serve to wrest us from the grasp (some might justifiably say imprisonment) of Western concepts and biases and give us an impetus for a meta-analysis of our field. Her historical survey of the concept of art in Western culture should remind us that the intellectual and social climate in which psychotherapy and therefore art therapy developed was quite different than that of other centuries. To what extent are our ideas about acceptable goals and techniques influenced by an undue stress on individual expression and fulfillment at the expense of group values? Our susceptibility to a culturally-induced blindness has implications not only for theory but for practice, especially for those who work with newly arrived immigrants. Only recently have there been art therapy articles dealing with the influence of cultural mores on clinical practice (Geraghty, 1985; Lofgren, 1981; Lomoe-Smith, 1982; Moreno & Wadeson, 1986; Steinhardt, 1986); rarer still are those with specific comments on what other cultures teach about art. While describing her 1987 trip to China, Cathy Malchiodi stated, “Unlike our culture, which encourages children to be spontaneous in their art, particularly during the preschool and early elementary years, little emphasis is placed on free, creative thought or expression in China” (Malchiodi, 1988, p. 55). This implies that the very foundation of art therapy may be fundamentally incompatible with contemporary Chinese social thought.

When we can see our field from the perspective of other cultures and other ages we will be able to question and evaluate those principles which presumably guide our clinical practice. For example, are we biased in favor of a particular type of art so that we consciously or unconsciously regard any other type in a perjorative way? Are we so fettered by the lack of rules in contemporary art that we blithely accept the most unformed and unfinished work as satisfactory?

Dissanayake’s reinforcement of the importance of standards in art is echoed by at least three other notable writers of interest to art therapists—Sarason (1990), Arnheim (1992) and Kramer (1961; 1966), each of whom recognize the psychological importance of art making to all people, not just the especially talented. Their voices, added to hers, affirm the idea that art is for life’s sake, for the fulfillment of fundamental human needs, and for human survival. According to Sarason, “...what needs to be challenged are axioms which, if they continue to remain unexamined, will have a negative impact on our society’s future. At stake is not art in any conventional sense but the ways in which people can experience satisfaction over their lifetimes from the ordered expression of their imagery, thoughts, and
feelings. The satisfaction that comes from making something, and being made and formed by it, is missing in the lives of most people” (Sarason, 1990, p. ix).

Kramer maintains that in contemporary art there is “an indiscriminate acceptance of any and every product that avoids the very concept of standards. Awareness of unwelcome feelings and facts is prevented by avoidance of intelligible statements and preference for amorphous, incoherent expression” (Kramer, 1961, p. 13). Arnheim agrees, “As its least attractive symptoms we notice an unbridled extravagance, a vulgarity of taste, and a triviality of thought. There is too much readiness to make do with too little, to be satisfied short of the ultimate effort, without the engagement of the full resources that used to be the conditio sine qua non of respectable art. The insufficiency shows up in the poor level of much of the work produced and the low standard of what is critically accepted in the mass media” (Arnheim, 1992, p. viii). But Arnheim does offer some solutions which are in accord with Dissanyake’s perspective: “What needs to be done . . . is to revive and explore the principles on which all productive functioning of the arts is based. If one believes that art is indispensable as a psychological and, indeed, as a biological condition of human existence, it must be assumed to grow from the very roots of our being” (Arnheim, 1992, p. ix).

In her closing paragraph Dissanyake states that “art is a normal and necessary behavior of human beings that . . . should be encouraged and developed in everyone.” By showing what has been important in the past to human survival and evolution she intimates what we must do to survive in the future. She gives us a coherent rationale for funding broadly based arts programs. Our ability to survive as a discipline will be directly related to our capacity to use theoretical material such as hers for analyzing our conceptual base and placing our work into historical and cultural context. In doing so we can argue forcefully and persuasively for the development and sustenance of programs which provide “art for life’s sake”—art that as Arnheim (1992, p. 170) says serves as “a helper in times of trouble, as a means of understanding the conditions of human existence and of facing the frightening aspects of those conditions, [and] as the creation of a meaningful order offering a refuge from the unmanageable confusion of the outer reality.”

Facilitating Artistic Expression in Captive Mammals: Implications for Art Therapy and Art Empathicism

David R. Henley, M.A., A.T.R. Chicago, IL

Abstract

A two-year pilot study involving the pre-art and proto-artistic behavior of high functioning animals was conducted. Focusing upon apes, elephants and dolphins, art activities were facilitated by both the author or through trainers in various zoological institutions around the country. Through first-hand practice and field observation, the author attempted to gauge both therapeutic and aesthetic responses to art media, as well as study artistic development in these animals.

Introduction

After months of art therapy, Shanti, an Asian elephant, had progressed to a phase I dubbed "playful destruction": tearing, smearing and ingesting her art materials with a joy and exuberance that often occurs in two year olds or those with special needs. Her coordination remains as yet unformed, her attention short, her strength and quickness virtually unregulated; Shanti's art process is a challenge to contain. Though at times she uses sensory activities to self-soothe (gently purring while nudging and blowing gently upon the paper), such self-absorption is usually short-lived. Soon her arousal levels again escalate, particularly when she wants the attention of others. She then literally climbs inside the drawing box to stand atop her Arches Paper, insisting that the others in the group can not avoid noticing her antics. In response, her mother would most patiently trace around her baby's feet, until her craving for attention is momentarily satiated.

During one memorable session, Shanti startled us all by making her first semi-controlled mark. Without the usual mouthing of her materials, Shanti took up her charcoal and began thrashing it upon the paper, swinging the burnt wood in great figure eights, all the while trumpeting and wiggling her ears.

Witnessing such fascinating mother-child dynamics and developmental achievements is most satisfying for those working with the very young or special needs—observing it in Asian elephants has been extraordinary. Thus began my third season with populations as yet unversed by the field of art therapy: the elephant, ape, and dolphin. Aside from the pleasures I have derived from working with these remarkably intelligent and feeling creatures, I hoped to learn more about the psychodynamics of very early artistic behavior. Sliding backwards along the developmental continuum, toward preverbal and presymbolic beginnings, would perhaps illuminate the evolutionary pathways that lead to true art expression.

This paper attempts to summarize three years of data, in which I have only begun to appreciate and understand the complexities of this topic which have been narrowed down to two lines of inquiry:

The first concerns providing art therapy services, which recognizes the affective, intellectual, and expressive needs of intelligent animals who must cope with protracted periods of captivity. In human culture, institutionalization usually occurs when someone is so severely debilitated that functioning in the community is impossible. In zoological settings, wild animals capable of natural behavioral responses are housed in artificial environments which can only approximate, at best, a normalized existence. This can sometimes result in sensory deprivation leading to neurotic behavior: pacing, listlessness, stereotypy, aggressiveness, etc. Many
modern zoos now attempt to minimize these reactions by offering more natural environments as well as introducing enrichment techniques as part of management programs (Schanberger, 1991a; Collins, 1991). It is in response to these initiatives that I offered my services to several zoos as a facilitator and consultant, to implement art programs that sought to engage and enrich these creatures’ lives.

The second intention was to research to what extent these animals have the capacity to learn art making and express affect through the art process. I observed the animals in the act of mark making to detect whether motoric activity could give way to intended marks or perhaps eventually, become configurations that suggest concepts have been formed and are being represented. Part of this question involved whether or not aesthetic viability could be assigned to animal-made markings. This issue requires consideration of an aesthetic criteria which may be applied not only to the art of animals, but can be generalized to others who create at an infantile or regressed level of development.

To plot their development, the art process was notated (Figure 1) using an outline developed by Wilson (undated) and others at New York University. Analysis of process notations enabled me to plot the animals’ affective responses, particularly their motivational levels. This was a major question that emerged during the study, one that echoed Dissanayake’s "What is Art For?" (1989). Two elements of motivation were examined: that of primary gain, the internally driven artistic impulse, done for purely self-gratification and that of secondary or environmentally reinforced satisfaction. These elements were charted, allowing me to discern when the art activity was self-initiated, done without cues, without audience, done for food rewards and so forth. In this way I sought to measure the authenticity of the artistic impulse or whether, as some have charged, it is merely a clever form of behavioral training practiced in circuses and zoos.

Indeed, the field of animal behavior (ethology) has traditionally belonged to that of behavioral sciences. In which behavior is shaped and data are gathered empirically according to strict scientific protocols. Subjective, anecdotal or affective interpretations of behavior have long been considered taboo. Any reference to personality or mind invited a charge of anthropomorphizing, which asserts that human attributes are wrongly ascribed to animal behaviors. It was Goodall (1990) who through the sheer brilliance of her studies with wild chimpanzees, forced a change of attitude within the scientific establishment. Her findings confirmed the richness of primate personality and social dynamics. Now that ethology has progressed beyond purely statistical inquiry to include anecdotal methodologies, the field may now be more receptive to the contributions of other professions. It is only a matter of time that art therapists may too share their insights regarding psychological development, behavioral dynamics and creativity of animals.

**Literature Review: Great Apes**

The chief source of literature on art-making with apes can be found in Desmond Morris’s *The Biology of Art* (1962). Morris cites chimpanzees who progressed in the scribbling stage of drawing, from random mark-making to one of increased control and “design making.”

In 1952, Hediger (1968) introduced the art process to the gorilla, who had been avoided as subjects in these experiments given their contrary nature and perceived inferior intelligence. Out of 32 art-making apes, only two were gorillas. According to Morris, the graphic capability of the gorilla was certainly equal to that of chimpanzees, with their strongest efforts being equal to the ordered scribblings of a 30-month-old human child. It was noteworthy that the authors report high levels of motivation and attention to task. Morris's chimp, Congo, demonstrated single-minded intensity to an extent that any interruption often brought on tantrums. Guza’s chimp, Jonny, would become stimulated to the point of sexual arousal (cited in Morris, 1962). Guza saw Jonny’s art experience in these instances as an available form of displacement activity providing pleasurable and productive release of drive energy.

Several investigators, as well as trainers, point to the quality of their relationship with the animals as a determinant in maintaining motivation and investment (Roberts, 1991; Schanberger, 1991a; Collins, 1991; Suss, 1991). Morris comments: “…it was essential for the relationship between the experimenter and the ape to be established to the point where there was perfect rapport, a complete trust and understanding” (p. 22).

The artistic development of apes did not progress beyond controlled and elaborate scribbles, until experiments in sign language training began in the 1960’s. The chimpanzee Moja demonstrated that once the rudiments of language (via sign language) were achieved, that indications of concept formation also developed. Gardner and Gardner (1969) found that the marks made by this lingual chimpanzee pos-
CAPTIVE MAMMALS

Process Notations: Modified for Large Mammals
Adapted from Laurie Wilson, Ph.D., A.T.R., New York University

Day & Date: 5/10/91    Time: 11:00 am    Media: Charcoal

Significant note. First visitation. Trainers allow us into
Ivory’s pen! Commotion with five elephants milling
around us, very curious, much eye contact. Very relaxed
atmosphere.

1. Observations of General Behavior

Ivory is very interested in me, touching my armpits,
crotch and other “scented areas.” Much eye contact
with trunk exploration. Ivory is calm, seemingly re-

daxed but very alert and engaged.

2. During Session

A. Response to Media

Ivory responded to trainers cue to “paint.” She
manipulated pencil, tasted, smelled, then handed it to
trainer. Handed back from trainer, began to make
marks with robust movements. Does not over-
work—stops on own accord. Work time elapsed 18
minutes.

B. Response to Facilitator (or educator, trainer or
therapist)

Ivory constantly looked to both the trainer and my-
self for approval during the drawing activity. She
occasionally required cues to stay on task and to
keep her from sucking on the charcoal. She accept-
ed all interventions with compliance while remain-
ing spirited and engaged throughout.

C. Interventions

Ivory took verbal cues without requiring physical
prompts with the askus. Trainer’s cues were low-
key: soft spoken, reassuring, with responses to her
drawings celebratory and enthusiastic. Food rein-
forcers were administered (peanuts) after each art-
work was completed. Media was minimally adapted
by adjusting easel at differing heights to discern op-

timum position. Different charcoal and chalks were
offered to discern preferences or “tastes.”

3. Art Production and Process

A. Detailed Description of Object or Image

Ivory’s strongest work, utilized trunk movements
resulting in a figure eight configuration punctuated
by flowing sweeps and zig zags. Contour drawing,
no shading. Composition is full bodied, utilizing the
whole of the pictorial field in varying degrees of

pressure and angles of charcoal application. Some
trunk sweeps noted and saliva blowing. Dexterity
excellent (African subspecies with prehensile upper
lip) Developmentally: clearly controlled scribble
(approx. 28 months equivalent). Affect reflected;
calm yet energetic. Responsive to spectator atten-
tion.

B. Pertinent Dialogue (vocalizations) or Body Lan-
guage

Body language robust, curious, relaxed. Vocaliza-
tions included throat gargles (favorite self-stimula-
tion) and trumpeting (very loud!). Ritualized head
weaving noted when Ivory waited for art activity to
begin (anticipatory gesturing).

4. Summary or Analysis of Session

Initial session was highly relaxed and productive. Ivory
is a nine year old African, wild born, who displays pre-
ococious drawing behavior. She is cooperative, even
tempered and well habituated to human presence and
intervention. Ivory worked productively despite being
stimulated by the special visitation. She was curious
and outgoing, seemingly enjoying my attention and sal-
utations. Despite the use of food-based reinforcers,
Ivory seems intensely invested in drawing activity.
Whether this investment is internally or externally
driven is open to question; potential for continued
drawing development is exceedingly positive. Recom-
mandation: continue arts programming with gradual di-

 diminishishing of food reinforcers.

Fig. 1 Process note outline developed by Laurie Wilson, A.T.R.
sessed a sensitivity toward spatial relations and balance (cited in Winner, 1981). Marks also became less motoric and scribbly when symbolic significance was assigned to the image. Moya’s “unnamed” pictures for instance, were on par with most of the other apes random kinesthetic scribblings. However, when the chimpanzee focused on creating an image which conceptually stood for an object, the change in pictorial organization was dramatic: the contours and spatial relationships were dramatically enhanced (Beach, Fouts & Fouts, 1984). Patterson has duplicated these findings with her work with KoKo, a lowland gorilla who has received one-to-one educational and language training for over eighteen years (1981).

**Literature Review: Elephants**

Mark-making in elephants has been documented by Guewa and Ehmann (1985), who studied a fourteen-year-old female Asian elephant named Siri. Their account is noteworthy in that Siri’s drawing was evidently a spontaneous untaught and unsolicited behavior. Isolated during the night, the following morning Guewa would find pebble scratchings etched into the concrete floor of her paddock. Though this behavior has been reported by other trainers and observers in the wild, those scratchings were created in the sand or dirt using sticks or other implements and were subsequently lost to the elements or the animal’s own trampling (Douglas-Hamilton, 1975; Hediger, 1968; and Moss, 1988). Hediger observed what he termed “trunk tracks,” as a kind of graphology that betrayed the wild elephants’ emotionality through various styles and rhythms, made as they moved their trunks in the sand during their travels.

Most ethologists viewed Siri’s art making as a “fooling around behavior” which relieved her unrelenting boredom and isolation of captivity. When Guewa began eliciting drawing as part of their weekly regimen, the behavior was attributed to the positive reinforcement of the trainer’s increased attention. Others suggested that Siri became skilled at manipulating the trainers into increasing the quantity of other reinforcers such as food, exercise, and spectator attention. In a more positive vein, Schmidt (cited in Guewa & Ehmann, 1985) saw Siri’s behavior as an attempt to alter her environment in a bid for self-enrichment, either as a cognitive game, a display of territoriality or sexuality.

Schaller’s (1991a) ongoing work at the Phoenix Zoo has incorporated art making as both enrichment and research activity. Ruby, an eighteen-year-old Asian (Thai) elephant has demonstrated the initiative to draw without trainer intervention. When food and art materials are simultaneously presented, Ruby often chooses to draw rather than eat. Furthermore, Ruby has actually left food when researchers set up the easel. A degree of concept formation seems to have been demonstrated by Ruby, as she is able to choose those colors that correlate to objects in her environment, particularly those in which she seems to be emotionally invested (see the fire truck vignette in the discussion).

**Literature Review: Dolphins**

While there are voluminous studies on the intelligence of dolphins (Norris, 1966), language (Herman, 1987) and social behavior (Nathanson, 1989), few reports of dolphin art making activity have been published. One study by Barbara Ann Levy (1990) correlated art therapy principles of psychoaesthetics and object relations of Robbins (1988), with Laban Movement Analysis (Hand, 1986). Levy analyzed the art making behaviors, social interactions and body language on an integrative continuum. She reported correlations between art activity and movement of “honed” dolphins and that a more unique expressivity existed in those animals who remained unpaired. She also correlated the possible connection between the dolphins’ signature whistles and other sounds to their painting rhythms and patterns.

Quayle (1988) reports on research that explores the social aspects of dolphin behavior. She cites Norris and Johnson (Quayle, 1988) who maintain that dolphins exhibit altruistic behavior (such as injured human swimmers being protected from sharks). Nathanson (1989) takes this idea further, asserting that dolphins possess a kind of empathy. Nathanson uses dolphins to interact with mentally retarded, psychotic and other handicapped people, to facilitate their learning and interpersonal relating. Roberts (1991) reports observing sessions whereupon a dolphin who was sometimes intolerant of being handled during encounters with normal people was being worked over by a deafblind child who probed the dolphin’s every orifice. Rather than resist, the animal held still and actually rotated himself so that the child could reach every part in the most accommodating way, much to everyone’s surprise. In this case and others, the dolphin might be seen as a kind of transitional object—whereby the client can establish a relationship with a comforting, yet benign object that sets the stage for more normative and demanding relations eventually with humans.
Case Accounts: The Apes

In 1989 Sara Reitz (1990), then an art therapy graduate student at the School of the Art Institute of Chicago, accepted an internship at the Gorilla Foundation in California, to work with KoKo, a twenty-year-old female lowland gorilla (Gorilla gorilla). KoKo is well known as one of the ten great apes to have learned some American sign language. During her years of one-to-one training with Francine Patterson, KoKo has developed extensive receptive and expressive language which enables her to express her needs, ideas, and feelings with almost unbelievable articulation. Patterson asserts that KoKo has developed a sense of self-consciousness given her mirror recognition experiments (Patterson, 1991).

During her year's residency, Reitz viewed over thirty hours of videotape and engaged KoKo directly in over a dozen sessions that involved drawing with pen, pencil, and crayon. This activity took place in a huge outside pen, with the art materials being handed to KoKo through openings in the mesh.

One of Reitz's objectives was to investigate the degree of intentionality that KoKo brought to her scribbling activity. She employed Morris's "interference patterns," which are comprised of shaded shapes that are preprinted on the drawing paper (Figure 2). Used concurrently with blank paper as a control, Morris envisioned these patterns as being stimulating to the apes' innate sense of design. He observed whether they attempted to complete an unfinished shape, balance an offset composition, or otherwise embellish, replicate or deface the forms in a kind of pictorial dialogue between pattern and ape. Of the twenty-eight works that Reitz collected, KoKo marked upon the interference patterns in 16 instances, with most markings being random scribblings in the general proximity of the pattern. On some occasions KoKo brought a verbal (sign) association to a scribble (such as "corn there"). However, Reitz found no appreciable advances in the control, placement, or configuration when the scribble had been "named." Nor did Reitz find an increase in KoKo's investment in the work when she attached a concept to it. However, in one of the parting sessions, KoKo appeared unusually absorbed as she embellished a drawing of a gorilla and her baby, that Reitz had sketched for her. (Reitz used this sketch as a kind of interpersonal interference pattern.)

Reitz's research eventually concentrated upon mirroring artistic and rapport behaviors for KoKo in an attempt to advance her schemas and cement a
greater bond between the art therapist and her "client." This modeling process entailed having KoKo observe Reitz (over her shoulder) sketching prior to presenting her with the art materials. This mirroring, or dialoguing process appeared to be increasing KoKo’s motivation, lessening her constant requests for food reinforcers. Unfortunately, Reitz had to terminate before more data could be collected to support this possibility.

At Lincoln Park Zoo, June (Pan troglodytes) has been drawing since the age of two with the same keeper, Pat Sass. Now close to twenty-five, June continues to draw in both a kinesthetic scribbling mode as well as a more schematic style (Figure 3). During my bi-monthly sessions, June has appeared to consistently display spontaneous drawing behavior with little concern for food rewards. She unhesitatingly takes her poster board and crayons and finds a remote perch in her habitat, where hand propped thoughtfully upon her brow, colors for usually 10 minutes before climbing down to hand the work to her keeper. On other occasions, June will seek out her peers for conjoint drawing sessions (Figure 4). During these instances, the chimps seemingly take great interest in each other’s work, judging by their focused and unwavering attending behavior.

As part of the primate project at Lincoln Park Zoo, I have also been conducting infant stimulation sessions with a male and female chimpanzee who are each two years of age. Both babies play with crayon, tempera paint as well as soap bubbles and other toys as part of their sensory activities (Figure 5). What is most striking about their behavior is how closely the chimps follow Mahler’s stages of relating (1968).

For instance the female would cling to her keeper for most of the initial sessions, only engaging the paint brush while enveloped in her protector’s arms (working over the keeper’s shoulder). She displayed classic approach/avoidance conflicts (Tinbergen, 1961) with intense stranger anxiety and withdrawal, being offset by an equally powerful urge to investigate this new creature introduced to her world. By the fifth session she began reaching out to me tentatively, eventually overcoming her trepidation by climbing on to me, clinging like an infant. Needless to say, therapist/client parameters had become hopelessly blurred, her attachment elicit powerful paternal transferences within me. The satisfaction that came with finally being not only accepted, but coveted in the most lovingly infantile way, was sufficient to send me scrambling for the nearest supervision. In any event, both babies have developed an attachment that associates me with a pleasant break in their routines. Upon my entry they unfailingly begin to rummage through the art supplies, flailing wildly when they find the brushes. That the art activity is robust is an understatement, as they splash, and smear the paint—a free-for-all made all the more chaotic by their possessing not two, but ‘four’ very hyperactive hands! Upon the termination of each session, an increase in clinging behavior in the female and an escalation of acting out has been observed in the male—reactions familiar to those who work with young children with special needs, who react strongly to loss and other changes in interpersonal care.

Case Vignette: Natua, Atlantic Bottlenose Dolphin

Natua was a sixteen-year-old Atlantic Bottlenose dolphin who was born at the Dolphin Research Center (DRC) and died last year of liver failure. He was considered among the brightest of the dolphins at the center, having descended from one of the original “Flippers” of television fame. Natua has appeared in numerous films, TV shows, and commercials as well as being one of the center’s premier research subjects, including participation in Levy’s Psychoaesthetics Project (1990).

Natua was seen with two other males: Delphi.
an adult in his twenties, and Kibby, a teenager. There were six sessions over the course of three days which lasted each about an hour. All three animals had formally gained experience in painting on T-shirts that were stretched over a board and held by the trainer.

Working with the dolphins required an approach similar to those used with orthopedically handicapped clients. These individuals often have limited motor control, but possess both intelligence and a fierce determination to be successful despite their disabilities. These traits also held true for the dolphins at the DRC, who displayed remarkable motivation and problem-solving ability during the art making sessions.

Since the dolphins lack a prehensile appendage, they are by default, mouth painters. This situation required an adaptive paint brush comprised of unfinished wood, and a short flat handle (to keep the brush from sliding down the mouth). Stiff bristles were effective at absorbing hard strokes and swipes against the paper.

The easel was also a crucial adaptation. I mounted a board made of tempered Masonite on a pipe-fitting frame which was cantilevered over the water and angled downward 20 degrees. By inserting different lengths of pipe, I could adjust the height allowing the dolphins to work comfortably while they tread water (Figures 6, 7, and 8).

The media was comprised of heavy weight Arches watercolor paper which was clipped to the Masonite easel, and acrylic paint in blue, yellow and green. These colors were applied to a palette which mounted vertically onto the face of the dock, allowing for clear visibility of the color choices. A shelf underneath supported the paint brushes, half of which rested on the wood, with the other half of the handle floating on the water. This arrangement encouraged the dolphins to grasp and release the brushes with optimum independence.

From the first session, Natua demonstrated a keen interest in the new easel and paint set-up. With a burst from the trainer's whistle, Natua rose awesomely out of the water and picked up the brush from the palette shelf. He then stood poised before the expanse of the white Arches paper on the easel. After a moment of hesitation (or contemplation?) he dabbed at the paper, then with a jerk of his head, dragged the brush across the pictorial plane (Figures 6, 7 and 8). Approximately six strokes were completed in yellow and green before Natua handed the brush back to the trainer and relished his reward of a whole mackerel.

![Figs. 6-8 The dolphins required an orthopedic set-up which enabled them to tread water comfortably while attending to the art materials. This sequence illustrates a few of Natua's head and brush strokes while his trainer supports his efforts.](image)

After completing six sessions, Natua had become fully acclimated and comfortable with the new painting procedures. His last work particularly bears this out, as it appears the strongest in terms of control and diversity of brushstrokes.

Natua painted Figure 9 while remaining unusually low in the water. Whether this positioning enabled him to increase his control or simply kept exposure to the tropical sun to a minimum (note the protective zinc oxide on Natua's head in Figures 6-8) is open to question. In any event he concentrated on the lower right area, working with unusual deliberation and control. The first strokes began as concentrated dabs that became wispy as the drying color.
Case Vignette: Bozie, an Asian Elephant

For the past two years, I have conducted drawing activities with three elephants at the Lincoln Park Zoo. Bozie, a 17-year-old Asian female, her two-year-old baby, Shanti, and Binte, a 14-year-old African female. All three of these animals had been taught by the zoo staff to "finger" paint with their trunks and thus had the rudiments of working a pictorial plane prior to my intervention. Sessions are held every other week for as long as the elephants show interest (usually about 10-15 minutes per activity) during a time period which they associate with their leisure time (playing ball, running through the sprinkler, etc.). There is no behavioral modification attached to this program beyond recreation and the elephants are free to refuse the activity altogether.

The elephant's trunk is a superb prehensile appendage which functions as a primary sensory organ, through which the animal smells, breathes, touches, communicates, and manipulates. Its fine motor control, particularly among the African species, is so finely tuned, that one elephant I observed drawing in chalk immediately broke the piece in two, a preference that is common among those who often use this material.

In an attempt to offer media that was "species appropriate," I chose charcoal, a material that they might encounter and use in the wild, as well as being non-toxic and aesthetically pleasing. These elephantine pencils were constructed of 1" of hardwood dowels that I charred at both ends in a kiln. The elephants drew on deckle-edged drawing paper which was taped securely into a 30" x 48" shadow box (see Figure 10). This arrangement presented the elephants with a sturdy object that withstood rough treatment while also providing a sense of structure or "territory" which helped define the activity space. As with handicapped children, the elephants respond to consistency and ritualization. By always presenting them with the same sequence, materials, props and verbal cues, I communicated a sense of structure while also providing a trigger that cued the elephants that it was time to explore and manipulate these familiar materials.

Throughout the drawing project, the elephants displayed remarkable curiosity, with the art materials and props being subjected to the most minute examination and manipulation. The drawing box was explored thoroughly before any manipulation of the media was initiated, with every thread, splinter or scrap of tape being picked over, smelled or ingested.
Then the media itself was probed, usually to test the durability of the paper and charcoal. For instance, once I had neglected to tape the entire perimeter of the paper to the board, securing instead only the corners. The elephants spent the entire session peeling up the tape and destroying the paper. Once the elephants are convinced that all is secure and durable, they turn their attention to the charcoal. With a few cues to grasp the charcoal, Bozie will begin to make marks.

Drawing consists of a range of trunk movements, whose motions register as different marks on paper. The mainstay is a vertical motion that translates into a series of fairly controlled lines that are reminiscent of bundles of grain or straw (Figure 11), and are quite organized. Bozie also uses more chaotic daubing, tapping or smearings in works such as Figure 12. These robust and playful scribbings are essentially multi-media pieces, with Bozie dropping straw or dung on the paper, blowing saliva, vacuuming bits of charcoal and other earthy embellishments that record her kinesthetic and tactile experience with the media. In some instances, I invite all the elephants up to the board to assist Bozie, resulting in a elephant free-for-all of marking, smearing, tearing and even trampling. When it is evident that Bozie was working in a more controlled mode, however, she was allowed to work unfettered by the others. Figure 13 from session seven is such a piece. The charcoal was applied with great concentration and density. Strokes are strong and deliberate, with an array of vertical, horizontal and diagonal lines. Even the smearing appears to be less impulsive and more integral to this particular composition.

Since the inception of the drawing project, Shanti, Bozie’s child, has observed her mother in the mark-making process. During these formative years, Shanti habitually traced her tiny trunk over the mother’s drawing, faithfully replicating the
mother's movements. At this time she was too immature to actually manipulate the charcoal without ingesting it. Recently, however, she has begun drawing at 2 years of age. Her strokes are surprisingly controlled. She smears the charcoal up and down, creating the tiniest of dots upon the paper, which are situated alongside of the mother's more varied linework. While her attention span is brief (as the opening vignette attests), what she lacks in attending is made up by the sheer joy she brings to the process. Viewing such a scene, I gladly succumb to the worst case of anthropomorphization and picture just another two year old preschooler scribbling away, at one with herself and her art.

Discussion

The Benefits of Artistic Expression

Much of this paper questions whether captive animals can benefit from art activity. Based upon current ethical thinking, we know that environmental stimulation must be provided if these high functioning animals' emotional/cognitive equilibrium is to be maintained without the opportunities for natural life occupations of feeding, defending territory or mating. Substitute activities must be forthcoming that provide an outlet for learned and instinctive needs. The question remains, however, whether art can arise to fulfill such requirements.

Sensory Stimulation

The adage “use it or lose it” is very much in operation with high functioning animals. For instance, a major rationale of performing captive dolphins is that such “showing off” fully engages their physical and mental faculties—just as dance, gymnastics or wrestling engages those in humans. With regard to visual art, one need only observe the anticipation behavior of elephants that includes purring, trumpeting, squealing and other displays of excitement when art materials are presented. These responses vary, according to each individual's varying needs for certain stimulation. These can often be categorized between visual and haptic modes of processing stimuli. For example, Binte, an African elephant at Lincoln Park, tends toward a tactile approach to media and design. She smears dung into her drawings, blows on saliva making a kind of sauce with the bits of charcoal, all the while flapping her ears and shuffling from side to side. In contrast to such a mixed media approach, her roommate Bozie is decidedly visual in her drawing behavior. She can be observed cocking her head to one side so as to make constant eye contact with her drawing. Ruby of Phoenix points to each of her color preferences and can successfully match color to sample. Occasionally, her keepers attempt to trick the elephant by giving her a different color, which invariably results in trumpeting and trunk jerking responses to such teasing (Schanberger, 1991b).

Needs for sensory stimulation also can be tempered by gender. Both Levy (1990) and I found that the male dolphins responded with greater physical robustness in their painting, while the female worked in a diminutive style. The infant chimps also appear of different temperaments according to gender. The male’s rough and tumble treatment of paint and crayon contrasted sharply with the more serene and focused activity of the female.

Sensory stimulation that came with art activity ceased to be stimulating, however, when presented too frequently, with too much structure, or in competition with other “easier” activities. In all three species, motivation dropped off if the activity was offered more than once a week. For programs with many opportunities for enrichment, art activity did not elicit strong preference, though in those settings with limited opportunities for stimulation, art was a preferred choice (Collins, 1981). These observations corroborate the findings of others who point to the need for novelty as a motivation stimulus (Humphrey, 1980, cited in Dissaneyake, 1989). Such an insight can be well appreciated by the art therapist who may use novel materials (such as glitter or fluorescent glue) on occasion to perk up lagging creative energies in his or her students.
Social Behavior and Art Making

Much of my art program has made use of group interaction and participants of animal families or cohabitants. Subsequently, many fascinating group dynamics emerged during the art sessions.

When for instance the chimps visit each other while drawing, often marking upon each other’s work, their keeper reports incidents of pacification and reconciliation of group conflict (Sass, 1991). During such potentially charged encounters the art process might have played a part in redirecting or dissipating aggression through the ritualization of the art process (Lorenz, 1966). Seen as a displacement behavior, the art process allows approach/avoidance conflicts to be negotiated through the channelling of affect (Tinbergen, 1961). Chimps who were lower in the habitat hierarchy could appear with lessened chance of retribution by their superiors during the drawing activity. The curiosity generated by each chimp’s drawings overcame long-standing feuds between cohabitants, with numerous truces appearing throughout the months of art programming (Sass, 1991). Such conflict resolution might be due to the propensity of the art process to deflect raw affects as a buffering agent for direct confrontation.

Social bonding was also observed in group behavior, with the elephants particularly taking advantage of opportunities for herding around the drawing box. They often mark each other’s foreheads with charcoal, smear each other’s marks and feed each other bits of charcoal (particularly between mother and baby). The dolphins were usually kept separate, though on occasion they were able to observe each other in which they took great interest. Much of this curiosity, particularly among the adolescent males, probably stems from wondering what special treat their cohabitant was receiving while they stood deprived. Often they would display for one another after a session as was described in the case vignette. Such self-proclaimed displays of physical power contrasted with the delicate touch needed to hold their paint brush triumphantly above their heads.

I sometimes became an unwitting participant in the displays as well, with one instance pitted in a hierarchical struggle with a silver back gorilla. After finishing the crayon drawing, the animal spent minutes posturing until he settled upon a particularly striking and intimidating pose. Staring me down, he then thumped his chest (which reverberated with tremendous volume) finally exploding toward the bars of his enclosure—all the while throwing leaves and making a wild ruckus. Almost instinctively I lowered by body, averted my eyes and psychologically submitted to this creature. Evidently satisfied at my passivity he nonchalantly lumbered off.

Aside from the social interactions between cohabitants, caretakers and observers, I believe that the animals developed a kind of relationship with the art materials as well. Such thoughts often came to me as I observed the elephants probing the perimeters of their drawing boxes prior to drawing. They seemed to be reacquainting themselves with a familiar, perhaps important place—a mark making place where something “made special” occurred (Dissanayake, 1989). The animals came to associate this place as uniquely their own—free to explore, destroy or create as the spirit moved them. I have witnessed similar responses in the most severely handicapped child, where the art room was associated with almost completed freedom to make an impact upon their otherwise sheltered environments.

Art as Therapy

Though we can never step outside our humanness and truly empathize with an animal’s emotions, several anecdotes have been reported that infer a therapeutic relationship with both the keepers and the art process.

Throughout the literature and my visits with the animals, I found that the degree of investment in the art process was inextricably tied to the quality of the animal/trainer relationship, with greater intensity displayed when the preferred trainer facilitated the art experience. (Though in instances where the relationship between trainer and animal was overly enmeshed or otherwise dysfunctional, the relationship could hinder the process as profoundly as in any art therapy session.) In most instances, however, the bond between trainer and animal was a healthy one with limit setting, mutual respect, security and empathy supporting the relationship. Given the early childhood nature of this relationship, one could view the animals’ performances as providing opportunities for narcissistic pleasure that arise from pleasing the mothering agent or “significant other.”

Without such opportunities for social bonding, psychopathology often occurs. Schanberger (cited in Gilbert, 1990) reports that when Ruby was the only elephant at the Phoenix Zoo she often lured the waterfowl toward her by using her trunk to dribble grain as bait. Once within range, Ruby would sometimes trample the birds to death. Schanberger reports that since introducing art and other enrichment activities, this sadistic behavior has all been
eliminated. Art activity also appears to displace or perhaps even sublimate sexual acting out behaviors.

Schanberger also reports that Ruby is often sexually stimulated by large vehicles that sometimes work by her habitat (I would assume a preference for well-endowed backhoes, though this has not been confirmed). Exposure to these vehicles would send Ruby to her favored masturbation tree trunk which she used assiduously. Painting activity was reported to not only lessen this behavior, but also increased a preference for bold red patterns in her paintings (Gilbert, 1990).

Problem Solving and Learning

In the literature review I cited several examples where research has proven high learning capacities in these animals, particularly in the chimps and dolphins. While I believe that art making certainly can and has contributed further to the problem-solving capacities of these animals, I tend to minimize an emphasis upon skill acquisition as part of my project. This is because I believe the place of education in therapy should remain minimized—that the animals should acquire sufficient skills in order to effectively engage the art process and maximize self-expression, but not become overly bogged down in developing a precocity that borders on being unnatural. Consider the ape who functions perfectly without an ego as we know it, and instead is governed by superbly evolved instinctual and learning mechanisms shaped by eons of natural selection. Should we overly develop the processes of self-awareness, cognition, reflection and other ego functions? Might this not constitute an intrusion upon the animal’s mind every bit as devastating as primary process intrusions are to the human psyche? In observing some of these heavily programmed creatures, I was first struck by their amazing cognitive abilities, though this gave way eventually to the realization that such giftedness was pervaded by a disturbing sense of neurosis. In these cases, the effects of over stimulation were just as pathological as those caused by sensory deprivation. Hence, one must remain objective with regards to one’s intentions and not allow research to exploit clients who are vulnerable in this way.

Aesthetic Sensibility

Reports of aesthetic sensibility are few in the literature, though I have heard some seemingly fantastic, yet plausible, anecdotes in which the animal in question was able to approach “formed” art expression. This entails the symbolization of personal experiences and affects which are comprehensible in their communication and display an evocative command of formal art elements (Kramer, 1971; 1992).

Such an act of integration was perhaps achieved by Patterson’s male gorilla, Michael, in a work done in response to the recent earthquake of 1989 (1991). Deeply upset by the quake, Michael refused to touch the ground for days after the incident. His first painting session after the quake took the form of a series of horizontal undulating lines painted in thick brown paint. The brown was then covered by streams of red. After scrubbing the surface with increasing agitation, Michael signed to Patterson “earth-shake-bad.” The finished work which I had the pleasure of seeing in photographs possessed a structurally powerful composition which was complemented by its emotionality. But, however lovely and moving this expressionistic painting appeared, ascribing aesthetic viability to it remains a clouded issue to which I now turn.

Aesthetics: A Matter of Intentionality and Critical Empathy

The aesthetic outcomes of these creatures’ efforts may be considered to be academic. It is probable that, even the most accomplished animal artist cares less about its work’s formal elements than the stimulation afforded by the process. However, this does not negate the potential for aesthetically rich outcomes from these and others from the “outside.” Many critics have drawn attention to those art makers who may not be able to conform to the accepted aesthetics preferred by their culture, or incorporate art world influences. Dubuffet (1987), Cardinal (1972) and MacGregor (1989) all exhort the critic not to dismiss the eccentric or psychotic art maker on the grounds of bizarre content or style, in which pictorial communication may be autistic or obscure by nature.

However, the academic issue of aesthetics, even in outsider art, requires working criteria that guide the critic in his/her arguments. The models often cited that recognize those marginal areas of creativity are Alland (1977), Kris (1952), Winner (1982), and Prinzhorn (1972). All of these writers commonly cite one criteria as being essential for aesthetic viability; that of “intentionality.”

Intentionality refers to the degree of purposefulness that one brings to the creation—for example, a client who, after spilling her paint in frustration, decided to mat the splattered newspaper
and pass it off as a masterpiece. While we might accept this as outpouring of emotion and part of a therapeutic experience, it has little to do with aesthetics. Consider the painting student who also decided to display not his paintings, but the splattered drop cloth instead. During his critique, however, he was able to conceptualize (or rather rationalize) that he was unconsciously attending to the space surrounding his canvases, all the time subliminally working those areas more intently than the paintings themselves. Such linguistic gymnastics are commonplace in art schools where students constantly probe the limits of art, though all too often conceptualization is used as a means of shoring up works that are weak in substance. It is interesting, however, that some aestheticians such as Dissanayake (1989) would consider the splattered drop cloth, or to use her example, an act of masturbation as part of a performance as art—only because they are acts “made special” by deliberation. Hence, she views the work of children, psychotics or precocious elephants as being more akin to acts of nature than the result of artistic license. I find this view to be limited, however, since I have found in my experience, severely retarded (Henley 1986), psychotic (Henley, 1991), autistic (Henley, 1999) or very young individuals (Henley, 1992) with seemingly no awareness of aesthetic expectation, able to create images of great power. It appears that naiveté, psychopathology or even retardation can act as a fuel that drives imagery to extraordinary levels.

To appreciate the efforts of such outsiders requires a critical stance that is undeterred by obscure artistic vision, regardless of how impenetrable the artist’s communication may be. I consider this process to be more a matter of empathetic than criticism, whereby the intentions of the artist are approached without any preconceptions or expectations. Cardinal (1989) expresses this article stance beautifully in his account of viewing petroglyphs in the rocks of Northern Italy:

If I were to bend to the task of drawing some further lesson out of these sensations, I would have to say that what the marks were asking me to adduce was my own vulnerability. I begin to divine that the way to grasp the Primitive Scratch must be to advance without inhibition, to participate in its presence as generously as possible. To establish a dialogue across thousands of years, I must open my own sensibility as fully as possible to the transaction. Canumunus artifex hic frui. Now I am here. The authentic apprehension of Otherness is perhaps grounded in some form of self-knowledge, or rather, knowledge of the Other is indissociable from the knowledge we concurrently gain of ourselves. (p. 125)

Art therapists are uniquely positioned to appreciate such an empathetic approach to art, given their experience in lending support to and deciphering the often covert or opaque intentions of our clients. However, empathizing with images which are not intended for two-way communication, challenges even the art therapist to respond and interpret with informed caution.

To illustrate some of this point, I begin by presenting one of Bozie’s most appealing images (Figure 14). Responding to its formal elements, one can make a case for aesthetic viability: variations of hard/sharp and soft flowing lines, subtle forms that appear misty, lyrical sweeping in calm yet forceful rhythms, etc. Before I take this description further, I should say that the piece was created after Bozie had expended her creative energies for the day. Urged on by her keeper (much to my disapproval), Bozie listlessly cut a few lines, then, hastily swept her trunk over the paper to feed on bits of broken charcoal. It is this kinesthetic movement of gathering food that is registered as the feathery wing forms that prompted my initial poetic waxing. Though it is perhaps a lovely movement in nature, its intentions lay not within the realm of art making but with feeding, hence the viewer is misled.

Fig. 14 Although one of Bozie’s more interesting compositions, this image is purely a record of the elephant’s feeding movements.
On the other hand, we can cite examples in the animal kingdom of impressive artistic intentionality, although aesthetic integrity remains questionable. Diamond (1991) recounts his observations of the bowerbird, a relatively nondescript, jay-sized bird that displays art-like behavior. Bowers weave circular huts that are decorated with natural objects that are installed with great care. Colorful flowers, fruits, fungi, butterfly wings which are all collated according to color, creating a most impressive “multimedia” installation. The purpose of this display however is to woo a female into courtship. Despite such intentionality, it falls somewhat short of aesthetic sensibility, since its purpose is aimed at manipulating the viewing female by being resourceful and impressive. Although the bower is instinctually programmed in its manipulative behavior, it is reminiscent of those less than noble intentions of some art-stars of the 80’s whose sensationalism or commercial savvy enabled them to tap the trendy tastes of an affluent art market.

While artists and their art can certainly prosper with deserved recognition and patronage, aesthetic integrity begins to falter when secondary gain eclipses the primacy of the creative act. By primal I refer to those internally driven forces that motivate one to sublimate instinctual yearnings and give form to matters of the soul. When exposed to the environment, these forces must somehow act in synthesis with the ego without diluting or perverting original vision. Kramer refers to such integration as “formed” expression (1971).

Imbalances between primal and secondary reinforcers occur, however, throughout the literature and field observations in both my work with humans and animals. Morris’s chimps actually lost interest in painting when food reinforcers were introduced. Reitz observed KoKo signing “nut-give” even before a single line was produced. On the other hand, motivation and intention also falter when narcissistic pleasures that come with audience response are not forthcoming. It is clear that much artistic motivation is tied to these significant others (i.e., trainers, mothering agents, respected critics or instructors). Indeed, I cannot imagine the dolphins bringing as much intensity and animation to their art without the approving support of an enthusiastic audience.

What I am seeking then, is not so much learning toward one form of motivation over the other as much as a healthy, productive relationship between the two. This relationship can be best fostered by informed, sensitively administered interventions that promote formed art expression through integration.

To adequately assess the aesthetic outcomes of such a process requires an informed analysis that recognizes the spirit of authenticity in art despite the likelihood that it may be cloaked in obscurity, alienation or incomprehension. Because such art criticism or clinical assessment is culturally driven, prejudice will occur, particularly when the viewer confronts a visual or conceptual vocabulary that is foreign to his or her orientation. This commonly occurs when Western analytical thought collides with the more non-linear, metaphysical reality of Eastern or indigenous cultures. And while it is true that we cannot step outside our humanness, when viewing the work of an adult elephant, it is possible to acknowledge that perhaps 30 years of rich life experience are reflected in this image; that joy, boredom, exhilaration, loss, pain and pleasure might all contribute to its quality of line, its smeared forms, its untouched space; just because we can never fully comprehend or identify with the forces that brought such an image into being it should not simply be written off as a “curiosity.” I deeply believe there are lessons taught by these and all creatures should we pause long enough to pay attention.

CAPTIVE MAMMALS

Brief Reports

Psychoaesthetics Dolphin Project

Barbara Ann Levy, M.F.A., M.P.S., New York City, NY

Abstract

Four Atlantic Bottlenose dolphins’ artwork and body and brush movement were the primary focus of this pilot study. Research was conducted by the author at the Dolphin Research Center, Marathon Shores, Florida, in June 1989. Psychoaesthetics (Robbins, 1989), child art developmental theory (DiLeo, 1970) and Laban movement analysis (North, 1975) were used to consider the dolphins’ painting behavior. Personality and individual graphic style of the dolphins were also noted.

Introduction

From June 19th to June 25th, 1989, I conducted a pilot study with four Atlantic Bottlenose dolphins trained to paint at the Dolphin Research Center (DRC) in Marathon Shores, Florida. At the DRC, dolphins were taught to paint on t-shirts by holding a brush in their mouths as a trainer held a t-shirt stretched on a piece of cardboard over the dolphins’ heads at an accessible angle (Figure 1).

The theory of psychoaesthetics (Robbins, 1988; 1989) was used to consider the dolphins’ artwork. Psychoaesthetics combines object relation theory and aesthetics to formulate a unique understanding of both the interaction between client (in this case, dolphin) and therapist and the quality of the resultant artwork. Art development theory (DiLeo, 1970) and Laban movement analysis (North, 1975) were also used to consider the dolphins’ painting behavior.

The Dolphins

Natua, a male dolphin, was born in December 1974 in captivity at the Dolphin Research Center. He is the son of one of the original “Flipper” dolphins. Natua has performed in television commercials and films and was recently featured in the film, “The Big Blue.” He has participated in research experiments on language acquisition, oil detection, and metal differentiation.

Kibby, a male, was brought to DRC from another facility where he was kept in a concrete tank and had developed stress related ulcers.

Delphi, a male, was nicknamed “The Fox” and has fathered many calves at DRC. He was brought to the research center from a facility where he was kept in a feeder pool: a pool at which the public may feed and pet dolphins. He was allowed no privacy and became aggressive. Delphi and Kibby bonded as has been observed with some dolphins of the same sex in the wild.

Misty, the only female in the study, came to DRC from an aquarium in St. Petersburg, Florida. Misty’s trainers report that she has a Janus personality. “When she is good she is very very good and when she is bad she is horrid” (Dolphin Research Center, 1989). At one moment she is a willing participant, at another, she may boycott a routine.

Data Collection

For seven days I observed the dolphins paint and videotaped many of the sessions. I observed the dolphins paint on t-shirts, 18” x 24” gessoed canvases, and paper of different sizes and shapes. At the end of the week, I discussed each of the dolphins with their trainers.
DOLPHIN PROJECT

An early childhood educator, DRC volunteers and staff members assisted in observations. We worked on the docks with the dolphins three times a day for approximately thirty minutes. Two types of exercises were administered to the dolphins as well as experimental variations of both. The dolphins were presented with cut-out paper shapes and were asked to imitate these by painting the shapes on a canvas. They were also shown cut-out wooden shapes held by a trainer underwater.

At one point, a trainer held a canvas as she walked along the dock and Natua followed her and painted on the moving canvas. Additionally, Delphi and Kibby were given one canvas to share. In another instance I imitated Natua by holding a brush in my mouth. I was given my own trainer, fish bucket, and canvas and treading water next to Natua at the dock. I imitated Natua. Natua’s response to this was to inch his way over to my canvas replacing my position at the dock. He then proceeded to paint on my canvas.

Two Laban movement analysts were enlisted to study the videotapes of the dolphin and trainer to investigate a possible correlation between trainer and dolphin movements, and dolphin graphics. Movement analysts watched nine sections of videotape of the dolphins painting. Each analyst looked at dolphin and trainer movement and described them using the Laban system of analysis. To my knowledge, this is the first time Laban movement analysis has been used to evaluate animal movement. One analyst described movement in terms of body, space, shape, and effort. She focused on the relationship of dolphin to trainer.

The second movement analyst spent most of her time viewing the dolphins’ movements and described the effort factors of weight, space, time, and flow. She compiled a quantitative chart for each dolphin. This process was used for observation of trainers as well. The analyst also looked at how each dolphin used combined effort factors in movement sequences.

Observations: Structured Exercises

As a structured exercise, the dolphins were asked by a trainer to imitate a geometric shape. In some of the paintings, a trainer or myself painted a geometric shape on one side of the canvas and the dolphin painted on the other side. In four of the paintings (Figures 2, 3, 4 & 5) the dolphins inverted the trainers’ shapes, providing the viewer with a mirror image. For example, in Figure 2, Kibby attempted to copy a vertical bar shape and a horizontal bar shape painted on the left side of the canvas. The trainer’s vertical shape is placed to the right of a horizontal bar shape and the horizontal is placed perpendicular to the center of the vertical bar. The dolphin placed a vertical shape, a horizontal shape, and some extraneous markings on the right side of the canvas. He also painted a horizontal bar shape in a semi-perpendicular direction to the right of the vertical bar.

In painting Figure 3, Natua attempted to imitate a trainer’s vertical and horizontal bar shapes. The human’s vertical bar shape is located on the left side of the canvas with a horizontal bar painted at its center to the right. Natua attempted to copy the trainer’s marks and placed a large mark on the right side of the canvas and a smaller one to its left mirroring the trainer’s mark’s relationship, a large shape in relation to a smaller one.

In Figures 4 and 5, Kibby inverted the triangle that he was asked to imitate and, in both paintings, he partially covered the trainer’s triangle. In painting Figure 4, it seems that he used the edge of the trainer’s triangle as a bottom for his triangle.

In painting Figure 5, Kibby attempted to imitate the scale and configuration of a triangle painted by the trainer. Again, it appears that Kibby inverted the triangle.

Laban movement analysts who observed the dolphins hypothesized that the dolphins not only followed commands by the trainers, but may have mir-
rorred the aesthetic of each trainer’s movements in the performance of a task (Levy, 1990). One movement analyst found a correlation between “time effort” in the trainers with “free flow” in the dolphins. “... when ... (a trainer) ... incorporates more time in relating to Misty ... and Natua ... than he did in working with Natua ... there is definitely more ‘free flow’ in the dolphin’s movements” (Levy, 1990, p. 51). In other words, when a trainer’s attitude toward the dolphin is relaxed, the dolphin’s movement also seems relaxed. When a trainer worked with Delphi in “quick time,” Delphi responded with less free flow and was more tense.

As I view the canvases, especially Figures 4 and 5, the dolphins’ marks seem to be a mirror of the dolphins’ reaction to the trainer’s movement toward the dolphin. The movements by the trainer may be reflected in the dolphin’s painted response to them.

The dolphin may experience phenomena similar to a human viewer if the human scanned canvases like a zoom lens advancing and retreating.

Natua and Misty were asked to paint on the same canvas, to imitate a human’s painted geometric shapes. In Figure 6, a trainer painted a pink circle. The dolphins attempted to mirror the circle with a series of dots and slashes that form two superimposed circles, a violet one and a green one. When imitating the circle the dolphins would, intermittent with painting, squeal and click as they swam in large circles.
DOLPHIN PROJECT

Observations: Unstructured Exercises

In an unstructured exercise, Natua and Misty painted circular shapes (Figures 7 and 8). Both of these painting sessions were recorded on videotape. In watching their movements, the circular shapes seem visually controlled by both dolphins; however, when compared, individual differences are evident. Natua and Misty both painted circular shapes by using a sequence of marks like “connect the dots.” However, Natua closed his shape by using slash-marks, whereas Misty used dots to define her shape. Misty, the only female in the study, is the only dolphin who consistently used dot or dab-like strokes; the three male dolphins use slash marks. Further study is needed to determine a possible correlation between sex differences and aesthetic differences in dolphin movement and painting. Vigario, a Laban movement analyst, discusses a possible correlation between movement and sex differences:

The first thing I notice is that I am seeing more indirecting (a flexible attitude toward space) from her than I saw from the other three dolphins. Could this possibly mean she is more flexible in her approach to life? Is this a feminine trait? My own bias? (Levy, 1990, p. 51)

Delphi and Kibby had a similar painting style. When compared to Misty and Natua, their marks were layered and covered more of the painting surface than did Natua’s or Misty’s slashes and dabs. Delphi’s and Kibby’s marks seemed more an extension of gesture, were less developed, and more slash-like than Natua’s and Misty’s canvases. Unlike Delphi and Kibby, Natua’s and Misty’s marks sug-

gest form. According to DiLeo (1970), circular forms appear in children’s artwork at about age three. Using DiLeo’s structure to view the dolphins’ artwork, one could speculate that Natua and Misty are the human equivalent of three years of age or older.

Throughout the week of observations, each dolphin repeated patterns of marks. For example, Natua commonly used sweeping petal-like marks. Misty typically juxtaposed a larger cluster of dab-like marks with a smaller one, both located in close proximity to the top edge of the canvas. In two other paintings Misty repeated what appeared to be a human-like form. Kibby repeated an arch-like shape in several paintings. Delphi, in several paintings on
paper and one on canvas, repeated three vertical brushstrokes that seemed to hug one side of the surface.

Conclusion

In terms of style, it seemed that each of the dolphins had an individual style of painting; however, a pair of bonded dolphins, Delphi and Kibby, had a similar graphic and movement style and by the end of the week, the female dolphin, Misty, began to mimic Natua's sweeping bold style. The initial observations also suggested that the dolphins looked at the canvas more often than they missed it which may indicate a degree of visual control over their movements. In general, the dolphins used more multiple strokes than single strokes and more vertical strokes than horizontal or diagonal strokes.

I speculate that the dolphins not only imitate their trainers, but may mirror them when performing a task. Mirroring is defined by Stern (1985) as “affect attunement,” the reflection of an inner state, the “. . . sharing or alignment of internal states . . .” (pp. 143-144). Mirroring is known to be important to the human infant’s sense of self. Through mirroring: “. . . the mother is helping to create something within the infant that was only dimly or partially there until her reflection acted somehow to solidify its existence” (p. 143).

Mirroring is distinct from imitation. Imitation “. . . maintains the focus of attention upon the forms of the external behaviors” (p. 142). (Mirroring or attunement behaviors) “. . . recant the event and shift the focus of attention to what is behind the behavior, to the quality of feeling that is being shared. Imitation renders form; attunement renders feeling” (p. 142).

Michael Bright (1985), in Dolphins, suggests an affinity between man and dolphin. “Some claim dolphins have ESP and telepathically understand a man’s thoughts and moods” (p. 6). Perhaps what Bright calls ESP is, far more simply and less dramatically, a case of mirroring.

The dolphins’ artwork was also compared with early child art development. Dolphins are thought to possess individually distinct whistles which may be used to identify self and neighbor. Young children make marks called “instinctive signatures” (Distler, 1978, p. 12). Captive dolphins that paint may have graphic signatures as well. Unique repetitions of patterns, painting rhythms and distinctive painting styles were found for each dolphin.

Sex differences as seen in the dolphins’ painting and movement were also explored. Misty, the only female in the study, used a controlled and contained style of painting. The three male dolphin marks covered more space on the canvases, used bolder marks, were less contained. However, it was impossible to draw any conclusions about sex differences due to the small population sample. Further research is needed in this area as well as the individual graphic style and painting behavior of dolphins in general.

Ritual and Art Making

Ewa Wasilewska, Ph.D., Salt Lake City, UT

In the catalog of the exhibition "Dreams and Shields: Spiritual Dimensions in Contemporary Art," curator, Frank McEntire, frequently refers to similarities between art making and performing rituals (1992). In fact, the process of art making was, is, and always will be associated with specific rituals that are deeply rooted in ourselves and our cultural traditions. These traditions, through their expression, go back to prehistoric times and so-called less complex societies.

In contrast, the modern concept of art, especially of "art-for-art's-sake," is a relatively new phenomenon which surfaced during the last two hundred years. The purpose of art works was not aesthetic in so-called primitive or less-complex societies. Instead, these works were, and are, primarily concerned with practical (from a religious point of view) functions. They were, and are, part of a larger concept, that of ideology, which often was and is equated with religion. Consequently, there would be no religion without rituals because religion, as a concept, may be reduced to two main areas: belief and ritual.

Rituals are absolutely necessary to every religion because they reflect and reinforce beliefs. Anthony Wallace wrote, "Ritual is religion in action" (1966, p. 102). Religious rituals would not make any sense if they were not supported by beliefs which explain, rationalize, and interpret their existence and necessity. On the other hand, beliefs would not make any sense if they were not supported by actions that proved and reinforced them, and, in fact, stimulated them.

The same reasoning can be applied to the concept of art, which can be divided into two main components: the idea to be expressed through art and the process of art making. Here, the art making process is the ritual: art in action. This action would not make any sense if it were not supported by an idea that would explain, rationalize, and interpret the necessity and existence of the whole process of art making. Furthermore, this idea for the final product would not make any sense if it could not be expressed, reinforced, and stimulated by the process itself.

But what is the purpose of rituals? What do people try to achieve when performing them?

In general, the main purpose of each and every ritual is communication between the world of the profane and of the sacred, between the surrounding reality and the unknown, between believers and the object(s) of their beliefs, between public and seemingly unapproachable entities. The reason for this communication may vary from a simple worship intended to bring both sides together, to requests for a better life and its assurance, to requests for wisdom, power, healing. The basic premise of each ritual is that this communication is possible, and through proper performance of a ritual, supernatural powers, the unknown, the unapproachable, can be somewhat "manipulated" by those on the other side. In other words, the sacred can be persuaded to share its knowledge and power.

Any ritual requires the presence of three elements: time, space, and performers. Time for performing rituals may be strictly prescribed among each society: for example, Sunday mass, New Year's, Christmas. A ritual can also be performed in a time of personal and/or social crisis. It often fulfills a need to express one's feelings: for example, in a time of
physical or mental sickness, drought, and war. Finally, it can be performed as an indication of an individual's status change within his/her society. These so-called rites of passage are celebrated by all of us, and include graduation, marriage, promotion. Any rite of passage goes through three general stages: separation, transition, and incorporation. These three stages are nothing other than the division of all human actions: separation as preparation: setting up the goal, gathering necessary information and materials in order to perform an intended act properly; transition as the actual performance of this act; ritual in process; and finally, incorporation—the final product, something which is finished, and adds a new dimension to an individual and/or to a group.

Thus, ritual time can be perceived in two ways: as setting aside time for the performance of a ritual and as the division of time with regard to different stages within the ritual itself. In fact, only one of these stages is considered to be sacred. This is the transition stage, the actual performance which connects two worlds: the sacred and the profane. In art, the equivalent is the actual process of art making in which an artist makes the link between the world of reality and his or her ideas set up for communication.

Due to the purpose of a ritual, communication with the unknown, the space that is required for performing a ritual action must be determined, too. This is because during this performance, two worlds, that of the profane and that of the sacred, are meeting. Some rituals, especially those that are performed frequently, may require permanent structures such as modern churches, mosques, or an artist's studio. Some other rituals may be performed almost anywhere but the place must be specially prepared for the type of behavior that is included in a planned ritual. But, no matter where this place is, it becomes sacred during the actual performance of a ritualistic act simply because the powers are there. In many cases, a space becomes sacred forever as a final product of specific rituals. Here, we can use again the example of modern churches that are consecrated through special rituals as well as art works that are the result of the ritual of art making. A specific communication between different dimensions can be repeated each time these spaces and objects are approached. They emanate their "sacrality" since this link between the sacred and the profane is enclosed within their boundaries.

Finally, performers are necessary for each ritual. The number of performers may vary due to the type of ritual, tradition etc. There are always special people who can make this communication possible. Such people are more qualified to establish the contact between the world of the profane and the one of the unknown. They can be born with such powers or educated in order to establish them. They can properly prepare the rituals and interpret their performance as well as their results. According to Ellen Dissanayake, "There is no appreciation of art without interpretation" (1991, p. 19). Thus, the role of special performers and religious functionaries can be easily ascribed to artists. Religious practitioners who specialize one way or another in mediating the relations between people and their supernatural/spiritual/unknown world, generally can be divided into two categories: shamans and priests/priestesses. Shamans engage in practices relating to individuals; that is, they are curers who use supernatural powers. Priests are religious functionaries who serve a group's ritual activities. Sometimes both roles may be played by the same person. This double role is often played in modern societies by artists, who are both curers and vehicles for transmission of the past, the present, and the future, through the rituals of art making.

The comparison of artist with shaman is well founded. A shaman is a religious practitioner who has power to contact the supernatural, i.e., the world of the unknown. Artists are spiritual, whether secular or religious, practitioners, who have power for creative expression that connects various dimensions both in time and space. A shaman's powers come from a personal experience such as a soul loss or even education toward this "profession." An artist's ability to express his or her self and the surrounding world originates from very similar sources. And, finally, a shaman performs various ceremonies, mostly curing rites, during which he or she puts himself/herself into a trance state. That is exactly what art performers are doing. In order to communicate with two worlds, they have to put themselves into a sort of trance.

Artists are curers, too. Art therapy interventions can easily be included in this category of rituals whose goal is to maintain human health. In the modern Western world, most of us will ascribe our health miseries to natural causes or bad luck. Because of our medical knowledge we believe that we have the means to deal with most sicknesses and that we can explain their natural source. However, many other, often considered less-complex, societies do not look at the matter of their own health this way. Sometimes so-called natural causes seem not to exist. The causes of illness and death are often seen
RITUAL AND ART MAKING

in the actions of other people (e.g., evil eye, witchcraft, voodoo), or supernatural phenomena (e.g., offending a spirit).

In spite of these cultural differences, the treatment is rather similar in both cases. First, the cause of the disease has to be found and made objective, so a proper cure can be chosen. Here, a shaman-diviner is a big help. If a sickness is caused by magic, a more powerful magician, sorcerer, or shaman is sought who can perform the magical rituals required to heal a patient. When illness results from a human action such as offending a spirit, undoing this action is the cure. Also, there is possession which is the cause of mental illness and can be cured only with the help of exorcism. Of course, everybody knows that instead of battling and/or driving the disease out, it is much better to take preventive action such as wearing talisman or amulet or constructing special charms. In the modern world this might take the form of quitting smoking or having your mammogram at the proper time. But, no matter what the cause, a shaman is the one who provides a satisfying cure. The cure is suggested or revealed to him during special rituals that are focused on proper communication with spiritual forces.

Apparently, shamans are successful in their healing practices, otherwise their advice would not be sought. However, from a medical point of view, often their identification of the causes for various diseases is absolutely wrong. Thus, it seems that the main function of a shaman during rituals of therapy and anti-therapy is to convince a patient that he or she can be cured through and thanks to the ritual itself. Such a realization is possible due to the presence of a deep belief that contact with the unknown world was made, and the wisdom of the past, the powers of the present and the hope of the future will come together through the shaman and his/her work. Shamans help their patients to express themselves through direct or indirect participation in the ritualistic act, thus making them feel better by bringing more understanding to their actions.

Isn’t that what art therapy interventions are all about? Through the process of art making, which is the equivalent of ritual, an artist and/or art therapist, as a modern shaman, helps people to express themselves and to release their deeply encoded emotions, sometimes even fears, in art forms. These may take forms that the client never before thought about. As modern shamans, artists connect the past, the present and the future through their art making. This is a ritual of communication between the artist’s or patient’s conception of the surrounding world (the world of the profane), and its perception expressed through its material “recreation” (the world of the sacred). Finally, artists and their works, as well as shamans, are not easily comprehended by the “profane” public, although they are admired for their ability to communicate with the unknown. We seek their works when we want to understand ourselves; we seek their works when we need visual, vocative, or musical expressions of the surrounding world. We seek them to teach us how to express ourselves; we seek their help when we are down, and enjoy their works when we are happy.

Today, we need artists with their rituals as much as so-called “primitive” societies need their shamans. Without them our world would be limited to the profane domain of the present. With them, we can cross boundaries and learn more about ourselves and our heritage from both the past and the future. As long as we do so, we are living in the human world which is continuously perceived. In spite of scientific achievements, the same way as in the eyes of “primitive” societies: in the world in which

... all things, real and ideal, of which men think [are classified] into two classes or opposed groups, generally designated by two distinct terms which are translated well enough by the words profane and sacred. (Durkheim, 1972, p. 29).

In such a world, there is, and always will be, a place for the shamans and/or artists who can help us to bring our “sacred” selves to the every day “profane” world. And this is what makes us all so human.

Homo Aestheticus: Where Art Comes From and Why

Reviewed by Elizabeth (Liz) Ratcliffe, M.S., M.F.C.C., A.T.R., Book Editor

Ellen Dissanayake’s book is one of the most stimulating and exciting that I have read in a long time; also, one of the most scholarly and difficult to encompass. Her style is complex and dense, her material vast, and her references (chosen as authoritative backup for her radical thesis), nearly overwhelmed me by virtue of the fact that I was not acquainted with either the authors named or their work. In spite of the above, I highly recommend this volume for its brave new adventuring. Under her stewardship, we go into the unchartered waters of late 20th Century confusion, the result of the age of left-brain, literate, rational thought. Dissanayake explores new ways of seeing the significance of art-making behavior in our evolutionary process; she even suggests there may be hope for the future of humankind.

Embedded in her title, Homo Aestheticus, lies the meaning of her thought-provoking thesis: just as our biological species has been described as Homo sapiens, Homo erectus, and Homo faber, human beings are biologically endowed with aesthetic abilities, and could, therefore, be called Homo aestheticus. Similar to the species’ unique evolutionary development attributed to possessing a large and complex brain, an upright stance and tool-making abilities, aesthetic ability has played an important part in our evolution since we emerged from pre-history’s darkness 40,000 years ago.

Dissanayake writes from the perspective of ethology, a branch of anthropology which studies animals in their natural habitat in order to understand what traits and behaviors have brought about their evolutionary adaptations. Her focus on Homo Aestheticus is on the human animal and how certain universal human traits and behaviors have contributed to our present level of civilization. Contemporary scholars acknowledge that throughout their existence, species Homo sapiens has exhibited art-making behaviors. However, the author tells us that although she consulted twenty-four of the “most acclaimed, comprehensive, or otherwise most noteworthy books on human behavior written or edited during the past twenty years by professional academic ethologists, anthropologists, sociobiologists, and others” (p. 9), only seven gave serious space in their texts to a consideration of the role of the arts in human evolutionary change.

Throughout the book, Dissanayake springboards the reader into the deep seas of her provocative ideas by interweaving and elaborating upon research from many related fields. The table of contents lists seven chapters, headed by such inviting titles as Why Species-Centrism?; Biology and Art: The Implications of Feeling Good; Dromena: Reconciling Culture and Nature; “Empathy Theory” Reconsidered: The Psychobiology of Aesthetic Responses and Does Writing Erase Art? Step by step, the author unravels her unconventional thesis. She says that it is through the making of art (in one form or another),
HOMO AESTHETICUS

that, when faced by unpredictable natural or human disasters, early human creatures were able to transform their feelings of overwhelming chaotic confusion into useful and good feelings about their own ability to surmount threatened catastrophe.

In the first chapter, Dissanayake introduces “species-centrism,” which she tells us she will be using interchangeably with “Darwinism.” In her usage, both terms refer to Darwin’s original 19th Century theory of natural selection, rather than to the modern “Social Darwinism.” The latter emphasizes the importance of cultural influences in the resulting differences among human beings. Her differentiation between the original century-old theory and its modern interpretation is based on her thesis: all humans are more alike than different, and our evolution as a species unifies us as much or more so than our cultural differences divide us.

Chapters on “Making Special” and Dromena present the reader with the author’s belief that universal human predispositions exist for making art and creating rituals. These have contributed to the survival of our species. In contrast to other species, early Homo sapiens (or Homo aestheticus) decorated their pots, their homes, themselves as ways of “making special,” and transforming everyday ordinary reality into extra-ordinary. The Greek word dromena means ritual or “things done.” By creating ceremonial rituals (which involved actively doing things as a group), early humans were able to transform untidy Freudian primary process feelings of powerless insignificance into a heightened sense of transcendent oneness and communitas or tribal merging. Aesthetic experience, even today, often involves a sense of boundary dissolution and reunion with the “other.” The author sees this inborn ability of human-kind as providing the sense of being able to control disorienting emotions or disturbing events, rather than just blindly reacting to them.

In “Empathy Theory: Reconsidered,” she discusses some of the recent neuroscientific findings on how people perceive, think and feel, which seem to indicate that empathy involves a physical body-mind experience. Conceding that the research in this new and complex field is, as yet, marked by controversy and disagreement, Dissanayake states:

The presumption of a nonspecialist who chooses to graze among competing theories may seem rash to specialists in the midst of the research who are aware of the difficulties. . . . (However, I believe that my theory) will eventually fit coherently into the total puzzle and thus substantiate my belief that the kinds of feelings comprising aesthetic empathy arise from our natural being-in-the-world and thus have a “natur

Contrasting with her impressive valuing of humankind’s aesthetic endowments is Dissanayake’s evaluation of modern and post-modern over-refined reliance on hyperliteracy. She points out that over the 40,000 years since human beings emerged, there have been some 1600 generations. About 4000 B.C., some 150 generations ago, pictographs were invented for special groups, like priests and scribes, to preserve records and enforce laws. However, it was only twenty generations, or 500 years ago, that the invention of the printing press provided the possibility that reading and writing could play a significant role in general society. By necessity, when preliterate people communicated, they were in face-to-face contact with each other. Oral communication permits personal communion and a sense of shared experience. In today’s world, where so much communication is done on the printed page, detachment and isolation are promoted. The neatly separated words are only references for something other than themselves. As readers shut themselves off from other living beings, loneliness and anxiety beset the human spirit. In our literate, post-modern era, with its stress on intellectual and technical advancement, knowledge replaces belief and impersonal exactness replaces warm, messy human interaction and emotional commitment.

In spite of Dissanayake’s dour views on how post-modern hyperliteracy, technology and commercialism have eroded and erased the intrinsic valuing of art and art-making, her theory of biological, species-centered aesthetics, seems, in the end, to provide a potentially hopeful beam of light. She says:

Perhaps it is (with) these precultural needs—for community and reciprocity, the extra-ordinary and transcendent . . . for attachment and bonding . . . that art is, and must in the West start again to be concerned with what is not accessible to verbal language . . . but nevertheless exists to be perceived by nonverbal, nonliterate premodern ways of knowing. (p. 215)

Among those of the healing professions who read this book, it seems to me that it is the art therapist who will most truly understand, through what the author calls “premodern ways of knowing.” By this, Dissanayake means art’s potential for binding up the gaping wounds inflicted on humankind by the evils of modern technological living.
The Aesthetic Experience: An Anthropologist Looks at the Visual Arts

One of the inherent difficulties of aesthetics, and specifically, in building aesthetic theory, is that what is put forward as “art” by critics, galleries, or government grants, is forever in flux. German philosopher Alexander Baumgarten first used the term in 1744; he was referring to “the science of the beautiful.” Formerly, the Greeks had used it (aesthetikos) to mean “pertaining to sense perception.” Today, it means simply “having to do with art” or “What is art?” (Crawford, 1987, 1991, p. 18). Margaret P. Battin (1986; 1991) reflects that the task of aestheticians is to examine “art and beauty” (p. 50), but the result often makes for “dreamy” reading about a field that is ambiguous and constantly changing. Typically, to present a new aesthetic theory, the aesthetician will examine existing theory, pointing out deficiencies, articulate the new theory, and cite to works of art or experience with art objects to confirm the new claims (Battin, 1991, p. 51)—or, in short, explication and destruction, construction, and confirmation.

Anthropologists have other methods that they bring to their work. Anthropology is “the science that deals with the origins, physical and cultural development, racial characteristics, and social customs and beliefs of mankind” (The Random House College Dictionary, 1975, p. 57). Its research methods follow the format of construction of theory, development of hypotheses, and testing of the hypotheses by observation. Aesthetic anthropology, according to Jacques Maquet, “is in continuity with anthropology as a social science and as a discipline of the humanities” (1986, p. 243). His ideas go back some years when he was studying traditional African art. He used typical anthropological questions to discover aesthetic properties:

What were the functions of the stunning Baga headdresses, the elegant Baule figurines, or the impressive Dogon statues in the societies in which they had been carved? Were they only perceived as ceremonial objects by the members of these societies, or were they also considered art objects by the users? Why were the Bambara and Senufo styles of sculpture different when Bambara and Senufo, both millet farmers, lived in similar environments and in the same region? I approached African artifacts as cultural phenomena, and it proved to be a fruitful perspective. (1986, p. 2)

His inquiries into “anthropology of art, art and culture, and cross-cultural aesthetics” were published in his Civilizations of Black Africa (1972a, French ed. 1962).

The differences among aesthetics, anthropology, and aesthetic anthropology come from the placement of art or aesthetic objects within the context of the culture while looking at them as would an anthropologist. Art is not separated out of context, nor are objects considered without recognition of their aesthetic importance or value to the society.

In The Aesthetic Experience, Maquet guides us into this new discipline through his first-hand experience with aesthetic objects—objects that may be termed art or artifacts. The resulting text is a long, complex essay abundantly illustrated with nearly every object discussed. In fact, we see his personal
collection of photographs of art works and artifacts throughout the book. Likewise, the text is a lively, often personal description of his encounters with, for example, a ritual figurine from Teke, Congo, a cup from Kuba, Zaire, Piet Mondrian's *Broadway Boogie Woogie* (1942-43), or the startling photograph by Robert Capa, *Death of a Republican Volunteer, Spain* (1938).

The book is divided into three sections: "Art in Human Experience," "The Aesthetic Object as Symbolic," and "The Aesthetic Object as Cultural." In the first section he asks the questions, "What is art and what is the experience of it; what is contemplation and how does it differ from cognition and affectivity?" (p. 242). Anthropology, like art therapy, is an interdisciplinary field. Aesthetic anthropology extends the scope of inquiry, integrating, for example, law, philosophy, sociology, Marxism, Freudianism, existentialism, phenomenology, surrealism, counter-culture, and consciousness movements. Maquet also claims that living during the 20th century has shaped his questions, exploration, and conclusions. Like art therapists, he says: "Anything that is relevant should be taken into account" (p. 1).

The "field," we find, is determined by the culture. If we are looking at art in Los Angeles, we consult the yellow pages, radio and television to determine what is meant by "art" in everyday reality. Likewise, we apply this approach to every time and culture. What is an "art object" to the Cokwe of Angola? A parallel term is *hamba*, meaning a category of material things which are valued (p. 17).

What is it that makes us value an object? It is something in the composition that strikes the viewer. When we are in an art museum, we say to our companion: "This painting is art, I mean good art. I don't know why this other painting is here; it is not art!" Maquet holds that an internal awareness of what is "good" and "not good" is intrinsic to all human beings, across time and cultures.

To explore this question further, he asks, what experience do you have when looking at an art object? He describes his encounter with Alexander Calder's *Les Renforts* (1963):

... I first saw the stabile from a distance. It is erected among trees with a light-colored foliage—silver birches, I believe. There stood huge, nonfigurative forms in black steel plates, very much in contrast to the green and sunny environment. Their presence imposed on my attention. Moving closer, I stopped where I could best see the stabile and I looked at it for some time, not being aware if the time was short or long. Later, I did not remember if I was standing or sitting; I was just looking. The image of the stabile is very clear in my mind; I still see the general shape as well as some details of the metal surface. Though I was looking with intensity, I did not try to analyze the different shapes of the plates, nor to figure out the height or the weight of the stabile. In fact, I did not think at all while I was looking, nor did I pay attention to my companions. I did enjoy the experience, but I became aware of the enjoyment only later, after the actual encounter was over. During the experience, I was not in an introspective mood, and I did not even notice my affective state: pleasure or absence of pleasure. In fact, "I, my usual self, was not in the foreground of my awareness: the visual experience of that sculpture was filling all my consciousness.

Later, he found he had little to say to his companions about the stabile, but he remembered the experience as being very intense and that he had, for some time, been "outside of (his) usual stream of thoughts, worries, and feelings" (ibid.). He recalled the emotional impact of the sculpture: "powerful, but latent and contained, energy... a non-threatening force, friendly, reassuring, not explosive or destructive" (ibid.). In preparing his text for this book, he discovered the title of the stabile, which translates to "the reinforcements" (ibid.).

Anthropologists intellectualize their experience of viewing objects. It can take the form of making notes, sketches, reasoning and analyzing, very much as do art historians. Maquet looks at old snapshots differently from, for instance, the way he looks at a map of Los Angeles, searching for a street. So do all of us. With these examples, he demonstrates that the "aesthetic experience" is different from "just looking." It is closer to the Eastern idea of meditation and contemplation. It has potential to help us separate art objects from non-art objects, by making us aware that some objects hold our attention for a long time and others do not. If we doubt our experience, we can check with authorities: art critics, gallery dealers, collectors and the listing of government grants to artists.

Part Two further explores this experience by searching for meaning in art objects and artifacts. The example of old snapshots is problematic. While the photographs hold a lot of meaning for me, the composition is not particularly aesthetic. You look at the snapshots and find no meaning. The difference lies in the universal quality of the experience. There must be meaning for more than just me. Aesthetic objects are "symbolic." They have meaning besides what they represent. Maquet demonstrates this by
looking at Mondrian’s *Broadway Boogie Woogie*. Literally, it is a composition of horizontal and vertical bands of color, intercepted with small squares of color and peppered with larger rectangles of color. Everything is at right angles. It looks busy but orderly, like a grid map of city streets. As with the Calder, Maquet was captivated by the painting. The aesthetic experience was the result of his associations to the lines, colors and energy of the painting. It corresponded to a part of his own life experience in Manhattan, at 42nd Street, and his discovery of jazz. These forms, not a photograph or photorealistic painting, elicits meaning in this painting. He uses this, and many other examples, to demonstrate the place of meaning in aesthetic experience.

A second point, equally important to understanding aesthetic experience, is that it requires the viewer to be ready for an “aesthetic encounter.” By this he means, ready for contemplation of the object. We have all experienced the need to change our attitude when entering an art museum or gallery. We prepare ourselves by slowing down and assuming an attitude of receptivity. Maquet describes the actual face-to-face encounter between viewer and object as detached or disinterested concentration on the object. This state is similar to what happens during the therapeutic process when the therapist allows herself to “merge” with the client as a method of gaining empathy. She then disengages, returning to herself as a disinterested (objective) listener or observer. Similarly, it happens in the process of making art: we merge with our painting or collage or sculpture, and then disengage, step back, and look at it. If it “looks good,” we continue working.

The theme of meaning in aesthetic form is explored in his discussion of aesthetic quality. Some objects are more compelling, more full of meaning, than others. What is the meaning in Pablo Picasso’s *Guernica* (1937)? Does it come through with compelling force? Maquet believes that aesthetic excellence is determined by the degree of “... internal congruence of forms, with the strength and clarity of expression, and with the presence of the object which compels and sets it apart” (p. 142). This reflects Edith Kramer’s criteria for “true art”: inner consistency, economy of form, and evocative power (1971, p. 67).

Part Three, to my mind, is Maquet’s most illuminating chapter for the non-anthropologist. Titled “The Aesthetic Object as Cultural,” it discusses aesthetic form within the context of the societal group. Three levels of culture are considered: the material culture, the social culture, and the mental culture.

An example of material resources is wood (trees). The objects made from trees will be oriented vertically, have vertical linear designs, grouped in a symmetrical composition. In a pre-industrial society, tools limit and determine the types of designs that can be carved into the surface. Techniques for production will be limited, and these will be produced by few craftsmen. Few objects will be made, but each will be relatively unique, for example, totems. In contrast, in an industrial society, where many materials are available, many tools are used, and production is abundant, the use of machines will yield uniform, mass-produced objects. Consider the impact of new materials on aesthetic forms and shapes. When acrylic paint became available, artists were able to exploit its quick drying and malleable properties to experiment with color in new ways. The earlier restrictions of oil to line, shape, texture and light and shade diminished in importance. Compare a Rembrandt with the color staining of Helen Frankenthaler. Compare a Michelangelo marble with a David Smith welded steel.

The material culture (what materials are available and are used) have an impact on the social culture, and this, in turn, influences mental (or, here, aesthetic) culture. Maquet cites the work of art historian, Jean Laude (1971), to demonstrate the intimate connection among material, social, and mental (aesthetic) cultures. Laude compared carved wood doors of the Dogon, Senufo, and Baule to molded or cast bronze plaques of the Dahomey and Benin. The Dogon, Senufo and Baule doors are characterized by “a nonsequential (placement) of figures carved on the surface, and an absence of depth,” (pp. 232-234) and low relief. The Dogon, Senufo, and Baule groups were farmers, maintaining a subsistence level of production (they produced only for themselves), lived in small villages ruled by a lineage of patriarchs which was determined by kinship and descent. The Dahomey and Benin bronze plaques are characterized by a sequential representation of historical events, and an attempt to render perspective by the use of high relief and “by placing the more distant (figures) at the higher part of the plaque ...” (p. 234). The Dahomey and Benin lived on large plantations ruled by powerful rulers, a government based on power and coercion, and a surpluss economy based on long distance trade networks and economic prosperity. The relationship between aesthetic object characteristics and the material, social, and mental culture is not accidental. The two, Maquet asserts, are intimately bound together.
DOLPHIN PROJECT

This complex, provocative book challenges us to think about ourselves, our culture, and certainly, other cultures. At a more intimate level, it allows us to examine our own involvement in the aesthetic experience and process, whether as artists, viewers, or art therapists. In its broadest sense, it impels us to take the anthropologist’s objective, observational stance when we are encountering other cultures. In many ways, the joining of aesthetics and anthropology parallels the art therapist’s clinical methods, and demonstrates research methodology we can apply to our work.

Maquet’s well reasoned explorations into aesthetic process, meaning, and a culture’s impact on aesthetic objects, demands many readings. The book has only two drawbacks: first, although many examples of art and artifacts are pictured and described, few are by women artists. Second, Maquet’s use of jargon, and some invented words, can be confusing and “dreary.” However, the copious use of examples and art objects combats this tendency, creating an exciting, dynamic presentation. Despite these criticisms, I strongly recommend this book to all who seek to better understand their own aesthetic experience, that of their culture and the cultures of others.

Psychoaesthetics Dolphin Project

Barbara Ann Levy, M.F.A., M.P.S.

Produced and directed by Barbara Ann Levy, 1990. Edited by John Ricardo. Sound by Scott Wynn. 5 minutes, color. Purchase only: $50.

Reviewed by Linda Gant, Ph.D., A.T.R., Bruceton Mills, WV

In 1989, Barbara Levy spent a week conducting pilot studies with four Atlantic Bottlenose dolphins at the Dolphin Research Center at Marathon Shores, Florida. This brief videotape shows snippets of “art” sessions conducted three times a day for approximately 30 minutes during which dolphins were given paintbrushes loaded with paint. The dolphins were asked to copy shapes and to make free-form marks on various drawing surfaces including canvas, paper, and T-shirts stretched on a frame which the trainers held at an angle over the pool.

The entire tape (with the exception of a quick
pan of the researchers and trainers and a visual sweep of some completed canvases) consists of scenes in which the dolphins perform according to their trainers' commands. A voice-over narration by Ms. Levy describes the various experiments and the type of data she and others collected. Some of the scenes are played in slow motion when she describes the possible correlation between dolphin and trainer movements. At these points the videotape becomes blurry, a probable result of the slower speed but nonetheless a distracting technical glitch.

Two basic types of exercises (copying specific geometric shapes and "free style" painting), with experimental variations, were given to the dolphins. Ms. Levy studied the resulting "paintings" and at the end of the week discussed the dolphins' personalities with the research center staff. Two movement analysts used Labanotation to describe and quantify the movements of both trainers and animals. This system of movement notation, first published by Rudolf Laban in 1928, is widely used by a variety of movement researchers including dance therapists. Some of the variables analyzed under this system are termed weight, shape, time, effort, and flow (Laban, 1974). Labanotation makes it possible to construct a permanent record of any movement event, to quantify it, and to compare it with other such events.

At the end of the tape Ms. Levy comments, "The findings suggest the dolphins looked at the canvas more often than they missed it which may indicate visual control over their movements. They used more multiple strokes than single strokes, and more vertical strokes than horizontal or diagonal strokes." (I wondered if the vertical strokes might possibly be an artifact of the way the canvas was held or the manner in which dolphins must partially rise out of the water in order to reach the canvas.) Ms. Levy concluded that the painting dolphins might have "graphic signatures" like those of children. "Unique repetitions of patterns, painting rhythms, and distinctive painting styles were found for each dolphin." The veracity of this statement must be taken for granted by the viewer since the narrator gives neither supporting data nor an indication of how the styles were classified (e.g., whether people who did not see the dolphins paint could match the paintings to a particular dolphin). Also, Ms. Levy contrasts the painting styles of the three males with the one female. However, I felt that this sample was too small to permit such generalizing about sex differences. Perhaps the differences were due to age, previous training, or some other variable rather than sex.

Along with the videotape I was given a paper which elaborated on the research project (which also was the subject for Ms. Levy's Master's thesis). The narration was excerpted from this report. Given the brevity of the tape, much information such as the background of the dolphins, the number of paintings analyzed, and a graphic description of the majority of the paintings was omitted. Also missing from both the videotape and the paper was any definition or explanation of the term psychoaesthetics. It was unclear to me whether the paper was intended to be a companion to the videotape or the tape was designed to stand alone.

I found the dolphins' behavior intriguing—they did indeed seem to be making purposeful movements with the paintbrushes. However, there is no information given on how this behavior was initially shaped. I presumed that the animals were rewarded with fish from the buckets sitting on the dock next to the trainers and that behavior from previous training routines had been incorporated into the art making process. But, this was not explicitly stated.) Especially fascinating to me were two small sequences—one in which a trainer presented a canvas with a black circle to a dolphin who then swam in a circle holding the paintbrush aloft and one in which a dolphin made a slight lateral roll and bubbled air out his/her blow hole. I was reminded of a child playfully experimenting with various sounds that could be made by blowing air through water.

Despite my interest in seeing the actual behavior (how many art therapists will ever get the opportunity to work with such a special group of intelligent non-humans?) I cannot recommend this videotape to others. The problems are two-fold: (1) technically, it is unfinished, and (2) it provides no context for understanding the import of such proto-art behavior. There is no formal introduction or conclusion, no titles or credits, and no change of pace or view (such as showing the narrator's face or using different camera angles) to set off the central points. The narration seems divorced from the visual material. Furthermore, it is impossible to tell the intended audience. Was this piece made to show beginning art therapists, other researchers, or the general public? What connection does it have to art therapy theory or research? The videotape does not present enough information for it to be judged as a piece of research since a literature review, exposition of the methods, and a detailed analysis of the paintings are missing. Granted, Ms. Levy does state at the beginning that she was conducting a pilot study. But this small vignette is not anchored to
larger concepts so that the videotape will be truly useful except as documentation.

There is a hint that the other researchers and Ms. Levy attempted to connect the dolphins’ behavior to theoretical issues and to compare the art with that of children. However, Ms. Levy’s characterization of the dolphins’ duplication of their trainers’ movements as “mirroring” seems tenuous at best. She states “I speculate that the dolphins not only imitate their trainers but may mirror them when performing a task” and that Stern (1985, p. 143-144) defines “mirroring” as “affect attunement”—the “sharing or alignment of internal states.” Here Ms. Levy goes too far afield. I do not see that the substitution of “mirroring” for imitation adds anything to the understanding of the animals’ behavior and, in fact, may serve to cloud some important issues by unnecessary anthropomorphizing. To guard against such a tendency is the most difficult aspect of any study with intelligent mammals (and I must admit that some people may charge that my description of the dolphin appearing to be experimenting with making sounds falls into that very trap).

As it stands now, this videotape resembles a stone that might be used in a piece of jewelry. However, it is neither polished nor properly mounted. A proper setting would place it within the matrix of other work on the biological and adaptive precursors of art and art-like behavior (Alland, 1977; Dissanayake, 1988; Morris, 1962) for it to have any implications for art therapists. Such comparative work, not only with animals but with other cultures and other ages (such as Dissanayake’s article in this same issue), is vital and must be encouraged. But in addition to the problem of anthropomorphizing, there are technical difficulties to consider. For example, since the dolphins must hold large brushes in their mouths, they are hampered by the lack of real control over the brush. In the videotape one can see what appear to be purposeful strokes mixed with what appear to be accidental ones. Was the second type of stroke coded differently in the analysis of the end product? Also, the trainers did not seem to be consistent in the manner in which they held the can- nases over the water and one could not tell from the brief segments how a trainer knew when a picture was finished. All of this leads to problems with scoring, interrater reliability, and proper interpretation. The use of Labanotation obviates some of these troubles when studying movement and similar rating instruments could be developed for the art.

I find this preliminary work reminiscent of the early attempts to teach oral speech to chimps. Until researchers finally realized that primates lacked certain vocal apparatuses necessary for the range of phonemes required for human speech, these experiments were doomed to failure. When they began teaching the animals sign language, they were successful (Harris, 1980, p. 83). Perhaps there are better methods of finding out what dolphins can do with art and/or symbolic communication without inadvertently introducing unwanted artifacts. I hope Mr. Levy will refine her methods, do some further work, and present them in a better setting.

The Art of Healing Trauma

The Southern California Art Therapy Association (SCATA) in association with the City of Los Angeles Cultural Affairs Department has created a monograph titled “The Art of Healing Trauma: Media, Techniques and Insights.” This publication was produced both in response to the Los Angeles riots in April 1992 and also as a guide to the appropriate use of both art products and processes with people in crisis.

Geared to elementary and secondary classroom teachers, this monograph takes a proactive stance in promoting the value of art therapy by sharing basic information on media, process and materials used in art therapy. A chart on the possible psychological effects inherent to art materials is featured in a concise and attractive format. Cautions are offered throughout the text to emphasize the inappropriate use of the art process and image interpretation. General suggestions are also given for how to accept and respond to art images, what to note in the art product, and how to support the process of recovery from trauma.

The Art of Healing Children

“The Art of Healing Children” is an art engagement calendar which features the images and poetry of children who have participated in a joint venture between the Napa State Hospital Children’s Art Therapy Program and the Arts in Mental Health Program. Al Friedman, M.A., A.T.R., Coordinator of the Children’s Art Program and Sally Denman, M.A., A.T.R., Artist Facilitator with the Arts in Mental Health Program, have spearheaded this project for the last several years, demonstrating a unique collaboration between art therapists and artists-in-residence. The calendar has received critical acclaim throughout California, highlighting both the emotional power of the children’s work as well as the importance of the arts and art therapy in the children’s psychiatric treatment and education. In a 1991 resolution from the Senate of the State of California, the calendar project was observed to have improved “the children’s self-esteem and increased the public’s awareness of the benefits of arts and art therapy in treating troubled children...and has stressed the important role art therapy has played in treating, educating, and enhancing the children’s quality of life.”

Funds from the project go to hiring additional creative arts therapists and artists-in-residence to work with the children at Napa State Hospital. In recent years, a poet-in-residence, a Japanese Taiko drummer, a sculptor, an actor as well as an additional art therapist and drama therapist have been hired as a result of the proceeds from calendar sales. Funding sources have included such broad-based support as Chevron, the Gasser Foundation, the Lef
Foundation, Pacific Gas & Electric Company, the Doctors’ Company and Beringer Winery.

The calendar now is marketed nationally and is being sold in bookstores throughout the country. It has also been in museum shops such as the Phillips Collection in Washington, D.C., the Crocker Museum in Sacramento, and at the San Francisco Museum of Modern Art where it has been a best seller among engagement calendars. If you are interested in receiving more information about this project or obtaining a copy of the calendar, please contact either Al Friedman, A.T.R. or Sally Denman, A.T.R. at Napa State Hospital, 2100 Napa-Vallejo Highway, Napa, California 94558.

International Networking Group of Art Therapists to Hold First International Conference

The International Networking Group of Art Therapists (ING) was founded in 1989 in San Francisco during the 20th Annual Conference of the American Art Therapy Association as a forum for the exchange of information among art therapists around the world and to encourage professional enrichment at a global level. As a result of this collaboration and the subsequent expansion of the group, ING will hold its First International Conference in Vilnius, Lithuania from September 4-5, 1993. The theme of the meeting will be “Art Therapy/Art Therapists: Cross-Cultural Exchange” to encourage a wide range of topics including media, symbolism, professional practice, ethics, publications, and diagnostic and treatment applications from a variety of settings and theoretical orientations.

Proposals for this conference are now being accepted for review by an international program committee. Proposals must include title, format of presentation; name, address and brief biography of presenter(s); a one-page abstract; and requested time allotment. Proposals or questions about this conference may be addressed to: Isolde Martin, A.T.R., Program Chair, Werstr. 21b, 8059 Oberding-Schwaig, Germany. Art therapists or others interested in joining ING may contact Bobbi Stoll, A.T.R., MFCC, 8020 Briar Summit Drive, Los Angeles, CA 90046.

Editor’s note: Noteworthy is a new section to the journal whose purpose is to highlight the collective efforts of art therapists and others in successfully promoting and making visible the profession in unique and newsworthy ways.

Call for Submissions to Art Therapy

Art Therapy: Journal of the American Art Therapy Association is currently seeking submissions in the form of full-length articles and brief reports on theoretical, methodological, and research for two special theme issues:

1. Art and Medicine. Articles may focus on the use of art expression in the assessment or treatment of physical disease; theoretical, ethical, or practical issues in the application of art therapy in a medical setting or with physical illness; original research in medical art therapy.

2. Professionalism in Art Therapy. Articles may focus on current professional issues in the field of art therapy such as, but not limited to, licensure, credentialing, job development and governmental affairs. Theoretical, historical, methodological, or research articles focusing on these themes will be considered.

Submissions must adhere to the “Guidelines for Submission” which are outlined in Art Therapy; please review these guidelines carefully because manuscripts which do not meet these guidelines will be returned to authors without review.

DEADLINE for submission of manuscripts is December 15th, 1992. Please send manuscripts to:

THE ORGANIZATION

The American Art Therapy Association, Inc. (AATA), a non-profit organization founded in 1969, is a national association which represents a membership of approximately 3800 professionals and students. It is governed and directed by a nine-member Board elected by the membership. The AATA has established standards for art therapy education, registration and practice; AATA committees actively work on governmental affairs, clinical issues and professional development. The AATA's dedication to continuing education and research is demonstrated through annual national and regional conferences, publications, films and awards.

Purpose:

• The progressive development of the therapeutic use of art.

• The advancement of standards of practice, ethical standards, education and research.

• The provision of professional communication and exchange with colleagues.

• The provision of legislative efforts to promote and improve the status of professional practice.

• The promotion of the field of art therapy through the dissemination of public information.

Chapters:

Affiliate Chapters of the AATA have been established throughout the U.S. Chapters conduct meetings and activities in an effort to promote the field of art therapy on a local level. Chapters provide a forum for addressing professional issues as well as a network of people working toward common goals. Information and support for Chapter members is passed on from the AATA Assembly of Affiliate Chapters to the local level.

You must be a national member to become a Chapter member. Information on locating the chapter nearest you is available from the AATA office.

MEMBER BENEFITS

Individual members receive:

Publications

• Art Therapy, the official journal of the AATA

• The quarterly AATA Newsletter

• Substantial discounts on AATA publications such as Annual Conference Proceedings, other professional journals, films, and membership directory

• AATA literature, such as Educational Programs List, Art Therapy Medin List, and Standards of Practice

• Mailings of professional interest

Services

• Insurance, including professional liability, major medical, life and disability

• Access to national experts in art therapy

AATA Conferences

• Discounts on registration fees to AATA national and regional conferences

Nationwide Advocacy

• Governmental affairs activities including Congressional review and monitoring

• State legislative and regulatory activities

• Promotion of recognition and reimbursement of art therapists by third-party payors

• National liaison with related professional organizations for recognition and promotion of the profession of art therapy

Professional Standards

• Development of model job and licensure laws

• Development and implementation of national guidelines for approval of Master's Degree and training programs in art therapy

• Development and implementation of nationally recognized Standards of Registration of Professional Art Therapists

GENERAL MEMBERSHIP APPLICATIONS

1. The membership year is the calendar year, January 1 through December 31.

2. Contributing, Associate and Student applicants for NEW MEMBERSHIP ONLY: Please follow the chart below when submitting membership application.

Applications received between:

- June 1 and Sept. 30: Half year's dues plus $5 payment. Membership expires Dec. 31 of same year.

3. Professional Members applicants must meet Criteria for Professional Membership. Formal application with documentation is submitted to Membership Chair for approval.

4. AATA Membership and AATA Registration (A.T.R.) each have a separate application procedure. Registration is bestowed only by the Standards Committee.

5. National AATA membership required for Chapter Membership. Please contact AATA office for information on AATA Chapters.

CATEGORIES AND FEES

PROFESSIONAL - by application only. Such members may vote, hold office, and serve on committees.

• Credentialled Professional Member: Individuals who have been dually approved for Professional Membership and Registration (A.T.R.) by AATA; dues are $95 per year.

• Active Professional Member: Individuals who have completed professional training in art therapy. Dues are $85 per year.

CONTRIBUTING - Individuals, organizations, institutions or foundations which contribute annually to AATA. Such members may vote, hold office or serve on committees. Annual dues are $120.

ASSOCIATE - Individuals interested in the therapeutic use of art who support the purposes and objectives of AATA. Such members may not vote, hold office or serve on committees. Annual dues are $95.

STUDENT - Individuals who do not meet the qualifications of Professional Membership and are currently taking coursework in art therapy or related fields. Requires a current statement from the institution indicating full-time status and coursework content. Student members may not vote, hold office but may serve on Student Subcommittee of Membership. Annual dues are $95.

Guidelines for Submissions

All submissions will be acknowledged upon receipt by the AATA National Office. *Art Therapy* uses a blind peer review procedure for full-length articles and brief reports; final decisions regarding publication are made by the reviewers and the Editor. Decisions regarding submissions to other sections are made by the Editor, Associate Editor and special section editors.

The following are guidelines for developing and submitting a manuscript. Manuscripts that do not conform to these guidelines will be returned to the author without review.

**Manuscript Categories**

1. **Full-length Articles.** Full-length articles may focus on the theory, practice and research in art therapy or related areas. Manuscripts must include an abstract of approximately 75-125 words summarizing the major point of the article.

2. **Brief Reports.** Short articles which focus on the results of research are appropriate for this section. Manuscripts should include information on the research design, methodology and results; an abstract of approximately 75-125 words should also be included.

3. **Viewpoints.** Short articles focusing on personal experiences, poetry or original art may be submitted to this section.

4. **Book Reviews.** Reviews of books of interest to art therapists may be submitted at any time. Books which authors wish to have considered for review may be sent directly to the AATA National Office at the address listed above.

5. **Film/Video Reviews.** Reviews of media (films or videotapes) may be submitted at any time. Media which producers wish to have considered for review may be sent directly to the AATA National Office at the address listed above.

6. **Comments.** Brief comments on articles published in *Art Therapy*, issues critical to the profession and practice of art therapy, or letters to the Editor may be submitted to this section and should conform to the style of all other submissions.

**Other Requirements**

1. Send five (5) clear copies of each manuscript to Cathy A. Malchiodi, A.T.R., Editor, *Art Therapy: Journal of the American Art Therapy Association*, c/o AATA, Inc., 1202 Allanson Road, Mundelein, Illinois 60060. Neither AATA nor the Editor can be responsible for submissions sent to any other address.

2. Only original articles that are not under consideration by another periodical or publisher are acceptable.

3. Manuscripts must be typewritten on 8½” × 11” white paper with margins of at least an inch. The body of the paper, references, tables and quotations must be double-spaced.

5. An abstract of 75-125 words must be included with full-length articles and brief reports.

6. Please avoid footnotes wherever possible.

7. A cover sheet should be prepared to include the full name(s) and degree(s) of the author(s), professional affiliations, and the return mailing address of the author to whom correspondence can be sent. Authors’ names, positions, titles and places of employment should not appear in the body of the paper to assure anonymity and to facilitate blind review.

8. Use tables sparingly and type them on separate pages. Refer to the APA *Publication Manual* for style of tabular presentations. All tables, charts or diagrams must be legible and able to withstand reduction.

9. Photographs must be at least 5” × 7” and black and white glossy prints, preferably with high contrast. Xerox copies of illustrations or art expressions are not acceptable for publication. Figure numbers and captions should be noted on the back of photographs; captions must be typed and submitted on a separate sheet of paper. Please refer to figures in the text as Figure 1, Figure 2, etc.

10. Lengthy quotations (300 words or more from one source) or reproduction of works of art (this does not include client art expressions, which is addressed below) require written permission from the copyright holder for reproduction. Adaptation of tables or figures from copyrighted sources also requires approval. It is the author’s **responsibility to secure such permissions**; a copy of the copyright holder’s written permission must be provided to the Editor immediately upon acceptance of the article for publication.

11. Client/patient confidentiality must be protected in the title, abstract, text, photos, illustrations and other accompanying material. Proper releases for use of client art expressions and other client information must be obtained and kept on file by the author.

12. It is expected that any manuscript accepted for publication in *Art Therapy* will go through at least one revision before publication. If authors have prepared their manuscripts on either an IBM, IBM-compatible or Macintosh computer, upon acceptance, they can send a 3.5” diskette containing an electronic copy of the manuscript to the AATA office. This will help speed processing, editing and publication.

**Note:** Authors bear full responsibility for the accuracy of all references, quotations and materials accompanying their manuscripts.
ATTENTION AUTHORS

In order to help us process your submission more quickly, please complete the following information and attach one copy to your manuscript:

Name: ____________________________________________

Degrees/Credentials: ____________________________________________

Address: ____________________________________________

Phone #: ___________________________ work ___________________________ home

Type of Submission (check one):

___ Article
___ Brief Report
___ Viewpoints
___ Book Review
___ Film/Video Review

Title of Submission: ____________________________________________

Checklist:

___ Five copies, typewritten on 8½" × 11" paper.
___ Abstract of 75-125 words (for articles and brief reports only).
___ Detachable cover sheet with author(s) name(s), affiliation, degrees and credentials.
___ Appropriate release forms obtained for use of client art expressions and client information. (You do not need to send these with your submission, but you must have them on file.)

STATEMENT OF PURPOSE: Art Therapy: Journal of the American Art Therapy Association is the official journal of the AATA, Inc. The purpose of the journal is to advance the understanding of how visual art functions in the treatment, education, development and enrichment of people. The journal provides a scholarly forum for divergent points of view on art therapy and strives to present a broad spectrum of ideas in therapy, practice, professional issues and research. An emphasis is placed on the use of the visual arts in therapy, but articles in related disciplines of interest to art therapists will be considered for publication.

ART THERAPY: JOURNAL OF THE AMERICAN ART THERAPY ASSOCIATION (ISSN 0742-1656) is published quarterly by the AATA, Inc., 1202 Allanson Road, Mundelein, Illinois, U.S.A. 60060. Telephone (708) 949-6064; FAX (708) 566-4580. Non-members may subscribe at the following annual rates: $40 (U.S.) and $64 (Foreign); institutions: $57 (U.S.) and $80 (Foreign). AATA members receive the journal as a benefit of membership.

Single Issues: For price and ordering information, call or write to AATA, Inc., 1202 Allanson Road, Mundelein, IL 60060 (708) 949-6064.

This journal is abstracted in: Psychological Abstracts, INNOVATIONS & RESEARCH, Art Bibliographies Current Titles and Art Bibliographies Modern.

Advertising: Please see advertising rates listed elsewhere in this journal or contact the American Art Therapy Association, Inc., 1202 Allanson Road, Mundelein, Illinois 60060 (708) 949-6064. The publication of any advertisement by the AATA, Inc., is not an endorsement of the advertiser or of the products or services advertised. About the Cover: “The Rock Lady,” 5' x 5' oil painting photographed in environment, by Helen B. Landgarten, M.A., A.T.R., HLM, art therapist, educator, author, and artist; Professor Emeritus of the Clinical Art Therapy Program Master Degree Program at Loyola Marymount University, Los Angeles, California; former coordinator of Art Psychotherapy in the Family/Child Department of Psychiatry at Cedars-Sinai Medical Center, Los Angeles, California. About the piece Landgarten says, “My environment has made a major impact upon my psyche. Often, without any conscious intent, the elements of nature appear in my work.”
Editorial

Cathy A. Malchiodi, MA, A.T.R., Editor

This year's Annual Conference theme, "Artist, Teacher, Clinician, Healer," sought to address aspects of professional life that art therapists have often struggled to integrate in their work. Certainly, the problem of maintaining an identity both as an artist and therapist has been a subject for debate in many past conferences (Ault, 1977; Landgarten, 1989; Rosenberg, et al., 1982; Wadeson, Landgarten, McNiff, Free, & Levy, 1977, to name a few), and will probably continue to be debated at future meetings. The past annual conference expanded on this theme, exploring the roles of artist, teacher, clinician, and healer in the opening general session (Ault, Lachman-Chapin, McConaghey, & Junge, 1992). This topic is of interest to most art therapists, both because of the inherent diversity in art therapy practice as well as because of the reality that many art therapists find their livelihoods from working in two or more of these roles as therapist/healer, educator, and/or visual artist.

Although I had a personal interest in this theme, an additional highlight of the conference for me was a panel presentation called "The AATA and Quality," given by Laurie Wilson, Paula Howie, Edith Kramer, Katherine Williams, and Gladys Agell (1992). This presentation was dedicated to the memory of Elinor Ulman; however, it took on a significance far greater than that of a memorial tribute, addressing diversity in our work from another perspective. In listening to the panelists, qualities such as dedication, ethical practice, standards, diligence, and honesty came to mind, intertwined with our roles as writers, academicians, educators, clinicians, and supervisors.

Early in the presentation, one of the panelists observed that the word "quality" should be replaced by the word "excellence," a characteristic that Elinor Ulman embodied and demanded of herself, her students, and the profession. A second characteristic, courage, was identified by panelist Paula Howie, who offered the following quote from Ulman's (1974) work:

Perhaps the quality most needed by the art therapist is courage. The frantic effort to plan elaborate art therapy procedures reflects the therapist's timidity, his need to attempt the impossible—that is, to chart in advance a voyage of discovery. (p. 14)

In response to the theme of the panel and this quote, Howie raised the question, "Are courage and excellence enough?" With this question and her own courageous self-searching, Howie artfully and passionately brought to light a variety of issues, further exploring the sense of disillusionment with the field of art therapy expressed in the 1991 panel "Art Therapy: Post Mortem" (Malchiodi, Cattaneo, & Allen, 1891). Howie observed that "... art therapists, quite frankly, are hurting. We are losing jobs,
programs, (and) we are being squeezed by demands to objectify care. . . ." She also noted that health care is undergoing many changes: for example, diagnostically related groups (DRGs) mean there is less time to work with patients and the emergence of managed care will radically change how the patient's needs are met. As art therapists, in her words, "we are at the mercy of" insurance companies and regulating bodies. I would also add to Howie's list that we are losing academic training programs in art therapy at an alarming rate and are in danger of losing more before this decade is over.

Considering these realities, are courage and excellence enough? In response to the latter, there are many ways each of us can contribute to the profession and association. For example, one area we can all focus on in terms of excellence is our annual conference. It is fair to say that we look to the annual conference for excellence in theory, methodology, and research to inspire us in our work. However, it is discouraging to seasoned professionals to return year after year to the conference only to be less than stimulated by repetitive or basic material on such perennial topics as geriatric life review or to listen to someone pointing out one more phallic symbol in clay. What I often hear in conference presentations makes me feel like an unwilling time-traveler going back to a previous AATA conference 5, 10, or more years ago when the same information was presented in a slightly different form. To glance over a conference program or to attend many of the sessions is often a déjà vu experience to a well-remembered past life.

These topics and others which are resurrected year after year certainly warrant further investigation, discussion, and formal presentation. However, many conference papers often lack rigorous research into what has been previously written and presented on these topics or, in the case of most, present no new material. This occurrence is not the fault of the conference planners or the program committee, who I believe have consciously tried to provide stimulating and contemporary programs. It is a responsibility for excellence that each of us who is accepted to make a presentation must take seriously by doing the extensive preparation necessary to present a scholarly paper or workshop to our peers.

On the other hand, the past conferences provided some surprises in areas of excellence the profession is actively striving to address. A study group on doctoral programs was extremely well-attended, attesting to the interest of art therapists in obtaining higher degrees and in contributing to our knowledge base through research. The open forum on the AATA journal was also surprisingly well-attended, by both professional members and students with questions about contributing to the field through writing. Art therapists are also striving to bring excellence to clinical work by understanding the multicultural needs and diversity of our clients as demonstrated by the symposium on multicultural issues, the Mosaic Committee Open Forum, and the Gay, Lesbian and Bisexual Caucus.

Lastly, excellence in one's personal work as well as the profession as a whole also means sharing a responsibility for the future direction of the field of art therapy. Panelist Laurie Wilson eloquently observed that "standing for quality (excellence) often, but not always, means standing for the more difficult solution." This means taking a longer view of a situation, whether it be training, standards of practice, ethical dilemmas, or certification, and looking at the given situation with the larger picture in mind.

Although excellence requires high standards, energy, and perseverance, the question of courage may be more difficult to address. Courage involves not only these qualities, but also the added elements of risk, honesty, and integrity. If courage is, as Ulman said, a quality needed by art therapists, then maybe it is something we should actively discuss with students in our training programs. More than 12 years ago, Doris Arrington, program director and professor at my alma mater the College of Notre Dame, gave the first small group of graduates from the masters in art therapy program a red badge with a ribbon bearing the word "courage" on it. Although we never discussed courage in the classroom, we all knew we would need it when we left the nest of our training program as the first graduating class to go forth and hopefully prosper as art therapists.

Since then I have kept that badge in a prominent place where I can see it each day. It was not easy to be an art therapist when I graduated, nor is it easy for today's graduates. In response to a dialogue at the conference examining the identities of artist, teacher, clinician, and healer, Conference Chair Randy Vick commented that even if our jobs were difficult at times, no one of us would ever settle for being a "shoe salesman." The obvious attraction of being a shoe salesman is that one does not have to describe what one does, nor does one need a lot of in-depth training; in comparison to being an art therapist, maybe one does not need as much courage either. Although thoughts of joining the ranks of retail sales have crossed my mind in moments of frustration, I would agree that I cannot give
up my work and interest in this field, despite the drawbacks.

In her Honorary Life Membership Award address, Janet Wadeson observes about her life and professional career that "art therapy has been a generous provider." There is a great deal that our professional lives provide each of us if we are willing to look for it; it may be in the long run what gives each of us the courage to continue. We are privileged as professionals to be able to witness what is unseen to others in the art of our clients. To view images from the human psyche is an experience that brought many of us into this field and keeps us in it. On the whole, most of us are willing to risk a little in terms of job security or stature to make this experience a central part of our lives and work.

One part of me is an idealistic dreamer, wanting to believe that courage and excellence are enough to keep the profession of art therapy alive and flourishing. I also know what Paula Howie said is true—that art therapists must actively think about licensure, certification, and achieving third-party payments, and work with health care professionals, insurance companies, and government. Despite any amount of courage and excellence, we cannot ignore these very real issues that affect the course of our development. We are a small group in comparison to related professions that are competing for health care dollars. The AATA has 4,000 members, while psychologists, social workers, and others have tens of thousands in their ranks. When considering this fact, each of us may have to make more than courage and excellence in the '90s to keep our professional lives afloat in a sea of health care providers.

But something more is needed than these practicalities—something that comes from both heart and mind if we are to survive as a profession. As Howie noted, our early educators were teaching us something more important than interpretation and technique. They were showing us that excellence, "courage, and vision" are necessary, for without these qualities we are indeed empty as individuals and as a profession. Without these qualities, there is no life, no soul, and possibly no future in our work as art therapists.

Letter to Associate Editor

Dear Dr. St. John:

You have been most generous in your comprehensive and positive review of my book, *Mommy, Daddy, Look What I'm Saying*. Thank you.

Permit me to take this opportunity to respond to some of your concerns. The least of these, "the many more examples than were illustrated" were, indeed, the result of the publisher's last minute editing. This was very disappointing to me, but the editors at M. Evans & Co. maintained that the cost would be too high with all of the illustrations included. But I agree with you—I was frustrated and it is frustrating to visualize the images. And color could not even be discussed.

The inclusion of directed artwork, in spite of my obvious encouragement toward spontaneous creativity, was in many instances pragmatic. I was fortunate in being able to obtain many artworks produced by children in a variety of settings here and abroad. In so many of these settings the artwork was often directed, supporting my premise that there is a need to encourage children to produce spontaneous artwork. And, in looking at the drawings, I agree, there is no difference whether it is directed or spontaneous.

I sincerely regret your impression that I imply the "art psychotherapist is superior and is therefore similar to the psychoanalyst." The text you quote on page 29 regarding the two schools of thought—"Art as Therapy" and "Art in Therapy"—is historical fact and appears in many texts by other art therapists discussing the field of art therapy. But on pages 30 and 31 I report how our numbers have grown, and that we, as a group, "have become more sensitive to the fact that some people benefit more from one approach than from the other, and more often mix the two approaches." I also point out that the "qualified art therapist today is able to provide the best means of artistic expression for a particular patient, regardless of which approach is recommended." The many ways and many facilities in which art therapists work are described briefly in this section.

However, while this work is intended to reflect my perspective, which is psychodynamic, and I do describe in more detail the ways in which I practice art therapy, the intent is to convey an approach that meets the needs of the individual patient, not to adhere to a particular approach. These schools of thought are different but in my view are equal parts of a whole that is art therapy.

American Art Therapy Association
Honorary Life Member Award—
Harriet Wadeson, PhD, A.T.R., HLM
Awarded at the 23rd Annual Conference of the American Art Therapy Association, Inc.,
Las Vegas, Nevada on November 7, 1992

Figure 1. Harriet Wadeson (t) at 1st AATA Conference at Airlie House.

Dr. Wadeson began her art therapy career more than 30 years ago (1961) at the National Institute for Mental Health where she was one of the first art therapists to work and conduct research with groups, couples, and families, as well as to work with such challenging individuals as those diagnosed with schizophrenia, depression, and bipolar disorders. In addition to her three major publications, Art Psychotherapy, The Dynamics of Art Psychotherapy, and Advances in Art Therapy, she has contributed five chapters on art therapy in psychology texts and five chapters in other texts. She has also published 45 articles in scientific journals and given 157 presentations at scientific meetings and universities. Dr. Wadeson developed an awareness of the field of art therapy through her national and international presentations, but most notably through her professional contact with the American Psychiatric Association. She has been the subject of national media coverage via the radio in Washington, D.C., Finland, and Australia.

Dr. Wadeson has taught art therapy at 15 colleges and universities, and created and directed two art therapy graduate programs—University of Illinois, Lindenwood-4 College and the art therapy program at the University of Illinois. In addition, she created the University of Illinois Annual Art Therapy Summer Institute. She has been an invited guest faculty at many colleges and universities, and has refereed articles for psychiatric journals and reviewed art therapy proposals for publishing houses.

Dr. Wadeson has been a member of the AATA since its inception, serving on the Executive Board for six years. She chaired the Ad Hoc Committee on Funding and the Committee on Ethics and Professional Practice. She was Publications Chair when the
Newsletter was revised and again when the Art Therapy Journal was started. She also served as Research Chair where she edited the Guide for Conducting Art Therapy Research. She served as Newsletter Editor and on the search committee for the Journal editor.

Dr. Wadeson won the AATA’s first prize for research in 1975. In addition, she has won the American Psychiatric Association Benjamin Rush Bronze Medal Award for Scientific Exhibits and the State of Illinois Resolution of Commendation for training art therapists who serve the citizens of the state. She has received 10 art awards, including first prize from the Smithsonian Institute in Washington, D.C. In addition, she has been curator for a variety of art exhibits. She has performed original poetry readings since 1983, and in 1991, she performed a poetry/karate and solo performance.

Dr. Wadeson began private practice in 1967 and continues to see clients privately to the present. Currently, she specializes in abuse and multiple personality disorders.

"The Happy Accident"

My most joyous moments in creating art are happy accidents—running paint or an unintended smudge—that change the direction of the work. My career in art therapy has that same sort of feel—meeting Hanna Kwiatkowska at the National Institutes of Health (NIH) 30 years ago and asking her what art therapy was. And when she told me, then asking, "How can I get training?" "I’ll train you," she replied, and so I began 13 years of work at NIH that afforded me many "happy accidents." The artist finds new possibilities in the work as one color bleeds randomly into another. I have been fortunate in the many opportunities that were afforded me in this way. So in thanking you for this most high honor, I feel grateful that life has provided me an abundance of creative opportunities, many of which I did not seek. It has been an exciting privilege to develop my professional career in an emerging profession. Art therapy has been a generous and challenging provider.

In reaching this important pinnacle in my career, Honorary Life Member of the American Art Therapy Association, my mind wanders back, not only to that fateful meeting with Hanna 30 years ago, but also to other images from our collective professional past. For example, when I first visited Elinor Ulman to observe her art therapy groups at D.C. General Hospital, Elinor had blonde curls! With pictures like that in my mind, I thought it would be fun to try to collect some to share with you.

Thanks to the generosity of a number of friends and colleagues whose visages you are about to view, "Art Therapy Productions" brings you "The Way We Were."*

Our first conference was in 1970 at Airlie House outside Washington, D.C. Figure 1 shows me outside. The local arrangements for the conference were made by my mentor, Hanna Kwiatkowska. I'm not sure when Figure 2 was taken of some of the early, active members of AATA. But from the hippie get-up of Ron Hayes, I suppose it was the early '70s. With him are Helen Landgarten, Bob Ault, Mickey

*The actual presentation included 30 pictures, of which five are reproduced here.
Rosen, and Mickey's husband. In 1974 Felice Cohen was president. Here she is (Figure 3) surrounded by her Board. In 1980 the Art Therapy Educators Convocation was held in a castle in New Palz, N.Y. One of the big thrusts of that meeting was the formation of a Competencies Task Force. Figure 4 is one of its meetings. Myra Levick and Shirley Riley look pretty stymied to me. Finally, in 1985, there was a "Meet the Ol' Timers" event at the New Orleans Conference. I had completely forgotten it until Aina Nucho sent me this picture (Figure 5). I had now become an "Ol' Timer."

It's natural to feel nostalgic for the old days, remembering the laughs and good times more than the fights and acrimony. I've been around a long time, and I can tell you we've had both. But we can't bring back the times captured in those old pictures. And I don't think we want to. We've come a long way since then, thanks to both the old timers we just viewed in their younger days and the many newer timers who have worked hard for our profession.

It was a different world 20 years ago. Back then, the initial reaction an art therapist was likely to get was "What's art therapy?" We tried to define ourselves, our work, and our place in the world, striving to balance ourselves with one foot in the world of art and the other in the world of therapy.

Those worlds seem more complex now, particularly in this period of economic instability and shrinking budgets. The opportunities afforded me at NIH, where I worked for 13 years with almost unlimited art materials, research support, and professional mentoring, that enabled me to publish in psychiatric journals with only a BA degree, would not be possible for a beginning art therapist today. Our creative endeavors now must be more fully conceptualized, more rigorously planned, less dependent on a benevolent fate to afford us a "happy accident" here and there.

For example, we pursue licensure for art therapists. In Illinois where I live, art therapists are looking into counselor licensing, following art therapists in other states who have already paved the way for inclusion of art therapists in the counseling license. Counseling licensure raises the question of the centrality of art in art therapy. Art therapy licensure raises questions of art therapy theory, cannons, dogma, diversity versus uniformity in training. We remain a hybrid profession, straddling as we do, art and therapy. Where do we belong? I believe we are at a crossroads. Twenty years from now when we look back will we cite licensure as a pivotal turning point in our profession's development? I think it is likely.

Our present shrinking job market challenges the art therapy profession to become essential rather than fringe—essential to the ever increasing needs within our society, of substance abusers, homeless people, battered women and children, more recently recognized needs of survivors of childhood sexual abuse, people with AIDS and their families, and on and on. So it behooves us to ask ourselves again at this time: "Who are we and whom do we want to become?"

My hope is that we look long and hard at the steps we are about to take so that as we continue to evolve as a profession, we will become the art therapists we want to be. The artist in us maximizes the "happy accident." She or he also recognizes the unwanted smudge. The nature of our special creativity
in art therapy is the art of synthesis. We work whole cloth, a human life, a community, our culture. We run amuck when we forget to be whole and split ourselves into factions, artists or therapists, licensed professionals adhering to training standards or freer healers, and so forth. We understand that a work of art is more than the sum of its parts. It is a creative synthesis of form and content, line and shape, color and texture. I hope a model of artistic synthesis can serve us as we continue to create ourselves as art therapists and to mold the shape of whom we will become. I believe that we who are so creative in our art, in our work with our clients, in our development of training, in the many accomplishments of our extraordinary professional association, will continue to maximize the possibilities for the creative growth of art therapy.

In accepting this Honorary Life Membership in AATA, I feel an overwhelming sense of gratification. There are many honors possible to attain. But to be honored by my peers touches more deeply than any other. If we’re fortunate, our parents may cherish us and our children may appreciate us, but rarely do our sisters and brothers do us honor. They see us for who we truly are, not for what they need us to be. For me, it is a deeply moving moment to be honored by you, my art therapy sisters and brothers, and it is with deep appreciation that I recognize you as my professional family, a group of people for whom I feel great admiration and affection.

Thank you for honoring me. Thank you for constituting a wonderful profession that has added immeasurably to my life. With all its ups and downs, good times and bad, AATA has felt like family. Art therapy has felt like home.
American Art Therapy Association
Distinguished Service Award—
Virginia M. Minar, MS, A.T.R.

Awarded at the 23rd Annual Conference of the American Art Therapy Association, Inc., Las Vegas, Nevada on November 7, 1992

Virginia M. Minar, MS, A.T.R., is currently an associate instructor in the Graduate Art Therapy Program at Mount Mary College, Milwaukee, Wisconsin. Her private practice is with cancer patients. Virginia retired in 1986 from the West Allis-West Milwaukee School District after 15 years as an art-exceptional education teacher/therapist. For 11 years, she was also an instructor in the undergraduate Art Therapy Program at Alverno College, Milwaukee, Wisconsin.

Virginia has held numerous positions with the Wisconsin Art Therapy Association, including 10 years on its Executive Board. Since 1978, she has served the AATA on the following committees: Finance, Art Therapy/Art Education, Appeals Study, Governmental Affairs, Nominations, Art for the Disabled, Education, and Standards, Ethics and Professional Practice; and has chaired the Registration Qualifying Board Central Division, the Honors Committee, and the Finance Committee.

Virginia has just completed three years as Treasurer of the AATA and has been elected to a two-year term as a Director of the association. She has been the Board liaison to the Membership Committee for two years and the Publications Committee for one year, and in 1993 will be the liaison to the Governmental Affairs Committee.
Remarks Upon Receiving the AATA Distinguished Service Award

I believe in magic—the magic of the creative process—the magic of the creative process as an agent of change unique to the creative therapies in general and to the art therapy profession in particular.

This is a magic moment for me. Because there are so many people in this organization who have given their time and energy to further the growth of our profession, I am deeply touched at being selected by the Honors Committee to receive this award. To know that the Board of Directors approved the selection, makes this moment more precious, for to be publicly recognized by your familiars is a rare occurrence.

I have often been asked why I have become so involved in this organization; why I have volunteered my services. It is because I believe so strongly in that mysterious, magical change in behavior that occurs when individuals can release their images and recognize their meaning. I have seen it happen for both children with developmental disabilities and adults living with cancer. In my own artwork, I am repeatedly awed by the experience of allowing the creative process to work—of finding answers to both recognized and unrecognized feelings and problems.

To those of you whom I have had the privilege of working with throughout my 17 years of membership in this organization, I thank you for your companionship on this journey toward wider recognition of our profession. To all of you who believe in the magic of the creative process, I ask you to use some of that energy and commitment in actively serving this organization. Winston Churchill, who painted to relieve the pressures of his leadership responsibilities, once said, “We make a living by what we get. We make a life by what we give.” I have given a part of my heart, my head, and my hands to art therapy; in return, it has given me many magic moments. In this magic moment, I sense the warmth of your embrace. Thank you.

Journey Toward Integration: The Use of Collages to Assess the Separation and Individuation Process of an Adult Identical Twin

Susan Neece Malone, MA, and Marcia L. Rosal, PhD, A.T.R.
University of Louisville, Louisville, KY

Abstract

In this paper, a single case study using art therapy to facilitate the separation-individuation process of an adult identical twin is presented. The client was self-referred to a university counseling center. After initial crisis intervention sessions, the problems of dependency and identity were addressed through art therapy. The uniqueness of this study rests with its innovative measurement tool, an inner circle collage which allowed the therapist to chart the client's intrapsychic move toward separation from her identical twin. The client used collages as a means of discovering differences between herself and her twin sister and to identify her own separate and unique sense of self.

Introduction

Thornton Wilder, himself a twin, described the pain of separation in The Bridge over San Luis Rey (1927). When Manuel dies, his twin brother, Esteban, cries, "I'm alone, alone, alone." For an adult exploring the issues of separation-individuation in therapy, the cries of Esteban can truly be understood. What awaits the client involved in the separation-individuation process may be one of the most painful experiences a twin will undertake, "for when self is part of another and another is part of self, self-identity is fragile and separation may bring fears of loss of self" (Siemon, 1980. p. 391).

This study is about Sally (a pseudonym), a 25-year-old identical twin, whose unresolved issues of separation and individuation from her twin sister, Sandra (a pseudonym), became the major focus of art therapy. Sally's concerns over her identity led to an examination of the literature on the issues of separation and individuation in the psychological life of twins. Thus, it is the purpose of this paper to examine the separation-individuation process in adult twins and to explore implications for treatment.

The Psychological Issues of Being a Twin

In a literature review on the separation-individuation process in same-sex twins, Terry (1975) provided psychological insight into the early development of twins. First, Terry theorized that twins never experience being the sole recipient of mother's attention. During the early months when children develop an early emotional attachment to mother, a twin develops two early attachments simultaneously: one to the mother and one to the twin. While the strong bond is developing between twins, a single child is experiencing the symbiotic phase with the mother. At the phase of differentiation, the twins are experiencing the feeling of not being alone.

Lassers and Nordan (1978) agreed that twins often substitute each other as surrogate symbiotic objects during separation from the mother. The
twins may not struggle toward individuation, but replace mother by each other. The substitution of the twin for the mother interferes with intrapsychic separation which includes differentiation, distancing, boundary formation, and disengagement from the symbiotic object. Terms used to define this close association between twins include twinning reaction, we-self, mutual interidentification, complementarity, and twin symbiosis (Terry, 1975).

Terry (1975) explored the ways that mutual dependency in twins is reinforced. First, the demanding work involved in caring for twins often calls for many modes of care. Thus, the one constant factor in the life of a twin may be the co-twin. When parents realize that each twin has a soothing effect on the other, they may frequently leave them together, depriving them of opportunities to relate to an adult. Therefore, being an identical twin offers a person a sense of security which may lead to a lack of individuation.

Mutual dependency may also develop due to imitation. One twin imitates the emotional reactions of the other, thus minimizing competition, conflict, and individuality. The more twins look alike, the harder it is for others to relate to them as individuals. Thus, Terry stressed the need for twins to be regarded as individuals. Parents need to develop an intimate relationship with each child by spending time with each child separately, thus encouraging individuality. Popular twin-rearing practices such as alike dressing, calling them twins, and praising or disciplining them as a pair should be avoided.

Siemon (1980) also saw the problems inherent in the development of identity as a twin as a substitute for identity as an individual. Siemon stated that as twins reach adolescence, the separation-individuation process becomes much more difficult than single children experiencing this at a very young age. Some responses to this later separation may be anxiety, denial, anger, and grief.

Siemon (1980) explored the issues of separation-individuation as they relate to the formation of other relationships as well. Problems with other relationships may be disturbed object relations, isolation, fear of intimacy, competition, mutuality, and psychology of the exception. In adulthood, having a child may pose a threat to self-identity. A relationship with a child may serve as a constant reminder of the kind of dependence a twin grows up with. Twins may also find it difficult to socialize because they have always relied on each other for support.

Ainslie (1985) referred to the "psychology of twinship" in presenting his theoretical framework for understanding the complications in twin identity formation and psychological development. Like Terry (1975) and Siemon (1980), Ainslie agreed that the problems in the psychology of twins are identity confusion, separation and dependency issues, and role complementarity. Through life history research of adult twins, Ainslie explored the fate of the twin relationship in both adolescence and adulthood. His research supports the hypothesis that early twin relationships continue to play an important role in the psychological life of adult twins.

**Therapeutic Interventions**

Intervention strategies for helping twins complete the separation-individuation process are reported in the literature. The need to treat twins as individuals is reinforced in an article by MacLean and Jones (1987). In work with a family with twins, MacLean and Jones helped the parents to treat the twin boys as individuals because one twin used acting out behavior as a means to assert his own identity. They suggested that therapy be focused on helping the child to express feelings in two ways: (a) to express anger at parents for not treating the child as an individual, and (b) to help the child express ideas which were different from his twin’s ideas and from the family norms. Terry (1975) also supported helping parents to treat the twins as individual children.

Siemon (1980) offered three intervention strategies for adult twins. First, information on the psychological dynamics of twinship should be provided so that twins can begin to see themselves as individuals and reduce the trauma of separation. In addition, reinforcing the positive aspects of intimacy, closeness, and security will help a twin struggle with the negative aspects of such closeness. Thus, the focus of therapy rests on "resolving the grief of separation as well as on working through the twinship by developing a better individuated self" (p. 398). Finally, twins should not be seen together in therapy as this sets up the old pattern of seeing them as one unit.

Adelman and Siemon (1986) discussed the need for therapists to help adult twins make a relational shift. Relational shift is the term used by Adelman and Siemon when a twin changes the psychological meaning of being a twin. Thus, a twin is still able to be close with the sibling, but the ability to be separate is achieved. To address this issue, the use of "I" is stressed rather than using "we" which is so com-
mon among adult twins. The use of "I" in talking about the relationship with the twin helps the client begin to discuss the relationship, share feelings about separation, and affirm affection for the other.

Knowledge of early twin development is vitally important in understanding the separation-individuation issues of adult twins (Anslie, 1985; MacLean & Jones, 1978). Certainly, understanding the unique psychological issues of being a twin was helpful in working with Sally. Also, the following intervention strategies found in the literature were incorporated into Sally's treatment plan: (a) providing information on the psychological dynamics of twinship (Siemon, 1980), (b) resolving the grief of separation (Siemon, 1980), (c) using the word "I" rather than "we" to assist in the relational shift (Adelman & Siemon, 1986), and (d) assisting the client in talking with the twin about the relationship (Adelman & Siemon, 1986).

Developmental Background. Sally described her home of origin as a "rather rigid, controlling, intellectual environment" in which there was an emphasis on thinking and doing and little importance placed on intuition and feeling. Affection was shown sparingly in the family.

At an early age, the twinship had a tremendous impact on Sally's growth and development. Although Sally's twin, Sandra, provided Sally constant attention and companionship, feelings of dependency began to form. The twins were expected to maintain and take care of themselves thus leading to distance and isolation from other family members, particularly the parents. They were often dressed in the same outfits although the colors were different. Sandra was often dressed in bold, bright colors such as red or orange while Sally was dressed in cooler shades of blue or green.

A traumatic situation regarding separation issues occurred during Sally's early adolescence when Sandra chose to move out of the bedroom they had shared since infancy. School friends told Sally that Sandra was acting strangely because she loved other girls. Sally remembered being devastated by this suspicion of her sister's homosexuality and she became the keeper of this secret. It wasn't addressed until the college years when Sandra confided in Sally that it was indeed true that she was homosexual.

Sally and Sandra chose to attend different colleges and Sally recalled the pain of separation during that period and considered the idea of transferring to Sandra's college. While Sally was dealing with the separation anxiety from her sister, she met her husband. It is possible that Sally married him to fill Sandra's role in her life. Sally reported feeling unsure about her decision to marry. She carried these doubts into her marriage and felt unfulfilled and uncertain during the first two years of the marriage. She became romantically involved with another man and admitted that her involvement was to sabotage herself, cause a crisis, and thus force herself to confront the problems in her marriage.

Treatment Prior to the Study. Twelve sessions of therapy were conducted before the research study which served to address immediate crisis-oriented concerns and to assess the client, identifying issues appropriate for longer term therapy.

The first five sessions were spent working on Sally's immediate concerns. When asked to identify her presenting problem on the personal information form, she stated she was pregnant, possibly not by her husband, and that the situation was causing her great distress. The therapist's role was a supportive.
one as Sally discussed several important decisions which needed to be made regarding her pregnancy, marriage, and extramarital relationship. It became evident that marital therapy was needed so that important joint decisions could be made about the pregnancy as well as the future of the marriage. Sally and her husband were referred to another therapist at the counseling center for this purpose.

Sally reported that both marital and individual therapy sessions helped her to make several important decisions. First, Sally asked her doctor to pinpoint the time of conception. The doctor was able to identify her husband as the father. Second, she decided to continue the pregnancy and keep the baby. Finally, she decided to end her affair and concentrate on making her marriage work. Once these decisions were made, emphasis was placed on identifying and assessing Sally’s other needs.

Assessment. Sally was given several assessments including the House-Tree-Person drawing test (HTP) (Buck, 1981) and the Kinetic Family Drawing (KFD) (Burns & Kaufman, 1972). The person portion of the HTP and the KFD indicated that Sally was dealing with fears surrounding her own sexuality and identity. Some ambivalence regarding her sexual identification was indicated when she struggled to define the gender of the first person drawing. It seemed as though Sally struggled with the person drawings in her effort to picture them alike as well as different. When asked to identify herself in the KFD, Sally pointed to two figures and replied, “these two” and made no distinction between herself and her twin. It was at this point that she seemed to understand the impact of the twinship on her life.

From information accessed through the assessment drawings, it was hypothesized that Sally was unable to view herself as a separate individual and had concerns that she may be homosexual. The assessment sessions clearly laid the groundwork for beginning the separation work which Sally needed to do in order to individuate.

Inner Circles Collage as a Measure

Throughout the assessment sessions, it became evident that Sally had an affinity for collage work. The collages she created in therapy helped her to discuss issues and identify problems and solutions. It was hypothesized that using collage to evaluate therapy outcome was appropriate for this client and, therefore, the idea for the inner circles collage was developed to assess the process of separation and individuation. The client was directed to make an inner circles collage representing both herself and her significant others. On 12” × 18” white paper, Sally drew concentric circles representing each layer of herself with the smallest circle in the center representing her most intimate core self. Then Sally drew and cut out a symbolic shape which represented each significant person in her life. The symbolic shapes were then placed on the circles representing herself according to her perception of intimacy. The symbolic shapes were not affixed to the self-circle drawing.

During each session, Sally was asked to replace the symbolic shapes on the collage so that it could be referred to during the session. The client was not aware that the collage was a measurement tool and nothing else was said to avoid biasing the project in any way. After each session, the distance between the intimate core self and the symbol representing each significant person in her life was measured. Thus, the collage provided a means for measuring the separation-individuation process. Although the client was asked to place all significant people in her life on the collage, only the symbolic shapes of her twin sister and her husband were measured for the purposes of this paper.

Collage as a means of assessing therapeutic change is unique and not well-researched in the literature. However, it seemed the best approach to use as a measure of individuation because the symbolic shapes could be easily manipulated by the client within the concentric circles format and measured by the researchers. Also, the client showed a preference for this medium in treatment, as previously mentioned.

As stated above, the main goal of therapy was to assist the client to become less enmeshed with her twin sister as well as with other family members, including her husband. Therapy would also help Sally become aware of the need to discuss being a twin with her sister. Thus, art therapy themes focused on separation and individuation issues.

Results

Sally’s movement of the shape symbols on the collage reflected the separation which was taking place (see Figure 1). When Sally completed the inner circles collage for the first time, her twin and her husband were overlapping and placed on Sally’s inner core circle (see Figure 2).

The shape symbol (which was orange) repre-
senting Sandra moved a total distance of 4.5 mm from the beginning of the study to the end, which seemed to be a major change. It took four weeks for Sandra’s symbol to begin moving and once it did begin to move, the husband’s shape symbol moved as well allowing the observer to see Sally’s inner core circle. The husband’s shape symbol (which was red) moved a total distance of 2.5 mm (see Figure 3).

The fact that Sally overlapped the shape symbols of her twin and her husband at the beginning of the study supported the concern that the husband was a replacement for Sandra during Sally’s college years. In addition, Sally used warm, bright colors (orange and red) for the shape symbols for both her twin and her husband. Sally identified Sandra with the warm, bright colors from her dress in childhood. Sally’s choice of red for her husband further supports the hypothesis that Sally’s husband was someone to replace Sandra.

Perhaps the most interesting result of the study was that as Sally became less enmeshed with her twin, she became less enmeshed with other family members as well. This can be observed by comparing Figures 2 and 3 and noting the separation and distancing of the other shape symbols.

**Treatment Overview**

During processing of the inner circles collage in the second session, fears regarding homosexuality were discussed. Sally recalled that homophobia had developed over the years since Sally’s discovery that Sandra was a homosexual. She stated that in order to deal with these fears, it was important for her to separate in order to understand her own identity. An article on twin separation and individuation (Adelman & Siermon, 1986) was given to her to read as homework.

In the following session, Sally chose to discuss the twin article and reported that she really identified with the author who was a twin. She said that she felt relieved and understood. She talked about how devastated she was at age 12 when Sandra had
chosen to be physically separate from her. Feelings of abandonment and isolation were buried within her, and she connected her need to “latch onto others” as a consequence of this past traumatic event. She constructed two collages: one answering the question, “Who is my twin?” and the other answering the question, “Who am I?” (see Figures 4 and 5) which she processed in the fourth session.

She chose to process the collage about Sandra first (Figure 4), followed by the collage about herself (Figure 5). She used a red gingerbread person to represent Sandra’s burning intensity and a green one to represent her own reserve. There was a strong division between the masculine and the feminine in the two collages. The collage about Sandra was filled with images representing the more masculine qualities of the personality. Sally was aware that she gave Sandra’s collage a car, sports items, and a sense of physical activity. In contrast, feminine qualities of the personality were represented by the images in Sally’s self-collage. In discussing the collage about herself, Sally noted the emphasis on passive, nurturing items and was aware of the opposite nature of the collages. As she placed the collages side by side, she stated that together they represented a whole; apart each collage was incomplete. Thus, the collage activity was very beneficial for Sally to identify her need to activate the more masculine side of her personality.

It was in session 5 and after the production of the self/twin collages that Sally began to move the shape symbols of both her twin and her husband away from her inner core circle (see Figure 1). The self-twin collages were referred to again in session 9. Sally commented that sad feelings caused her to feel less whole and stated that it was important for her to stay in touch with the “red” within her. Sally stated, “I’ve spent my life looking at Sandra and trying to
figure her out and now it's time for me.” She continued by saying, “We are both whole . . . we both have gifts, some alike and some different.”

During session 11, Sally initiated a discussion about the realization that she had not fully separated from Sandra. She identified the importance of talking with Sandra explicitly about their relationship. Sally also realized the importance of saying good-bye in therapy so that she could learn to say good-bye to the wounded part of the self. In addition, she acknowledged that it had never been difficult to say good-bye before because she had never allowed herself to become invested. She stated, “I can feel my feelings for the first time in my life. After Sandra burned me, I became guarded and protected. I don’t have to be any more.”

Sally’s realization that she needed to discuss her relationship with her twin was the final goal of therapy. As Adelman and Siemon (1986) stated, it is important for the twins to discuss their relationship in order for identity separation to occur.

Discussion

It was the expectation of this study that art therapy would facilitate the separation-individuation process of an adult identical twin. Art therapy touched Sally in a way that verbal therapy alone could not because of her ability to think metaphorically through the art therapy process. It was through her collages that she was able to integrate thought with feeling.

It became obvious that Sally developed a more integrated self. This was evident through the movement of shape symbols in the inner circles collage as well as through her growing ability to assert herself and to identify the more masculine side of her personality.

There is a need for more research regarding adult twin individuation-separation as illustrated by the limited literature found for this study. There are many questions left unanswered such as: (a) How do twins negotiate their relationships in later life? (b) How do relationships with significant others impact on the twin and vice versa? and (c) Is intimacy between twins critical in decisions to marry and divorce? The single case study presented here only begins to answer some of these questions. There is a need to replicate this research and to research other aspects of the use of art therapy with twins.

The collage as a tool to measure the individuation-separation process was an integral part of the study and served to support the efficacy of art therapy. The inner circles collage was adapted specifically for use with this client and was easy to administer. Although the inner circles collage was not tested for validity or reliability, it proved to be a valuable tool to measure clinical changes. The specific use of collage to measure therapeutic change in this study demonstrates that it should be investigated as an assessment tool in art therapy.

As the present study indicates, art therapy provided a unique opportunity for a twin to move toward wholeness. Through art, the therapist was able to identify that the client had not psychologically separated from her twin and continued to see herself as part of a unit. The artwork reflected the divided, yet enmeshed, personalities of both Sally and her twin. The client eventually worked toward acceptance of personality traits which she had given over to her twin. Art facilitated Sally’s journey to find the other half within herself. The use of collage as a tool for assessing therapeutic change in the separation-individuation of twins was exciting and presents possibilities for future use.

Charlottesville, VA

Abstract

The authors are approved MARI® instructors in mandala assessment and Board members of the Association of Teachers of Mandala Assessment, Inc. who have been using the MARI® Card Test developed by art therapist Joan Kellogg, MA, A.T.R., in their clinical work. After several years of testing artists and/or art therapists, the authors observed specific patterns unique to this population. Thus, the question was raised: Is there a personality profile for the artist? A research project was designed to test the authors' hypotheses about the creative personality. The MARI® Card Test was administered to an artist group (70 subjects) and a control group (70 subjects). Results yielded significant differences in card and color choices.

The MARI® Card Test, developed by art therapist Joan Kellogg in 1978, is a projective psychological instrument that is now being researched and validated in various parts of the country. The test is based on the archetypal imagery found in mandala drawings, or drawings in a circular form. According to Jung's theory, the images or archetypes found in the collective unconscious contain ancient memories of the development of human consciousness, common to all humankind (Jung, 1965). Each archetype reflects a psychological process or instinct, with the mandala representing the most powerful archetype of all, “... the ultimate unity of all archetypes” (Storr, 1983, p. 292).

Editor's note: The authors wish to express their appreciation to David Cox, B.S., for his technical knowledge and assistance in computing the data and tabulating the results.

The ritual mandala has ancient roots in Eastern religious tradition as a form of visual meditation and as a symbol of wholeness and perfection. The personal mandala, on the other hand, reflects one's psyche at any given moment, one's inner struggles, the light and the dark, many levels of consciousness, and the potential for change.

Mandala is a Hindi word derived from Sanskrit meaning “circle.” Jung considered the mandala to be an archetypal symbol representing wholeness. He said that drawn mandalas were like “cryptograms concerning the state of the self” (1965, p. 196). During his many years as a psychotherapist, numerous mandalas were described as dream images and often drawn, painted, modelled, or danced by his patients during moments of crisis or transformation. They were symbols for the process of individuation which he defined as, “the coming to self-hood or self-realization,” a drive toward psychic wholeness (1979, p. 78).

Joan Kellogg's work has deepened our understanding of the archetypal images found in many personal mandalas. She has worked with psychiatrists in clinical settings with a variety of patients. In her consultant work at the Maryland Psychiatric Research Center near Baltimore, mandala drawings were used as a monitor of change and progress during treatment. Patients would be asked to color with oil pastels a pencil outlined ten and one half inch diameter circle. Having only demographic information about the patients, Kellogg interpreted these mandalas on the basis of color, movement, and symbols.

Beginning in 1969, after reviewing hundreds of drawn mandalas at different institutions and in private practice, she began to notice recurring images, patterns, and shapes depicted in the drawings. She

Joan Kellogg 1991
organized these images into a circular design with 13 basic structures which she calls the “Archetypal Stages of the Great Round of the Mandala” (1978) (Figure 1). Out of this theoretical work she developed in 1978 the first version of the Mandala Card Test, which has since been renamed the MARI® Card Test (1991). (MARI® is the registered trademark for the Mandala Assessment Research Institute.)

The test, in its present revised version, is composed of 26 design cards, representing the 13 archetypal stages (2 versions in each stage). For research purposes, a letter of the alphabet is assigned to each card. There are 38 colored cards and one in foil. A number is assigned to each color card. The designs are embossed in black on clear plastic cards. The color cards are on paper stock. The colors in the test match the oil pastels Kellogg used in her study of the mandala drawings. All the patients’ mandalas were drawn using a standard set of Holbein oil pastels. Kellogg selected matching color stock for the test.

The client is asked to select five design cards which appeal to him/her and is then asked to select a color card for each design chosen. The color card is placed under the transparent design card. The resulting five design cards, each with an appropriate color, is ranked according to preference. Art therapist Phyllis Frame has included an additional request, the choice of a sixth card which she calls the rejected card. She has the client choose the design card which appeals to him/her the least along with a color card which best matches his/her feelings about the design card. In her clinical work, Frame also has the client select a second color card that seems to make the rejected card more acceptable.

The MARI® Card Test is a nonverbal test which assesses an individual’s present state. It tends to be situational; subsequent test choices may be influenced by time, treatment, and significant life events. From clinical observation it seems that over time, the more healthy subject will choose a variety of stages and colors. Less healthy subjects tend to be more restricted, and repetition in either designs and/or colors is common. It has been observed that some movement reflected in a change in design and color choices can be generated through therapy. A choice selected repeatedly over time warrants investigation of its significance for the client, however, and might indicate ongoing psychological and/or physiological issues and/or basic personality traits.

The MARI® Card Test gives clues as to different psychological processes at work within the individual at any given moment and assesses the person’s current state. The stages are cyclical and should not be thought of in terms of one being more significant than another. All reflect a continuing process of change and growth.

**Brief Description of the 13 Stages**

0 Clear Light: Source of all being
1 Void: Deep unconscious
3 Bliss: Passive/receptive, generative space
3 Labyrinth, Spiral: Focused movement of energy
4 Beginning: Symbiotic, narcissistic space
5 Target: Defense, boundary setting
6 Dragon Fight: Struggle, ambivalence, separation
7 Squaring the Circle: Integration, union of opposite
8 Functioning Ego: Self-identity, autonomy
9 Crystallization: Socialization, completion
10 Gates of Death: Acknowledgement of loss
11 Fragmentation: Ego disintegration
12 Transcendent Ecstasy: Change of consciousness

Advantages in using this test are ease of administering, unattended self-testing (although the process of selection is always interesting to observe and may contribute to an overall understanding of the client), use with clients unfamiliar with the English language, and with inarticulate and nonverbal clients, as well as with those who may be psychologically defended. The test is generally perceived as acceptable and nonthreatening. It has not been validated and is currently considered a research instrument. It is important to note that this is a potential projective test, developed by an art therapist, that uses both color and form whereby results can be quantified for purposes of statistical analysis.

Interpretation of the MARI® Card Test is based on Kellogg’s theory of the stages and her theory about color from the perspective of the Great Round of Mandala. Kellogg’s hypotheses about color are derived from many interdisciplinary sources and theories, including anthropology, biology, physics, and psychology. Continuing research on the MARI® Card Test will not only determine the validity of Kellogg’s theories, but will also expand the theoretical base for its use as a projective test.
Research Design

The authors decided that it might make an interesting research project to take advantage of the art therapists gathered at the 1985 AATA Conference in New Orleans and to devise a systematic study using the MARI® Card test with this population. The purpose of this research project was to determine if artists and art therapists differ as a group from the general population in their choice of symbolic stages and colors, using criteria developed by the MARI® Card Test. For purposes of simplicity, the artists and art therapists shall herefore be referred to as the artist group. It was assumed by the authors that art therapists have had training in visual art and have an understanding of the creative process.

A demographic form was devised with questions relating to age, sex, ethnic background, education, art education, current physical or emotional problems, and sexual abuse. Current feeling states were assessed by the selection of two descriptive words for each stage. Participants were asked to circle the words which seemed applicable to them at the time of completing the form. The MARI® Card Test was administered by art therapists familiar with the test and who were certified in Mandala Assessment (i.e., having taken Kellogg’s 30-hour basic MARI® Course in Mandala Assessment). Fifty percent of the testing of art therapists was done at the AATA Conference. The others were tested later in Washington, D.C., Maryland, and Virginia, and included artists who were not art therapists. Participants who elected to be part of this research were asked to take the MARI® Card Test and complete the demographic form.

The control group was given the test after the data from the artist group had been gathered. The control group consisted of a nonpsychiatric population of individuals who had no art beyond grammar school and were not actively involved in any type of creative activities. This criterion was determined from the demographic questionnaire and a personal interview.

The following hypotheses were formulated:

1. That there is a significant difference in color and stage preference between the artist and control group.
2. That the artist group more often selects the axis 6-12, with the implication that creative struggle precedes a new level of artistic inspiration.
3. That colors and stages that Kellogg has noted to be sometimes associated with somatic distress are more significantly chosen by those under a doctor’s care for physical problems.
4. That certain stages or colors are more significantly chosen by individuals who are currently seeking professional help for emotional problems.
5. That certain colors and stages are more significantly chosen by sexually abused persons.
6. That the feeling state word choices correlate significantly with the stages selected on the MARI® Card Test.

Of the 140 people who participated in this study, 119 were females and 21 were males. This is due to the fact that the majority of art therapists tested at the conference were females. The age distribution ranged from age 18 to 80, with the largest distribution in the 30-40 age range. The respective ages of the artist group and the control group were fairly equally distributed.

The SPSS-X®, a statistical program for social sciences, was used to analyze the data. After running a frequency distribution of colors and stages by both the artist group and the control group, a basic chi square level of significance interpretation was done. A null hypothesis was established. For example, the artist group shows no preference for color (i.e., colors are selected with equal frequency). This hypothesis was then tested against the research hypothesis, that is, that the artist group shows a preference for color (i.e., colors are selected with unequal frequencies). The typical research chi square level of significance of .05 or less was used. A significance level of .01 was considered to be highly significant. The Yates correction for continuity was used for all chi square levels of significance.

Results and Discussion

The completed results turned out to be highly significant, that stages and colors were selected by preference and not randomly chosen. These results, of course, are what would be expected, but research procedures indicate the necessity for establishing this basic level of significance for preference.

1. The following stage selections were significant: Stage 0 (.0045 significance), Stage 6 (.0201), and Stage 7 (.0201) were chosen by the artist group rather than the control group. Stage 9 (.0006) was chosen by the control group.

Possible explanation for stage selections:
• Selection of Stage 0 by the Artist Group—Artists by the nature of their work are often
in touch with the universal source of creativity stemming from the deep unconscious.

- **Selection of Stage 6 by the Artist Group**—
  Creative struggle is a necessary part of the artistic process. Artists often address conflicts, opposites, and dichotomies in their work in order to achieve a sense of harmony in what they do.

- **Selection of Stage 7 by the Artist Group**—
  The creative struggle is often followed by a sense of unification and integration. Fully functioning artists need to utilize both right and left hemispheres of the brain.

- **Selection of Stage 9 by the Control Group**—
  The energy of the control group may be more focused on the here and now, socialization, and their lifetime goals rather than on struggle, the unconscious, and personal growth.

**II.** The five most popular stages for both groups combined were 3, 8, 9, 11, and 12. Stage 12 was the most popular stage choice for each group. The only significant difference in color choice for these particular stages was that in Stage 12 the artist group selected aqua, turquoise, and yellow, and the control group selected azure blue and royal blue (.0269).

Possible explanations for stage and color selections:

- **Popularity of Stage 12 for Both Groups**—
  Stage 12 suggests the longing for wholeness and renewal. Both feelings are common to most people at various times in their lives.

- **Selection of Aqua, Turquoise, and Yellow for Stage 12 by the Artist Group**—
  Aqua and turquoise in Stage 12 imply energy directed toward healing and growth, while yellow in Stage 12 brings consciousness into the renewal process.

- **Selection of Azure Blue and Royal Blue for Stage 12 by the Control Group**—
  Blues on Stage 12 speak to trust in the process, use of intuition, and support for change.

**III.** The following color choices of the two groups compared to one another were found to be significant:

1. **Azalea.** A very hot pink, was highly significant in that it was more frequently chosen by the control group (.0062).
2. **Chartreuse** was found to be significant in that it was more frequently chosen by the control group (.0198).

3. **Turquoise was found to be significantly chosen by the artist group (.0150).**

In other words, a significant relationship existed between the selection of these colors and whether or not a person was an artist or a member of the control group.

Possible explanations for color selections:

- **Selection of Azalea by the Control Group**—
  Azalea is a color which reflects high energy and anxiety. Its significant selection by the control group suggests a higher level of anxiety for this group than for the artists who have more chance to express these feelings through their art.

- **Selection of Chartreuse by the Control Group**—
  The choice of this color is mainly significant due to the fact that fewer artists (2) chose it than did the control group (11). Chartreuse is a color that sometimes represents burnout. This could mean that fewer artists feel burned out on their jobs than the nonartist. Although these numbers are small, it is an interesting difference to note.

- **Selection of Turquoise by the Artist Group**—
  As stated previously, turquoise is a healing color. It is often used by people who have experienced early wounding. Perhaps artists engage in creative endeavors to help heal themselves.

**IV.** The axis choice which was found to be the most significant for the artist group is axis 6–12 (.0273). The axis choice most significant for the control group is axis 2–8 (.0484).

Possible explanations for stage selections:

- **Selection of Stages 6–12 for the Artist Group**—It was previously theorized by Kellogg that the artist's axis would be stages 3–9. Stage 6, struggle, versus Stage 12, transcendence, may reflect the creative process for many artists. Rollo May so aptly describes this inner process: "A dynamic struggle goes on within (an artist) between what he or she consciously thinks on the one hand and, on the other, some insight, some perspective that is struggling to be born" (1975, pp. 62–63). "...the struggle with limits is actually the source of creative productions... Creativity arises out of the tension between spontaneity and limitations" (May, 1975, p. 137). Suzanne Langer also speaks of this tension: "A work of art is a composition of tensions and resolutions, balance and unbal-
ance, rhythmic coherence, a precarious yet continuous unity” (1957, p. 8).

- Selection of stages 2–8 for the Control Group—This was an unexpected finding. This axis choice speaks to the control group’s need for a sense of self-identity which may be attained through career (Stage 8, functioning ego) along with the need to let go, relax, and escape the demands of everyday pressure (Stage 2, bliss).

V. In a cross-tabulation of color choice and people who indicated they were under emotional or physical care by a physician, it was found that people under care significantly chose peach (.0373), but significantly avoided dark rose (.0426). Another significant finding was that people under care did not tend to choose Stage 3 (.0151).

It is interesting to note that 15 out of 70 in the control group indicated they had problems (3 emotional and 12 physical). There were a total of 24 artists out of 70 who indicated they had problems (16 emotional and 8 physical). There was no significant difference between the stages or colors chosen for emotional versus physical problems.

Possible explanations for color selections:

- Selection of Peach and Avoidance of Dark Rose by People Under Emotional and Physical Care—This population selected peach, a body color, raising issues around the body/feeling state as being important. This choice implies a sense of vulnerability and/or a need for positive touch or a positive body/feeling state. The avoidance of dark rose, a color suggesting wounding on an emotional or physical level, may be an unconscious avoidance reaction to these negative states. Both of these colors are sometimes considered somatic indicators in Kellogg’s hypotheses on color.

- Avoidance of Stage 3 by People Under Physical and Emotional Care—This population may be unwilling to move into the unknown because of a high level of anxiety and fear related to their problems. They already are in a state of uncertainty and Stage 3 would make this state even more intense.

VI. With the sexual abuse question, the hypothesis was that the abused and the nonabused would differ in their preference for stages and colors. Out of the 70 control group members,

only 7 people indicated that they were sexually abused. However, of the 70 artists, 22 people indicated sexual abuse. When abuse by color and stage for the artist group only was cross-tabulated, the results showed that those who had been sexually abused did not choose Stage 7 (.0310). Another finding was that those who were abused significantly chose magenta (.0284).

Possible explanations for stage and color selections:

- Avoidance of Stage 7 by Sexually Abused People—Those who had been abused did not select Stage 7, the stage of unifying opposites, the masculine and the feminine. This stage correlates with Freud’s genital phase. A person who has experienced sexual abuse would not necessarily be attracted to a stage reflecting sexual issues.

- Selection of Magenta by Sexually Abused People—This color relates to anxiety and inflammation and perhaps a call for help. It also may reflect a positive desire for self-assertion, all of which relate to abuse.

VII. There was no correlation between feeling words and stages. This may be due to reaction-formation or the fact that many people are not consciously aware of how they are feeling. Also, the forms and colors of this test tend to elicit unconscious material which may be preverbal and not linked at all to actual words.

Conclusion

Artists seem to have a propensity for dealing with conflict and unresolved issues and tend to go inward for inspiration and healing in their process of integrating dichotomous aspects of their creative struggle. Healing self and/or others seems to be a motivating force for artists/art therapists.

People who are not engaged in creative pursuits seem to be more involved with their roles in society and family, accept outward circumstances with a certain amount of trust and sense of support, and seem to be less apt to address inner struggle and conflict. The anxiety level of these people seems higher than artists, perhaps because they have no usual means of discharging inner tensions as artists do through their artistic process.

More of the artists acknowledged emotional problems which may reflect a higher level of psycho-
logical wounding. The choice to create may relate to their need for self-expression and healing. The non-artists acknowledged a higher percentage of physical problems and very few emotional problems. One might question whether these people may somatize emotional problems as they have fewer outlets for creative self-healing. People who are under emotional or physical care seem to feel vulnerable and are trying to repress their anxiety about their condition. They seem to want body contact, physical reassurance, and support in a safe context from their caretakers.

Artists reported more frequent incidence of sexual abuse than the nonartists, which raises questions about the validity of the control group's response since recent statistics reveal that approximately one out of three women have been molested by the age of 18 (Russell, 1988, p. 25). People who have been sexually abused tend to avoid intimate relationships or to seek a sense of power or control within a relationship in order to allay their anxiety.

The results of this study support the assumption that the person who actively creates functions differently from the person who does not. Artists have long known of their uniqueness and their differences from the norm. One of the hopes of this study is that these unique traits of the artist can be elucidated and understood more fully.

This study focused on the visual artist only. Future studies are recommended to test other kinds of artists, such as musicians, poets, and dancers, to see if they fulfill the criteria established by this study for the profile of the artist or if there are other profiles for different types of creative artists. Further research is also warranted to see if there are differences between visual artists who are art therapists and visual artists who are not art therapists. The MARI® Card Test appears to be an excellent tool for these types of study, since it tests for many levels of functioning, both conscious and unconscious.

Making the Unknown Visible: Panel Rounds at Franklin County Medical Center East Spoke Psychiatric Unit, Greenfield, MA, March 17, 1992

Panelists:
George S. Patrick, MD, Medical Director, Mental Health Services, Franklin Medical Center; James R. Shortell, PhD, Chief Clinical Psychologist, Franklin Medical Center; Nicholas Fleisher, MSW, LICSW, Social Work and Group Program Manager, Franklin Medical Center; Victoria J. Wilk, RN, MS, Program Manager, Inpatient Mental Health Services, Franklin Medical Center; Gwen Brown, BFA, MA, Candidate in Art Therapy, Recreation Therapist, Franklin Medical Center; Elizabeth Zemelka, BA, Art Therapy Intern, Franklin County Medical Center.

Introduction
by Victoria J. Wilk

Mental health, like other medical treatment modalities, is struggling with a mandate to provide good care in the shortest time possible. The unit manager is charged with bringing the talents of her team to prevail on the ubiquitous nature of mental illness in as rapid and cohesive a fashion as possible.

Our 20-bed psychiatric unit is housed within a general hospital in a predominantly rural setting. As a generic psychiatric unit, it admits patients ages 14 to the elderly, with no upper age limit or limitation due to physical illness.

Art therapy has been part of the treatment modalities since Summer 1991. During that period the artwork of one psychotic patient was particularly powerful and allowed the team to interact with him when there seemed to be little hope for his progress. This confirmed the multidisciplinary team's belief in the usefulness of artwork in this setting. It culminated in this collaborative presentation.

An Introduction to Art Therapy
by Gwen Brown

The connection between art and healing has existed throughout history. Shamans from many cultures have used carved figures in their healing rituals. Native American Navajo shamans heal with sand paintings. In Tibet, a tanka or scroll painting might be given to a patient as a prescription for meditation.

In Western Europe, an interest in the art of psychiatric patients began in the 1800s when Hans
Prinzhorn, a German psychiatrist and art historian, collected many works by patients. At about the same time, Freud was studying dreams and Jung was exploring archetypal symbolism. Both generated interest in the imagery of the unconscious. Children's art was given serious attention for the first time during the 1880s, resulting in the identification of developmental stages in children's art.

Art therapy as a distinct practice was born during the 1940s. Margaret Naumburg and Edith Kramer applied psychoanalytic theory to their work in art education and therapy with children. Naumburg used art in addition to verbal therapy, while Kramer viewed the process of artmaking as therapy. The field of art therapy expanded in these two directions and now is approached from many philosophical perspectives and used with individuals and groups in a wide variety of settings.

We are familiar with the powerful way art can communicate feelings. Artists themselves have been both admired and ostracized. I believe people react strongly to artists because art taps the unconscious of the artist, who communicates with the viewer on many levels through his/her artwork. This both intrigues and scares us. When we encounter a non-representational painting or sculpture we may think, "I don't understand this." What we feel is different. There is a level of recognition that is difficult to describe with words; it is an emotional, even visceral response. John Berger wrote, "Seeing comes before words. The child looks and recognizes before it can speak" (1972, p. 7).

Art's ability to tap the unconscious can be useful in diagnosis. For example, the Ulman Assessment (Ulman, 1975), designed for use in art therapy, is a series of four drawings that provide the therapist with visual information about a patient or client. As a series, the drawings provide a wealth of information about a client's use of materials and time. The therapist can observe attitudes, behavior, verbalization, and body language or movement while the client is drawing. The formal elements of the drawings (line, shape, color, composition, for example) and the content reveal much about the individual's feelings, self-perception, wishes, weaknesses, and strengths. The art therapist can use this information during sessions and share it with other members of the treatment team.

During individual art therapy, the patient engages in direct interaction with art materials. He or she learns that choices are plentiful and decisions have direct results. One can also learn from mistakes, start over, try again, and witness concrete evidence of internal changes by reviewing the artwork. In artmaking we are confronted with the same challenges we find in our lives. Similarly, we persist at improvement until we are satisfied. In these ways art therapy can be practice for life. If a patient uses the work for self-reflection, further insight can be achieved. Art products provide a tangible record of the patient's progress or regression.

Group therapy is the most common mode of treatment in inpatient settings. In group art therapy, clients find nonverbal as well as verbal ways to communicate, and participate simultaneously, at their own levels. Art can be enjoyable, leading to an experience in positive sharing. Verbal discussion of art products provides an opportunity for self-reflection and feedback from others. The art can also be used to explore group dynamics. For example, we might discuss which roles people played in the creation of a mural, and what it was like for them to be in those roles.

The art therapist's role is that of a guide through both the artmaking and the verbal processing of the artwork. The art therapist also interprets visual language for members of the treatment team.

**The Patient: Donald**

by Nicholas Fleisher

The patient is a 42-year-old man whom I will call Donald. We chose Donald because his art was especially useful to our understanding of him. Painting, drawing, and sculpture were important outlets for Donald; and they were also important to our continued ability to interact with him, especially during a period when he was extremely paranoid and psychotic.

For most of his hospitalization, Donald was an enigma to staff because he refused to talk. He is a large, stocky man, with long, disheveled hair. On the unit he was predominantly quiet and reclusive. Typically, I would find him alone in his room, staring into space. Sometimes his roommate was present, but they did not talk. Despite Donald's silence, he attended therapy groups and activities where he listened, but would not participate. His standard response was "No comment."

My initial information on Donald was sketchy and came from an intake report. It described an incident that Donald said he did not remember. It reads:

Donald is a 42-year-old married, white male, who was brought to the Emergency Room last eve-
ning by local police department after he was found to be randomly discharging his rifle in the air at trees in the context of rather rambling and incoherent speech while he was hunting yesterday afternoon in the woods near his house (sic).

Donald described the incident as "being taken completely by surprise," that for reasons that are unclear to him, he began shooting wildly thinking he must protect someone else, someone (whose) identity he could not recall. He said that at the time, he had rather racing thoughts thinking that perhaps he was back in Vietnam, that other people might be shooting at him, or that he was hearing helicopters. He was not aware of any similar incidents. He says that he was able to "look at himself" with some small part of himself not involved in the action and "wonder what this was all about." He denied any other participants. He used one tablet of Ibuprofen for left calf discomfort the morning of the incident. He denied any drug or alcohol use. He denied any other physical symptoms.

Donald had no history of hospitalizations or of psychiatric treatment. His mother suffered from periodic bouts of depression and had been hospitalized several times in the past. No other family members were known to have psychiatric problems.

Donald's wife of 12 years contributed additional background information. Donald was the second of three brothers. He lived with his parents until he married at about age 30. The couple have no children. After graduation from high school he immediately entered the service. His duty in Vietnam did not directly involve him in combat and was not thought by his family to be traumatic. After completing his military duty, he became a taxidermist through a mail-order course and practiced taxidermy for several years. Becoming tired of this for reasons he could not explain, he moved on to a series of maintenance jobs where he has a successful employment record.

Donald continues to be close to his brothers and parents, but apparently has not sustained any friendships on his own. He is described as always having been awkward socially, preferring solitary activities such as hunting. He and his wife work different shifts, allowing for considerable time apart.

You can imagine some of the questions we had because Donald did not remember clearly and spoke minimally. I wondered about the possibilities. Was he having a reaction related to his experiences in Vietnam? Was this a new manifestation of an affective illness like his mother's depression? Had he sustained a head injury or ingested a toxic substance? I especially wondered about the presence of a crisis in his marriage or his family, given his exceptionally isolated lifestyle.

My initial goal was to find something safe for Donald and me to talk about, but this was not to happen easily. We were able to have brief discussions with superficial friendliness, but when I asked anything about his hospitalization, he would quickly end the meeting. I did learn a few things from these talks.

He said that he liked "STAR TREK" and that being on the unit was a bit like being in a STAR TREK movie. He also said that he felt as though he were in outer space without a space suit. Then I thought we were starting to make progress. These were images worth pursuing, but he would go no further. In one session he appeared more relaxed and gave me an even clearer statement of his fear. He asked me, "How do you do all of this?" and added, "One person couldn't be in charge of it all!" Finally I began to understand the extent of his fear and isolation. His world had become a totalitarian state where virtually everybody was included except himself. This helped me understand why, several days later, he began refusing visits from his parents. It also clarified why, when his wife visited, he returned his wedding ring and sent her away. I also understood why he began refusing medication that he had previously taken through the encouragement of his family.

Not knowing Donald raised my anxiety as I tried to work with him. He was there for all of my projected fears and confusion. I wondered what he was thinking, and how much to ask of him. Was he angry with me? I found myself wondering if he could be violent. The incident which resulted in his hospital admission was an ambiguous one, and I still didn't know why he had been shooting his gun.

Two factors at that time were particularly helpful in containing my own anxiety. The little information he had given me suggested he wanted some contact, although not too much. The other factor which helped us was his artwork.

Donald's art reflected enormous depth and sensitivity, as well as inborn talent. These positive qualities helped to balance my fears. The art was so different from my apprehensions that it challenged anything that I might have been thinking about this man. At the time, it was this kind of information that told me to suspend any conclusions I might have.

While I was doing a fine job of managing my own anxiety, Donald was not improving. In fact, he appeared to be getting increasingly more hopeless. When I tried to talk with him about planning, he
toliri me that he did not expect ever to leave the unit. He was having more difficulty meeting with me and said that for him, things (sic) were worse. At a staff meeting, we decided to press the issue of medication even harder with greater insistence. Dr. Patrick and I had a particularly unpleasant meeting with Donald. We threatened to force medication with a court order if he refused to comply voluntarily. We explained our reasons to him. Donald showed no reaction or willingness to compromise at this meeting and appeared to be farther away than ever. To my surprise, several hours later, he approached the nursing staff and began a trial of Haldol.

The medication was significantly helpful. After several days, I could see Donald’s mood changing very gradually. He did not talk much, but he no longer appeared to carry the weight of the world. He began to discuss the possibility of going home and even returning to his job.

I have had the opportunity to see Donald several times since he left the hospital, resumed his life at home, and returned to work. I have come to know Donald in a different way. I now know him as an extremely open and talkative person with a dry sense of humor. I also perceive him as a person who is acutely sensitive and aware of other people—so much so, that he is sometimes too vulnerable. He deliberately keeps to himself much of the time because he worries about being hurt. I now realize he is a person who cares very much about relationships.

Donald has been able to tell me about his hospitalization. His descriptions have been remarkable, although not surprising. His experience, he reports, was a darkness that is beyond description. The hospital unit often felt like a concentration camp with the nurses, Dr. Patrick, and me as Nazi collaborators. This image helps me understand why he thought he would never leave. My office was a place of enormous power; he says I was more powerful than I could ever know. He does not still see me this way, but he gasps when he describes the memories.

I was relieved to hear Donald describe the positive aspects of his experience as equally powerful. He knew there was a complete division between his inner experience and external reality. He would hear us talk to him, but our words made no sense, adding to his confusion and fear.

When Donald began to recover, his inner and outer experiences began to integrate. He felt relief as people started to make sense again. The initial experience of integration was fragile. He described objects and events as interconnected in the same magical way as before, but at this point, with positive intentions. The unit took on qualities of perfection, with staff and patients conspiring to be helpful. While not yet normal, this was a period of rapid progress. After discharge, Donald initially continued this idealization and felt strongly that everyone should have at least one experience on an inpatient mental health unit.

More recently, Donald has returned to work. He paints as a hobby and spends leisure time with his family. His idealization of the unit is diminishing as is his fear of recurrence of a psychotic episode. An important aspect of his progress is that he no longer dwells on his hospital experience. Now his thoughts are focused on the present and his daily activities and responsibilities. He is more grounded and personally more enjoyable. He remains a very intense person who enjoys and usually prefers solitude to a more sociable existence.

Art as Therapy with Donald
by Elizabeth Zemelka

We all have ideas about what art is. My definition is instrumental in how I understand people as well as myself.

Seeing is more than a way of identifying—it is a very real way of feeling and knowing. It is about light and space and a dialogue with materials or matter. It is a way of comprehending and showing me to myself and to others. Artmaking makes me visible. Moreover, it is very difficult for me to talk about my own work, so I understood what Donald meant when he said to me “it’s all in the picture.” He was not facile with words, but he left a wealth of information about himself in a large collection of drawings and several sculptures and paintings. Out of 65 works, there are 56 drawings, 6 sculptures, and 3 paintings. Only six pieces are not concerned with landscape or animal life. Of these six works, three are very sparsely detailed interior scenes. Pencil drawing was Donald’s preferred medium, and he favored depicting outdoor space.

Space Track

His first drawing shows outer space at a traveling star ship. He calls this drawing “space track—the last fronteer” (sic).

The first image is significant. I wondered if Donald conceived of himself as a frontiersman pushing the borders of space. I thought about the theme of wilderness and what it might mean for him in the
context of his art. Space is explored in several subsequent pieces.

**Butterfly**

Distance shrinks dramatically, almost reversing itself in touching closeness to this butterfly, with its wings made of glitter and its antennae made of wire. This was Donald’s second drawing.

**Cabin in Landscape**

Then space reappears but it is the familiar space of a landscape. As Donald explored the effects of paint and pastels, he made many drawings of a solitary house in the country.

When I first looked at this painting I did not see the house, with its front porch facing the sunset. The house, which actually looks like a cabin, is private and camouflaged by the foliage and the mountains. It is separated completely from the viewer by a body of water, and the viewer is prevented from entering the scene.

The house image underwent several transformations over several drawings. In one pastel, stairs began to appear, suggesting access. In another drawing, when he used red paper, the whole picture seemed to warm up. The house was big and looked more like a lodge. This particular work was one of Donald’s more dramatic uses of color. His work often reflected low light. By that I mean pigment value and saturation were kept to a minimum.

The house at sunset appeared to be a cabin—or was it a shed? Who is outside looking at these houses? What is this outsider feeling? Who is inside?

One of the objectives of art therapy is to give the patient the opportunity to bring some words to the picture as a final *product*: Is it successful? And to the *product*: How was it made? This goal was not realized because Donald made many of his drawings privately in his room. When he handed me a stack of 30 drawings, not only was he unable or unwilling to say much about the work beyond the titles, but he was also unable to recall the order in which they were made. He had difficulty distinguishing between the drawings he copied from magazine pictures and his own original work. I was taken aback by this because, as an artist, I am keenly aware of what is my own work and what is not. He leaves us guessing.

In addition to landscape drawing, another striking aspect of Donald’s work are his many animals. He often used them to “tell stories” or portray “heartfelt” feelings.

**Yellow-eyed Wolf**

For example, while this wolf pays close attention to us, by looking and listening, another wolf calls out in the distance (bottom right hand corner of the drawing). This call was magnified and amplified in further drawings by using a similar body position in other drawings to convey loss and confusion.

**Dog**

A variety of animals appeared in his work, from tigers and lions to chipmunks, mice, buffalo, deer, and dogs. Donald’s clay sculpture received the most applause and his sudden eminence spurred him on. He was inventive though not concerned with permanence, using chalk over clay on this deer’s head to achieve the suede-like texture of its coat. He used hair for the whiskers and beads for the eyes, as though he were constructing a model.

This dog has distinct visual focus appearing to look up at Donald, while he gave the dog palpable form. Donald often said that if he could not see the form in his mind, he could not make it. His visual and tactile memory is remarkable.

**Not Caged**

Donald presented an affinity for the outdoors and animals. If this is true, then how does this next drawing make sense? He titled this picture “not caged” showing the buzzing life of beaver, moose, chipmunks, squirrels, and birds. We see debris in the foreground: beer cans and cigarette stubs.

The dichotomy of freedom and control is pre-
sented in this drawing. Is this dichotomy a part of his belief structure, or is it a statement about his being on the unit? Even if this is Donald’s sardonic sense of humor about the carelessness and disrespect of humanity, what could inform me that this picture did not include Donald as part of humanity? It is unmistakable that Donald was suffering loss of control, craving freedom, and angry about being caged.

What about Donald’s control? When we look at the art that he made on the unit we see his distinct preference for pencil drawing. Pencil drawing allows for the highest degree of cognitive and motor control, in comparison to other media, like paint: the more fluid it is, the more it can have a mind of its own. Paint is more difficult to control. In each case the dialogue with material is very different.

Christmas

Fear, anger, and sadness often dance together. Donald expressed sadness on Christmas Day when he chose not to see anyone, or be seen by anyone.

Taxidermist

A similar self-image appears in “Two Taxidermists Chining” (sic).

As his discharge date approached, his fears of being retained intensified. After all, he thought he was in a concentration camp.

Donald with His Psychiatrist and Social Worker

In these last two drawings, each on the reverse side of the other, Donald expressed concern. On one side of the paper he stands between a quick exit...
MAKING THE UNKNOWN VISIBLE

doctor at the left and his psychiatrist and social worker on the right. The psychiatrist is smiling, his head is beaming, and his hands are in his pockets. Donald is frowning and pointing to himself. I wonder what the psychiatrist has just said to Donald?

**Police**

We flip the paper over and see the police riding toward us. Who is speeding off into the distance in the opposite direction? Has Donald made a quick exit?

**Art as a Catalyst in Group Therapy**

by James R. Shortell

As the clinical psychologist, one of my duties is to conduct group therapy three times a week on the Inpatient Unit. Although this does not relate directly to art therapy or a patient’s artwork, a particular group session in which Donald was a participant came to mind.

This group consisted of five patients, of which only one was particularly verbal. The group included a 75-year-old, significantly depressed man who was quite withdrawn and relatively nonverbal; a 65-year-old woman, who, likewise, would generally sit and remain almost uncommunicative; a recently reconstituted psychotic woman who was very concrete; and a 45-year-old woman who had been suicidal at the time of admission, but who was now quite verbal. She was the one person in the group who would volunteer spontaneous conversation.

A major goal for one session was to initiate conversation in which each of the members could participate. This was a formidable task, since most members were relatively withdrawn.

The session began by my focusing on the patients’ plans after discharge, particularly on activities they might pursue to maintain any positive momentum generated in the hospital. Donald volunteered that he had enjoyed artwork. Group members who recently had observed his sculpture and some drawings responded with a good deal of praise, and Donald appeared pleased to hear others compliment him on his artwork, enabling him to feel a valued member of the group.

The discussion turned to other areas of interest. The depressed gentleman mentioned that until recently he had gone dancing with a female partner. He missed this activity. Other members of the group asked him where he used to dance. A good deal of discussion ensued concerning which big bands had appeared and whether group members had been involved. The 65-year-old woman began to brighten up a good deal, and with a sparkle in her eye, confided that she used to be much slimmer than she is now, had been quite a good dancer and had won some prizes. The discussion soon included everyone who shared previous experiences involved with music and dancing. The tone was quite positive with everyone feeling included.

When the ability for insight in such groups is limited, a worthwhile goal is simply to enable group members to feel included and valued. This goal was clearly met. A valuable stepping-stone to our discussion had been the mention of Donald’s artwork and the enthusiastic response of group members.

Donald remained relatively nonverbal, although he did make comments at times. It was clear that his artwork had been a means for him to communicate his feelings to others. His art enabled me to become
an active participant during this session. The group was able to reexperience past positive feelings, thereby countering their current emotional distress.

Donald, Art, and the Inpatient Unit by George S. Patrick

As I was thinking about how to talk about the artwork and its effects on the unit, particularly in relation to our patient Donald, my wife’s description of our daughter Jenny, when she was about 14 months old, kept coming to mind. She described sitting in her dark room. Suddenly, Jenny became excited, pointed to the moon, and said over and over in her beginning-to-talk way, “FOON in the sky! FOON in the sky!” Jenny seemed to want to leap from Josie’s lap and touch the moon.

How does this story make sense in relation to the artwork, the inpatient unit, and Donald? The inpatient unit is a powerful place, particularly if you are locked in with patients and staff. Implicit in the patient’s need for hospitalization is his or her inability to handle strong feelings: hate, envy, rage, lust, love, and the potential consequences of these feelings: murder, self-mutilation, suicide, psychosis, for example. The trained staff often know something of the terribleness of the feelings, but, in contrast to the patients, are able to be ordinarily defended against these feelings.

Most of our patients employ rather extra-ordinary defenses such as splitting, denial, projection, and projective identification. These defenses are about “disowning” feelings and leave their mark. As George Vaillant says: “You know when you are near someone with a character disorder; it is like being on an elevator with a person smoking a cigar. You can’t disregard the effect” (1977).

Psychosis is worse. One way of conceptualizing psychosis is that the person has no defenses, and has nothing to cushion any sensation from the environment, including intrapsychic events. The fear that this unmediated contact with reality provides must be awesome. Nick’s evocative description of Donald conveys this. It is what Donald means when he says, “East Spoke is a powerful place.” Anyone experiencing psychosis can be a potent transmitter of fear, perhaps terror. It is similar to being near a tuning fork: You see no motion, but the resonance can be searing. In my imagination, the fear is secondary to experiencing complete abandonment, or, as I heard one patient describe it, feeling “terminally lost.” A corollary to this lost feeling is feeling small. In psychosis, a person faces the threat of annihilation.

I did not really want to be around Donald. Around him, I had the sense that I could be siphoned off into some remote part of the universe, or, he could be a Star Trek alien, trying to squash me. I wanted to go to the cafeteria, but, there, I could not eat. I wondered, “What are we going to do with him anyway? Maybe he’s always been crazy. After all, this is a short-term unit. His wife could take care of him at home.” When it came to Donald, I was irritable.

Then, his artwork started coming. One morning, on the table in the room where Bounds are held, I saw Donald’s sculpture of the deer’s head. I was looking at a delicate, vulnerable doe. I became very excited; I had to touch it. I wanted the security of contact, of possibly obtaining some of this beauty and softness for myself. At this point, I knew that we could treat Donald and the limit to which I was willing to go to provide treatment.

For several months before Jenny had found the moon, Josie and I had read the children’s book, Goodnight Moon, over and over to her at bedtime. This book has a small child in bed saying good night to all the objects in the room before the lights are turned out. “Goodnight, mittens, Goodnight, room.” Then, when the lights are turned off, “Goodnight Moon.” Donald had been working with us for several weeks before we found him.

What is common to both stories that allowed Jenny to be less afraid of night, and us to be less afraid of Donald? D. W. Winnicott’s description of psychotherapy contributes to our understanding.

Psychotherapy takes place in the overlap of two areas of playing: that of the patient, and that of the therapist. Psychotherapy has to do with two people playing together. The corollary of this is that where playing is not possible, then the work done by the therapist is directed towards bringing the patient from a state of not being able to play, into a state of being able to play (1982, p. 44).

Before Winnicott could formulate this idea about play he developed his concept of the transitional object. He describes this object as one that allows an infant to mediate the absence of mother. It is an object that gives the illusion of mother in mother’s absence. It usually embodies some of mother’s qualities, being soft and cuddly, like a piece of blanket, and can withstand all the love and hate of which the infant is capable. The illusion is created by the infant’s simultaneous experience that the ob-
ject is me, under my omnipotent control. It is also not me. The object is real, and also not real.

On the way to separation from mother, the infant must sustain a paradox concerning this object; no decision is made about the real absence of mother, or about the real identity of the object. This "thing" can not be only part of a blanket or a stuffed animal; it must also be partly mother. Winnicott extends this concept to assume that the task of reality acceptance is never completed, and that none of us is free from the strain of relating inner and outer reality. Release from this strain is provided by an intermediate area of experience.

Playing, then, is the activity that creates this intermediate area. Beyond infancy, when we can stand literal separation from significant others, we are constantly playing. Particular transitional objects, like art or other cultural products, are the result of playing. Since trying to come to terms with reality is universal, Winnicott is saying that the patient and therapist obtain security when they find the familiar in each other's playing. Jenny found increased security by finding the moon. We found the security to treat Donald by finding him through his art.

In my experience on the inpatient unit, patients experience safety and begin to feel secure when they can relate to and be included by other patients and staff. The phrase, "providing space for feelings," sounds like a cliche, but I think that is just what we provide. We provide a transitional or intermediate space through all of our activities on the unit: nursing contacts, psychotherapy, groups, and creating art. The transitional phenomena act as buffers to make the love and hate more palatable to everyone.

The evidence that playing leads to group relationships is all around us. Murals were created by groups of patients. These murals have changed the unit. Initially, the walls were insipid and blank, and I felt like a laboratory specimen about to be dissected. Now I actually feel warmer and included in the space. Similarly, this presentation is an example of our team's group process and how we work together on the unit.

Art Therapy in Mexico: Five Perspectives

Phoebe Dufrene, PhD, A.T.R., West Lafayette, IN

Introduction

A Fulbright grant enabled me to conduct research in Mexico, investigating art therapy/art education for special populations. In May 1992, I served as Visiting Professor/Researcher at the Universidad Autonoma de Nuevo Leon in Monterrey, Mexico. My responsibilities involved teaching seminars on art therapy and art education to the faculty and administrative staff and assessing the use of art therapy in various sectors of the state of Nuevo Leon. Later that summer, I assessed the use of art therapy in other Mexican cities and states by visiting and talking with professionals who use therapeutic art.

Cross-cultural studies such as this are analyzed and interpreted from the perspective of the investigator. Definitions of disciplines such as art therapy and the credentialing of the art therapist are compared to those used in the United States or Europe. This paper does not do that. Instead, it presents, through interviews, the Mexican perspective on art therapy, without interpretation or analysis.

These interviews offer the reader a brief view of how five very different professionals adapt therapeutic art to their cultural environment. The interviews were conducted in Spanish and English depending on our mutual comfort level in speaking and understanding. Responses are translated to the best of my ability and without any editing of the content.

Lic. Saskia Juarez Green, Professor of Fine Arts

I had previously met Lic. Saskia Juarez Green, Professor of Fine Arts at the Universidad Autonoma de Nuevo Leon, in Monterrey, Mexico, when I was a presenter at the University’s Biennial Symposium. She was now enrolled in my post-graduate seminar at the University.

Recently, Lic. Green was involved in therapeutic art education through a collaboration with the Monterrey Special Education Department and the Department of Visual Arts at the Universidad Autonoma de Nuevo Leon. Special education teachers enrolled in her one-week experimental art program, including those who worked with her and the Fine Arts staff. Several special education teachers were physically disabled. In Mexico, handicapped students are encouraged to major in special education so they can be role models for children with similar problems. One teacher, who had one arm, was experiencing her first painting session.

P.D.: What types of students were involved in this program?
S.G.: The group consisted of the emotionally disturbed, physically handicapped, and mentally retarded (Down Syndrome). In Mexico all types of disabilities are mixed together in special education. Children with various disabilities got along well and shared materials cooperatively.

P.D.: What ages were the students?
S.G.: Seven to 15 years old.

P.D.: What art activities did you explore?
S.G.: One of the main activities was mixing the primary colors and black and white to make secondary colors, tints, and shades. The favorite color they made was “color café,” a tan or light brown. The emotionally disturbed worked with paints brilliantly and the Downe’s (sic) Syndrome children liked to work on tactile projects. The group was also involved in sculpture and pantomime.

P.D.: Are there plans for this experimental art program to continue?
S.G.: It all depends on funding possibilities and local politics.

Video is one of the main sources of documentation of children’s art programs. The video of this pro-
ART THERAPY IN MEXICO

gram highlighted students emerging from the school bus, their awe at the university surroundings, and various instructors assisting physically handicapped children in the classroom. Exposure to art and exploration of media were emphasized, rather than assessment of individual work. Therefore, no slides or direct examples of student work were shown.

When asked about her other experiences with special education students, Lic. Green stated:

A few years ago I worked in a mural program as part of an urban project for youths with psychological, social, and delinquency problems. As the art coordinator I helped the participants select mural themes, many dealing with social problems. One of our most popular themes was "Pollution." Because of the pollution theme and its health hazards, this unit had the assistance of university biology professors as well as social workers.

Lic. Green, whose background is in fine arts, has received numerous awards for her landscape painting. She has no formal training in art education, art therapy, or special education. When asked how she prepared herself to teach art to special needs children and adolescents, she said:

In Mexico there are very few art teachers working at any level in special education or regular education. I did not receive any inservice training for either art project with special education students. For me, the ability to teach art to special populations seems to come naturally. I feel comfortable with all types of people and enjoy exposing others to art.

Yolanda M. Farias, Art Therapist in Private Practice

Yolanda M. Farias is also affiliated with the Universidad de Nuevo Leon where she will be teaching a course, "The Psychology of Art," during the 1992-93 academic year. I interviewed Ms. Farias at her private office in a suite that she shares with her psychiatrist husband and another psychiatrist. Their clients are wealthier Mexicans who can afford private therapy.

Our initial conversation dealt with Ms. Farias' plans for her upcoming course and her theoretical influences. She described the course:

My course will discuss the history of creativity in hospitals. I'll show slides of patients' art from the 1800s in Europe, primarily from the collection of Dr. Prinzhorn. He was a psychologist and art historian who collected Swiss/German patients' art. In the course I will also teach the theories of Jung, Edith Kramer, and Laurie Wilson, as well as provide opportunities for studio exercises. My influences are primarily Freud and Jung. I am very influenced by psychoanalytic theory and have had four years of psychoanalysis. It depends on the patient's ability to benefit from long-term analysis or short-term therapy. With children, I'm more inclined toward a Jungian approach and use a combination of art, play, and verbal therapy.

Ms. Farias discussed the relationship between art and psychology in Mexico:

For me it is very close because I am an artist. But the relationship of psychology to art and creativity is not promoted much in Mexican universities in our psychology or art departments. The only exposure psychology students have in the relationship between art and psychology is through courses in projective techniques where students are exposed to the D-A-P (Draw-A-Person) and H-T-P (House-Tree-Person) tests. There is not much student interest in this topic. To my knowledge, Cuba is the only country in Latin America that is involved in art therapy. Cuba is more advanced in mental health than the other Latin American countries.

I am the only trained art therapist in the city of Monterrey, and there is one in Mexico City. A few psychologists in our hospitals use art therapy with their patients, but they are primarily psychologists and not trained in art therapy.

P.D.: How is art therapy used here in Mexico? For what populations? How are people in Mexico prepared to practice art therapy?

Y.F.: I use it with children, adults, and prisoners. I'm doing research on art therapy with a prisoner group because I am fascinated by the violent mind. Our prisons are not as humane as in the United States and the prisoners do not get much rehabilitation. The prisoners draw freely a subject of their choice. It is for self-expression and motivation. Prior to working in private practice and part-time with prisoners, I worked a few months with our Department of Health in a substance abuse program. We worked on posters dealing with prevention of substance abuse. I worked with families who had drug addicts or substance abusers. In the Department of Health I also used art therapy in an early stimulation program for children from infancy to age four.

P.D.: What is your educational background?

Y.F.: I have a master's degree in psychology from a Mexican university and an MA in Art from New York University. The MA from New York University involved courses in art therapy, fine arts, and art education.
lic. Enrique Lurpicio Padillo, Psychologist

Ms. Farias referred me to Lic. Enrique Lurpicio Padillo, Chief of the Psychology Department at the Hospital Psiquiatrico del Estado (state psychiatric hospital). Lic. Padillo uses therapeutic art techniques in his practice.

Our interview took place at the hospital, a sharp contrast from a private office and university art studio. It was my first visit to a psychiatric facility outside the United States. Located in an urban working-class neighborhood, the hospital is a sprawling one-story structure with an inner courtyard, typical of Moorish/Spanish architecture. There did not appear to be any security guards. Only the more violent patients were on locked wards. At that time of the morning most of the patients were leisurely strolling in the courtyard and some were gardening. The area is large enough for exercise and privacy.

Unlike my interviews with Lic. Green and Ms. Farias, which were in a combination of Spanish and English, my interview with Lic. Padillo was entirely in Spanish. Due to my Spanish-speaking limitations, this interview was more formal than the others.

P.D.: Please tell me about your art therapy work at this hospital.
E.P.: My patients work with drawing media, oil, gouache, et cetera. The patients illustrate their family life, the inner self, and similar topics. Drawing is a projection of the inner self. Other psychologists and psychiatrists bring their patients to me because sometimes art is the only way they can communicate. Art is a manifestation of the patient’s conduct. I also use poetry and art and have patients read a poem and illustrate it. We practice community therapy and group therapy.

P.D.: What types of patients do you work with?
E.P.: Paranoid schizophrenics, catatones, the retarded, and chronically mentally ill adults. Schizophrenics are ... their own world. Their work is perseverative as is their language.

P.D.: What are your theoretical influences?
E.P.: They are eclectic: Freud, Fromm, Jung, and Gestalt theory.

P.D.: What is the opinion in Mexico and other Latin American countries of the relationship between art and psychology?
E.P.: Here the artist is often considered insane because of the literature on famous artists. Artists are considered neurotic. Poetry therapy as an artistic modality is seen as one of the relationships between art form and psychology.

P.D.: Do any of your colleagues practice art therapy?
E.P.: No. I’m the only one in this hospital. Some of the staff practice occupational therapy.

P.D.: What is your educational background?
E.P.: I have a BA in the humanities and an MA in psychology.

P.D.: Are you interested in exchanges with psychologists or art therapists in other countries?
E.P.: Yes. Germany and the United States.

P.D.: What is your personal involvement in art?
E.P.: I recently made a video titled Documental Picopatología de la Pintura. It’s an animated film showing the bizarre nature of artists’ work like Picasso, artists inspired by strange dreams and sexuality. I’m also a painter, muralist, and licensed art teacher in Los Angeles, California. At the age of 21, I traveled the Mayan route through the Americas. My art is influenced by Mayan, Aztec, and mestizo culture. The Indian influence is strong in my work. I participated in the 1974 conference on Latino/Chicano art in California and painted a mural for Mill Valley State College in California. My murals deal with social problems such as the Vietnam War. Artists should be socially conscious. Also I am interested in experimental film and documentary photography. In Mexico photography is used more as criticism against societal problems, but in the United States photography is used...
more as a creative, artistic form without a message. In addition to working as a psychologist and art therapist here at the hospital, I'm a professor of communication at the Universidad Autonoma de Nuevo Leon where I teach aesthetics, photography, and the psychology of art.

P.D.: Are you interested in exchanges with doctors in other countries?
M.J.: Yes. England, the United States, and Argentina. Argentina is active in music therapy and psychodrama.

Ana Rosa Garcia Mayorga, Artist

In Colima, Mexico, I visited Maestra Ana Rosa Garcia Mayorga, director of the Taller Magistral Sobre Liberacion de la Creatividad (Masterly Studio for the Liberation of Creativity). The taller (studio or workshop) is housed in a designated historic building. Most of the activities take place outdoors in the inner courtyard that is open to the sky. Gallery and storage space is located in rooms surrounding the courtyard.

Ms. Mayorga is a Columbian artist currently living in Mexico. Her textile designs are based on Columbian and Peruvian traditions. She teaches art in her studio to teachers, professors, psychologists, parents, and children in both regular and special education schools. The classes usually consist of a mixture of typical and atypical populations.

Ms. Mayorga, who speaks Spanish only, explained her theories and techniques of creativity liberation. Samples of adult and children’s art, gallery brochures, and her written curriculum supplemented the interview.

Her main objectives are to:

...comprehend creativity as an innate part of development and to release inhibitions. I support the comprehension of the liberation of creativity as a method of communication and expression, as an essential part of the global formation of the individual. I want to improve my client's self-esteem and personal evolution.

Ms. Mayorga's methodology involves group and individual exploration, encounter sessions, sensory stimulation, perceptual exercises, communication with body gestures, motivational activities, oral and written narratives, respect for physical space, respect for the psychology of the other, exploration of individual and collective memories, and creative play as spontaneous expression.

Studio techniques include exploration of color using crayons, paint, and colored pencils, printmaking, collage, clay modeling, and small cabinetry/woodworking projects that they sell to raise money to buy more arts and crafts supplies.

P.D.: What is your educational background?
M.J.: I have an MD in psychiatry and am a trained pianist. I am very interested in music therapy.
Ms. Mayorga would like to earn a master’s degree in art therapy and wishes to collaborate with psychologists in the United States. Many of the special education students in her program are referred by psychologists. A student exhibition brochure states: *El ser humano es esencial un ser creativo.* Roughly translated, this reads, “To be human is in essence to be creative.”

**Conclusion**

When I reflect on these interviews and many others that were conducted in mental health clinics, shelters for abused children, special education departments, and art studios, I can only admire and respect these Mexican professionals. They are using art in therapeutic settings despite limited resources and often without training. Through self-motivation and concern for clients, these professionals train themselves and use their natural creative abilities.

These five professionals demonstrate that the natural power of art can transcend limitations such as lack of training programs, job descriptions, and licenses.

The author would like to thank Lic. Gabriela Pendroze, Lourdes Avila, and Laura de la Mora for their invaluable assistance in arranging these interviews.

**Associate Editor’s Note:** This impressionistic view of the practice of therapeutic art in Mexico can stimulate the reader to consider our similarities and differences. When training programs are not readily available, the therapeutic use of art forms around the background and experience of the professional and the needs of the clients. Dr. Dufrene provides us a rare glimpse of some of these configurations.

**LOYOLA MARYMOUNT UNIVERSITY**

Graduate Department of Marital and Family Therapy (Clinical Art Therapy)

offers a

Master of Arts in Marital and Family Therapy

For more information contact Dr. Debra Linesch Loyola Marymount University 7101 West 80th Street Los Angeles, CA 90045 (310)-338-4562

- Approved by AATA since 1979 (One of the first five programs in the country to be approved)
- Meeting California state requirements for MFCT licensure
- Family Systems/Psychodynamic Orientation
- Full-time and Part-time programs
- Nationally respected and distinguished faculty
- Committed to innovation and integration in models of art therapy and student-centered approaches to learning
Reviews

Exceptional Children, Exceptional Art: Teaching Art to Special Needs

280 pp., 271 black & white illustrations, 7 color illustrations. $34.95 cloth.
ISBN 0-87192-238-X.

Reviewed by Betty Jo Troeger, PhD, A.T.R., Tallahassee, FL

David Henley presents two major challenges to art educators working with students who have exceptional needs: first, that significant art experiences are within the grasp of all children, and, second, that a studio model of mainstreamed, individualized art instruction is the best way to facilitate artistic expression. Henley builds a theoretical foundation for therapeutic art education, dividing his book into three parts: exceptional children, exceptional art, and adaptations.

In Part One, exceptional children, Henley presents the guiding principles that inform his work, crediting Viktor Lowenfeld's art education therapy (1957) as the primary source for his concepts. Henley describes art education therapy as a "philosophical perspective which promotes the art experience with sensitivity that appreciates the sheer wonder of the child artist" (p. 5). Henley's definition of art therapy falls within the parameters provided by Edith Kramer (1979), and he distinguishes art psychotherapy from therapeutic art education and from general art education. Practitioners who work within a cognitive, behavioral, or developmental model may find exceptions with Henley's psychoanalytic definition of art therapy. All other adaptive experiences are defined as therapeutic art education.

An introduction to typical and atypical children, including the artistically talented individual, provides the reader with a psychoanalytic view of child development and an understanding of individual learning needs. Brief descriptions of learning disabilities, visual impairments, hearing impairments, orthopedic impairments, retardation, and emotionally handicapping conditions are included in this first section. The omission of other exceptional conditions (i.e., the health impaired and hidden disabilities) is a significant oversight in the text. Nevertheless, Henley does maintain that each exceptional condition poses unique presenting problems and he offers multifaceted suggestions for their remediation.

Based on his interpretations of Public Law 94–142, Henley advocates providing the art experience in the least restrictive environment. In keeping with his position on mainstreaming, "(e)ach child is assessed as to his or her emotional, cognitive and aesthetic needs and each is accommodated in an environment where strengths and weaknesses are camouflaged so as not to make an issue of the disability" (p. 66). Camouflaging is defined as selecting different facets of art experiences and scaling them to different levels of complexity for each student without sacrificing the integrity of the process or product. A
reasonably small teacher/student ratio is imperative to individualized teaching and learning. From this reviewer’s perspective, Henley’s concept of the least restrictive environment is designed for the master teacher who is working under ideal conditions.

By establishing as normal an art learning process as possible, a child’s imagination and socialization can be challenged simultaneously. The therapeutic art educator motivates, nurtures, and intervenes through verbal and direct hands-on assistance with the art expression. Instruction includes reflection, which may begin with student awareness that he or she has made a product. Then, it may move to more complex cross-referencing processes involving art history and criticism. Creative expression, generated through personal experience, is Henley’s ultimate goal for each learner. While motivation is based on psychodynamic phenomena, Henley’s discussions of honesty, firmness, sensitivity, confidence, and concern, generally can be adapted to any art teaching perspective.

Part Two specifically addresses processes involved in drawing, painting, printmaking, sculpture, and ceramics, using case studies to demonstrate specific ways to adapt instruction to disabling conditions. In the section on drawing, Lowenfeld’s (1957), developmental theory is applied. He believes children should be “encouraged to draw in the spontaneous, naive style of a child. . . . (and be left) to express what they know about, how they feel, imagine or dream. . . .” until they begin to exhibit an appropriate cognitive and perceptual level of development (p. 94). His approach emphasizes art as an academic discipline only after the child begins to work in a realistic mode. Accordingly, he does not support instruction in drawing techniques until approximately age 11.

Painting is the “most emotionally charged and expressive of all media” (p. 128), and, therefore, painting presents strong responses related to motivation and to regression. When adapting this media for a broad range of abilities and developmental levels, the therapeutic art educator is challenged to control the stimulation produced by paint’s color and fluidity. Henley incorporates technical aspects of media, specific subject matter, and artists’ styles into painting processes. Color illustrations enrich the verbal descriptions throughout the chapter.

Printmaking presents great potential for integrating diverse skills and providing adaptations to a variety of problems. Techniques in monoprinting, collographs, embossing, jigsaw printing, and block printing expand our perception of a least restrictive environment. For impulsive students, the cautious use of tools and equipment is often a powerful behavioral device. Therefore, the art teacher must continually assess whether the student is capable of handling particular printmaking processes.

Henley believes that sculpture begins with block play and early developmental activities such as making toys, shadow box relief, and free-standing sculpture. He suggests using large scale works and environmental constructions to entice the young and the severely disabled. The process of casting in a variety of media (clay, sand, paper, metal) can engage many levels of learners. Collage is introduced as a process that stimulates grasping, placing, and arranging elements into sculptural compositions. Carving is a useful technique for students who have proven their capabilities for handling tools, by moving from simple to more complex operations.

Clay is “among the most therapeutically dynamic art media” (p. 172). Henley describes the ceramic studio: furniture, tools, equipment, and the hazardous dust and fumes generated through the art process. Specific properties of clay are discussed to help the therapeutic art educator make wise and safe choices when selecting materials. He describes figure modeling and methods of constructing (hand building, slab building, coiling, molding) and throwing on the potter’s wheel in terms of their suitability for individual achievement. Glazing and firing procedures are also included.

The final section of this text addresses adaptations. Henley states, “Art expression becomes the first step in actually mastering behaviors, by virtue of working through emotions instead of simply acting upon them—or—the other extreme—oppressing them” (p. 200). He advocates an empathic stance rather than behavior modification techniques when dealing with problems. Special problems presented by psychotic and autistic behavior, self-stimulation, and compulsive behaviors are also addressed in this section. Additionally, he discusses attention deficits, mood swings, fearful reactions, defeatism, depression, and anxiety reactions. His examples of personal responses to behavioral issues provide the reader with a glimpse into the relationship between understanding issues and overt behavior.

Henley convinces the reader that the artwork of children can convey some aspect of the child’s state of mind. Through brief, anecdotal examples of specific problems, a clearer understanding of the messages contained in art and dialogue emerges. Detailed models for assessment notation are provided in five domains: motivation, behavior, skill acquisi-
tion, aesthetic/expressiveness, and affect. He gives examples of process notes, individualized educational plans (IEPs), and a rationale for the use of video in assessment. Finally, Henley implores us to "suspend preoccupation with rational analytical thought and perception... and acknowledge that there are other ways of seeing, feeling and expressing" which may run contrary to a viewer's parameters of Western aesthetics (p. 273).

Exceptional Children, Exceptional Art is a welcome addition to the growing body of literature that addresses the artistic expression of children who have special needs. Henley joins Edith Kramer (1979), Judith Rubin (1984), and Frances Anderson (1978), as a major contributor to the knowledge base for work with this population. The text clearly demonstrates the author's devotion to children of all ages and abilities, a passion for the art process, and an abiding belief in the power of the therapeutic art experience. The major strength of the book lies in the many challenges the author offers for experiencing the art processes. The major problem with the book is the questionable practice of camouflaging the child's level of aesthetic response. It provokes questions about teacher adaptations of the learning process that are made at the expense of an opportunity to learn to appreciate similarities and celebrate differences. Nevertheless, Henley's views provide a conceptual basis for an informed dialogue about practices in art therapy and therapeutic art education.

Silver Drawing Test of Cognitive Skills and Adjustment: Drawing What You Predict, What You See, and What You Imagine

92 pp., 30 black & white illustrations, paper, $40, complete test battery (includes 10 test booklets); $28, manual only; $16, expansion set (includes 10 test booklets, 10 scoring forms, and one layout sheet). ISBN 0-9621429-1-3.

Reviewed by Anna R. Hiscox, MA, A.T.R.

The new edition of the Silver Drawing Test (SDT) is a must for any professional interested in obtaining information that may be bypassed using standardized tests. Silver concurs with Piaget (1968), who asserts:

the roots of logical thought are not to be found in language alone, even though language coordinations are important, but are to be found more generally in the coordination of actions, which are the basis of reflective abstraction (p. 18).

Clinicians will find this revision of the SDT a precise and effective measurement tool of cognitive and affective development. As art therapists we are inundated with assessment measures from other dis-
ciplines. Our viability depends on developing tools with retest reliability. In refining the SDT, Silver has paved the way for novices as well as pioneers.

The introductory chapter of the manual is important to understand the author's sensitivity and empathy when obtaining cognitive and emotional measures from language-impaired children. Silver describes her relationship with Charlie, a child who is deaf, who was instrumental in encouraging her research. Silver's work with Charlie culminated in a task that would assist not only with the evaluation of latency age children, but also with adolescents and adults.

The SDT is a five-point scale instrument containing three primary scoring measures: the ability to order sequentially and conserve by using a predictive drawing test; the ability to associate and represent concepts by drawing from imagination; and the ability to perceive and represent concepts of space by drawing from observation. It enables the assessor to identify cognitive skills that are independent of verbal skills, depression, and at-risk individuals.

The SDT has no time limit, but generally the test can be administered to groups or individuals in 18-20 minutes. The recommended age range for use of the SDT is five years to adult. It can be used as a pre/post evaluation tool. The SDT is not, however, a tool that should be used by a lay person. Although this assessment is easy to administer, it should not be utilized without a thorough understanding of psychological and artistic development. Art therapists, school counselors, psychologists, and other professionals who implement assessments and evaluations will find that the SDT is an invaluable addition to their repertoire.

Silver postulates, "Drawing takes the place of language as the primary channel for receiving and expressing ideas" (p. 3). This statement is validated by significant correlation between the SDT and other accepted measures such as the Otis Lennon School Ability Test, the Iowa Test of Basic Skills, the Canadian Cognitive Abilities Test, the Wechsler Intelligence Scale for Children, the Metropolitan Achievement Test, and the SRA Mathematics Achievement Test (p. 21).

While significant correlations have been found when the SDT is compared with other standard assessment instruments, limitations are observed in the SDT percentile ranks and T-score conversions. The standard deviation and the cumulative normal probabilities for children in the ninth, eleventh, and twelfth grades are omitted and must be estimated. Although the SDT has been administered to adults, the small number of subjects provides insignificant data, thus decreasing the validity and reliability of data for adult subjects.

The second edition of the SDT provides a comprehensive, easy-to-read guide to the author's hypothesis and her rationale for scoring each subtest. Silver notes that scores on projection (emotional content) are excluded from the total score because the rating scale does not reflect a cumulation or progression from emotional disturbance to mental health (p. 17). Conversely, Silver postulates that the emotional content of the projective component offers clues to the emotional state of the individual.

The current edition of the SDT contains many of the same illustrations as the previous edition. The most significant revision occurs in the language of the scoring guide which, in fact, modifies the scoring criteria. This change increases pictorial clarity and reliability, and greatly decreases subjectivity.

Another improvement is found in scoring the test of predicting verticality. Silver does a nice job of describing how one would achieve the maximum number of points. Here she demonstrates what constitutes adequate support for a house, thus assisting in determining a score of four or five. Under the section "Drawing from Observation—Horizontal Relationships," Silver gives a specific description, thus eliminating the need for the assessor to ponder the difference between a score of four or five. Another noted distinction between the original SDT and the current revision are the simplified instructions for measuring relationships in depth (front-back). In order to receive the maximum score of five points, "the relationships in depth are accurate and the layout sheet is included in the drawing" (p. 41). In the original publication, the examinee received a score of five points if "all four objects are related; fine discriminations" (p. 31).

The many semantic changes in the guidelines for administering the SDT render the current edition superior to the previous version. The 1990 edition also has a concise format for "Drawing from Imagination" and "Drawing from Observation." This revision of the SDT provides tighter scoring guides and eliminates many of the ambiguities of the original test.

Compared to other disciplines, art therapists have been on the periphery in developing, implementing, and researching assessment tools. Silver has advanced the field of art therapy by her continued research to refine the SDT. This is a positive step for the advancement of art therapists as quantitive clinicians. Our work with clients is always

1399

evolving. This evolution includes the tools we use to implement change. The 1990 revised SDT provides art therapists and other professionals with a bridge with which to link standardized assessment tools and nonverbal measurements.

Editor's note: Art Therapy is planning to offer reviews of art-based assessments in coming issues. If you are interested in reviewing an assessment or have an assessment you would like to have reviewed, please contact Dr. Patricia St. John, A.T.R., through the AATA National Office.

Video Review

Psychimagery: Healing the Child Within

30 minutes, color. Purchase only: $80
Available from: James J. Consoli, MA, A.T.R., NCC, Eastern Virginia Medical School, Graduate Art Therapy Program, P.O. Box 1980, Norfolk, VA 23501

Reviewed by Mindy Jacobson, MCAT, A.T.R., Philadelphia, PA

Psychimagery: Healing the Child Within introduces the viewer to the language of art and the application of imagery techniques in exploring childhood traumatic experiences. The videotape begins with a melodic interlude and a man drawing, thereby setting the stage for what is to follow.

The narrator states:

The language of art, the imagery of the child within. There is healing in these images as the hopes, fears and emotions of the inner child are recognized and honored. But the child may be reluctant, traumatized beyond expression by pain, fear or guilt. A wall is thrown up against memory and the language falls silent.

Consoli, the pioneer of a technique known as Psychimagery, is introduced as an art therapist who can break through to the inner child. In discussing the case of “Anne,” a woman who is blocked and who uses intellectualization as a defense, Consoli outlines the initial treatment issues of trust and performance anxiety. Such issues are not uncommon in the treatment of individuals who have been sexually abused (Jacobson, 1985), but Consoli does not identify the relationship of these issues to Anne’s traumatic childhood until later.

The video traces the progress of Anne’s treatment through narration, artwork, and a demonstration of two sessions. Issues surrounding the treatment of abuse victims are brought to the forefront, thus exposing the viewer to the “healing powers” of the image and its use in uncovering repressed traumatic material. Provided we listen carefully and read between the lines, we are subtly introduced to the dissociative spectrum. The process of art therapy is
complex, however. It would have been helpful if Consoli mentioned that this type of work may traumatize the inexperienced therapist (Chu, 1988; Kluft, 1989).

The major intent of the video is to demonstrate the technique of Psychimagy. After multiple viewings, however, I found it difficult to define Psychimagy, and surmised that the use of spontaneous imagery to explore unconscious material constitutes Psychimagy. Referring to the work of Margaret Naumburg (1966), Consoli suggests that Psychimagy is an original technique. Based on the text, however, I did not find this to be the case. Instead, the analytic framework developed by Naumburg and expanded by Wadeson (1980), Rubin (1984), and others, seems to be at the core of Consoli’s work.

A lack of integration of the various methods used contributes to the confusion in defining Psychimagy. Consoli suggests that he relies on systematic desensitizing and relaxation techniques to reduce Anne’s agoraphobia, and employs hypnotic interventions to reach the inner child. The viewer is left to wonder if these techniques are part of Psychimagy or if Consoli’s pioneering work is a combination of imagery and hypnosis.

David Grove’s hypnotic methods are highlighted when Consoli uses the technique to return the wounded child to “T-1,” the moment just prior to the trauma. Like Grove, Consoli uncovers details surrounding the trauma, moves the patient through it, and processes the material, thereby dissolving the developmental arrest. Essentially this process, known as abreaction, is used by most therapists when working with abused patients. It is well documented in the literature on Post Traumatic Stress Disorder and Dissociation (Cooper, 1983; Kluft, 1988).

The film raises several diagnostic and treatment issues and the viewers are left with questions. For example, why doesn’t Consoli use the images produced by Anne to reach her “other parts”? Anne’s artwork is richly symbolic, containing the answers Consoli needs to break through her amnestic barriers. Is the “inner child” actually a dissociated part of Anne that developed in response to severely traumatizing childhood events? Consoli does not choose to explore this. Neither does he explore nor mention the variations within Anne’s artwork which suggest dissociative phenomena, despite her suggestion that she dissociates.

Because the video is generously illustrated with Anne’s artwork, we have numerous opportunities to see images and phenomena which suggest dissociative processes. For example, there are consistent changes in handwriting, numerous references made to “fading out,” self-portrayals which intimate various age states, elevated perspectives which suggest floating, and disconnections between the head and torso. Anne reports that her father was “like two different people.” Her paradoxical relationships with him and Mother are consistent with the histories presented by patients who dissociate.

Anne’s treatment with Consoli terminated after one year, leaving the diagnostic issues clinically unresolved. If this patient was dissociating, and this was not explored in its entirety, what may we surmise about Anne’s recovery? Although her initial symptomatology was resolved and traumatic material was processed, might there be other dissociated aspects of the self which were left to fester?

Despite my concerns about Anne’s diagnosis and my suggestion that a more comprehensive case review might have illuminated these concerns, I found the video to be educationally beneficial. It is appropriate for use with art therapists and other clinical groups.

In terms of production, I found the video technically sound and aesthetically appealing. The artwork is dramatically alluring, the music well chosen, the videography professional, and the text inviting. Anne’s interjected statements and the use of two in-session videos are ingredients that further dramatize the seriousness of this type of work. The only offensive technical element is the simultaneous elicitation of a male patient’s inner child and the narration of new text. This can be disruptive and confusing.

In support of Consoli’s efforts, Psychimagy: Healing the Child Within is a moving video which sensitizes the viewer to the artwork of the traumatized patient. Despite my concerns surrounding the lack of reference to dissociation in art therapy, I plan to use the video (in conjunction with inservice discussions of dissociation) as a training film for art therapy students. Anne’s case is intellectually stimulating and raises diagnostic and treatment issues for the viewer. Consoli deserves credit for taking on such an endeavor. Certainly video is an emerging format, suitable as a means for art therapists to share their work.

References

**James Consoli responds:**

Mindy Jacobson raises questions and infers that not only do the diagnostic issues remain unresolved in this case, but Anne’s recovery seems questionable. I could not agree more with her statement that “... a more comprehensive case review might have illuminated these concerns...” However, the intent of this 30-minute video was to highlight a case that visually demonstrated the therapeutic potency of imagery and to introduce the technique of Psychimagery. Incorporating a comprehensive review of this year-long case, including a more thorough description of the Psychimagery process, practically would have required a mini-series. (An instructional video is currently being considered as a follow-up to the first film.)

Psychimagery is a term developed to explain more clearly the therapeutic usefulness of imagery. Elinor Ulman (1975) wrote, “It is hard, sometimes impossible to find the ideal name for a complex and subtle discipline. The title ‘art therapy’ can easily be dismissed as inadequate or inaccurate, but I have not found a better one” (p. 3). Some art therapists hold that “if you are not doing art, you are not doing art therapy.” Clearly, the use of art materials is a prerequisite to this theoretical approach. Other art therapists perceive themselves as psychotherapists who incorporate all three forms of communication (lexical, kinesthetic, and imagery) (Shore, 1978), to promote healing. When speaking of imagery, I am referring not only to that which is created externally, in plastic and graphic form, but also to internal creations, such as dreams or mental images, whether spontaneous or guided (Rubin, 1985). With certain populations, my theoretical position is more closely related to the latter. If this is considered to be art therapy, there is no need for a new word.

Margaret Naumburg (1928) pioneered the use of spontaneous drawings, and, as Jacobson writes, others have expanded on this approach in an attempt to make the unconscious conscious. Bernard Stone (1975), incorporating this approach, developed the technique of sequential graphic gestalt. This process takes the spontaneous renderings a step further by moving them forward in time. By creating a narrative, one can raise insight on a sequence of events rather than on a “snapshot” view, that displays only a particular moment in time. This technique more closely resembles an abractions while incorporating art materials and metaphor or metonymy. David Grove (1989) uses what he refers to as epistemological metaphors: mental images originated by the client. He also includes clean language: a way of speaking that allows the therapist to choose his or her words carefully so as not to traumatize the client through an abreactive intervention. As in art therapy, he uses the metaphor to provide a safe distance while addressing the intrapsychic conflict. Although Grove’s approach employs only the use of internal mental imagery, there are many similarities. Similar to Naumburg’s approach, the client’s images are spontaneous; similar to Stone, the images evolve over time.

My reason for introducing the technique of Psychimagery is twofold: to clarify the semantics of a therapeutic process that incorporates both the noniatrogenic interventions of guided mental imagery with the imagery created externally in graphic or plastic form and, to demonstrate the potency of the combination of both modalities. As stated by the video’s narrator, “... psychimagery then joins the communication with the inner child with proven art therapy techniques to create a dynamic healing process.”

Regarding the “inner child,” the viewer might surmise that Anne had dissociated a part of herself in response to a traumatizing event. It is my assumption that she had dissociated in an attempt to survive the emotionally overwhelming experience of the abuse. It is unfortunate that many therapists do not incorporate the use of metaphor and instead take the approach of having the client actually re-live, and re-experience, the feelings, only to be re-traumatized (in the name of therapy!). Referring to dissociative
experience, Ross, Joshi, and Currie (1990) summarize that they

... are common in the general population, (with a tentative prediction of dissociative disorders in the range of 5%-10%), we suspect that dissociative symptoms may occur in a wide range of psychiatric disorders, just as anxiety and depression can be components of many different entities (p. 1552).

I have many concerns about the propensity of therapists, swayed by popular mental health issues (e.g., sexual abuse and multiple personality disorders are "fashionable") to quickly diagnose and perceive their clients in a preconceived framework (Harakas, 1992). At the close of her book Approaches to Art Therapy (1987), Judith Rubin reminds us of an old tale of six blind wise men who come across an elephant. They try to discern its shape, each touching only a part and assuming that the animal is "... a spear ... a tree ... a rope ... a wall ... a fan ... a rope!" (p. 320).

It may appear to the viewer that it was my decision to continue treatment through the behavioral technique of systematic desensitization, even after Anne had found relief from her presenting problem of agoraphobia. Or, that it was my decision to end treatment after she had developed sufficient insight into the etiology of her condition. In fact, however, it is my conviction that the client remain empowered through the therapeutic process so as to not be re-victimized. Another client may have been satisfied with relaxation techniques which allowed him or her to leave home and be productive. Another may have wanted to explore further the possibility of "other parts," or more amnesic barriers. In my view the decision is the client's, and Anne stated that she was ready to terminate.

I do appreciate the comments and concerns that Jacobson addresses. I believe that it is imperative that we have open dialogue about these important issues that have an impact on the field. I invite others to do the same. I am pleased that Jacobson will find the video useful as an academic tool, and I hope others will as well, whatever the endeavor or context.

The American Art Therapy Association, Inc. 1993 Media List

Updated by James Consoli, MA, A.T.R.

This media list is provided to assist AATA members and others in locating films and tapes on art therapy and related subjects. Inclusion of a film or tape in this list does not imply endorsement by the AATA. It is the responsibility of the film/video producers, directors, and/or consultants to have obtained appropriate release forms for clients and client visual work appearing on film or tape. Descriptive information has been provided by producers and distributors; for more information on specific films/tapes, please contact them at the addresses given below.

Films, Videotapes, and Filmstrips:

Archetypal Images and Art

Produced by Emporia State University, Emporia, Kansas. The art of Peter Birkhauser is discussed from a Jungian approach. The tape focuses on Jung’s concept of the archetypal basis essential to personal wholeness and the importance of the unconscious in any creative activity. Birkhauser’s art is utilized to illustrate these concepts. Excellent resource for graduate-level art therapy coursework.

VHS ½"; 40 minutes. Purchase only: $40 (plus postage). Contact: Dean L. Frantz, 3831 Evergreen Lane, Ft. Wayne, IN 46815

Art and Therapy

VHS ¼"; 22 minutes. Rental or purchase. Contact: Hughes Lavergne, Unicorn Productions, 67 East 4th Street, #14, New York, NY 11225

Art Therapy

Produced by the American Art Therapy Association, 1981. A short introduction to the field of art therapy for general use. 16mm; color; 12 minutes. Rental only: $35 (members), $45 (nonmembers).

VHS ½"; color; 12 minutes. Purchase only: $50 (member), $80 (nonmembers). Contact: American Art Therapy Association, 1202 Allanson Road, Mundelein, IL 60060

The Art Therapist’s Third Hand

VHS ¼"; 55 minutes. Purchase: $400; rental: $40.

Contact: Recycled Images, Inc., 761 South Blvd., Alpha, NJ 08865

Art Therapy

Produced by T. Dalley, D. Waller, and J. Beacham, University of London Goldsmiths’ College, 1985. An introduction to the theory and practice of art therapy featuring a student training group, a one-to-one session, work with mentally handicapped people, and case studies.
1993 MEDIA LIST

VHS, PAL, U-matic; 30 minutes. For purchase from: Tavistock Publications, 11 Fetter Lane, London EC4, England

Art Therapy: Beginnings

Produced by the American Art Therapy Association, 1977. Documentary film in which four art therapy pioneers discuss and illustrate their use of art therapy in a medical health context. Includes Margaret Naumburg, Elinor Ulman, Hanna Yaxa Kwiatkowska, and Edith Kramer. The latter three demonstrate procedures for assessing clients through art therapy.
16mm; color; 45 minutes. Rental only: $40 (members), $50 (nonmembers). VHS: 1/4"; color; 45 minutes. Purchase only: $50 (members), $80 (nonmembers). Contact: American Art Therapy Association, 1202 Allanson Road, Mundelein, IL 60060

Art Therapy and Children

Produced by T. Dalley, D. Waller, and J. Beacham, University of London Goldsmiths' College, 1987. Featuring a school for disordered children and an adolescent unit, the art therapists discuss their approach. Extracts from actual sessions are shown. The role of the art therapist in a team is clearly demonstrated.
VHS, PAL, U-matic; 30 minutes. For purchase only from: Tavistock Publications, 11 Fetter Lane, London EC4, England

Art Therapy: The Healing Vision

VHS, Beta 1/2", U-matic 1/4"; color; 49 minutes. For rental or purchase. Contact: Menninger Foundation, Box 839, Topeka, KS 66601, or 1-800-345-6036

Art Therapy: It Is Progressive, It Is Effective

This tape educates viewers about art therapy’s usefulness for aiding self-expression. Two case studies are presented (multiple personality and handicapped teenager), which take viewers deeper into the definitions and applications of this progressive therapy.
VHS; 12 minutes. Purchase only: $19.95; check or money order made payable to Kathy Gotshall-Sollars. Price includes shipping and handling. Contact: Kathy Gotshall-Sollars, P.O. Box 501049, Indianapolis, IN 46250

Art Therapy with a Group of Latency Age Girls

Produced by Mildred Lachman-Chapin, A.T.R., CCMHC, MEd, and Peter Volkert, 1970; re-edited, 1991. This video documents one year of group art therapy sessions with latency age girls in a psycho-educational facility.
VHS 1/2" and 1/4"; black and white. Purchase only. Contact: Mildred Lachman-Chapin, 903A Waukegan Road, Deerfield, IL 60015

Art: How Does a Child Grow?

Written by Pearl Greenberg, EdD, Kean College of New Jersey. Shows the artistic growth of one child in order to offer clues to what is possible for all children.
91-frame color, two-part filmstrip with 37 minute cassette and guide. Purchase only: $45. Contact: International Film Bureau, Inc., 332 South Michigan Avenue, Chicago, IL 60604

Art Therapy and Psychiatry

Produced by Trevor Scott, University of London, Audio Visual Centre, 1988. Program consultants: D. Waller, N. Minton, and J. Weller. Filmed in a large psychiatric hospital near London, this video shows how art therapy can be effective with a range of acutely or chronically ill patients. A panel discussion is included, chaired by Professor Christopher Conford, Professor Emeritus of the Royal College of Art, London.
VHS, PAL, U-matic. For purchase only. Contact: University of London, Audio Visual Centre, North Wing, Senate House, Malet Street, London WC1, England

Art Therapy: Releasing Inner Monsters

Produced by Cathy Malchiodi, A.T.R., University of Utah, Salt Lake City, Utah, 1987. Focuses on how art therapy can be utilized in the treatment and assessment of children from violent homes. The tape
gives a basic definition of art therapy and includes art expressions by children who have been physically abused, sexually abused, or exposed to domestic violence.
VHS ½"; 15 minutes. For purchase only: $40 (which includes study guide). Contact: Cathy A. Malchiodi, A.T.R., 2768 Comanci Drive, Salt Lake City, UT 84108

Art with Elders in Long-Term Care: A Visual Legacy
Produced by Hillhaven Convalescent Hospital, 1984. Documents an ongoing art program at a long-term care facility for the elderly. It celebrates the work of these artists and provides convincing evidence for inclusion of art programming with elderly populations. Features Mary Ann Merker-Benton, an artist, teacher, and consultant to Hillhaven Convalescent Hospitals of Northern California.
VHS ½"; 15 minutes. Purchase: $150. Rental: $35. Contact: Filmmakers Library, 133 East 58th Street, New York, NY 10022

Children and the Arts
Produced by Judith A. Rubin, PhD, A.T.R., HLM. This film emphasizes the emotional and social growth possible for young children involved in music, dance, art, and drama. Self-definition, self-confidence, control, mastery, and interpersonal sensitivity are among the values shown common to all art forms.
Film 16mm; 22 minutes. Rental only. Contact: Judith A. Rubin, PhD, A.T.R., HLM, 128 North Craig Street, Pittsburgh, PA 15213

Clinical Art Therapy with the Family (three videocassettes)
Three videocassettes show the synthesis of art and psychotherapy. Intended for the educational training of mental health clinicians.
TWO HANDS. Produced by Helen Landgarten, MA, MFCC, A.T.R. A dynamic art therapist demonstrates her unique combination of theory and practice. Using simple interventions, Landgarten shows the power of the art metaphor to illuminate a father-daughter dyad.
GOING HOME. Produced by Maxine Junge, MSW, LCSW, A.T.R. A young family's struggle with a major life transition is met with therapeutic flexibility by Junge. Her sensitivity and understand-
ing of the value of imagery helps the family to identify and explore issues of ethnicity, culture, individuation, and community.
MOTHERS & DAUGHTERS. Produced by Shirley Riley, MFCC, A.T.R. Combining systems theory and strategic intervention, Riley investigates a three-generational family's confused roles, redundant patterns, and unresolved grief. She shows understanding of adolescent and family dynamics as the art therapy illuminates issues and demonstrates the application of therapy to practice.
VHS ½"; color. Purchase of complete set: $225. Purchase of individual tapes: $90 each. Rental of individual tapes: $55 each (applicable to sale price). Please state title of individual tapes. Contact: AT/VIDEO, 14008 Mira Montana Drive, Del Mar, CA 92014, (619) 481-3311

The Color Bunch
16mm; color; 17 minutes. Contact: JKR Productions, 650 Midfield Lane, Northbrook, IL 60062

Creative Art Therapy with Children
Produced by Kim Pawley, A.T.R., and Terry Conheady, 1984. This tape provides an introduction to Creative Art Therapy. Artwork and movies that were made by emotionally disturbed children are shown to illustrate the way in which these children perceive themselves and their world. It explains the role of art therapy in self-expression, self-understanding, and personal growth.
VHS ½"; 8 minutes. For purchase or rental. Contact: Kim Pawley, A.T.R., Convalescent Hospital for Children, 2075 Scottsville Road, Rochester, NY 14623

Creative Arts Therapies at the Pace School
Produced by Simone Alter Muri, 1987. This video focuses on how art and music therapies can be used with developmentally delayed and autistic youth. It also presents an overview of the PACE program and the value of creative arts as therapy.
VHS ½". Contact: Simone Alter Muri, A.T.R., 56 Bradford Street, Northampton, MA 01060, (413) 584-9223
Creative Expression

Produced by Pat Sandor and Pat O'Sullivan, Ridgeview Institute, 1987. This video presents specialized vehicles for expression of feelings as demonstrated by artwork and accompanying musical selections. Its purpose is to creatively present information to professionals about the progression of emotions as addressed through art and music therapies. Reviewed in Art Therapy, 5 (3), pp. 106–107, 1988. VHS 1/2", 20 minutes. Purchase: $295; BETA 1/4", Purchase: $350; Rental: $50 for seven days. Contact: Ridgeview Institute, Attention: Finance Department, 3995 South Cobb Drive, Smyrna, GA 30080

Draw from Within: An Introduction to Art Therapy

Produced by Don L. Jones, A.T.R., Harding Hospital. An introduction to the practice of art therapy using two cases in which important turning points were reached through expressive therapy techniques. VHS 1/4". Available for rental or purchase. Contact: Harding Hospital, 445 East Granville Road, Worthington, OH 43085

Expressions

Produced by R. Wieske, Adult Service Center, Inc., 1984. This tape is about people feeling good about themselves through self-expression. It documents the results of a series of workshops in literature, music, drama, and mime. The project was funded by the Michigan Council for the Arts. VHS, BETA II 1/4"; 25 minutes. Purchase or rental. Contact: Adult Field Services, Inc., 1413 Field, Detroit, MI 48214, (313) 921-6238

Gestalt Art Experience

In this film Janie Ryane outlines the principal concepts of Gestalt art experience and leads a group through three therapeutic experiences: "Finding Your Own Rhythm Vocabulary," "Creating Your World in Clay," and "Building a World Together." 16mm color; 27 minutes. For purchase or rental. Contact: Extension Media Center, University of California, Berkeley, CA 94720

Gravity Is My Enemy

Produced by Churchill Films, 1977. Film about Mark Hicks who is without nerve or muscle function below the neck. He demonstrates his artistic skill and techniques and discusses his life and images. Academy Award winner for Documentary Short Subject, 1977. 16mm; 26 minutes. Contact: Churchill Films, 662 North Robertson Blvd., Los Angeles, CA 90069

The Green Creature Within

Produced by Drs. Judith A. Rubin and Eleanor Irwin. A record of a two-year outpatient group for male and female adolescents using expressive modalities, with emphasis on art and drama. Included are some necessary conditions in the therapeutic environment, two individual case studies, and specific therapist behaviors that seem to facilitate such work. 1/4" tape; 24 minutes. For rental. Contact: Judith A. Rubin, PhD, A.T.R., HLM, 128 North Craig Street, Pittsburgh, PA 15213

Life and Art of Peter Birkhauser

Produced by Emporia State University. Emporia, Kansas. This presentation highlights the artist's life with particular attention to his dreams and to the crisis which changed the direction of his life and art. More than 70 reproductions of his paintings are included, with comments by the artist and Jung. Valuable for art therapy graduate classes. VHS 1/4"; 31 minutes. For purchase only: $40 (plus postage). Contact: Dean L. Frantz, 3831 Evergreen Lane, Ft. Wayne, IN 46815

Lonny: A Case Study in Clinical Art Therapy

Produced by Jane Shulman, MA, A.T.R., MFCC, 1985. This videotape tells the story of art psychotherapy with a six-year-old schizophrenic child. Employing the child's artwork and words, it serves as an introduction to the use of clinical art therapy with children. VHS 1/2" and BETA 1/4"; 28 minutes. Rental: $3.5. Contact: Jane Shulman, A.T.R., MFCC, 942 Embury Street, Pacific Palisades, CA 90272, (818) 796-3515

The Maze

Produced by Dr. James B. Maas, Cornell University, 1970. This film features the Canadian artist, William Kurelek, who reviews his life and years of depression. He focuses on images and symbols he
16mm; color; 30 minutes. Contact: Audio Visual Services, Pennsylvania State University, University Park, PA 16802

Michael: Demonstration of a Diagnostic Interview Using Art Therapy Techniques
Produced by The American Art Therapy Association, 1977. The first art therapy session with a six-year-old boy of divorced parents.
16mm; color; 12 minutes. Rental only: $30 (members), $35 (nonmembers).
VHS ¼"; color; 12 minutes. Purchase only: $50 (members), $80 (nonmembers).
Contact: American Art Therapy Association, 1202 Allison Road, Mundelein, IL 60060

Perpetual Arts Relaxation Tape #2
This video provides stimulating and relaxing imagery which could be utilized by art therapists with individuals and groups.
VHS; 30 minutes; purchase or rental. Contact: Perpetual Arts, Mr. Alma Bulkely, 9848 Wimbledon Drive, Sandy, UT 84092

Psychimagery: Healing the Child Within
VHS; color; 30 minutes. Purchase only: $80. Contact: James Consoli, Graduate Art Therapy Program, Eastern Virginia Medical School, P.O. Box 1980, Norfolk, VA 23501

The Shape of a Leaf
Produced by Campbell Films, 1967. This film documents an art and educational program for developmentally delayed and mentally retarded children at the Perkins School. It is helpful to the professional working in a school-based setting with these populations.
16mm; color; 29 minutes. Contact: Very Special Arts, Kennedy Center, Washington, DC 20566

Stevie's Light Bulb: Graphic Art in Child Psychiatry
Produced by Ralph D. Rabinovitch, M.D., and Francis C. Pasley, M.D. Available in either film or video, this is an illustration of the use of graphic art in child psychiatry through applications in diagnosis and treatment. It covers 35 years of involvement by the authors. Numerous case studies demonstrate the elements of art that are crucial in work with children. Reviewed in Art Therapy, 2 (1), pp. 45–46, 1985.
16mm; color. VHS ¼", BETA ¼"; 76 minutes in two parts. Rental or purchase. Contact: Hawthorne Center Films, Hawthorne Center, Northville, MI 48167, (313) 349-3000

Suicide: A Teenage Dilemma
Executive producer and writer, Evelyn Virshup, PhD, A.T.R.; producer and director, Jim Stimpson, 1987. This Emmy-award-winning video explores why teens attempt suicide, discusses behaviors that may indicate someone is suicidal, and suggests ways to help. It stresses that teens often express suicidal feelings through writing, drawing, and painting. Virshup discusses the symbols of death in a series of drawings by a 19-year-old girl who was hospitalized after a suicide attempt. The program is accompanied by an instructional guide containing an introduction, objectives, and instructions for using the film. Reviewed in Art Therapy, 1 (3), pp. 148–149, 1984.
VHS ¼", ¼", and BETA ¼"; 30 minutes. Purchase: $192 (Health Sciences Consortium Member); $385 (non-member). Contact: Health Sciences Consortium, 210 Silver Cedar Court, Chapel Hill, NC 27514

Understanding Children’s Art Expression Series
Produced by Ruth M. Freyberger. Illustrates children’s progress from an early object-naming scribble to the depiction of the final space concept, and the realistic portrayal and concept of figure and space in terms of basic developmental levels.
Purchase only: Set of three color filmstrips and an eight-page guide: $40. Individual filmstrip and guide: $15. Contact: International Film Bureau, Inc., 332 South Michigan Avenue, Chicago, IL 60604
A Very Special Arts Festival

Produced by Dr. Claire Clements. More than 700 handicapped children, adults, and senior citizens from Northeast Georgia enjoyed and participated in this Very Special Arts Festival. This video illustrates a wide range of art activities and dimensions of art therapy with special needs populations.

VHS ½"; 15 minutes. Rental only. Contact: Dr. Claire Clements, 850 College Station Road, Athens, GA 30610

**NOTE:** Very Special Arts, John F. Kennedy Center for the Performing Arts, Washington, DC 20566, is a national/international resource for information and media on the use of arts with the handicapped. Most states have active VSAs which may also have media available.

Vision of Paradise Series

Produced by award-winning filmmakers A. Light and I. Saraf. This series consists of magical and entertaining films on folk art and native artists of differing ethnic backgrounds and styles. It is an exploration of creativity and process, intended for use by groups interested in art, aging, and creativity.

16mm (other formats available); color; 28 minutes each in a series of five films. For rental or purchase. Contact: Light-Saraf Films, 131 Concord Street, San Francisco, CA 94112

We'll Show You What We're Gonna Do!

Produced by Judith A. Rubin, PhD, A.T.R., HLM. This film shows an exploratory art program for multi-handicapped blind children. They are seen using the art experience for sensory exploration and awareness, to define their individuality, as a way of relating to each other, and as a means of expressing and coping with feelings.

16mm; color; 28 minutes. For rental only. Contact: Judith A. Rubin, PhD, A.T.R., HLM, 128 North Craig Street, Pittsburgh, PA 15213

With Eyes Wide Open

Produced by Dr. Laurence Becker and Ron Zimmerman. This film explores the life and work of Scottish artist, Richard Wawro who is described by some as "hopelessly retarded, with severely impaired vision, and an IQ of 30." The film offers a warm, personal view of a young man with joy and confidence in his work, in his world, and in himself.

16mm; color; 56 minutes. For rental or purchase. Contact: Laurence Becker, Creative Learning Environments, 507 Park Blvd., Austin, TX 78751

Resources

For additional sources of information on films and videotapes, see:

The AATA Media List will be updated on an annual basis. Members who have produced films or videos on art therapy, or who can update the above information, are asked to submit the following information to the AATA office:

- Name of Film/Videotape
- Producer(s)
- Format—16mm, VHS, BETA, U-matic
- Color or Black & White
- Length
- Rental price; purchase price
- Address where film/tape may be rented or purchased
- Brief description: 50 words or less

Send to: American Art Therapy Association, Inc., 1202 Allanson Road, Mundelein, IL 60060. Attention: Film/Video Review Editor.

Courage! Together We Heal

Courage! Together We Heal: Mural Messages from Incest Survivors is a 25-page monograph describing the development and implementation of an art therapy group for incest survivors. The monograph is authored by Frances E. Anderson, Ed.D., A.T.R., HLM, Distinguished Professor of Art, Illinois State University, who also served as a principle investigator for the project. Karen Deske, M.S., A.T.R. assisted Dr. Anderson in compiling the information and also served as a principle investigator.

The monograph provides an overview of adult incest survivors, including material on the characteristics of this population, emotional, social, somatic and sexual issues, and treatment strategies. The mural project is thoroughly described, with quotes from participants as well as black and white illustrations of group members' work. An extensive reference list is included at the end of the monograph.

The publication is part of “A Pilot Demonstration and Training Project on the Therapeutic Use of Ceramic Art with Adults Molested as Children” and was supported in part by a grant from the Peoria Area Arts and Sciences Council, and the Illinois Arts Council. Additional funding was provided by Lutheran Social Services of Illinois and Illinois State University. The project was implemented between December 31, 1989 and November 30, 1990, at Lutheran Social Services, Peoria, Illinois. For more information or to purchase copies of Courage! Together We Heal, please contact Dr. Frances Anderson, A.T.R., HLM, at the Department of Art, Illinois State University, Normal, Illinois 61761.
A Call for Artwork and Articles

_Treating Abuse Today_ is interested in publishing artwork by survivors of abuse and articles by professionals in the field of abuse treatment.

_Treating Abuse Today_ is a magazine for clinicians working in the field of abuse survivorship. Offering articles by such renowned experts as Laura Davis, Christine Courtois, Wendy Maltz and Barry Cohen, _Treating Abuse Today_ offers clinicians information on the most vital and revealing area of psychotherapy: abuse. Covering clinical issues (rage, shame, grief), multiplicity, family and partner issues, transference and countertransference, the sexual abuse of males, ritual abuse and legal issues, _Treating Abuse Today_ discusses the latest phenomena and treatment strategies. _Treating Abuse Today_ offers in-depth articles as well as book reviews, current events and a network of upcoming conferences. Currently, _Treating Abuse Today_ offers columns on art and the expressive therapies, partners of survivors of sexual abuse, survivor litigation and male survivorship.

NINTH ANNUAL SUMMER INSTITUTE IN THE HUMAN SERVICES

JULY 9–17, 1993
CONTINUING EDUCATION/GRADUATE SCHOOL OF SOCIAL WORK
UNIVERSITY OF UTAH, SALT LAKE CITY, UTAH 84112

Courses in Art Therapy

Using _Art in Therapy_, a one-credit course on Saturday, July 17 from 9:00 a.m.–5:00 p.m. For psychologists, social workers, and mental health professionals interested in the therapeutic application of art in treatment.

_Imagery as Medicine_, a one-credit course on Friday evening, April 30 and Saturday, May 1, 1993. For psychologists, social workers and health care professionals who are interested in the current research on imaginal techniques with individuals who are physically ill.

For more information on these and future offerings, please call Social Work Continuing Education, (801) 581-8913.
Guidelines for Submissions

All submissions will be acknowledged upon receipt by the AATA National Office. *Art Therapy* uses a blind peer review procedure for full-length articles and brief reports; final decisions regarding publication are made by the reviewers and the Editor. Decisions regarding submissions to other sections are made by the Editor, Associate Editor and special section editors.

The following are guidelines for developing and submitting a manuscript. Manuscripts that do not conform to these guidelines will be returned to the author without review.

**Manuscript Categories**

1. **Full-length Articles.** Full-length articles may focus on the theory, practice and research in art therapy or related areas. Manuscripts must include an abstract of approximately 75-125 words summarizing the major point of the article.

2. **Brief Reports.** Short articles which focus on the results of research are appropriate for this section. Manuscripts should include information on the research design, methodology and results; an abstract of approximately 75-125 words should also be included.

3. **Viewpoints.** Short articles focusing on personal experiences, poetry or original art may be submitted to this section.

4. **Book Reviews.** Reviews of books of interest to art therapists may be submitted at any time. Books which authors wish to have considered for review may be sent directly to the AATA National Office at the address listed above.

5. **Film/Video Reviews.** Reviews of media (films or videotapes) may be submitted at any time. Media which producers wish to have considered for review may be sent directly to the AATA National Office at the address listed above.

6. **Comments.** Brief comments on articles published in *Art Therapy*, issues critical to the profession and practice of art therapy, or letters to the Editor may be submitted to this section and should conform to the style of all other submissions.

**Other Requirements**

1. Send five (5) clear copies of each manuscript to Cathy A. Malchiodi, A.T.R., Editor, *Art Therapy: Journal of the American Art Therapy Association*, c/o AATA, Inc., 1202 Allanson Road, Mundelein, Illinois 60060. Neither AATA nor the Editor can be responsible for submissions sent to any other address.

2. Only original articles that are not under consideration by another periodical or publisher are acceptable.

3. Manuscripts must be typewritten on 8½" × 11" white paper with margins of at least an inch. The body of the paper, references, tables and quotations must be double-spaced.

5. An abstract of 75-125 words must be included with full-length articles and brief reports.

6. Please avoid footnotes wherever possible.

7. A cover sheet should be prepared to include the full name(s) and degree(s) of the author(s), professional affiliations, and the return mailing address of the author to whom correspondence can be sent. Authors’ names, positions, titles and places of employment should not appear in the body of the paper to assure anonymity and to facilitate blind review.

8. Use tables sparingly and type them on separate pages. Refer to the APA *Publication Manual* for style of tabular presentations. All tables, charts or diagrams must be legible and able to withstand reduction.

9. Photographs must be at least 5" × 7" and black and white glossy prints, preferably with high contrast. Xerox copies of illustrations or art expressions are not acceptable for publication. Figure numbers and captions should be noted on the back of photographs; captions must be typed and submitted on a separate sheet of paper. Please refer to figures in the text as Figure 1, Figure 2, etc.

10. Lengthy quotations (300 words or more from one source) or reproduction of works of art (this does not include client art expressions, which is addressed below) require written permission from the copyright holder for reproduction. Adaptation of tables or figures from copyrighted sources also requires approval. It is the author’s responsibility to secure such permissions; a copy of the copyright holder’s written permission must be provided to the Editor immediately upon acceptance of the article for publication.

11. Client/patient confidentiality must be protected in the title, abstract, text, photos, illustrations and other accompanying material. Proper releases for use of client art expressions and other client information must be obtained and kept on file by the author.

12. It is expected that any manuscript accepted for publication in *Art Therapy* will go through at least one revision before publication. If authors have prepared their manuscripts on either an IBM, IBM-compatible or Macintosh computer, upon acceptance, they can send a 3.5" diskette containing an electronic copy of the manuscript to the AATA office. This will help speed proc-essing, editing, and publication.

**Note:** Authors bear full responsibility for the accuracy of all references, quotations and materials accompanying their manuscripts.
ATTENTION AUTHORS

In order to help us process your submission more quickly, please complete the following information and attach one copy to your manuscript:

Name: ____________________________________________________________

Degrees/Credentials: _______________________________________________

Address: _______________________________________________________________________

Phone #: _______________________________ work _______________________________ home

Type of Submission (check one):

____ Article

____ Brief Report

____ Viewpoints

____ Book Review

____ Film/Video Review

Title of Submission: _________________________________________________

The American Art Therapy Association, Inc.  
1202 Allanson Road/Mundelein, IL 60060  
(708) 949-6064
STATEMENT OF PURPOSE: Art Therapy: Journal of the American Art Therapy Association is the official journal of the AATA. The purpose of the journal is to advance the understanding of how visual art functions in the treatment, education, development and enrichment of people. The journal provides a scholarly forum for divergent points of view on art therapy and strives to present a broad spectrum of ideas in therapy, practice, professional issues and research. An emphasis is placed on the use of the visual arts in therapy, but articles in related disciplines of interest to art therapists will be considered for publication.

ART THERAPY: JOURNAL OF THE AMERICAN ART THERAPY ASSOCIATION (ISSN 0742-1656) is published quarterly by the AATA, Inc., 1202 Allanson Road, Mundelein, Illinois, U.S.A. 60060. Telephone (708) 949-6064; FAX (708) 566-4580. Non-members may subscribe at the following annual rates: $40 (U.S.) and $64 (Foreign); Institutions: $57 (U.S.) and $80 (Foreign). AATA members receive the Journal as a benefit of membership.

Single Issues: For price and ordering information, call or write to AATA, Inc., 1202 Allanson Road, Mundelein, IL 60060 (708) 949-6064.

This journal is abstracted in: Psychological Abstracts, INNOVATIONS & RESEARCH, Art Bibliographies: Current Titles and Art Bibliographies: Modern.

Advertising: Please see advertising rates listed elsewhere in this Journal or contact the American Art Therapy Association, Inc., 1202 Allanson Road, Mundelein, Illinois 60060 (708) 949-6064. The publication of any advertisement by the AATA, Inc., is not an endorsement of the advertiser or of the products or services advertised. The AATA, Inc., is not responsible for any claims made in an advertisement.

Authorization to copy: No part of this publication may be reproduced, stored in a retrieval system or transmitted in any form or by any means, electronic, electrostatic, magnetic tape, photocopying, recording or otherwise, without permission in writing from the copyright holder.

Change of Address: Notices should be sent at least six weeks in advance to AATA, Inc. Subscribers should notify the post office that they will guarantee forwarding postage. Undelivered copies resulting from address changes will not be replaced, but single issues may be purchased at the single issue price.

About the Cover: "Dead or Alive," 54" × 29", cardboard, sticks, plaster gauze, acrylic paint, by Pat Allen, PhD, A.T.R. "This piece is influenced by Mexican art associated with El Dia de los Muertos, the holy day which honors and welcomes back the spirits of those departed with food and celebrations. In keeping with this spirit, the piece overlooks my dining room table. An awareness of death in life and an aesthetic which incorporates the detritus of everyday life—egg cartons, toilet paper rolls, newspaper—informs the work."
Editorial

Introduction to Special Issue: Art and Medicine

Cathy A. Malchiodi, MA, A.T.R., Editor

This special issue of the journal addresses the application of art therapy within a medical context. The high response rate to the initial “Call for Papers” on the topic of art and medicine indicates that many art therapists are investigating the unique role of art expression in the medical setting. This special issue also comes at a time when Hillary Rodham Clinton may have made public her comprehensive plan for the nation’s health care. Where or if art therapy is included in this plan remains to be seen, but it is certain that art therapists have been active in providing their services to a variety of patient populations in medical settings.

The term medical art therapy has been applied to the specific use of art therapy with individuals who are physically ill, experiencing trauma to the body, or undergoing aggressive medical treatment such as surgery or chemotherapy. However, the exact definition of medical art therapy varies as much as the practitioner, the population, and the setting in which it is presented. Over the last few years, art therapists have contributed knowledge on the use of medical art therapy with patients suffering from cancer (Cotton, 1985; Dreifuss-Kattan, 1990; Jeppson, 1983; Mango, 1992; Minar, 1992; Minar, Erdmann, Kapitan, Richter-Loesl, & Vance, 1991; Perkins, 1977); pediatric burns (Levinson, 1986; Levinson & Ousterout, 1979); arthritis (Lusebrink, Turner-Schikler & Schikler, 1982); acquired immune deficiency syndrome (Rosner & Sagman, 1985; White, Fenster, Franklin, Rosner-David, & Weiser, 1991); and on general connections between art expression and health (Long, Chapman, Appleton, Abrams, & Falmer, 1989; Lusebrink, 1990; Malchiodi, 1993; Tartakoff, 1991). Others outside the field of art therapy have also explored the use of art expression (particularly drawing) with physically ill individuals (Achterberg, 1985; Achterberg & Lawlis, 1978, 1984; Seigel, 1987; Simonton, Simonton, & Creighton, 1978).

There are distinct differences between art therapy conducted in a psychiatric milieu and art therapy conducted in a medical setting, due to the environment, goals, and focus of each. For example, medical settings may have different objectives than psychiatric milieus, one obviously being the primary concern for the physical care of patients. Although psychological dimensions of treatment are important in a medical setting, the first goal is to expediently treat the presenting illness or physical condition. Therefore, art interventions must be designed with the overall medical treatment of the patient in mind, and with a knowledge of the particular illness, medications, or procedures involved in each individual case.

In contrast to most psychiatric settings, hospitals provide crisis care for patients’ physical needs, including urgent medical assistance such as surgery, pharmacological interventions, or emergency evaluations. Appleton (in this issue) cites the need for crisis intervention models of art therapy, models which differ from those used in long-term psychotherapy settings. In a medical setting, crisis models of treatment are more applicable to the changing needs of
patients whose physical conditions may be unstable and who have to cope with issues of loss surrounding body image and self.

Additionally, it is obvious that the physical condition of the patient affects how art therapy can be presented. In some cases the patient is fragile and susceptible to infections, and the art therapist must be cognizant of maintaining the sterile environment through appropriate use of media and tools. At other times the patient may be unable to participate without physical adjustments, such as arrangements for art therapy at the bedside or creation of special devices to help the patient draw or paint. For example, Cotton (1985), in her work with pediatric cancer patients, describes her patient Sabrina as unable to hold a brush at one point because of the deterioration of her health and the damage to her hands from intravenous injections.

The circumstances under which art therapy is conducted in a medical setting may also be different than in a psychiatric setting. For example, Council (in this issue) notes that art therapy with pediatric cancer patients may be offered in the hospital waiting room where children await chemotherapy, radiation treatments, or check-ups. The family, including siblings, may be present and may become part of the art therapy. Confidentiality is not easily maintained in this open environment where patients come and go at will, and where art therapy essentially takes place in a public arena, such as a waiting room or at bedside.

In addition to the uniqueness of the application of medical art therapy with client populations, some additional questions about art therapy within a medical setting come to mind. For example, do art expressions reveal disease and/or recovery processes? A body of evidence supports the idea that the somatic aspects of a patient’s condition appear in his or her art product (Bach, 1966, 1975, 1990; Cotton, 1985; Levinson, 1986; Malchiodi, 1991; Perkins, 1977). In this issue of the journal, Judith Wald presents the case of Mel whose progressive neurological deterioration may have been evident in the art expressions he made during the last several years before his death. As investigation of the somatic component in art expressions continues, it is likely that art therapists will be able to contribute to the overall medical evaluation of patients through graphic clues to regression, remission, and recovery from disease which appear in art expressions.

In addition to the material presented in this issue of Art Therapy, there is a larger context in which medical art therapy could become a major player in the future. The recent Public Broadcast System presentation of “Healing and the Mind” (also see accompanying text, Healing and the Mind, Moyers, 1993) explored the mind/body connection and the increasing interest in so-called “alternative” forms of health care. The series investigated the field of psychoneuroimmunology, the use of Eastern methods of health care such as acupuncture, Tai Chi, and meditation, and progress in understanding the role that the mind and emotions play in health and well-being.

“Healing and the Mind” highlighted the recent advancements that health professionals, including art therapists, should be cognizant of in the care and treatment of patients with life-threatening illnesses. A particularly moving segment addressed the treatment of patients with breast cancer and how group support may be a key element in prolonging the lifespan of those patients with metastatic breast cancer. Dr. David Speigel at Stanford University found that women who participated in support groups in which they expressed a complete range of their feelings about their disease lived, on average, twice as long as women who were assigned to a control group. Although Speigel agrees that this research needs further validation (he is currently conducting additional studies to verify his initial findings), there seems to be a strong connection between social support, opening up to others, and resistance to physical illness (Pennebaker, 1990; Schaefer, Coyne, & Lazarus, 1982; Speigel, Bloom, Kraemer & Gottheil, 1989; Wortman, 1984; Wortman & Conway, 1985).

This segment emphasized the necessity for considering aspects of social support theory, resilience, and stress reduction when tailoring interventions to meet the needs of patient groups in medical settings. For example, if it is true that social support and opening up to others are beneficial to individuals who are experiencing a life-threatening illness such as metastatic breast cancer, then perhaps art therapy may be useful with this population in a group setting where talking and sharing the content of art expressions are the focus. McNiff (1992), although not specifically discussing medical populations, cites the inherent value of art therapy and art making in telling one’s story to other members of a group. This type of “storytelling” about one’s images may prove to be useful in providing a socially supportive way to express feelings about illness, particularly with patients whose lives are threatened by cancer or other diseases.

Although art therapy as an adjunct to medical treatment was not specifically cited in the “Healing
and the Mind” series, the segment on Commonweal Cancer Help Program in Bolinas, California, showed participants engaging in art activities, along with other experiences such as creative writing and sandtray. Michael Lerner, president of Commonweal, described the program’s goal as helping “individuals find their own personal pathways to healing in an effort to optimize their chances for recovery” (p. 12, Graham, 1993). In this sense, the approach of Commonweal is in sync with the goals of medical art therapy which utilizes expressive modalities to meet each person’s needs for exploration of his/her disease experience in a way that is most comfortable and accessible.

A question concerning the profession of art therapy emerged from the Commonweal segment: Is art therapy a form of alternative health care? Although many art therapists do not wish to be included in the same ranks with Ayurvedic medicine, massage, biofeedback, etc., it may be that art therapy is perceived by the larger public as something less than mainstream and, therefore, part of the alternative health care movement. As the view of health care shifts during the 90s, this may not be as distasteful as it seems. Alternative forms of treatment are currently being given attention by government agencies, in particular the newly formed Office of Alternative Medicine (OAM) of the National Institutes of Health (NIH). Included on the OAM advisory panel are O. Carl Simonton, pioneer in the use of visualization with cancer patients (Simonton, Simonton, & Creighton, 1978) and Bernie Siegel, surgeon and popular author (1987, 1989), among others. It is interesting to note that both Simonton and Siegel have used drawing in conjunction with their programs, although generally as an adjunct to guided visualization and relaxation.

Lastly, does the use of art therapy with physically ill individuals present any implications for the healing process itself? The answer to this question involves many variables, including how the art process is presented, whether it is presented in a group or individual setting, the characteristics of the population, etc. Long-term outcome studies, such as Speigel’s work with patients with breast cancer, may be necessary to begin to identify if there are properties of art expression which contribute to the health and well-being of a specific patient population or to physically ill individuals in general.

Fortunately, healing is not defined only by blood chemistries or the eradication of tumors. Playwright and writer Barbara Graham (1993) notes that “being healed isn’t the same as being cured. Healing is a process of becoming whole—physically and psychologically... healing takes place even as the body weakens” (p. 12). It may be that future research in the field of medical art therapy will be in the areas of evaluation of somatic conditions and assistance in the physical recovery of some patients. However, the greatest impact of medical art therapy also could be in the art process’s ability to synthesize and integrate client issues such as pain, loss, and death, and the art therapist’s ability and training to help patients do this through art making. By Graham’s definition of healing, the use of art expression in conjunction with a total medical treatment program may be one of the most viable avenues through which our patients can find true healing in their lives.

Excerpts from a letter to the Editor from Ellen Dissanayake ("Art for Life's Sake," Volume 9, No. 4)
February 19, 1993

Dear Cathy,

I do want to tell you how extremely pleased I am that someone has conceived a whole issue around the importance of biology (and anthropology) to our understanding of "art." I think Linda's (Gantt) commentary, more than anything else that has been written about my work, catches, comprehends, and clearly states the ramifications and importance of the "palaeoanthropological" approach. I am really thrilled to see it all set out—and wonder if anyone has commented. Liz Ratcliffe's review of Homo Aestheticus was wonderful; she really read it closely and is the first to have mentioned the psychology chapter, which I think is one of the most important contributions of the book.

My year here (Sri Lanka) has been most enjoyable—a real change from American life . . . my very best to you.

Sincerely,
Ellen Dissanayake, Fulbright Senior Scholar
Bahirawakanda, Kandy, Sri Lanka

Letter to the Associate Editor
January 13, 1993

Dear Dr. St. John:

Thank you for inviting me to reply to the review of the Silcer Test of Cognitive Skills and Adjustment (2nd edition) and for the opportunity to thank Anna Hiscox for her thoughtful observations.

The review criticizes, rightly, the absence of norms for students in grades 9, 11, and 12, and the inadequate number of adult norms. These norms were not developed because I did not believe they would be useful, assuming that older respondents would have acquired the cognitive skills under consideration. I was wrong.

Maggie McCready presented the Silcer Drawing Test to a class of college students who received a mean score of 39.67 points, out of a maximum of 45. One respondent received low scores in Drawing from Observation together with a strongly negative Drawing from Imagination. (A small mouse stabbing a cat through the stomach and back with a large, bloodied knife, scored one (1) point.) Morbid responses, scored one point, were found to be associated with adolescent depression (Silver, 1988), suggesting that preoccupation with emotional problems had affected the cognitive functioning of this respondent.

Glenda Hunter, in a doctoral project at the University of New England, Australia (1992), used the Silcer Drawing Test with 65 male and 128 female college students. She found gender differences in spatial thinking and problem-solving among 10 variables: abilities to select, combine, and represent (concept formation, creativity, and problem solving); horizontal, vertical, and depth relationships (unrestricted spatial thinking and problem-solving); predicting horizontality and verticality (conversation); and projection (adjustment). The findings suggested that females are characterized by higher performance in unrestricted spatial thinking and problem-solving.

Although I would like to expand the norms, I am now retired and no longer have access to sample populations. If any readers have used the Silcer Drawing Test with older populations, or would like to do so, I would greatly appreciate hearing from you.

Sincerely,
Rawley Silver, Ed.D., A.T.R., H.I.M.
Sarasota, FL

Associate Editor's Note: Readers who are interested in contacting Dr. Silver may write directly to her at 3332 Hadfield Greene, Sarasota, FL 34235.
An Art Therapy Protocol for the Medical Trauma Setting

Abstract

Art therapy as crisis intervention is relatively new in the field of medical trauma care, outside of the psychiatric setting. Art therapy on a trauma unit provides unique opportunities for clinical intervention and field research. This paper presents an art therapy intervention protocol developed for a burn trauma unit over a 10-year period. A research paradigm for assessing artwork and the psychosocial transition from trauma, rationales for art therapy in a medical setting, and documentation are considered. A case study illustrates the ways that art media were used to review, integrate, and express the personal experience of recovery from severe burns.

Introduction

Crisis intervention has been developed only within the past few decades. It cannot be directly related to any single theory of human behavior as all have contributed to some degree (Aguilera & Messick, 1986). At a minimum, the therapeutic goal of crisis intervention is the psychological resolution of the individual's immediate crisis and the restoration of functioning that existed precrisis (Watkins, Cook, May, & Ehlben, 1988). A larger goal is improvement of functioning above the precrisis level (Aguilera & Messick, 1986). The implementation of these goals requires an integration of allied professionals in the total care of trauma victims (Bowden, Jones, & Feller, 1979).

Lusebrink (1990) notes the body of research evidence (Achterberg, 1985; Achterberg & Lawlis, 1980; Korn & Johnson, 1983; Sheikh & Kuzendorf, 1984; Simonton, Simonton, & Creighton, 1978) sup-porting the notion that "imagery can be used as a healing agent to supplement conventional medical procedures" (p. 219). Also, color, line quality, and themes in artwork were observed to assist medical patients in the expression of feelings surrounding illness, hospitalization, surgery, body imagery, and medical procedures (Abel, 1953; Bach, 1966, 1975; Furth, 1973, 1988; Lusebrink, 1990; Machinsky, 1982) as well as about home and family (Landgarten, 1981; Levinson & Ousterout, 1979), and staff (Miser, 1979). A panel describing innovations in "medical art therapy" was presented at the 20th Annual Conference of the American Art Therapy Association (Long, Chapman, Appleton, Abrams, & Palmer, 1989). Art therapy functions clinically in psychosocial burn care as: (a) a projective base, (b) a diagnostic tool, and (c) a mode of treatment (Levinson & Ousterout, 1979).

As a colleague of Levinson's, the author wrote a research grant to provide art therapy with adolescent and young adult burn patients. The study ranged over a 10-year period, between 1981 and 1991. Lee's (1970) model of the salient psychosocial issues in the transition from trauma provided the foundation for the research paradigm. Artwork descriptors were found to reflect Lee's four stages as follows:

Stage 1. Impact: Morbidity was expressed in color choice, line quality, and images reviewing trauma impact.

Stage 2. Retreat: Regression was expressed through fantasy imagery, superhuman figures, sunsets, and design/abstracts.

Stage 3. Acknowledgement: Family and social interactions were reflected in images of trees, and self-concept through self-selected "healing" colors, and mandalas.
Stage 4. Reconstruction: Psychosocial issues of mastery, independence, and future goals were observed in the patients' selections of art processes and in home images (Appleton, 1989).

Intervention Protocol

The following is an overview of the protocol developed for art therapy interventions on a burn trauma unit. The interventions are based on the achievement of eight clinical objectives. Each is cited below with supporting rationale.

1. To establish a therapeutic framework for art therapy interventions with the patient.

A trust relationship that reinforces the therapeutic alliance is established with the patient through art processes. Symbolic processes are the focus of the intervention and offer ways to transcend the verbal limitations exacerbated by the trauma sequelae (Lusebrink, 1990). Furthermore, symbolized feelings and experiences can be a more powerful mechanism of expression and communication than verbal description alone, and at the same time render these feelings and experiences less threatening (Dalley, 1984).

Art therapy interventions occur at the patient's bedside with media that are chosen by the patient from a consistent selection presented by the art therapist. For instance, the art media may include dry watercolor cakes (12 colors), felt pens (wide and thin), watercolor cartridge brushes, soft pastels (24 colors), and collage materials for use on paper or boxes (magazines, colored papers, glitter, and medical supplies such as cotton swabs, tongue depressors, and syringes). Both the art therapist and the media provide the patient with a sense of continuity. In recovering from trauma, a consistent relationship with key caregivers is essential, both for the quality of the therapeutic relationship and as a reality reference for the trauma survivor who suffers from a sense of depersonalization, disorientation, and loss of identity.

2. To utilize the patient's natural coping mechanisms of denial and projection through art processes.

The process of art therapy is based on the recognition that an individual's most fundamental thoughts and feelings, derived from the unconscious, reach expression in images rather than words (Naumburg, 1973). When the symbolic aspects of imagery are accessed, along with the verbal and cognitive, art therapy can provide an integrative and healing opportunity for the individual (Rubin, 1984).

The art therapist works with the patient to evaluate his or her coping capacity. Art processes are discussed and ideas and media offered to the patient. The majority of the art therapy activities are either spontaneous or impromptu. For the purposes of assessment and projection, the art therapist specifically requests that patients render the traumatic event and subsequent experience of hospitalization and administers Buck's (1978) House-Tree-Person diagnostic.

3. To clear up misconceptions regarding hospitalization, medical procedures, and/or the burn injury event.

The therapist works with the treatment team preparing patients for surgery and daily hospital procedures in burn care. Through art processes patients are observed to place the burn/trama event into a temporal perspective. The art products provide, as Dalley (1984) describes, a concrete visual record that exists over time. The visual and symbolic images become important for both the staff and the patient, recording gains or setbacks in psychosocial adjustment.

4. To encourage mastery and creativity, enhance self-esteem, and reaffirm the patient's appropriate age-level abilities.

It is documented that burn patients who are actively involved in their own care have better prognostic outcomes than those patients who remain passive (Scanlon & Levesque, 1981). The art therapy activities provided on the trauma unit (drawing, painting, and building collages on paper and boxes) require active and creative interaction with media. The ability to control media becomes an opportunity for the patient to control the feelings of anxiety, helplessness, immobilization, and sensory deprivation common among trauma victims.

Burn and trauma victims typically regress during crisis and the stress of injury and hospitalization. Extremely regressed patients are not compliant with procedures and may become overwhelmed, exhibiting behaviors ranging from acute depression to hysteria. Art processes offer the patient a vehicle for self-expression through creative and generative activity.

5. To offer the patient emotional, physical, and social outlets to decrease stress.

As pain is directly linked to stress response, the relaxation benefits of art activities assist in pain control. The therapist can encourage more compliance with nursing staff and physical therapy by initiating activities where the focus is nonmedical. For example, art activities where the patient must reach with
a paintbrush or move around a sculpture indirectly encourage the stretching of scarred areas and the getting out of bed and becoming mobile, and enhance social interaction with others. Art products in the patient's room or conjoint art-making processes between patient, staff, and family facilitate discussion and verbalization.

Art materials are offered to the patient from a full range of color and media choices. The patient's level of physical energy can be seen in his or her selection and use of the media, each of which has specific physical properties and capabilities. Media are viewed on a continuum ranging from those more easily controlled, such as sharp pencils and felt tip pens, to those more difficult to control, such as watercolor paint (Landgarten, 1981).

6. To bridge the gap between home and hospital through all phases of the recovery from trauma.

The goal is to return the patient, as much as possible, to precrisis life. Thus, predischARGE planning and preparation are an important phase of care. Patients need to feel they will be cared for after they leave the hospital. After the home situation is evaluated, follow-up art therapy may be recommended. Also, the therapist may refer the patient to a social worker and/or psychiatrist for postdischarge psychosocial therapy, when appropriate. Patients often report that they learned through the therapeutic relationship with the art therapist that it can be appropriate to "ask for help."

7. To evaluate the premorbid family situation and to assess evidence of abuse, neglect, or family crisis in the course of ongoing art therapy and psychosocial evaluation.

The art therapist is an advocate for the patient and works with the treatment team during assessment. Abuse may not be overtly verbalized, but can appear projectively in artwork. The art therapist reports graphic representation of abuse for the legal defense of victims.

8. To provide art therapy follow-up groups and appropriate referral to support agencies in the community prior to discharge from the hospital.

Patients often experience a regression to less effective levels of coping when faced with returning home. Often the patient will be returning to the locale of the original burn trauma and will suddenly be fraught with unexpressed feelings. Art therapy facilitates the transition from the hospital to home by reinforcing the expression of feelings. With the patient's permission, the art therapist utilizes the patient's artwork in predischARGE evaluation with the burn team where a plan is created to support the physical and psychosocial needs of the patient outside of the hospital. Follow-up art therapy groups or individual sessions may be indicated at this time.

Documentation

Art therapy interventions are documented in the medical chart much the same way as other treatments accorded the patient. These notes are part of the patient's records referenced by all members of the team: social workers, psychiatrists, physicians, nurses, and consultants. Charting reflects intervention protocols in the following ways:

1. The art therapist meets the patient upon admission to the hospital. As the patient proceeds through hospitalization, the art therapist continues to evaluate the interventions that might be required through consultation with patient, the medical staff, and the medical record.

2. The patient is seen for art therapy two to five times weekly at the bedside, which helps prepare the patient for surgery and other medical procedures, and for discharge.

3. Notes of the doctor, nurses, psychiatrists, social worker, and art therapist are kept in each patient's medical chart and reviewed at case rounds and meetings.

4. Artwork is dated, and the art therapy interview and interventions are documented in the medical chart according to a format designed by the author to avoid duplication of services with other members of the team. The charting format includes: Interaction, Affect, Process/Product, Observation, and Plan (IAPOP). Direct quotes and patient descriptions of art processes are recorded verbatim to preserve idiosyncratic meaning.

5. With the patient's signed permission, original artwork and/or slides of artwork are kept as part of the research data. Patients are informed that their art contributes to an understanding of the experiences of medical trauma patients.

Case Example

The following is a part of a case study developed for a research dissertation (Appleton, 1989) and preserves the anonymity of the study participant. It presents the ways "Michael, patient #13," used art media to make therapeutic gains—moving from regression toward a sense of mastery over his recovery from severe burns.
While driving home intoxicated after his high school reunion, Michael, age 24, was burned after his car rolled on an exit ramp. He claimed throughout hospitalization that he was not drinking that night. Michael's medical report noted fractures to the vertebra of the spine and sixth rib, requiring a long period of immobility and physical dependency on nursing care. He was emotionally overwhelmed, with his burns, exhibiting overly dependent, regressive behavior and low pain tolerance. His behavior was described by the nursing staff as "acting like a four-year-old."

Art therapy interventions were begun as soon as Michael was conscious for 24 hours, the ninth day of his 35-day hospitalization (5 weeks). He stated then "I just want to be dead. This is the worst pain I have ever had" and rendered the accident in black and red including a diagram of the highway, an image of what a passerby would have seen, and an image from his perspective pinned underneath the car (Figures 1, 2, and 3). The next day he drew a nightmare of the accident and tore it up to throw away. These images reflect the impact of trauma, and his artwork is characterized by black, orange, and red color choices often observed among burn patients (Appleton, 1989). During this period he was beset with nightmares of the accident.

After some relaxation training with the art therapist, he painted a mandala and began to explore a difficult media, watercolor. He worked slowly, was absorbed in the painting process for two hours, and called the work "the many aspects of pain" (Figure 4). He continued painting on his own throughout the week to complete the mandala. At this point in his recovery, his main concern was how people (women, in particular) would react when they saw the scars on his chest and abdomen.

Figure 1. "Accident diagram of freeway exit."

Figure 2. "Accident from my perspective."

Figure 3. "What the passers-by saw."

Figure 4. "The many aspects of pain."
The acknowledgement stage, as described by Lee (1970), is typified by periods of mourning and frustration when the patient realizes that his former self has been significantly altered. Michael drew an image in soft pastels which he titled "Frustration (sic)" (Figure 5). The image includes scratchy lines, restriction of the body posture, and lack of hands and lower body, and may reflect Michael's emotions regarding his changed body as well as his physical limitations at this stage of healing. He was still immobilized in bed at this point in his care.

By the midpoint of his hospitalization, the 19th day, Michael painted a watercolor of Hawaii and was able to hold the paper without assistance from the art therapist (Figure 6). This ability pleased him and he stated, "I'm not in as much pain now." His attitude with the media was exploratory and his behavior became less demanding, regressive, and dependent. By the 26th day of hospitalization, he requested a re clarification of the art therapist's role. He stated, "I want you to know, I have my own ideas about my care, and I don't need all the help I did before. I'm accepting my burns better now." The following day he asked his mother to leave his bedside for the first time. He told her, "This is my therapy time now." During this session he created images reflecting his world travels while in the Army. The collage, called "The Old World," includes images of Europe (Figure 7).

The final stage of Michael's recovery from burn trauma was reflected in three works (Figures 8 and 9, and a clay piece; no figure available). "Spanish Galleon" with three masts was created before returning home to his three family members (Figure 8). The ship is a form of transportation, perhaps symbolic of sailing away or a way out of the hospital. However, Michael expressed ambivalence about leaving intensive care. This ambivalence may be
Figure 9. "The City."

seen in the fact that his sailboat has no sails. The image titled "The City" (Figure 9) leans toward the left, perhaps reflecting his stated hesitance to leave the unit and concern over his ability to care for himself. This resistance to leaving the burn unit was temporary. His last art process while an inpatient was to build a house in plasticene clay. The sides were cleverly constructed so the structure would not fall when the roof was positioned. He stated, "Notice how my house can stand without supports." Buck (1966) suggests that the house is a projection of the self; perhaps Michael was symbolically stating his ability to support the burden of his own care.

During the last session with the art therapist, Michael made numerous statements about his plans to do things for himself. He wanted to see his medical chart and arranged for in-home art therapy visits postdischarge. He stated, "I learned from this art therapy that sometimes it's O.K. to seek counseling—something I never would have done before." He had overcome the emotional and physical regressions he experienced in burn trauma through the mastery of art media and had acquired a new perspective and value of his own care.

Conclusion

Art therapy in the sterile, medical environment validates the deeply personal nature of the patient's experiences by focusing on feelings and expressive processes. In this way, art therapy supports the clinical understanding of trauma as an idiosyncratic process that is impacted by social perception, premorbid adjustment, prior psychiatric diagnoses, support systems, coping styles, cultural reference, gender, and personality (Andreason, Noyes, & Hartford, 1972; Gaines, 1986; Jacobson, 1965; Mestrovic, 1985; Peterson, 1986, 1983; Silverman, 1986; Viney, Benjamin, Clark, & Bunn, 1985).

At the burn unit, patients ranging from pediatric to geriatric age groups were extremely receptive to art therapy interventions. On a Likert-style survey developed for this research, 100 percent of the study participants reported that "art therapy has been helpful to me during my hospitalization” (Appleton, 1989).

The protocol described in this paper offers a therapeutic and educational tool for settings other than the burn trauma unit, when and wherever brief therapy and/or trauma assessment and counseling services are required. Such services may include crisis and emergency housing, disaster intervention, abuse recovery counseling, psychiatric surgery units, emergency rooms, intensive care units, oncology units, and rehabilitation units. Examining the artwork of trauma survivors contributes to the understanding of the complexities of their adaptations. Thus, art therapy allows the exploration of the many ways individuals make the transition from trauma to recovery, a most beneficial process for all concerned.

Art Therapy with Pediatric Cancer Patients: Helping Normal Children Cope with Abnormal Circumstances

Tracy Councill, MA, A.T.R., Washington, DC

Abstract

Art therapy with pediatric cancer patients addresses the emotional and developmental needs of an essentially normal population under extreme stress. Assessment and intervention must be made in response to the unique emotional impact of cancer and its treatment on young patients. This paper reviews the literature on the problems likely to be encountered by the pediatric cancer patient and presents case examples to illustrate the emergence of these issues and their management in art therapy.

Introduction

Art therapy with pediatric cancer patients presents a set of diagnostic and theoretical challenges distinct from those encountered in working with psychiatric populations. Traditionally, art therapists have used artwork to identify psychopathology and to resolve internal conflicts. The medical patient, in contrast, may not only need to resolve internal conflicts, but also to negotiate physical illness and/or disability so that she or he can continue to grow and develop as a person.

In the medical setting, art therapy may be considered as an adjunctive treatment, since patients come to the hospital primarily for medical treatment. However, when the art therapist is part of the overall treatment team, she or he can provide a uniquely humanizing influence in the midst of an experience that threatens the child's sense of self and trust in the world (Rollins, 1990). Also, the art therapist's evaluative skills can help the medical team identify psychiatric and behavioral problems that can affect a child's response to diagnosis and medical intervention.

Literature Review

Psychosocial intervention with pediatric cancer patients is predicated on the notion that the diagnosis of cancer and the treatment that follows represent stressors that warrant intervention. Even without expressions of distress, such as noncompliance with treatment, school refusal, or self-destructive behavior that typically result in requests for psychological or psychiatric intervention (Tovian, 1991), pediatric cancer patients may benefit from early psychosocial support. Sanger, Copeland, and Davidson (1991) suggest that screening pediatric cancer patients for adjustment problems is worthwhile, given that psychological sequelae of illness and treatment may extend well beyond the treatment period. Glazer (1991) and others have suggested that bone marrow transplant patients may experience symptoms of post-traumatic stress disorder, and thus extensive psychosocial support for such patients and their families is in order.

Many authors have described the following problems likely to be encountered by chronically ill children: (a) separation anxiety (especially in preschool children), (b) the belief that illness and/or treatment is a punishment for some misdeed or bad thought (in school-age children), and (c) conflicts over dependency versus autonomy (Pfefferbaum, 1989; Schowafter, 1970). Depression, anxiety (both
situational and generalized), and disturbances of body image and self-esteem are reported to occur widely in cancer patients (Lesko, Massie, & Holland, 1987; Pfefferbaum, 1989; Sanger, 1991). Bull and Drotar (1991), in a study of coping mechanisms used by pediatric cancer patients, report that children use different coping mechanisms when encountering cancer-related stressors than they do for other life stressors. Rather than problem-solving strategies they describe more intrapsychic, emotion-management coping devices for cancer-related stressors. In general, much of the literature suggests that children who were preschoolers at the age of diagnosis are most successful in adapting, while children who were adolescents at diagnosis have the most difficulty (Koocher & O'Malley, 1981).

Art therapists have identified several potential applications of art therapy intervention with medically ill patients. Jeppson (1982) describes how to use art therapy to reduce symptoms of depression and anxiety, increase patients' sense of control and autonomy, and facilitate communication with family and the health care team. She also notes that art therapy can promote effective coping strategies outside the hospital and therapeutic session, including relief of pain through distraction. Crowl (1980) describes how art therapy can be used to help a child master his or her anxiety regarding impending surgery. Cotton (1985) presents a case analysis based on the work of Perkins (1977) that highlights the value of nonverbal communication through artwork and suggests methods of interpreting pictures specific to life-threatened children. Bach (1990) emphasizes the interpretation of artwork as a preconscious expression of a patient's physical condition while Jessee (1992) measures body-image in burn patients through art assessment. Themes of helplessness, anxiety, isolation, and body-image emerge in Geraghty's (1985) work with a hospitalized Alaskan girl. Numerous authors have written about their work with the terminally ill: Kern-Pilch (1980) emphasizes the value of choice and control, Rudloff (1985) describes the therapeutic process, and Fenster (1989) explores the search for meaning.

Overview of the Art Therapy Program with Pediatric Cancer Patients

The author works as an art therapist and member of the Pediatric Oncology treatment team at a medium-sized cancer treatment and research center where art therapy is available to all patients, from toddlers through young adults. Since much of the children's chemotherapy is given on an outpatient basis, they spend many hours in the waiting room. Thus, art activities are provided in the waiting room on clinic days. In this very public setting, the traditional boundaries of therapy—a separate room, a closed door, an uninterrupted hour—are unavailable. Parents, siblings, and friends sit close by and sometimes participate. During therapy, patients are called to exam rooms to undergo medical procedures and often return hooked up to IV poles, nausea, aches and pains, or fatigue often disrupt participation. Even when sessions take place in the relative privacy of an inpatient hospital room, the primacy of medical procedures and the child's physical limitations supersedes the therapeutic process.

Though all patients are encouraged to participate, as both in- and outpatients. the child decides whether he or she is able or willing to participate on a given day. It is believed that this measure of choice, given the innumerable procedures over which the patient has no choice, is essential to building a therapeutic alliance in this setting. Hans Peter Weber, the "clinical artist" who collected many pictures for Susan Bach's study of the artwork of medically ill children, emphasizes the element of choice in working with the medically ill. "Children under medical treatment have few opportunities to choose what they do, so I find it not only important but also necessary to allow the child to choose if, when, and what he will draw for me" (Bach, 1990, p. 13). A child's choice not to do artwork may represent a general sense of isolation and social withdrawal that often accompanies cancer treatment. or it may be the result of anxiety over an upcoming procedure, lack of interest, or simply a chance to exert control by saying "no." Thus, every attempt is made to assess the child's behavior in the clinic to help parents and staff support the child effectively.

Case Material

The case material presented reflects work accomplished during the first year and a half of the art therapy program. In the examples that follow, themes of separation anxiety, alienation, anger, aggression and fear, and body-image and self-concept, beliefs about disease and treatment, and images that may represent concepts of death itself are observed. The use of art therapy in the beginning phase of diagnosis and treatment, during middle or maintenance phase of therapy, and following relapse or in advanced stages of disease with poor prognosis are grouped together in order to pinpoint interventions.
ART THERAPY WITH PEDIATRIC CANCER PATIENTS

that may be particularly useful at these stages of treatment.

Diagnosis and Early Treatment

The earliest phase of cancer treatment assaults children's body image, identity, and self-esteem. Embarrassment, anger, and social withdrawal may accompany the child's sudden loss of self. Children may try internally based coping strategies, resulting in depression, withdrawal, self-blame, and alienation. A supportive, client-centered, and at times nonverbal approach can help the patient both express troubling feelings and regain some sense of bodily integrity and self-worth. The active presence of the art therapist in both inpatient and outpatient encounters and the relative safety of art materials for displaced expression can afford valuable psychosocial support.

Bonnie

Bonnie, a five-year-old diagnosed with an extremely large abdominal tumor, was immediately hospitalized for evaluation and possible resection of the tumor. I was urged by medical staff to visit her as soon as possible and to begin preparing her for surgery that might be both disfiguring and disabling due to the size and location of the mass. It was expected that the surgery would take place within the next few days.

At our first session I offered play-doh, and she chose to make Easter eggs which we took turns hiding and finding. The hiding and finding game may have expressed Bonnie's efforts to find her own hidden tumor. Though invisible without x-rays and special scans, this mysterious thing had brought Bonnie into the baffling new world of the hospital. Bonnie was so delighted with our game that she used it to begin every subsequent session while she was an inpatient. In our daily sessions, she also created preschematic representations of "Barbie" and used glitter with enthusiasm.

Although I could see the trust-building value of these early sessions, I felt compelled to raise the issue of Bonnie's tumor because of the potentially imminent surgery. I asked Bonnie to make a picture of herself in the hospital. She frowned at first, but proceeded to draw two tadpole figures, a small one with a frowning expression to represent herself and a larger one with what appears to be two smiling mouths to represent her mother (Figure 1). The self-figure is interesting in that the area below the neck is suggested only by a series of dots, which Bonnie indicated represented her tumor. No body outline is used, and a strong horizontal line suggesting bed covers separates the head from the rest of the figure. Bonnie commented that she felt better when her mommy was with her in the hospital. She abruptly concluded our discussion of her tumor by saying she did not like to talk about it, that it made her feel like she had "glitter on [her] head," and she wanted to hunt Easter eggs again. When I wondered aloud what it felt like to have glitter on your head, Bonnie giggled, then looked sad, and said that "people would look at you funny."

Bonnie seemed to express a mix of curiosity, anxiety, and embarrassment about her tumor. Her early work with me seemed to encapsulate the struggle with body image and self-esteem that a cancer diagnosis can bring. Faced with being looked at and monitored by many new people and strange machines, Bonnie used indirect play (hiding and finding eggs) to search metaphorically for her tumor. She drew "Barbie" repeatedly, rehearsing her premorbid identification with an ego-ideal that seemed to represent a fantasy of grown-up femininity. Also, Bonnie used drawings to work out her ideas about her tumor, its appearance, and location within her body.

Bonnie's surgery was subsequently delayed in favor of a period of chemotherapy. As a new surgery date approached some months later, Bonnie again drew her tumor. In the second figure, there is a boundary around the dot-filled tumor; the figure has two-dimensional arms with fingers, a smiling head, and indications of two internal organs, the lungs and the heart. Bonnie made this picture, again at my suggestion, to illustrate the "ultrasound" findings on a doll during a medical play session. Bonnie expressed pride in her drawing, saying that at first she wasn't sure how to draw it, but she thought she did
pretty well. Medical staff commented that her depiction placed her tumor rather accurately within her abdomen.

A client-centered approach was employed to sensitively follow Bonnie’s lead and allow her feelings to emerge without overwhelming her fragile defenses. Bonnie did not ask many questions or attempt to assign blame. Rather, she sought to work things out within herself, using metaphoric play and representations of her own body and an ideal female form in artwork.

Benjie

Benjie was a quiet boy who sometimes mystified me. Although he liked art and seemed to connect well with me during his initial inpatient stay, his participation in art activities in the clinic was infrequent. Many days he sat in the hallway with a family member, far away from the art table, declining invitations to participate. One day Benjie came into the clinic, smiling, and presented me with an illustrated story (Figure 2). The story tells of a boy who “went to a boat,” which was painted red by some “men” and then looked “as good as new.” The illustration shows the newly painted boat on a calm sea, with a jumping dolphin beside it and a wealth of marine life under the water. A large half sun is attached to the left edge of the page. This picture was followed by many pencil drawings of dolphins, boats, and marine life of many kinds.

Although Benjie’s initial phase of treatment was completed without further hospitalizations, he did experience hair loss from chemotherapy and temporary weight gain due to steroids. His burst of marine pictures and renewed communication with me came during a time when his hair had grown back and his weight had returned to normal. The content of his story suggests hope that the doctors would make him “as good as new.” His use of the color red for the boat is interesting in the light of Bach’s work, which suggests that in leukemic children the absence of red may represent the profusion of white cells within their blood (Bach, 1990, p. 45). Within Bach’s framework, his red boat may relate his own perception that his health is being restored by his treatment.

In this early phase of cancer treatment, Benjie withdrew from an activity and an expressive outlet he enjoyed. The work of Koocher and O’Malley, in reporting the insights of childhood cancer survivors, makes a case for the adaptive value of denial and suppression of feelings during active cancer treatment (1981). It may be that such denial and withdrawal, rather than representing pathological depression, allow the child to conserve his or her emotional resources for the concrete hurdles ahead. It was only when Benjie felt better physically that he rejoined the art therapy group. The constant availability of art therapy in the waiting room seems to have significant value for children like Benjie, who may withdraw as the cancer and its treatment attack their bodies and change their outward appearance and rejoin when they are physically able.

Arthur

Arthur, a 12-year-old boy, had surgery to remove a tumor immediately upon diagnosis and hospitalization. Though I visited him during inpatient treatment, his initial artwork was created at his first outpatient clinic visit. He used clay to create a human head with a gaping mouth, upturned eyes, exaggerated ears, and a large scar on the side of his face (Figure 3). After creating this head, Arthur pointed out his own scar, at the back of his head, from removal of his tumor.

After he was hospitalized for a course of chemotherapy, Arthur began a series of clay heads, which he described as “space aliens.” Each of the figures has a gaping mouth and some combination of human, animal, and insect-type features. In one notable session, Arthur said he wanted to make an alien that was “really scary.” After several attempts, he made two creatures, the first a bell-shaped head
with round eyes and an open, round mouth (Figure 4). Next, he completed a dinosaur-like creature with one sharp horn, a scar on his face, and a wide-open mouth. Expressing frustration with his work, Arthur finally blurted out, “I think they look more scared than scary.” During this time, Arthur was experiencing many painful side effects of chemotherapy and was having difficulty complying with treatment, especially swallowing pills and adhering to daily routines. Arthur stated that he just wanted to sleep and kept his drapes closed and the lights off most of the day. He often would not acknowledge the presence of staff members in his room, pretending to be asleep. I offered clay, a material Arthur enjoyed, and a chance to interact without talking unless he chose to. Participation in art therapy was one of the few avenues of communication with hospital staff that Arthur kept open.

Arthur seemed overwhelmed by the disfiguring and disabling aspects of his treatment. Hair loss, scars, pain, fear, and social isolation may have left him feeling like an alien creature. His forced regression to dependence on his parents and staff for daily care and the fear of death caused Arthur to become depressed. Arthur’s work in art therapy allowed medical staff to better appreciate the roots of his withdrawal and to regard him as a young man with complex emotions rather than simply an uncooperative and unappreciative adolescent. The clay figures also gave Arthur a way to express his feelings in the safe displacement of artmaking.

Middle Phase of Treatment

In the middle phase of treatment, intervention is aimed at supporting the patient through the long-term stress of treatment. Denial may be an important ingredient of the patient’s defenses. During this phase, careful attention must be given to helping restore the patient’s sense of self. Often, the cancer treatment team becomes a primary social support. Art therapy can provide a valuable outlet for reflection of feelings about loss and self within a supportive environment.

Jason

Five-year-old Jason was forced to undergo a series of scans requiring ingestion of a thick, chalky barium liquid prior to the test. Jason had great difficulty swallowing enough of the substance to suffice, and several times had to have tubes placed to forcefeed him the substance. Jason and his mother worked closely together to devise strategies that might help him drink the liquid, but these visits most often ended in trauma and humiliation as he was forced to have tubes placed. Before and during much of this period in his treatment, Jason had drawn a figure on nearly every clinic visit. His schema included a squarish yellow head (Jason had blond hair), smiling face, a rectangular body, and two-dimensional arms and legs, and was generally placed in the center of the page. Sometimes Jason placed himself beside another similar figure representing his brother or his dad. His repetitive schema appeared to be a self-image. As the frequency of invasive procedures increased, Jason began to come to the clinic armed with various toy weapons such as armor, a knife, a bow and arrow, and a water pistol.

Once, when Jason had been through the ordeal of tubes and completed the scan, he insisted on returning to the clinic to see the art therapist before going home. Upon entering the room, he requested materials and created Figure 5. He said this image
represented himself, and he left it in the clinic for display. His strong need to create this image seemed to represent his efforts to maintain bodily integrity and a concept of himself in the face of necessary but traumatic violation of his body boundaries.

As Jason neared the end of his treatment protocol, with the invasive procedures limited to periodic but comparatively infrequent monitoring, a greater expressiveness evolved in his self-representations. After a family fishing trip, Jason depicted himself rowing a boat (Figure 6). He also began to draw deer and other animals, places, and vehicles he had encountered in his life outside the clinic, suggesting both renewed energy and an appropriate focus on life events.

Frank

Frank was a nine-year-old boy who had suffered many impairments as a result of his treatment. In addition to temporary side effects, he was left with visual impairment, motor difficulties, and premature signs of puberty. He had visited many doctors at various hospitals, and his approach to the clinic staff was that of an “old hand.” He was outgoing and cheerfully demanding in eliciting support from caregivers, sometimes resembling a little old man in his sophisticated banter, and other times behaving like a demanding two-year-old. He had an articulate, engaging, and supportive family.

Frank was always willing to relate to a new patient how frightened he himself had been upon first coming to the clinic. Frank’s family had moved to America from another country to obtain treatment for Frank, and he did not know English on arrival at the hospital. Frank reported that art therapy helped him feel less anxious about upsetting treatment procedures, especially blood drawing. Despite his apparent adjustment to the treatment setting, Frank one day drew a very messy, smeared, and layered picture of the clinic (Figure 7). He labeled it “Hospital Map,” and marked several “exits” along the bottom of the page. Frank included no entrances to the hospital. In commenting on his picture he laughingly said that if he owned the hospital none of the kids would ever have to get shots, and they would all get well. Frank adamantly did not draw himself in the “clinic” picture, and he never pursued themes of feelings about his illness when they arose, saying it made him feel “too sad” to think about his cancer. Frank seems a salient example of the adaptive use of denial in coping with cancer diagnosis and treatment during a middle phase, when the outcome is uncertain.
Eugene

Eugene was diagnosed with cancer during college. Because of his age and the type of cancer, he was classified a pediatric patient though he was in his early twenties. An introspective and artistically talented young man, Eugene resisted participating in the art therapy program, perhaps because the predominant clinic population were young children. Eugene became more engaged in the art process when invited to prepare a canvas for a patient art exhibition. Following that event, which brought him in contact with other older patients, Eugene occasionally ventured some artistic expression.

Figure 8 represents a tiny painting of a "parade" of assorted characters and animals making their way along a narrow, serpentine precipice surrounded by a black void. By applying Bach’s quadrant method of analyzing artwork, the path along the precipice leads into what she terms the "minus-minus" quadrant, described as the place of darkness and the unknown (Bach, 1990). According to Bach’s method, this aspect of the painting and its overarching darkness may be a poor prognostic sign. Eugene explained that the inspiration for his painting came from a song by the Doors, but he did not explain what the song meant to him.

Some months later, Eugene again produced a tiny painting (Figure 9); this one shows an aerial view of a streetcorner in a deserted cityscape dominated by red and grey. Though this second painting is more firmly grounded than the first, the mood of isolation and danger is profound. After a staff member expressed an interest in purchasing the first painting, Eugene appeared to gain some confidence and questioned the therapist about artists whose work he had seen in museums. Then he produced a sketch (Figure 10) showing a hermaphroditic figure dominating the page, with a bald, bespectacled figure behind him on one side and a tall palm tree on the other. A small, multicolored sun is placed above. Eugene laughed and made self-effacing remarks about this drawing. His artwork alludes to late-adolescent identity concerns, with an overlay of rather brooding and perhaps death-related imagery. It is impossible to know whether Eugene’s artwork expresses concerns related to an individuation process, but he certainly expresses significant worries about himself, his potency, and his capacity for relatedness discussed in the literature on cancer survivorship.
Relapse and Palliative Care

During relapse or palliative care, heightened uncertainty replaces the now-familiar routines of treatment. Anger and isolation may resurface, and communication with family members and staff may break down (Kubler-Ross, 1969). Art therapy may be especially helpful in facilitating communication at this difficult time. Parents and staff members may feel their decisions about treatment are responsible for the patient's imminent death; e.g., if only some different route had been chosen, perhaps it would not have come to this.

The transition from working to save the patient's life to allowing him or her to die is extremely difficult for care givers. Often, it is the patient who first senses that death is imminent, and that isolation becomes painful if it cannot be expressed somehow. The power of art to give expression to profound existential themes and the relationship with the art therapist can be a strong support to the patient when words are too difficult either to say or to hear.

Paul

Six-year-old Paul was considered in remission and then suddenly relapsed. Following the recurrence of his disease he did many paintings and drawings directly focusing on issues of loss and death. When first hospitalized after relapse, Paul's play often related to hearses, and he drew pictures about burglars and a "16-year-old boy" who had died of AIDS. Shortly after his relapse was diagnosed, Paul asked the doctor straightforwardly, "Am I going to die?" Paul displayed none of the denial associated with other cases, but rather a disarming awareness of his own mortality.

Paul's best hope was a bone marrow transplant at another center after several rounds of chemotherapy. He was hospitalized several times during a three-month period. His parents were unable to be with him for long stretches of his inpatient stays, though they kept in close touch by phone. On one occasion, when Paul was particularly lonely and angry with his parents and acting out with staff and other patients, he was asked to draw a picture to show how he felt. Paul painted a simple schematic figure in red watercolor, surrounded by slash-marks in green. He called the figure "Freddy Krueger" (Figure 11) and explained that Freddy was angry because "people keep bothering him."

Hoping to help Paul accept his own intense feelings while conveying that I accepted them, I asked Paul to draw another picture, this time showing Freddy with someone who understands him. Paul then produced Figure 12, a representation of a smiling "Freddy" alongside a larger female figure. Both figures are shown with upraised arms. Paul related that Freddy's friend was a girl, older than he, who understood how he felt. After producing this picture, Paul said he would like to "just rest," and he busied himself in bed with a favorite toy. Paul's work in art therapy seemed to relieve his anxiety at being separated from his loved ones, and to give him a vehicle for expressing both anger and trust of adult care givers.

Paul sailed through his bone marrow transplant with flying colors, only to relapse again. This time his cancer progressed rapidly despite aggressive chemotherapy. Around the time of his second relapse, Paul created a picture of a person picking an apple from a tree. It shows a tree that is completely overtaken in red, possibly the "tumor red" identified by Bach (1990) which symbolizes the burning, pain-
ful force of disease. The tree holds five large apples, the sixth about to fall, a poignant suggestion that Paul's sixth year might be his last.

**Wanda**

Wanda was a young woman in her early twenties first diagnosed and treated at age 12. Failure to achieve remission had resulted in prolonged treatment and eventual failure of her immune system; eventually she chose a course of palliative care over prolonged chemotherapy with no likelihood of cure. Wanda's youth had been disrupted by her illness and treatment. She was in some ways immature and had made few moves toward individuation. Wanda strongly resisted talking about her feelings and had difficulty trusting anyone outside her family, but she was engaging toward staff members and quite talented in art. She related to me, seeking my advice on materials, techniques, and subject matter, but preferred to work at home and bring her artwork in to discuss it.

Her first major work in this context was the large painting she created for the patient art show. This image (no photograph is available) is of a light blue mask-like face floating in a watery green atmosphere, with long, vertical tendrils of seaweed in the background. Within the mask, several goldfish swim. Following this image, Wanda began to do many more creative projects at home and to sell her handcrafted jewelry and items of painted clothing to staff members.

Several months later, she produced the "Firebird" image (Figure 13). In this dramatic, crisply articulated image, the firebird rises over a moonlit lake hidden within a grove of trees. It is surrounded by iridescent paint, giving the bird an ethereal presence. The patient clearly articulated the meaning of the Firebird story as having risen up from the ashes. She did not, however, relate the image to herself. It is my opinion that Wanda used artwork effectively to sublimate her concerns about the meaning of her own impending death. The bird, placed centrally and ascending in the landscape, unmistakably announces that Wanda will soon leave this world, though she was not to speak of her death in words until the very end. She visited our clinic for the last time only a few days before her death, but she did not say goodbye until she asked her mother to telephone us just hours before she died.

Bertman (1991), Kuhler-Ross (1989), and many others have written of the existential aloneness that surrounds the time of death. Wanda's way of preparing for her death was not to talk about her life and her leaving, but rather to allow images to arise from within. When she began the Firebird image, she told me it was something she had always wanted to paint. My role as her art therapist was to provide technical advice, materials, and encouragement, so that in the context of our relationship her innermost experience could find expression.

**Conclusion**

The preceding discussion and case material illustrate psychological characteristics, issues, and coping mechanisms of pediatric cancer patients. The efficacy of art therapy intervention with medically ill children is demonstrated, especially through the following therapeutic benefits:

1. Patients control their own choices of art materials, subject, and verbalization, and many of them are given the opportunity to express themselves as active creators as opposed to victims of a disease or helpless recipients of treatment.
2. Patients maintain communication with the treatment team through art expression at times when relationships are strained by anger, withdrawal.
fatigue, and feelings that are too emotionally charged to be said with words.

3. Patients continue the process of development through visual communication, supporting social and mental growth and mitigating the isolation of the hospital experience.

4. Patients rehearse troubling events and work out concepts of self in art expression, supporting a sense of mastery over feelings about illness and treatment.

As art therapists, we are well acquainted with the value of artistic expression in communicating what is not spoken and in marshalling psychic energy to support the work of life. In medical centers, where science and technology bring about the miracles of modern medicine, the image making along with careful listening can support the work of healing. Familiarity with the emotional consequences of diagnosis and treatment, sensitivity to patients' graphic messages, and trust in the value of opened creativity allow the art therapist to be a valuable support to physically ill children.

Art Therapy and Brain Dysfunction in a Patient with a Dementing Illness

Judith Wald, MS, A.T.R., South Salem, NY

Abstract

The clinical course of a patient whose dementing illness defied DSM III (APA, 1980) diagnostic labeling is followed. Through the patient's art therapy work, the author attempts to corroborate the patient's behavior and performance with clinical and medical tests. This information is then related to present-day knowledge of brain dysfunction and impairment and to the autopsy findings. Art therapy served a special role for the patient, providing him with self-esteem, grounding, and boundaries, as well as with an emotional outlet and means of communicating the realities of his disease. While his well-drawn houses somewhat disguise his impairments, his drawings of people clearly illustrate aspects of the organic disease—regression, depression, and psychotic ideation.

Introduction

Mel was a patient in a Dementia Day Treatment Program for two years. His dementing illness followed a unique course, defying DSM III* (APA, 1980) diagnostic labeling. Attempts to characterize his dementia were made, and changed, as his clinical and morphological symptoms evolved. This paper describes the interesting clinical course of Mel's dementing illness, particularly through his art therapy work, and attempts to corroborate his behavior and performance with clinical and medical tests. This information is then related to present-day knowledge of brain dysfunction and impairment. Finally, findings from the patient's autopsy are described in order to clarify his case.

The Case of Mel

Mel was 80 years old when he was brought to the Geriatric Evaluation Service of a rehabilitation center with complaints of memory impairment and disorientation. Past medical history included bilateral hernias operated on 30 years ago, pneumonia twice in his 20s, pancreatitis, hearing loss (he wore a hearing aid), and heart disease. His medications were Lasix, Lanoxin, Isordil, Potassium Chloride, Hydergine, five vitamins, and Mylanta. Formerly a successful, sociable, hard-working professional, Mel had become withdrawn, uncommunicative, agitated, and increasingly forgetful. His wife reported episodes of nocturnal confusion, odd behaviors such as abruptly leaving the phone, and disorganization in ADL (activities of daily living) skills such as leaving clothes about the house and losing them.

It was noted that since sustaining a head injury with concussion in a car accident a year previous to the evaluation, Mel had failed noticeably. At the time of the accident, the attending physician felt that the patient had a mild to moderate organic mental syndrome. For that reason a CT (Computerized Tomography) scan was performed to rule out subdural hematoma (swelling or mass of blood located beneath the outer membrane of the brain). Indeed, there was no subdural hematoma on the CT scan, but cerebral atrophy (decrease in size of the cerebrum) was noted. Progressive degenerative disease involving cerebral structures was diagnosed. He was put on Elavil to help in the management of dementia.

*Editor's note: This case took place during the time of DSM III; the DSM III-R (APA, 1987) added a "catch-all" category of Organic Mental Disorder NOS (not otherwise specified) which could apply to the client described by Ms. Wald.
Cerebral atrophy causes a pathological state characterized by a breakdown in the stability of dynamic processes; wakefulness and memory disorganization result. These marked behavior changes, as well as others, result from a weakened cortex that becomes easily distracted and unable to discriminate between significant and insignificant stimuli. Mel's altered sleeping patterns, reduced behavioral spontaneity, lack of initiative, and reduced interpersonal exchange pointed to the possibility of frontal lobe damage or depression, which can be masked in dementia-like behaviors. The evaluation team signed Mel out with a diagnosis of cognitive impairment with depression, noting the medical condition of arteriosclerotic cardiovascular disease. It was recommended that Mel attend a Dementia Day Treatment Program. The patient was put on Trazodone, due to suspected depression.

The Dementia Day Treatment Program emphasized memory retraining and socialization through a multidisciplinary approach to manage patients with dementing illnesses. When Mel entered the program, he presented as pleasant, articulate, and eager to participate in all activities. Though abrupt and with a mechanical affect, he was also capable of real humor.

Because Mel was a former architect, a person with previously developed art skills, art therapy served a special role in his treatment, management, and diagnosis. In addition, Mel was considered an interesting case because his failings were so irregular. Although he signed each drawing with his name and the date, scored well on the Kahn-Goldfarb Mini-Mental Status Test (9 out of 10), and brought up current events, he also perseverated endlessly on a topic or theme. While able to hide his failings with a witty remark, his artwork revealed the realities of his disease. For example, in art therapy Mel produced a well-conceived self-portrait as his first drawing (Figure 1). However, his failing perceptions were apparent in his simplified, awkward representation of the chest, arms, and stick fingers. Subsequent portraits similarly revealed good organization for the head, but with increasing disorganization on the rest of the figure. In addition, Mel tended to work impulsively in art therapy without awaiting directives; by providing him with additional subjects and paper, his excessive energy was channeled in a productive manner.

Mel's art was a source of pride and accomplishment to himself and to others. Both patients and staff frequently complimented his ability and encouraged further production. His drawings of realistic scenes demonstrated a good sense of proportion and perspective, although confusion appeared in the perseveration of repeated arches (Figure 2). Premorbidly hard-working and productive, Mel was able to reinforce these traits in art therapy, which seemed to give him a sense of security. He always sat in the "best pupil seat" (next to the teacher) and got his own apron. However, even though the art room was also used for other programs, Mel would instinctively get an apron and sit down in "his" seat whenever he entered the room, no matter what the activity.

In other parts of the program, Mel showed declines in social behavior. He exhibited a voracious appetite for food, his movements were impulsive and ill-considered, and he showed a strong sexual

Figure 1. Self-portrait executed in early stage dementia.

Figure 2. Drawing skill retained in proportion and perspective, but confusion appears in the perseveration of arches.
preoccupation. Altered sexual behavior and impulsiveness are typical of frontal lobe patients who lose the mechanism to monitor and regulate behavior and actions. Mel was presenting generally as more disabled than had been revealed in the evaluation testing.

At one point in his treatment, Mel was away from the program for two months on a vacation in Florida. His wife encouraged him to paint, and he brought back attractive watercolor scenes, but as she said, "not like he used to paint." A change in environment often proves difficult for dementia patients, who respond best to as few changes in environment as possible. Upon returning to the program, Mel was more difficult to manage. Trazodone was discontinued as it didn't seem to effect any notable behavioral change. Because his impulsiveness and belligerence were increasing at home and in the program, Mel was placed on Haldol; he responded well to this medication.

A follow-up GES (Ceriatic Evaluation Service) evaluation changed his primary diagnosis from cognitive impairment with depression to mixed-type dementia. Certain behaviors revealed Mel's continuing behavioral status decline: he would forget to zip his trousers; his eating habits deteriorated; and he misidentified his clothing. Sexual confusion became apparent in his choosing to dance with a male. In art, he painted breasts on a figure he described as a male (Figure 3). (Also, note the ears on the face, the mustache below the mouth, the awkward body, and sideways feet—all contained within a clock going to numeral 24, with a Roman numeral 12, nevertheless, in the appropriate place.)

Mel's perseverations were particularly interest-

ing. For example, unlike most dementia patients, he was able to bring up current events topics; however, he would bring up the same topics week after week and showed a lack of true understanding or the ability to express himself on a deep level. In addition, learning to put his hands on the shoulder of the person in front of him in group dance therapy caused him to put his hands on another patient's shoulders outside the dance therapy sessions, too. Also, in a poetry therapy session, he repeated the same phrase five times.

In art therapy, Mel would repeat a subject for weeks, no matter what new instructions the art therapist gave. When a staff member became a father, Mel perseverated on "Joe, his wife, and their baby." Very concrete and unable to abstract, he added a figure to a group abstract mural. Using art to orient him to task and to get him to notice what others were doing, Mel finally contributed balanced, wavy lines. These wavy lines in turn became a new source of perseveration to add to his future artworks. In one session to get him started the art therapist drew a triangle on a sheet of paper. Mel filled it in with a person and surrounded it with wavy lines. During the next session five days later, he drew a triangle before the art therapist had a chance to explain the lesson; his ability to remember the previous session was remarkable and pointed to a unique variety of "intrusions." To a certain extent it was possible to redirect him to the general topic, after he had completed his first idea. Such inflexible perseverative behavior reflects impaired response inhibition, which is common in frontal lobe patients whose sequencing and organization of elements are disturbed. Unable to shift response strategies, modify or stop a sequence, these individuals endure the lingering sensory experience of previously viewed material. This "pathological inertia of an image" (Luria, 1973, p. 241) results in lack of spontaneity in drawings, intrusions, or omissions.

For a period of time, Mel developed a peculiar behavior—compulsively washing his hands every few minutes in art, especially during clay sessions. Therefore, "messy" media proved to be of little therapeutic value. Instead, his compulsiveness was appropriately channelled with more controlled pencil drawings (see the house, Figure 4. Note how he represented each brick until time ran out. Though well drawn, this three-sided view of a house reflects his organic brain damage). Similarly, Mel would paint pictures of people at the art table, compulsively including every square of the checkboard-patterned tablecloth.
Mel responded best when art therapy was structured; he needed the focus and boundaries of a specific task. Always a willing contributor to group murals of a realistic nature, Mel drew happily from the concrete suggestions of others. For example, his distractibility and impulsiveness in trying to leave the room could be redirected by handing him a magic marker with a suggestion for a contribution. Moreover, classical music played in the background helped Mel to relax. In this atmosphere, with topic suggestions such as “draw memories of a pleasant vacation” and concrete redirections when he got distracted or blank, Mel was able to paint lovely scenes from his trips. Art projects which drew on memory helped offset his memory losses and gave him a sense of pride in his past accomplishments as well as in his immediate art product.

Though productive, Mel’s figure representations showed increasing deterioration—arms originating from the head, ears within the face, and awkward proportions. At times he attached legs to arms, represented women as men or vice versa. One time he gave a girl four legs, noting after he had drawn the figure with straight, standing legs that they were actually bent and seated. Hair on a sculptured clay face multiplied to eight layers (Figure 5). Often he would omit the head, working in an unusual manner from the bottom up. Although Mel continued to enjoy drawing and produced three to four drawings a session, he did not react to graphic errors (another sign of increased dementia). These disconnected and misconnected drawings graphically mirror descriptions of disjointed behavior in frontal lobe patients.

Mel’s social discoordination continued. As he became more and more restless in the program, he developed odd clinical symptoms such as snorting, buccal movements, and tongue thrusting (possible tardive dyskinesia associated with Haldol). Another neurological examination was given to see if neurological changes accompanied his progressive memory deterioration and disorientation: Mel had gotten lost in his community, had deteriorated in self-care, and had difficulty remembering conversations from moment to moment. However, he scored 9 out of 10 on the Kahn-Goldfarb orientation scale, with the same neurological results as originally. A CAT scan showed some cerebellum atrophy, but no other change. It was primarily on the behavioral scale that deterioration occurred. The attending physician noted that progressive deterioration in behavior suggests progressive dementia—not Alzheimer’s disease or depression—a degenerative disease of the central nervous system.

Although failing intellectual capacity was noted in his lack of input in current events discussions, Mel continued to sign his pictures with the correct date. Of note in his figure drawings was a new angular rendition of both arms and legs, perhaps symbolically representing his further loss of ability to reach out and maintain effective control. Asked to make an animal in art, he made bizarre constructions of men and beasts combined, with angular arms and legs (Figure 6). In addition, figures had faces within their rounded bodies (Figure 7). Angular arms and ears became confused and interchanged and mouths were eliminated (coinciding with his failing speech). Representation of an additional face within a body revealed psychotic ideation (Wald, 1984) and drawing skeletons within the body outline in x-ray-like vision revealed his confusion in distinguishing the int-
side from the outside and generally recognizing
boundaries (Figure 8). One theory of schizophrenia
postulates that psychotic symptoms are due to ab-
onormal dopamine activity. Another theory describes
pseudopsychotic behavior in right frontal lobe dys-
function. This psychotic ideation was transient in
Mel, lasting a month.

Mel became more eccentric socially, more diffi-
cult to control, and more aggressive and deter-
mined. Also, his drawing ability continued to re-
gress. He drew a disproportionate tree with a too
thick trunk, thin spike-like branches, isolated leaves.
Noses became triangles, bodies became ovals. Mel
became more machine-like in his movements and in
his drawings. He relied on a stereotyped manner of
drawing himself—even a snowman became a self-
portrait. His figure drawings became "humpty dumpty"
like and feet were omitted. Mel drew a
confused version of a face, although he did notice an
extra ear and wanted to erase it. Reality orientation
was reinforced through artwork by asking him if he
noticed anything wrong or missing in his picture and
if he wanted to add anything he may have forgotten.
Failing vision and hearing appeared to compound
decreasing sensory input. Although he drew an ex-
cellent three-dimensional house, it took him the en-
tire session to notice and correct a missing wall and
to add steps to connect the doors to the base.

Although Mel originally initiated his own draw-
ing ideas, at this point he took them from others.
Having drawn a logical portrait, Mel noticed a pat-
tern in another person’s drawing of a circle and il-
logically (except that the face was a circular shape)
painted the same pattern over his portrait (Figure 9).
He even mimicked another neighbor by drawing
stick-like hair and by signing the neighbor’s name to
his own painting. When the art therapist pointed this out to Mel, he painted over the wrong name with his own name. Symbolically losing more of his own self, Mel needed to draw support from another patient.

Further merging is evidenced in his house drawings, with the appearance of stick arms on their side walls and simplified grinning mouths and chins at the base. (Mel described them as such without any notice of their incongruity.) Though usually drawn as simplistic frontal views, the houses were sometimes accurately drawn three dimensionally. This high skill level reflected the former architect’s training in drafting. This graphic merging, seen in Rorschach’s in percept contamination, can be viewed as Mel’s symbolic need to merge psychologically with another to help take over his failing ego or cortical functioning (Wald, 1986).

At this time, noting a deterioration of verbal skills (including misdating his drawings), Mel was once again tested clinically. Surprisingly, he produced a perfect MSQ score and high MMS score (27 out of 30), placing him within normal, not demented, intellectual range. However, his behavioral score decreased from 5 to 17. The neuropsychologist reported Boston Diagnostic Aphasia Examination results similar to an anomic aphasic (inability to remember names of objects, impairment in ability to communicate), noting that Mel’s auditory comprehension was lower than expected for this disorder. Although his comprehension of single words was good, he was unable to follow two-step commands. He answered only two questions correctly on complex ideational material. He read difficult material out loud fluently, but gave little evidence of understanding what he read with multiple choice responses. On the Boston Naming Test, his score of 34 placed him at the level of an aphasic, showing moderate deficits. The neuropsychologist concluded that his scores on formal language assessment presented a pattern compatible with organic dysfunction, suggesting in particular memory and frontal dysfunction.

In sharp contrast to his well-drawn houses, which somewhat disguised his impairments, Mel’s drawings of people clearly showed his regression and symbolic merging with others. They illustrated sexual confusion, fused men-beasts, psychotic skeletal structures, and faces within bodies. Confused perceptions appeared in awkward proportions, arms originating from the head, misconnected and disconnected arms and legs. Regressed drawing ability was represented in angular arms and legs, a body becoming an oval, a nose becoming a triangle. Body parts were multiplied or omitted. The ears in particular underwent a transformation—drawn within the face, angular renditions, interchanged with arms, merged with eyeglasses. The left ear was omitted and later, the ears became increasingly elephant-like. Though emphasis on ears can often indicate possibilities of paranoia or auditory hallucinations, in Mel’s case it could be largely attributed to his increasingly failing hearing (he wore a hearing aid) and his increasing loss of auditory sensory input.

Mel’s pictures eventually became more bizarre and his simplified smiling mouths turned downward. Asked if he felt sad he replied, “Joe is sad...” again identifying with another staff member (who, ironically, actually appeared happy). These sad mouths perseverated up to nine mouths. Depression was one of Mel’s original diagnoses, but antidepressant drugs had been discontinued early in his treatment when no affective or behavioral improvement was noted. Depression may be due to underactive noradrenaline: Mel’s sadness could also be attributed to a psychological reaction to his failing abilities.

Mel further deteriorated in ADL skills, with incidents of urinary incontinence. He now needed supervision in the bathroom and needed to be seated on the toilet. Mellaril medication was necessary so he would remain calm and nonviolent. An NMR (Nuclear Magnetic Resonance) portrayed his brain as showing diffuse cortical and cerebral atrophy. The physician attributed the results to Alzheimer’s disease with a rather unusual course.

In the last months of his life, Mel’s behavior was so regressed and disturbing to his wife that he was placed in an SNF (skilled nursing facility). He continued to come to the Dementia Day Treatment Pro-

Figure 10. Loss of structure and boundaries: feeling the weight of failing speech and hearing, resulting in a depressed affect.
ART THERAPY AND BRAIN DYSFUNCTION

Figures 11, 12. Omissions, confusion, simplification, depression, disturbed bowel function as patient declines.

gram twice a week, but appeared sleepy and inattentive, with possible hallucinations, he became more active in the program when his Mellaril was reduced. His drawings (Figure 10) had multiple sad mouths (depression and loss of speech), multiple buttons (dependency needs), and multiple stripes on the body (possible feelings of imprisonment). The facial features at times lacked outlines to contain them and sometimes lacked a head (Figure 11), as his brain no longer functioned properly. Instead, new emphasis was placed on disturbed bowel control by multiple balls emitting from the bottom of his body (Figure 12).

Results of Mel’s Autopsy

Mel passed away four months after his SNF placement, just prior to his 82nd birthday. His general autopsy revealed changes expected in an older man with a severe dementing illness: bronchopneumonia, collapse of lungs, heart disease in atherosclerosis and enlarged heart with scarring, enlarged prostate, gallstones, and mild kidney infection.

Results of the brain autopsy presented an opportunity to correlate behavioral, clinical, and medical findings. Before the microscopic results were available (due to the time required for fixation of the brain), the physician described the patient’s brain as within the normal size range, with the two hemispheres of nearly equal size. The gross structure was consistent with the latest medical impression of mixed dementia (both Alzheimer’s disease and some cerebrovascular disease). However, a microscopic neuropathological examination of Mel’s brain did not lead to a simple diagnosis. Neuronal losses were noted; focal loss and neuronal atrophy were noted in the cerebral cortex. The hippocampus showed focal atrophy and spongyous (swelling and excessive fluid in the tissue spaces).

The attending physician at the Dementia Day Treatment Program explained that Mel’s loss of nerve cells occurred in the area characteristically affected by Alzheimer’s disease, the cholinergic nucleus basalis. Nerve cells were also lost in other areas, notably in the locus ceruleus, which is frequently affected by Alzheimer’s disease, and in the substantia nigra, which is affected in Parkinson’s disease. The diagnostic plaques and tangles of Alzheimer’s disease were not found, nor was any evidence of strokes.

These pathological findings explained Mel’s mental and behavioral deterioration. Focal atrophy and neuronal loss in the cerebral cortex were noted in x-rays as well as in the autopsy. Indeed, its function as main coordinator and regulator of thinking and behavior had become disorganized. This correlated with the staff’s and the art therapist’s notation of the continued deterioration in Mel’s behavior, and later in his cognitive abilities.

Frontal lobe deterioration, as suspected, accounted for the personality, social, and behavioral changes, sexual confusion and disinhibition, intrusions, perseverations and omissions, loss of spontaneity, and possibly pseudodepression. Swelling and fluid in the hippocampus accounted for Mel’s memory loss. While memory is stored in many areas, the hippocampus plays a significant role in the process of memory formation, particularly in memory consolidation, storage, and retrieval of new memories.

Marked neuronal loss damaged the nucleus basalis, which has a modulatory effect on neurotransmitters and appears to play important roles in learning, memory, and attention—all of which had become dysfunctional in Mel. In addition, Mel’s artwork at times showed psychotic ideation in skeletal structures and merged and fused percepts. The substantia nigra, the locale of dopamine production, showed marked deterioration. While Mel had no Parkinsonian physical symptoms, such as a stumbling gait or facial rigidity caused by inadequate dopamine production, excessive dopamine activity has been implicated in schizophrenia. Moreover, neuronal loss in the locus ceruleus could account for Mel’s depression. As the main site of norepinephrine production, depression may be due to its underactivity. It is also hypoactive in Alzheimer’s disease, thus the
patient was unable to put current sensory information together with past experience.

The final evaluation of Mel particularly noted degeneration of the substantia nigra, locus ceruleus, and nucleus basalis consistent with Parkinson’s disease. Although morphologically the findings pointed to Parkinson’s disease, clinically Mel did not present with Parkinsonian symptoms. It has been noted that “movement disorders, especially Parkinson’s disease, produce symptoms that are similar to those of frontal-lobe lesions—most particularly, reduced spontaneity of behavior, changed social behavior, and impaired corollary disease” (Kolb & Whishaw, 1980. p. 304). Parkinson’s disease patients can behave much like depressed or schizophrenic patients, and the presence of neurochemical abnormalities in schizophrenia and depression implicates the neurotransmitters noradrenaline, dopamine, serotonin, phenylethylamines, and endorphines. The substantia nigra and the locus ceruleus are significant sites for the production of some of these neurotransmitters.

Conclusion

The pathological findings did not clearly point to a simple diagnostic label to apply to Mel’s dementing illness. Since medical literature does report other patients with a degenerative disease with many characteristics of Alzheimer’s disease but without plaques and tangles (Heilig, Knopman, Mastri, & Frey, 1973), the physician concluded that this may prove to be an emerging syndrome not yet accepted in medical literature. Whatever the diagnosis, Mel’s art paralleled the degenerative course of his disease, providing an additional avenue for understanding the complexities of a dementing illness.

Portrait of an Illness

Mary Lynne L. Ricci, MA, A.T.R., Baltimore, MD

This is the story of my own debilitation, survival, and ultimate rehabilitation from the often devastating and potentially fatal disease, lupus. Emphasis in this paper is on the art experience. The artwork presented evolved long before I understood the art therapy process or appreciated the therapeutic impact that process had on my life.

I had just completed my sophomore year of college, majoring in physical education. Following a difficult separation from my parents at the beginning of the fall semester, I felt that I had finally reached a level of growth that allowed me to look forward to returning to school. Soon after I moved home for the summer, I was stricken with lupus.

The Columbia University of Physicians and Surgeons Complete Home Medical Guide (1985) defines lupus as:

Systemic Lupus Erythematosus, also referred to as SLE or simply lupus, is one of the most serious of all rheumatic diseases because it can involve the kidneys or other vital organs. Like rheumatoid arthritis, lupus occurs predominantly in women, but the reasons for this are not known. It may strike at any age, from childhood into the sixties and seventies, but most patients with lupus will develop it when they are young adults. The symptoms largely depend upon the organs involved, and as the disease runs its course, usually over a period of years, different target organs may be affected. The degree of disease activity varies from potentially life-threatening flare-ups to complete recovery.

The cause of SLE is not known, but certain facts have emerged as a result of years of intensive research. It appears that patients with SLE have a defect in their immune system, particularly with the regulation of the production of antibodies, the protein substances that normally help to defend against infections (pp. 583–584).

The high doses of steroids used to treat the disease have many side effects, one of which (steroid myopathy) caused me to lose the use of my arms and legs. In essence, I found myself slowly becoming paralyzed. I was transported over 200 miles from my home to a hospital for specialized care. My parents were able to accompany me and remained with me over the next three months.

Ultimately, the drug therapy overtook my body. Only my left (nondominant) hand could move, and then, only a few inches above the mattress. I felt robbed of my dignity as I lay there, helpless. My body violated by tubes and needles. I identified with babies I saw on television, sadly envying them because they could crawl. During periods of steroid-induced psychosis, I desperately tried to understand how they managed to crawl, when I could not move. Much of the time I felt like an infant—innocent, vulnerable, and frightened. I was a young adult trapped inside the totally dependent body of an infant. I understood the incredible fear children must experience, the fear of not being nurtured and of being abandoned in their state of helplessness. I was not only unable to do anything for myself physically, but also could not raise my voice to call for help, due to a failed medical procedure that had damaged my vocal cords. I had a new perspective on the frustration a child must feel when attempting to communicate unmet needs.

My thinking and behavior took on primary process features. I could not separate my unconscious
fantasies from current reality, and I expected immediate gratification. Not only did I make unrealistic demands of my caretakers, but I paid scant attention to the requirements of the external environment. The intense conflict within surfaced, and I exhibited little control over my impulses. What little verbal output I had was, at times, most repugnant! As I attempted to gain control to foster more organized thought, my chaotic, unorganized impulses emerged to diminish my sense of self. My ego functions were limited and, therefore, I was incapable of postponing immediate gratification or of regulating my behavior.

I experienced great ambivalence about my situation. Many times I simply wanted the struggle to end; I wanted to die. My parents were with me most of the time. I appreciated their attentiveness, but frequently resented their looming over me. Their ability to move without restraint frustrated me greatly. I also discovered that the nurses were putting crushed medications in my jello, so I refused to eat. My depression intensified as I began to turn my anger inward. My raging anger and frustration became a destructive force within my limp, voiceless body. The days seemed endless.

I frequently experienced delusions and hallucinations as a result of the steroids. My interpretation of reality became very distorted. For example, I was convinced that I heard family members talking in the hallway, and I was convinced that a team of doctors spied on me from inside the light above my bed. I was certain that mouse-sized cockroaches scurried across the floor. (At the city hospital where I was staying, those cockroaches certainly had the greatest potential for being reality-based!)

After 2½ months in the hospital my condition stabilized and I was able to attend physical therapy. The steroid doses were gradually lowered and I was beginning to feel more hopeful about my survival. The physical therapists exercised my limbs to prevent muscle atrophy. One day I worked with a physical therapist who was new to the department. As she seemingly abruptly moved my arms and legs, she said, "You know, you’ll probably never walk again, but at least you have your brains." Her statement catapulted me into a state of deep depression. I stopped eating, would not communicate, and refused to return to physical therapy. A few days after this incident a psychiatrist visited me. I was unable to express my feelings and share my interest in art. She wrote orders for me to attend occupational therapy.

The hospital did not employ an art therapist, but the occupational therapy department was equipped with some art materials. I sat in my wheelchair at the end of a long table and watched stroke survivors place pegs in holes. The physical therapist’s words echoed in my mind. The sights and sounds of the occupational therapy department left me quite unmotivated; I felt trapped both physically and emotionally and needed, but was unable, to communicate my deepest fears and raging anger.

The occupational therapist, aware of my interest in art, devised an apparatus to suspend my barely functional left arm from a rubber sling, thereby allowing me to paint. I finally had an outlet; my creative needs were being met and I regained hope. I felt a surge of determination to prove the physical therapist wrong. Now I believe that her threat of what I perceived to be eternal imprisonment may have been the spark that ignited my motivation to regain both mental and physical health. Further, I suspect that my depression and resignation following her comment represented my need to return to more infantile patterns before I could progress. I identified with the infant’s natural tenacity to survive and its relentless determination to have its needs met.

Now I wonder how my experience would have been different had I worked with an art therapist. My path, perhaps, would have been less rocky and unclear, my journey less lonely. Although it represented only a fraction of my premorbid autonomy, regaining the freedom to paint was a cathartic experience. My aggressive energy finally found a constructive outlet in artwork. Initially I feared failure because I was working with my left hand. However, I soon learned to view that as just one more hurdle to clear.

The Artwork

The image I created developed slowly as I became more comfortable manipulating the swinging apparatus. At first I struggled to steady my hand to accumulate paint on the brush. Working slowly, I applied broad blue strokes across the center of the paper. I became invested in the art process. Each brush stroke became a conquerable challenge. A giant leap toward freeing my body and mind from the heavy physical and emotional burden each had endured.

It took me several minutes to wash the blue paint out of the brush. Then I applied a light wash of yellow-green around the blue. My image suddenly became alive, bringing me comfort as the representation of a pond emerged. My painting began to develop into a landscape (Figure 1). I tested my skill...
Typically, I strive for perfection; therefore, allowing the unexpected “sun burst” to remain may have been part of the process of acceptance. Slowly, my sense of self was restored. I was able to abandon some of my old patterns and enjoy this new experience. Perhaps, on some level, the bright burning orange sun corresponded to my anger. The yellow, added possibly to subdue the rage I felt, softened the intensity of the sun’s rays. Sun can be particularly harmful to lupus patients.

The painting appears to have three main elements: water, sun, and the tree. Unconsciously, these may have represented my parents and myself. Water represented my mother; the sun, my father; and I, the tree, receiving nurturing from both. Spatially, the tree is closer to the water; I am generally more dependent on my mother. My father (sun) oversaw my care in the hospital; likewise, I feel he always had a clear view of my situation.

The stable, upright tree may have indicated my need to stand alone, but it also confirmed my continued dependence and need for nurturing. Further, it suggested two strong urges: the need to venture out into the world and the need for safety. The sparsely covered branches may have reflected both my unhealthy mental state and my underlying doubts about my ability to overcome paralysis. Autumn leaves may have suggested death, but, more appropriately, they depicted a constructive destruction of something old (dying leaves), necessary to build something new (spring blossoms). The heavily painted tree trunk suggested the tree had enough strength to survive the winter and bloom in the spring. Highlighting the leaves of the tree with colors of the sun may have suggested my relationship, on some level, to my father. A final addition to my painting was to carefully paint my last name, using the blue of the water. Again, this suggested another tie to my mother. While the landscape was sparse, located in empty space, it could suggest an element of the unknown.

I believe these symbols fit between my fantasy to be healthy and individuated and the reality of this happening only after a long recuperation. The artwork enabled me to make sense of my world, albeit on an unconscious level, and to separate fantasy from reality by achieving some level of mastery.

I felt some peacefulness; the artwork provided a healthy way to deal with my conflicting feelings and supplied previously unachievable pleasure by constructively redirecting my energy. This increased energy resulted from healthier ego-functions as I moved out of the steroid-induced psychotic state.

and depicted an almost vertical tree trunk. I reinforced the trunk several times with brown paint and then lightly painted a few tree branches with the drying paint that remained on the brush. I was tired but felt that the picture was incomplete. My resolve intensified when I decided to further challenge myself to create a round sun. This was a frustrating process, requiring even more control. At one point, when my swing took an unexpected bounce, a drop of orange paint fell to the side of the sun. It looked like a sun burst! I added yellow inside the circle to soften the intensity of the bright sun. Using a dry brush technique I had learned in high school, I added orange leaves to the bare branches. Although somewhat sparse, the leaves seemed to reflect the sun’s rays, illuminating the scene. This “simple” painting took 1½ hours to complete. I recall the excitement of my parents who noticed a positive change in me when I returned from that therapy session.

The Symbolic Content
Unconscious symbols emerged spontaneously. Only now do I realize they stood for something quite complex. Blue was my favorite color, so it was appropriate that both my first application of color and my initial outlet of deep inner turmoil reflect a form of self-nurturing. After I applied the yellow-green wash and realized that a pond had formed, I felt in control. The yellow-green seemed to add support, provide boundaries for the water, and suggest new life. I believe that I reinforced the trunk with brown paint to provide the tree with the physical and emotional stability I was yet unable to feel.
My creativity increased. Slowly, as the steroid doses were gradually lowered and I engaged in physical therapy, I regained the use of my limbs. A little over one year from the beginning of my bout with lupus I graduated from using a wheelchair to ambulating with a walker.

During my rehabilitation I was constantly involved in creating art. The art experience served several functions. While I was ill the art process was my therapy, albeit on an unconscious level; it provided inner peace. Now, as an art therapist I use it at a cognitive level. Training has allowed me to interpret the symbolic content of the artwork; it confirms the catharsis I felt. In addition, it has helped me be more sensitive to what my patients may be experiencing. My experience of the intense frustration of being unable to communicate has increased my empathy for patients who struggle for expression, either verbally or artistically. The difficulty I had manipulating art materials has helped me understand those patients who feel frustrated when using unfamiliar art materials.

It has been more than 14 years since the onset of my illness; I have been in remission for almost 12 years. At times my memories of the illness are vivid, as though it had just occurred. Persistent dreams about that time suggest that I continue to repress thoughts and feelings related to my illness. On a more positive note, I can say that being able to express my thoughts and feelings through artwork always brings back memories of the enormous pleasure of overcoming seemingly unconquerable challenges. As an art therapist, I hope my patients can reach a similar level of peace in their journeys toward mental health.

The American Art Therapy Association
24th Annual Conference

**Common Ground:**
**The Arts, Therapy, and Spirituality**

November 18 - 22, 1993  Atlanta, Georgia
Atlanta Hilton and Towers

AATA members will receive program information as it becomes available. All other interested individuals are invited to contact the AATA National Office for Conference information.

AATA
1202 Allanson Road / Mundelein, IL 60060
(708) 949-6064  Fax: (708) 566-4580

Preconference Courses and Opening Reception will both occur on Thursday, November 18, 1993. Conference activities continue through Monday, November 22, 1993.
Reviews

Art as Medicine: Creating A Therapy of the Imagination

Reviewed by Vija B. Lusebrink, PhD, A.T.R., Louisville, KY

In his fourth book on art therapy Shawn McNiff sets out to further describe and substantiate his approach to art therapy. The approach is a composite based on the creative arts, parts of James Hillman’s archetypal psychology, Jungian philosophy and the concept of active imagination, his observations from his leadership of “art therapy studios,” and introspection on his own images.

As in his previous books, McNiff writes in the first person and weaves his own experiences with a discussion of ideas and quotes from various sources, including a number of poems. This results in an uneven text. However, at the same time, it gives a taste of the creative process whereby the personal becomes interwoven with general knowledge and archetypal intuitive generalizations. Nevertheless, this book is McNiff’s most mature work on the importance of the role of arts and images in art therapy. Similarly, his rendering of the images that illustrate part of the book shows a new richness, expressiveness, and intuitive aesthetic quality.

Art as Medicine is divided into three parts: Context, Dialoguing and other methods, and Demonstration. In the introduction McNiff defines his approach as a psychology that “desires to activate and move soul by striving to speak its own language” (p. 1). He differentiates this from approaches that explain “the artistic emanations from soul” (ibid). The basic principles underlying his approach are dialogue and interplay between the image and its creator, and an emphasis on increased awareness rather than on a specific image.

The first part of the book, Context, comprises eight subsections. In Simple Beginnings, McNiff covers the evolution of his work in art therapy from the beginning of his work as an artist in a state hospital to his leadership of internationally offered “art therapy studios,” where the main components are relaxation and watching “the flow of painting from the soul” where “deep movements of psyche are made visible through paint” (p. 14). This process constitutes art as medicine.

The shamanistic continuities inherent in this approach are ascribed to images that emerge through engagement in the expressive arts’ therapeutic rituals. This process counteracts the loss of soul or detachment from feelings and estrangement from others and nature that results in bodily and mental illness. Involvement with materials and the subsequent freedom of expression “embrace soul’s varied expressions” (p. 23), without the classification of its pathology.

According to McNiff, the attuning to the archetypal dimension is achieved in the act of painting
through *responding* instead of *strategic planning.* He illustrates this with a personal account of a transformation in his perspective when he encountered difficulties while renovating his house. McNiff also describes the retreat environment of the art therapy studios where he is a co-therapist. He emphasizes that his approach is in opposition to science and that his commitment is *"to liberating art and art therapy from the narrow perspectives of scientism which have discouraged artists from realizing their potential as psychological savants"* [italics mine, VBL] (p. 43).

McNiff discusses surrealism and its psychic automation as art therapy’s clearest link to the *"art world"* of the 20th century. The art therapist is a witness and guide who participates in the shared group experience and its affirmation of the presence of soul in images and personal interactions. McNiff perceives the soul as the *psychic movement or kinesis.* This movement is present during *"interaction with paint.* By *"(s)ticking with the image"* we experience a *"sustained communion"* with the *"image or painting"* (p. 55), in transformations and *"transmigra- tion of soul from one phase of the product to another"* (p. 60). A sense of presence of soul first is evoked through attuning to the perceptual and structural elements of the image.

McNiff assumes an intimate collaboration between artist and images which he sees as the artist’s *"psychic offspring"* (p. 64). *Imaginal realism* directly represents the life of the artist’s imagination. The artist’s own reflections upon the manifestations of the psyche in images and direct dialogue with images are seen as the best research method for indepth art therapy.

McNiff sees artistic images as angels that affirm *"the painting’s existence as a living, expressive phenomenon."* (p. 75). The ensuing dialogue thus becomes one between the *artist and angel.* McNiff bases this approach on Henry Corbin’s concept of images as angels that represent an archetypal dimension of self that always is a guide, leading the person. For example, McNiff elaborates on Nietzsche’s Zarathustra as a guide to his soul. The subsequent discussion of the *daimonic tradition* is based on Greek daimones who, as autonomous figures, guided human actions.

The second part of the book, *Dialoguing and other methods,* briefly covers loquacious meditations, creation stories elucidating the images, responding, talking with images, and the value of dialogue.

In *loquacious meditations* the creator silently explores the visual aspects of the image which, in turn, elicit responses in the viewer. This visual meditation is followed by *creation stories* about the images, which treat the images as *"ensouled"* with the corresponding *"enactment of feelings and psychological tensions."* (p. 100). The *responding component of this process focuses on feedback by the therapist and other participants in the group as they consider the image and feelings aroused by it.

Exploration of the work culminates in *talking with images* or dialogue that *"is based on acceptance of the autonomous life of pictures within a world of interactions and multiple perspectives."* (p. 105). The images thus become *"angels of transformation"* as the creator explores and speaks with various images and their distinct physical and aesthetic attributes. *The value of dialogue* refers to recognizing the autonomous nature of the image and articulation of its *"plural qualities."* This dialogue may be elaborated upon, taking the form of a *performance* of the imagination through movement, voice, dramatic action, and costumes. *Dreaming* and exploration of dream images become part of the process of healing through the images or *"art as medicine.*” McNiff rejects the notion of gestalt therapy, that every part of the dream is part of the dreamer. In his opinion this view results in *"the loss of the daimonic world,"* and he prefers to see images as *"partner,"* with whom the dreamer establishes relationships (pp. 128–129).

The last third of the book, *Demonstrations,* consists of McNiff’s own *image dialogues* with 26 oil pastel paintings. These expressive images depict development of a theme that begins in ancient Babylon with associations to the recent Persian Gulf War. They end with a *"Yankee house,"* presumably McNiff’s own. The essential difference between his discussion of his personal expressions in *Depth Psychology of Art* (1989) and the present book is that the latter presents an evolution and elaboration of his previous more descriptive approach.

The focus of the dialogues is on the interaction between the masculine and feminine aspects of the creator’s psyche, elaborated through the presence of images of animals, trees, house, and walls. McNiff’s image dialogue is, for the most part, cerebral and reflective. He describes the sensory and pictorial aspects of the images, but, curiously, emotions are missing from the dialogue. The representations of the images have depth in moods created and in the immediacy of their presence, but the dialogue has a tendency to become overly intellectual and repetitious, thus contradicting McNiff’s own assertion about the independence and *"daimonic"* nature of images.
ART AS MEDICINE

My synopsis of Art as Medicine reflects McNiff's crystallization of a personal style and his approach to art therapy. It is based on the Jungian method of active imagination. McNiff is a facile writer, offering many sensitive and insightful observations on the interaction of the psyche, or soul, the image, and the intellect of the creator during the process of art therapy. The archetypal intimacy of the subject, however, carries its own dangers, to which McNiff is not immune. Treading on the interface between the archetypal psyche and the ego inflated by identification with the archetypal psyche, he succumbs, in a number of instances, to the latter.

One of the biggest shortcomings that appears throughout the book are frequent derogatory, inaccurate, and undocumented statements about art therapy. Outside of McNiff's previous work, the only reference to art therapy is Helen Landgarten's and Darcy Lubbers' Adult Art Psychotherapy (1991), and then only within the context of McNiff writing a forward for this book.

Among the undocumented comments regarding art therapy and art therapists are the following: diagnostic perspective that dominates their work (italics mine. VBL) (p. 39), "diagnostic labeling [in art therapy] that does not permeate the other creative arts therapies to the same degree" (p. 41), "egocentric assumptions that the image fits into the a priori theoretical bias of the interpreter" (p. 53), "practices of art therapy that attempt to 'fix' the work in definitions offend the imago" (p. 80), "prepackaged conclusions that are all too often associated with the psychological interpretation of art" (p. 151), "the hierophants who will tell us that the doorways are vaginal openings that the man desires" (p. 172), "interpreters are apt to make assumptions about an artist's psyche on the basis of one picture" (p. 173). These comments culminate in: "I enthusiastically and graciously say 'Thank you' to all of the interpretive confabulators (italics mine. VBL.) labelers, and their fleet of diagnostic tests, handbooks, and outrageous statements about the motivations of artists" (p. 219). From a Jungian perspective one can make the observation that the above generalized statements are negative anima's comments. They are not a valid representation of the field of art therapy, nor of the approaches to the theory of art therapy used by most art therapists (Rubin, 1987).

McNiff presents as his original thought the inquiry into and meditation on perceptual aspects of the image, as well as the dialogue with those images. The focus on perceptual aspects has been discussed in art therapy literature (Betensky, 1973; Lusebrink, 1990), and the dialogue has been used in different approaches to therapy that involves imagery.

Another shortcoming is the lack of elaboration of terms, such as "art studios" (which are apparently weekend or week-long workshops) and "art as medicine." McNiff never fully credits James Hillman or the concept of "daimons" or "daemones." In regard to the illustrations, it would have been helpful to number them in the first two-thirds of the book.

In summary, McNiff's latest book is an important contribution to the understanding of the role and dynamics of visually depicted images on the function of the psyche. If one is willing to overlook the shortcomings discussed above, it offers an elucidation on a depth aspect of art therapy from the viewpoints of philosophy and art. Application of McNiff's approach appears to be most appropriate for a clientele similar to himself—intelligent and functional individuals who have the personal means to attend international self-exploratory workshops. This approach is less useful to art therapists who work with individuals who have serious impairments and psychopathology, given the constraints of time limits and reimbursement through insurance.

Despite its shortcomings, Art as Medicine contributes to the literature a valid, in-depth, and vital view of one of the many aspects and uses of art therapy.

Creativity and Disease: How Illness Affects Literature, Art and Music (7th edition)

Reviewed by Patricia St. John, EdD, A.T.R., Associate Editor

In his preface to Philip Sandblom’s Creativity and Illness: How Illness Affects Literature, Art and Music, Carl Nordenfalk, director emeritus of the Swedish National Museum, warns, “Once you start reading, you will not easily put the book aside...” (p. 8). Readers be forewarned. This seamless, elegant essay, delivered with grace and power, is the marriage of a skillful surgeon and a sagacious humanist. Written with warmth and humor, Philip Sandblom’s inquiry into the effects of illness on art and artists never patronizes the artist nor dismisses the potent effects of pain. Sandblom bases his thesis on the assumption that “art is always founded on experience; one cannot create from nothing” (p. 11). Illness inevitably affects art, but how, when, and where are cause for examination.

Frida Kahlo, who had the congenital defect spina bifida, painted her illness countless times. At the other extreme is Matisse whose bout of appendicitis turned him from his plan to be a lawyer to painting, as a diversion, and then as a career. Illness visited him again in the form of bronchitis, causing him to move to Nice for a cure. At the age of 70, he developed colon cancer. This left him partially bed-ridden for much of the rest of his life. Sandblom interviewed Matisse, who admitted that illness had altered his life and art. He believed art should give happiness, he was “so convinced of the beneficial radiation of his colour and its power to heal that he hung his pictures around the beds of ailing friends” (p. 33).

Illness can both stimulate and enrich creativity. The text is generously laced with testimony from artists. Edvard Munch stated that “(w)ithout illness and anxiety I would have been a rudderless ship” (p. 20). While Sandblom has gathered no statistical evidence of a link between creativity and illness, he accepts the position that a link often does exist. He bases this position on “many excursions through the provinces of art I have collected” (p. 19).

Sandblom explores those features of the creative personality that set the artist apart from the typical person. “Are artists... at all to be counted among the mentally normal?” he asks, and answers, “No, ‘one is not a genius because one is mad’ but it may help!” (p. 35). Bipolar depression, schizoid personality, the neurotic, depressed and paranoic, may successfully seek relief or resolution of life’s tensions and conflicts through creative pursuits, including the arts. To rank among the world’s great creators it takes more than the trauma of illness. The ability to “see everything with innocent eyes,” a desire to share and communicate deepest feelings, the “urge to seek new and personal means of expression,” a pioneering attitude that risks going into unknown territory without “fans or followers,” a sense of one’s own individual identity, and a complete dedication to pursuing art, despite handicaps, disease, isolation, or old age, are some of the characteristics of the creative personality (pp. 38-39).

Many artists used artificial substances to stimulate creativity. A comparison of two versions of the
windmills of Montmartre by Utrillo illustrates the long-term effects of alcohol. Sandblom selected two examples, one dated 1912 when the artist was using alcohol slightly, and the second, dated 1953 when the artist was alcohol dependent. The subtle whites, blues, and greens of the earlier painting have changed to harsh, expressive brush strokes of predominantly oranges, reds, and bright greens. The delicacy and refinement of the 1912 work has evolved to a vigorous and rough application of paint. Opium was a popular stimulant during the 19th century; it was also used medicinally. Keats, Berlioz, Coleridge, and Piranesi used it. Piranesi's "Prison of Imagination" "convey(s) . . . feelings of desperate helplessness" as the effects of the drug wore off. The use of opium combined with the artist's manic-depressive tendencies so that Piranesi's engravings evoke dark, fantastic, and terrifying visions.

Sandblom also explores the effects of mental illnesses on creativity. Giving support indirectly to art therapy, Sandblom writes: "Works of the insane have provided fundamental insight into certain manifestations of mental disorder, and in certain cases can even help us to reach a diagnosis" (p. 67). Sandblom traces "prints" of the schizophrenic in Charles Meryon's etching. Ernst Josephson, a Swedish artist, painted while in sound health, and later, when he became schizophrenic (p. 76). His later work is considerably more expressive, although the composition has suffered.

For the combined effects of physical and mental illness, Sandblom discusses epilepsy and how it affected the work of Van Gogh, with its periods of "terrible anxiety, confusion and aggression" (p. 87). In an exploration of defects of sight, Sandblom recounts how cataracts obscured Claude Monet's vision, causing him to complain, "I see everything in a fog" (Ibid). After a cataract operation, Monet changed the color in some of the cataract-influenced paintings and destroyed others. A period during the 1890s demonstrated the combined effects of disease and operation in his series The Japanese Bridge. Sandblom presents four of Monet's paintings of the Japanese bridge executed at different times: in health, disease, and pre- and postoperation. Tinted glasses and further recovery were captured in his final series, the water-lilies. The tranquility of these paintings reflects Monet's regained peace.

For other examples, Sandblom explores the role of deafness on Goya, Swift, and Beethoven. Congenital malformations affected Henri de Toulouse-Lautrec, and the impact of old age can be traced in the work of Cezanne. Marc Rothko became obsessed with death, exploring it in the murals of Rothko's Houston chapel "where light and life fade away in the almost black purple, predicting his suicide" (p. 101). At the close of the book, Sandblom concludes: "In great artists, the passion to create generates a willpower strong enough to defeat the worst disease" (p. 180).

Sandblom treats his topic with care and a keen eye. His observations are astute, and he supports each hypothesis with well-chosen examples. The book's value lies in its breadth of scope, rather than in long, detailed examinations of artists' lives and works. Sandblom has left to the scholar the task of a fully developed historical examination of life and disease. As a starting point for study of one or several artists with similar afflictions, this book cannot be equaled. Were another edition written, Sandblom would undoubtedly include the effects of HIV on creativity. Although Sandblom does not mention art therapy, outside of the context of William Styron's (1990) recollections (p. 147), his work eloquently supports the efforts of art therapists and demonstrates possibilities of creativity within the clutches of illness.

Music Medicine

411 pp., $29.92 paper. ISBN 0-918812-72-0.

Reviewed by Therese Marie West, MMB-BC, Concord, CA.

These are exciting times for the expressive arts therapist. As the United States faces the daunting task of bringing about major reforms in our system of health care, we observe trends which point towards a new place for the arts in modern medicine. Not merely a renaissance of ancient healing arts, this change is a sign of human development, a coming together of art and science to meet human needs at the most basic levels of personal and societal survival.

Music Medicine is a timely and valuable resource for anyone exploring the role of music in this dynamic arena. It contains the proceedings of the Fourth International Music Medicine Symposium sponsored in 1989 by the International Society for Music in Medicine.

This book will be valuable to all those working and doing research in any of the creative arts and medicine because its contributors explore theoretical and practical issues facing all medical arts practices. Recurrent themes point to the problems, obstacles, and opportunities facing us as we attempt to bridge the long-established separation between creative art and scientific medicine. As clinicians and researchers attempt to understand the language of science and art and to comprehend works published in foreign languages, the need for many kinds of improved communication becomes clear.

The reader of Music Medicine quickly gets a sense of the scope and volume of work currently being done in "musicmedicine," and the international energy fueling the movement. Its contributors explore the growing need for an international database of research and publications in allied fields. At a practical level the reader is provided with suggestions and valuable information on already existing resources.

Technological advances in communications and medical research, specifically in neuroscience, have provided methods to assess the effects of music and sound vibrations on physiological, psychological, and social functioning. What in the past were considered as only subjective and elusive experiences can now be brought to light through scientific methods. What was once the domain of esoteric practices of healing arts is coming out of hiding to the potential benefit of mankind. This growing momentum of interest, along with dedicated efforts to uphold the highest possible standards of research and clinical practice, ultimately serves the consumer. Today's consumer wants safe, reliable, and cost-efficient treatments and is ready to participate actively in regaining and maintaining good health.

The arts therapies stand in a unique position to contribute to the rehumanization of medicine. They not only offer methods which support existing medical treatments, but also provide newly acknowledged potential as recognized and medically prescribed treatments in themselves. The writings of the physicians and researchers of Music Medicine clearly suggest that this rehumanization of medicine is already taking place, and they point out there is much work yet to be done to bring this about.

Many of the 57 authors contributing to this instructive new volume are nationally and internationally recognized leaders in this rapidly developing field. They are physicians, musicians, music therapists, educators, researchers, scholars, and movement and physical therapists. Their common ground is music. The 36 articles are grouped into six areas:
Visual Arts for the Physically Challenged Person

I. General Considerations, where definitions and models are proposed for integrating music and medicine; II. Aspects in Physiology and Physics, which is often highly technical but well worth the reading; III. Applied Research, which represents work in pain reduction, psychoneuroimmunology, immune-related disorders, and social and emotional development; IV. Therapeutic Applications and Workshop Transcriptions, which span a broad range of traditional and innovative practices and health issues; V. Aspects of Occupational Health Care, where the focus is on areas of concern to the performing musician; and VI. Toward Standards of Research in MusicMedicine and Music Therapy, which concludes the book with articles which should stimulate thinking and dialogue among all interested parties.

MusicMedicine is a fascinating compendium of the current state of research in the role of music and medicine. Although it raises many more questions than it answers, that is the nature of human investigation and problem solving. As food for thought, it is a feast.

Video Review

Visual Arts for the Physically Challenged Person

Produced by HVS Productions for the Young Artist Workshops Programs, St. Norbert College, De Pere, WI, and the Agency for Instructional Technology with support from the National Endowment for the Arts Artists-in-Education program, 1989.

25 minutes, color. Rental: Basic program rate of $47, plus school enrollment rates depending on enrollment populations. For more information, call the Agency for Instructional Technology in Bloomington, IN (800) 457-4509.

Visual Arts for the Physically Challenged Person is designed to assist visual arts teachers in involving students who have disabling conditions. A strength of this video is its strong argument for the importance of art to all children, especially those with special needs. At the close of the video, Professor Charles Peterson sums up this position: “Within a medically impaired body, there can be a highly creative and intellectual mind.” We need to work with individuals according to their unique capabilities in order to overcome disabling situations.

The video incorporates a humanistic approach that emphasizes self-realization and the attainment of individual goals. It covers work with two- and three-dimensional materials, photography, and state-of-the-art computer graphics.

The major focus is on the adaptation of art materials for physically challenged individuals and individuals with communication disorders. These adaptations, which draw on the expertise of occupational and physical therapists, are geared to increase students’ ranges of motion, grasping skills, and ability
to work with materials. Several devices are demonstrated including styrofoam balls on paintbrushes, rubber spatulas as extensions of mouth guards, hand levers on potters wheels, and computer hardware and software. The range of examples is good, but I question the implicit assumption that art teachers and therapists would not be trained to adapt materials for the physically challenged.

Another strength of the video is its application to classroom teaching. College students unfamiliar with federal special education laws P.L. 94-142 and the Education for All Handicapped Children Act (1975) will gain an understanding of the current legal requirements. Considerable attention is given to the importance of mainstreaming and working within a multidisciplinary team. However, the video could do more to demonstrate how a special needs child's weaknesses could be camouflaged in an integrated classroom through careful choices of art activities that emphasize the child's strengths (Henley, 1992).

From a technical perspective, the producers did an excellent job of incorporating voice over narration, clear visuals, and special editing techniques. The video comes with an excellent facilitator's guide that classroom teachers can use as a follow up to the program. Detracting from the overall technical excellence is background music that is sugary, reminding one of a dental office. Some of the cuts, including one of an individual in a wheelchair with a sticker on the back stating, "I brake for sexy women," are in questionable taste and have no relevance to the arts.

The art therapy audience will also be frustrated with the video's focus on product as opposed to process. Within the first few minutes of viewing, an art teacher repeats to a deaf student and her interpreter, "I want all the white spots covered, I don't want to see any white spots showing." Though the video stresses the importance of art activities that feature built-in success, designed to increase the self-confidence of physically challenged people, this product-oriented approach goes against the grain of a developmental approach to art (Lowenfeld & Brittain, 1987).

Visual Arts for the Physically Challenged Person is a good starting point for classroom teachers. However, restricting the scope of the video to the adaptation of art devices also limits the audience who might benefit from its message. While I am pleased that the video makes no pretense of being art therapy, it is time for a video by art therapists on this topic. Such a video would go beyond the adaptation of materials and deal with the psychological and developmental issues that often manifest during the process of creating art.

Note: The target audience for this video is K-12 students and teachers.

Response

Dr. Gantt raises a point about the "anthropomorphic objection" when she states, "I do not see that the substitution of 'mirroring' for imitation adds anything to the understanding of the animals' behavior and, in fact, may serve to cloud some important issues by unnecessary anthropomorphizing" (1993, p. 208). I believe she misses the point and makes the assumption that animals do not have mental experiences. Others have written on this topic. I refer the reader to Donald R. Griffen's response to the "anthropomorphic objection" in The Question of Animal Awareness (1981). He describes the argument as concocted and compares it to..." the Pre-Copernican certainty that the earth must lie at the center of the universe," a species-centric view. He warns of the dangers of circular reasoning whereby the accusation reiterates the original objection (pp. 124–125).

Mental experiences have been documented by ethologists in a variety of species. Honeybees and some species of birds have been found to use elaborate rituals to communicate. Denise Herzog, in her presentation Social Interactions Between Humans and Dolphins (1989) (Delta Society 8th Annual Conference) discussed anthropomorphism as a useful tool.

In recent years, a paradigm shift has occurred in the dolphin-human interspecies interaction and communication field. Previously, the emphasis was on teaching research dolphins to be like us so that we
might communicate with them. An example of this is John Lilly’s dolphin studies (1967), where human language was taught to bottlenose dolphins. Today, interspecies interaction is studied in the dolphins’ environment at sea and on their terms. Dolphins come to research boats, swim with the research participants at will, and are unintrusively videotaped and documented. Researchers from The Oceanic Society of San Francisco, California, and Denise Herzog of the Wild Dolphin Project in Jupiter, Florida, collect interspecies interaction data in the wild as well as conduct more traditional longitudinal wild dolphin population studies.

In my study (1990), I used a psychoaesthetic framework to describe what I experienced when viewing dolphin-human interaction and dolphin marks or “paintings.” I did not shape or participate in training sessions where the animals’ behavior was shaped, but conducted my study within the system that was already in place.

Psychoaesthetics is a way to view artwork and human interaction through the lens of psychology, specifically using object relations theory and aesthetics. Artwork is seen as a container for the art therapeutic matrix and a reflection of the quality of the therapeutic relationship (Robbins, 1987, p. 67). Two dolphins’ interactions were recorded through the psychoaesthetic qualities of a painting that I discuss in Psychoaesthetics and Dolphin Personality (1990):

Misty . . . interacted with Natua’s marks. Her yellow marks intercept and extend his. They change and pull a viewer’s eye from right to left, balancing the painting and acting as a stabilizing force that allows a viewer’s eye to stay within the boundaries of the canvas. As a result, I ask myself the question: Does Misty have a calming effect on Natua? (p. 29)

Anthropomorphism has been confused with aesthetic understanding. Artists have something unique to offer observers of animal behavior: “empathy for the object” is a necessary ingredient in fine arts studio training. Aesthetic sensibility or “connoisseurship,” a way of seeing according to Elliot Eisner (1991), is necessary for the construction of a reality that is called “art.” An artist’s reconstruction of a still life, for example, is only part of the art equation. The expressive quality of the marks made by an artist in the reconstruction of a still life completes the picture. The artist’s self and subjectivity inform the viewer about the qualities of the perceived reality. This is similar to the “process recording” format used in social work training, where students record the dialogue between themselves and their clients to determine the “gist” or phenomena of a session or interview. In addition, this is useful in finding their voice within the session. In this way countertransference issues and the therapist’s style are illuminated and documented.

Since the dolphins made marks that mirrored the trainer’s marks, special relationships, and placement, it is possible that the dolphins were “creative.” A dolphin could have reconstructed a triangle in a variety of ways that would not have reiterated or reversed the trainer’s special orientation or the scale of the marks made on the page. “Imitate” was the command made by the trainer, not “Imitate the trainer’s marks by painting your mark in a position under the trainer’s mark and upside down.” More work is needed in this field, using a larger sample to determine a dolphin’s creative capabilities.

At the University of Hawaii, Lou Herman (1988) found that dolphins could conceptualize. In the Kea Language Study, it was determined that the dolphins generalized commands given by a trainer. For example, “Fetch” was a command given to a dolphin. The dolphin generalized the concept, fetching whatever object was requested, and used whatever body part it found appropriate to complete the task (p. 413). The painting dolphins at the Dolphin Research Center in Grassy Key, Florida, may “create” when they reverse the order of the trainer’s configuration or composition. A composition is similar to the creation and use of syntax.

In memory of Elizabeth “Grandma” Layton, 1909–1993
by Robert E. Ault, MFA, A.T.R., HLM

A cold wind was blowing across the flat Kansas prairie on March 17th, as friends and family huddled together for warmth and comfort. They had come to say their goodbyes to Elizabeth “Grandma” Layton, an extraordinary woman who had died two days earlier. The Wellsville cemetery, a field dotted with trees and stone markers, seemed strangely similar to the other open fields that surrounded it. One was keenly aware of the seasons and rhythms of life so important to the people of the small rural community where Elizabeth was born and where she died. Out of the earth had come life that had struggled, flourished, given life, withered and died and was now replanted. Following a ceremony, mercifully made brief because of the bitter cold, we gathered at the local VFW hall where cake and hot coffee were served by church women, and people could greet the family, express their sympathy, reconnect, and partake of the age-old ritual of healing grief.

Two weeks later there was a different type of gathering in Lawrence, Kansas, where several hundred friends, admirers, and some family members came together for a memorial service. They brought drawings she had given them and hung them from floor to ceiling in the auditorium, forming a backdrop for the many friends who spoke of their relationship with her and her art. There was the sharing of stories, some laughter and tears, and thankfulness for the simple but profound gift and message of her life. A reception was held afterwards at which pink lemonade and oreo cookies were served, as I’m sure Elizabeth would have wanted.

I was asked to be one of the speakers and shared the following comments with the group: “How do you summarize many years of contact, study, sharing, caring, and love in a couple of minutes? It is so personal. But that was what her life and her art were about. Everyone who knew her or saw her art felt something personal. She opened her life in a way that was very rare, not only in personal relationships but especially so in the arts. There were an honesty and openness and lack of pretense that were like a breath of fresh air—air the public eagerly gasped.

As an art therapist I have always been interested in not only the product of art but also the process. These two elements contribute to the meaningfulness of an art experience. Elizabeth was a gold mine for study, for she had experienced firsthand the healing power of art and was willing to open her life for examination. She enthusiastically participated in the studies that we did in trying to understand what happened to her that made her well. The research was done, and we have now been able to reproduce in others the process of healing that she experienced. It is now being practiced across the United States.

Last summer Elizabeth participated with us on behalf of the American Art Therapy Association to present testimony to the U.S. Senate in support of the inclusion of art therapy in the Older American’s Reauthorization Act. At the same time, she was having a one woman show at the Smithsonian Institution’s Gallery of American Art.

Elizabeth loved art therapy and art therapists, since she knew from her own experience about the healing power of art. She was like a beacon of inspiration and a validation of our belief in our profession. She showed us the direction to new territories that needed exploration and encouraged us to proceed. Through that she left a legacy equal in importance to her art for which we will be forever grateful.

Finally, I wanted to take a moment to share my own personal experience. It is ironic that she taught me a process of dealing with loss and grief that I was able to use in dealing with my loss of her. I did a drawing last week and felt much better afterwards. It is of myself with Glenn and Elizabeth, still a part of my thoughts and feelings. She places her hand on mine and quiets the pain. I am surrounded by her...
images of flowers and her thoughts on art therapy. I am wearing one of her “I am loved” buttons. She was a safe zone and indeed an affection connection.

Elizabeth Hope Layton died Monday, March 15, 1993 at the Olathe Medical Center. Her death was the result of a stroke suffered February 17th. She was born October 27, 1909, in Wellsville, Kansas, the daughter of Asa Finch and May (Frink) Converse. Her father was the editor of the Wellsville Globe and her mother, a Poet Laureate of Kansas in the 1920s, wrote a column and front page poem for the Globe each week.

Elizabeth grew up in Wellsville, where she lived the rest of her life. She completed two years of college, married young, and had five children before her marriage failed. When her father died, she became responsible for the paper which she ran until 1957 as a single working mother in the 1940s, long before such a status became more commonplace. For 40 years she experienced depressions that became more cyclic, with alternate states of agitation. She sought out treatment and was given psychotherapy and medication. She was also hospitalized and underwent 13 electroshock treatments in an attempt to modify her violent mood swings. She married Glenn Layton in 1957, and became a full-time wife, mother, and grandmother continuing to struggle with her illness.

At the age of 69, following the death of her son, she again experienced severe depression and decided, instead of seeking more psychiatric help, that she would take an art class at a nearby university. The only class available was one in contour drawing. Not knowing what to draw one night, she got out a mirror and drew herself, the first of over 1,200 drawings she was to complete in her remaining years. She drew herself as others—in different moods and fantasies, grieving, loving, dressed up and nude. She examined her values, her sexuality, and her multitude of relationships. After a while a "miracle," as she called it, occurred. Her bipolar type symptoms ceased and she remained symptom-free the rest of her life.

Her drawings, done with colored pencils on cardboard bought at the local drugstore, began to receive attention from people in the art world. Don Lambert, a journalist for the local newspaper, while writing a review of a student art show at Ottawa University saw for the first time contour drawings of an older woman. She signed her name as “Grandma,” the way the younger students in her class referred to her. Don was taken by the images and thus began his journey to promote her work, acting as her friend and agent. One of her first shows was held at Menninger’s in Topeka, following his attempt to get
the Topeka Public Library and the Mulvane Art Center of Washburn University to exhibit the drawings. They had refused him on the basis that she had been a patient and they weren’t interested in that type of art. In more recent years both places have had one woman shows of her work.

Elizabeth Layton’s art has now been viewed by people all over America via shows that have traveled extensively. She has never sold any of her work although it was in great demand, but gave it freely to friends and charitable organizations. A book about her life and art, *Through the Looking Glass*, was published, as well as countless articles. Several plays have also been written about her life and she has appeared on national television programs and on the National Public Radio. In all of these forums she proclaimed the value of art therapy and her conviction art could be done by anyone and it would make you feel better. She opened her life for examination and was most generous with her time to all who asked. She became something of a grandmother for the country.

At her show last summer in the Smithsonian, hundreds of people wrote pages of letters to her in the gallery books. These were sent to Elizabeth. She read and enjoyed them greatly, answering many of the people. One such letter said:

“Dear lady... Your heart must be as beautiful as your great green eyes. You are more than ‘The Grandmother of us all.’ You are our conscience, the voice from within our hearts that reminds us of what is right and good and true. Thank you so much.”

The cold prairie winds have diminished now and the season is starting to change. The yellow daffodils that she loved so much are beginning to bloom and the earth stirs again. The fields surrounding the cemetery are showing the first touches of green. A rich legacy has been left by this extraordinary woman who described herself as a “drawer of pictures” and a “one word poet.” We might add, “a creator of wonderful visual poetry” and “giver of unconditional love.” She will be missed.

- Chickering, Nancy Barrett—PORTRETT OF SPIRITUALITY IN RECOVERY: The Use of Art in Recovery from Co-Dependency and/or Chemical Dependency. '93, 254 pp. (7 x 10), 71 ill., $49.75.

  This book explores the experience of the contribution of art to spirituality in recovery from codependency and/or chemical dependency. This exploration resulted in gathering together ten personal stories which are woven with many common themes, creating the powerful portrait of recovery presented in this book. Since much of the previous work in these combined areas is theoretical, there is a need for research which highlights the essence of the experience of recovery including the spiritual dimension as experienced through art and art therapy. Very little research is currently available which interfaces these areas, and spirituality is an important component in the process of recovery. Therapeutic knowledge about the contribution of art to recovery is valuable. Addiction results in self-esteem, whereas recovery is finding healing and wholeness through an interior journey. This book, about the interior experience, attempts to add clarity to the literature on the recovery process.

- Moon, Bruce L.—ESSENTIALS OF ART THERAPY TRAINING AND PRACTICE. '92, 188 pp. (7 x 10), 21 ill., $35.75.

  Central to the author's approach is the manner in which the mentor and the beginning art therapist come together in their efforts to learn and grow. The author demonstrates how the deep, intimate, alive and complex training relationship that can lead to the awareness of meaning in the lives of both. The concern for authentic engagement in the training relationship enhances the beginner's ability to use the self to help clients learn to use art and artistic expression to identify and integrate new insights in their lives. The book is ultimately concerned with the use of art and an artistic relationship to promote human growth. The author's deep understanding of both art and existentialism makes this book a high point in the ever-evolving fields of existential psychotherapy and art therapy. It is an important contribution to the development of creative, effective psychotherapists who value human growth. It will be of particular interest to those involved in art, art therapy, existential psychotherapy and the development of a future generation of psychotherapists.

A Child's Story is a riveting autobiographical, and pictorial account of the process of recovering from the devastating effects of childhood sexual abuse. The author—artist, survivor, and activist—tells her personal story in three voices, corresponding to her stages of recovery:

- THE WORDLESS VOICE OF INTENSELY PERSONAL ART (33 color plates)
- THE VOICE OF A WOUNDED SURVIVOR STRUGGLING TO HEAL, expressed in poems and personal journal entries
- THE CALM VOICE OF KNOWLEDGE AND INSIGHT, expressed in the objective essays that synthesize scholarship from over 30 experts

Book Excerpts

"One day I told my therapist that, for me, 'some feelings just don't have words.' What I painted or drew became my voice, my way of speaking those unspeakable feelings. Art is a means in which emotions can be retrieved before the survivor can verbalize the experience. After visual communication is accomplished, the story can be put into words, thus beginning the healing process."

Pat Harris, Author, artist, incest survivor and activist.

Reviewer Statement

"One of the few books written which allows an analysis of the trauma of sexual abuse to be made by a journey through a survivor's pictorial images. These memory images probably are less adulterated than those embellished by linguistic maturities made when adult survivors recall their stories only through language. The art is raw and painful: the text is instructive and teaches healing."

Bernice L. Collins, Ph.D., Clinical Psychologist, East St. Louis, Ill.

Guidelines for Submissions

All submissions will be acknowledged upon receipt by the AATA National Office. Art Therapy uses a blind peer review procedure for full-length articles and brief reports; final decisions regarding publication are made by the reviewers and the Editor. Decisions regarding submissions to other sections are made by the Editor, Associate Editor and special section editors.

The following are guidelines for developing and submitting a manuscript. Manuscripts that do not conform to these guidelines will be returned to the author without review.

Manuscript Categories

1. Full-length Articles. Full-length articles may focus on the theory, practice and research in art therapy or related areas. Manuscripts must include an abstract of approximately 75-125 words summarizing the major point of the article.

2. Brief Reports. Short articles which focus on the results of research are appropriate for this section. Manuscripts should include information on the research design, methodology and results; an abstract of approximately 75-125 words should also be included.

3. Viewpoints. Short articles focusing on personal experiences, poetry or original art may be submitted to this section.

4. Book Reviews. Reviews of books of interest to art therapists may be submitted at any time. Books which authors wish to have considered for review may be sent directly to the AATA National Office at the address listed above.

5. Film/Video Reviews. Reviews of media (films or videotapes) may be submitted at any time. Media which producers wish to have considered for review may be sent directly to the AATA National Office at the address listed above.

6. Comments. Brief comments on articles published in Art Therapy, issues critical to the profession and practice of art therapy, or letters to the Editor may be submitted to this section and should conform to the style of all other submissions.

Other Requirements

1. Send five (5) clear copies of each manuscript to Cathy A. Malchiodi, A.T.R., Editor, Art Therapy: Journal of the American Art Therapy Association, c/o AATA, Inc., 1202 Allanson Road, Mundelein, Illinois 60060. Neither AATA nor the Editor can be responsible for submissions sent to any other address.

2. Only original articles that are not under consideration by another periodical or publisher are acceptable.

3. Manuscripts must be typewritten on 8½" × 11" white paper with margins of at least an inch. The body of the paper, references, tables and quotations must be double-spaced.

5. An abstract of 75-125 words must be included with full-length articles and brief reports.

6. Please avoid footnotes wherever possible.

7. A cover sheet should be prepared to include the full name(s) and degree(s) of the author(s), professional affiliations, and the return mail address of the author to whom correspondence can be sent. Authors’ names, positions, titles and places of employment should not appear in the body of the paper to assure anonymity and to facilitate blind review.

8. Use tables sparingly and type them on separate pages. Refer to the APA Publication Manual for style of tabular presentations. All tables, charts or diagrams must be legible and able to withstand reduction.

9. Photographs must be at least 5" × 7" and black and white glossy prints, preferably with high contrast. Xerox copies of illustrations or art expressions are not acceptable for publication. Figure numbers and captions should be noted on the back of photographs; captions must be typed and submitted on a separate sheet of paper. Please refer to figures in the text as Figure 1, Figure 2, etc.

10. Lengthy quotations (300 words or more from one source) or reproduction of works of art (this does not include client art expressions, which is addressed below) require written permission from the copyright holder for reproduction. Adaptation of tables or figures from copyrighted sources also requires approval. It is the author’s responsibility to secure such permissions; a copy of the copyright holder’s written permission must be provided to the Editor immediately upon acceptance of the article for publication.

11. Client/patient confidentiality must be protected in the title, abstract, text, photos, illustrations and other accompanying material. Proper releases for use of client art expressions and other client information must be obtained and kept on file by the author.

12. It is expected that any manuscript accepted for publication in Art Therapy will go through at least one revision before publication. If authors have prepared their manuscripts on either an IBM, IBM-compatible or Macintosh computer, upon acceptance, they can send a 3.5" diskette containing an electronic copy of the manuscript to the AATA office. This will help speed processing, editing and publication.

Note: Authors bear full responsibility for the accuracy of all references, quotations and materials accompanying their manuscripts.
ATTENTION AUTHORS

In order to help us process your submission more quickly, please complete the following information and attach one copy to your manuscript:

Name: ____________________________________________

Degrees/Credentials: ____________________________________________

Address: ____________________________________________

Phone #: ____________________________________________ work ____________________________________________ home

Type of Submission (check one):

___ Article
___ Brief Report
___ Viewpoints
___ Book Review
___ Film/Video Review

Title of Submission: ____________________________________________

________________________________________________________________

Checklist:

___ Five copies, typewritten on 8½" × 11" paper.

___ Abstract of 75-125 words (for articles and brief reports only).

___ Detachable cover sheet with author(s) name(s), affiliation, degrees and credentials.

___ Appropriate release forms obtained for use of client art expressions and client information. (You do not need to send these with your submission, but you must have them on file.)

Author’s signature ____________________________________________ Date ______________

Please send completed form with submission to: Editor, Art Therapy: Journal of the American Art Therapy Association, c/o AATA, Inc., 1202 Allanson Road, Mundelein, Illinois 60060.

THE ORGANIZATION

The American Art Therapy Association, Inc. (AATA), a non-profit organization founded in 1969, is a national association which represents a membership of approximately 3800 professionals and students. It is governed and directed by a nine-member Board elected by the membership. The AATA has established standards for art therapy education, registration and practice. AATA committees actively work on governmental affairs, clinical issues and professional development. The AATA's dedication to continuing education and research is demonstrated through annual national and regional conferences, publications, films and awards.

PURPOSE:

- The progressive development of the therapeutic use of art.
- The advancement of standards of practice, ethical standards, education and research.
- The provision of professional communication and exchange with colleagues.
- The provision of legislative efforts to promote and improve the status of professional practice.
- The promotion of the field of art therapy through the dissemination of public information.

CHAPTERS:

Affiliate Chapters of the AATA have been established throughout the U.S. Chapters conduct meetings and activities in an effort to promote the field of art therapy on a local level. Chapters provide a forum for addressing professional issues as well as a network of people working toward common goals. Information and support for Chapter members is passed on from the AATA Assembly of Affiliate Chapters to the local level.

You must be a national member to become a Chapter member. Information on locating the chapter nearest you is available from the AATA office.

MEMBER BENEFITS

Individual members receive:
- Publications
  - Art Therapy, the official journal of the AATA
  - The quarterly AATA Newsletter
  - Substantial discounts on AATA publications such as Annual Conference Proceedings, other professional journals, films, and membership directory
- AATA literature, such as Educational Programs List, Art Therapy Media List, and Standards of Practice
- Mailings of professional interest
- Services
  - Insurance, including professional liability, major medical, life and disability through Maginnis & Associates
  - Access to national experts in art therapy
- AATA Conferences
  - Discounts on registration fees to AATA national and regional conferences
- Nationwide Advocacy
  - Governmental affairs activities including Congressional review and monitoring
  - State legislative and regulatory activities
  - Promotion of recognition and reimbursement of art therapists by third-party payors
  - National liaison with related professional organizations for recognition and promotion of the profession of art therapy

Professional Standards
- Development of model job description and recommendations for licensing standards
- Development and implementation of national guidelines for approval of Master's Degree and training programs in art therapy
- Development and implementation of nationally recognized Standards of Registration of Professional Art Therapists

GENERAL MEMBERSHIP APPLICATIONS

1. The membership year is the calendar year, January 1 through December 31.
2. Contributing, Associate and Student applicants for NEW MEMBERSHIP ONLY: Please follow the chart below when submitting membership application.

   Applications received between:
   Jan. 1 and May 31: Full dues payment
   June 1 and Sept. 30: Half year's dues plus $5 payment. Membership expires Dec. 31 of same year.
   Oct. 1 and Dec. 31: Full dues payment. Membership valid for remainder of current year and next full year.

3. Professional Member applicants must meet Criteria for Professional Membership. Formal application with documentation is submitted to Membership Chair for approval.

4. AATA Membership and AATA Registration (A.T.R.) each have a separate application procedure. Registration is bestowed only by the Standards Committee.

5. National AATA membership required for Chapter Membership. Please contact AATA office for information on AATA Chapters.

CATEGORIES AND FEES

PROFESSIONAL - by application only. Such members may vote, hold office, and serve on committees.
- Credentialled Professional Member: Individuals who have been duly approved for Professional Membership and Registration (A.T.R.) by AATA; dues are $95 per year.
- Active Professional Member: Individuals who have completed professional training in art therapy. Dues are $95 per year.

CONTRIBUTING - Individuals, organizations, institutions or foundations which contribute annually to AATA. Such members may vote, hold office or serve on committees. Annual dues are $120.

ASSOCIATE - Individuals interested in the therapeutic use of art who support the purposes and objectives of AATA. Such members may not vote, hold office or serve on committees. Annual dues are $95.

STUDENT - Individuals who do not meet the qualifications of Professional Membership and are currently taking coursework in art therapy or related fields. Requires a current statement from the institution indicating full-time status and coursework content. Student members may not vote, hold office but may serve on Student Subcommittee of Membership. Annual dues are $35.

"Each issue of The Arts in Psychotherapy is a seasonal enlightenment indispensable for the many who want to stay up to date on the professional and theoretical aspects of the creative arts therapies."
– Rudolf Arnheim, Ph.D., Professor Emeritus of the Psychology of Art, Harvard University

THE ARTS IN PSYCHOTHERAPY
AN INTERNATIONAL JOURNAL

Editor-in-Chief: Robert J. Landy, Ph.D., Director, Drama Therapy Program, New York University, New York, NY
European Editor: David Aldridge, Ph.D., Music Therapy, Universität Witten, Herdecke, Germany
Managing Editor: Sylvia M. Halpern, 20 Ridgecrest East Scarsdale, NY 10583

Highly acclaimed in the field, THE ARTS IN PSYCHOTHERAPY presents innovative research in art, dance, movement, music, poetry and drama psychotherapists, and its use in the treatment of mental disorders.

THE ARTS IN PSYCHOTHERAPY is an international journal for professionals in the fields of mental health and education. The Journal publishes articles (including illustrations) by art, dance/movement, music, poetry and drama psychotherapists, as well as psychiatrists and psychologists, that reflect the theory and practice of these disciplines.

In an effort to expand the Journal's focus to include more international articles, the new Editor-in-Chief, Robert J. Landy, has appointed a European Editor, David Aldridge, and has updated the Editorial Board. These changes will allow the Journal to offer even more diverse coverage, while opening up a dialogue among creative arts therapists all over the world.

The Editors welcome original manuscripts. Submit papers in triplicate to: Sylvia Halpern, Managing Editor, 20 Ridgecrest East, Scarsdale, NY 10583.

Submissions from Europe should be sent in triplicate to: David Aldridge, Ph.D., Music Therapy, Universität Witten, Beckweg 4, D5804 Herdecke, Germany

STATEMENT OF PURPOSE: Art Therapy: Journal of the American Art Therapy Association is the official journal of the AATA, Inc. The purpose of the journal is to advance the understanding of how art functions in the treatment, education, development, and enrichment of people. The journal provides a scholarly forum for divergent points of view on art therapy and strives to present a broad spectrum of ideas in therapy, practice, professional issues and research. An emphasis is placed on the use of the visual arts in therapy, but articles in related disciplines of interest to art therapists will be considered for publication.

ART THERAPY: JOURNAL OF THE AMERICAN ART THERAPY ASSOCIATION (ISSN 0742-1656) is published quarterly by the AATA, Inc., 1202 Allanson Road, Mundelein, Illinois, U.S.A. 60060. Telephone (708) 949-6064; FAX (708) 566-4580. Non-members may subscribe at the following annual rates: $40 (U.S.) and $64 (foreign); institutions: $57 (U.S.) and $80 (foreign). AATA members receive the journal as a benefit of membership.

Single Issues: For price and ordering information, call or write to AATA, Inc., 1202 Allanson Road, Mundelein, IL 60060 (708) 949-6064.

This journal is abstracted in: Psychological Abstracts, INNOVATIONS & RESEARCH, Art Bibliographies Current Titles and Art Bibliographies Modern.

Advertising: Please see advertising rates listed elsewhere in this journal or contact the American Art Therapy Association, Inc., 1202 Allanson Road, Mundelein, Illinois 60060 (708) 949-6064. The publication of any advertisement by the AATA, Inc., is not an endorsement of the advertiser or of the products or services advertised. The AATA, Inc., is not responsible for any claims made in an advertisement.

Authorization to copy: No part of this publication may be reproduced, stored in a retrieval system or transmitted in any form or by any means, electronic, electrostatic, magnetic tape,photocopying, recording or otherwise, without permission in writing from the copyright holder.

Change of Address: Notices should be sent at least six weeks in advance to AATA, Inc. Subscribers should notify the post office that they will guarantee forwarding postage. Undelivered copies resulting from address changes will not be replaced, but single issues may be purchased at the single issue price.

About the Cover: "The Artist's Studio," 25" x 31", watercolor, by Cay Drachnik, MA, A.T.R., MFCC, HLM, past President of the American Art Therapy Association. "This represents my return, after 20 years of practicing art therapy, to my first love—painting. What better way to symbolize this than to paint the clutter of my studio!"
Editorial

Introduction to Special Issue on Art Therapy and Professionalism: Is There a Crisis in Art Therapy Education?

Cathy A. Malchiodi, MA, A.T.R., Editor

This issue of *Art Therapy* focuses on the broad topic of professionalism in the field of art therapy. Many topics in our discipline are connected with professionalism; in this issue of the journal several important ones are addressed, including licensure of art therapists (Good), ethical aspects of supervision (Carrigan), malpractice insurance (Wirtz), and our identities as art therapists (Lachman-Chapin; Junge, Finn Alvarez, Volker, & Kellogg; Rabin).

As major players in the evolution of the theory and practice of art therapy, art therapy educators have an important influence on professionalism, both as teachers and as role models. However, it appears that art therapy education may be floundering in its ability to address certain professional aspects of the field. An article in the Spring edition of the AATA Newsletter (Riley, 1993) reported that a small group of art therapy educators met to discuss issues critical to the development and survival of graduate level art therapy training, identifying several areas that they felt needed some immediate attention for the overall health of the profession. These areas included networking, sharing professional skills, and decreasing isolation among art therapy educators; supervision and development of supervisory guidelines for art therapists; examining the current process of approval of art therapy training programs; reviewing and updating the content of art therapy education, and the impact of recent closures of approved art therapy training programs.

It is fair to say that these are anxious times for art therapy educators and art therapy education.

This past year, three AATA-approved programs have closed their doors to new applicants (Wright State University, Dayton, OH; State University College at Buffalo, NY; and the University of Utah, Salt Lake City, UT), with others threatened, but stabilized (see discussion of California State University Sacramento, later in this editorial); still others may be in jeopardy over the next few years. One general observation that has been linked to program closures is the sluggish economy, and the fact that limited tax dollars have had a direct effect on the ability of statesupported programs to survive. Although tax dollars do have an effect on both the quality and quantity of education funded through the public domain, it would be simplistic to say that this is the only problem that affects art therapy education or program closures. We need to acknowledge that there may be intrinsic weaknesses in art therapy education that put it at particular risk.

In the course of writing this editorial, I polled various art therapy educators across the United States to get their input on what they considered problematic in art therapy education. Although this polling was not very "scientific," many similar observations were expressed; from these observations, the following topics emerged as prominent contributors to the overall problems in art therapy education.

Art Therapy: Modality or Field?

The age-old question of whether art therapy is actually a bona fide discipline or merely a modality
still lingers. Is art therapy a separate discipline (albeit a hybrid), or is it a modality such as various frameworks of psychology (cognitive, rational-emotive, Jungian, etc.)? When Janie Rhyne, PhD, A.T.R., HLM, entertained this thought several years ago (1989), more than a few art therapists were upset:

I’ve said this to lots of top-notch art therapists and you might as well know it, too: we don’t even know that art therapy is a separate field or will it last as a separate field. Quite a few of us are doing other things more than we’re doing art therapy. Should it be a separate field? I’m one of the ones who think it probably should not be. Gradually we’ll become a part of other fields: psychologists and social workers who use art therapy. (1989, p. 12)

Rhyne’s observations raise fundamental issues about our field. If art therapy is truly a modality rather than a distinct discipline as she says, then it is dubious that it will be able to survive within colleges and universities unless it is incorporated into other fields of study. Rhyne supports her premise with the fact that many who have studied art therapy with the intent to practice it, often end up doing things other than art therapy (casework, verbal therapy, etc.). This may become more of a truism as increasingly large numbers of art therapists become licensed under job titles such as counselor, marriage and family therapist, or psychologist.

Our body of art therapy literature may also be a contributing factor in whether or not we are considered to be a bona fide discipline. Although we have a great deal more literature on art therapy than we did 10 to 15 years ago, the available literature that has been generated often lacks rigor or relies heavily on the foundations of other fields. In this sense, the articulation of art therapy as a separate discipline has not yet been fully accomplished.

Additionally, as one educator observed, we are still not able to explain exactly what it is that we do in a way that is convincing to other professionals. For this reason, we often lack credibility among professionals in related fields such as psychology, art education, visual art, etc., largely because we have not succeeded in defining ourselves. We are also utilizing models of theory and practice that have not been informed by ongoing developments in other disciplines. Our inflexibility or unwillingness to incorporate new paradigms into instruction severely compromises our own vitality as a profession. Art therapy education’s ability to adjust curricula to the times will likely play a major role in whether art therapy departments are retained in academic environments in the future.

The Role of Visual Art in Art Therapy

Mildred Lachman-Chapin states in her article in this journal issue that “we . . . as art therapists are seen as lesser or not quite real artists . . . Perhaps this reflects the art world’s rejecting response to artist-as-healer.” Art therapy has struggled for recognition by the visual arts; training programs housed in art departments at universities or art schools have most acutely felt this strain. Often, art therapy is seen by studio art faculty as not quite art, and is even looked upon with outright disdain by the art world in general.

Some of this disdain comes from the fact that the basic philosophy of art therapy does not generally encourage individuals with whom we work to make art in the true sense of the word. What is created during an average art therapy session is generally rudimentary visual expression; according to Allen (1992), such “art may reflect the impoverishment of the environment which is ill equipped to sustain the production of more realized work” (p. 22). It is easy to see why studio artists find art therapy difficult to understand, and fail to grasp why it is called “art” therapy at all.

Additionally, the role of visual art in art therapy training still haunts our profession. Some years ago, the AATA decided to forego requesting that applicants for the A.T.R. submit a slide portfolio of visual art. Although it was obviously difficult to judge art portfolios as part of the registration process, the decision not to request them was symbolic of our trend to minimize the value of visual art skills and training as professional requirements. The Guidelines for Academic, Institute and Clinical Art Therapy Training (AATA, 1993) also clearly spell out that studio art courses at the graduate level are not acceptable. As state licensure becomes a requirement to practice therapy in some states, training programs often adapt curricula to meet these guidelines; any remaining art courses are generally the first things to go to make way for the clinical courses needed for eventual licensure. Granted, this is an economic reality and a difficult decision that a training program must make for its students; however, such decisions are often made in tandem with the exclusion of art from the core curriculum.

The Purpose of Art Therapy Education

Determining the purpose or goal of art therapy education consistently plagues art therapy educators. What is it exactly that we are educating students for in the workplace? Is it to work in a traditional mental
INTRODUCTION TO SPECIAL ISSUE

health setting such as a hospital? Is it to do inpatient or outpatient work, or both? Are we educating students for adjunctive or for primary roles as mental health professionals? Are we educating artists who use art in therapy? Are we educating psychotherapists to use art as a modality? Art therapy educators are constantly confronted with addressing these and other questions in their teaching and curriculum development. Then, there is the really scary question that art therapy educators have to face—Are there really any art therapy jobs out there for graduating students? Telling students that they have to be creative and develop their own positions may still hold true, but it is getting repetitive to rely on this old saw. As programs in higher education, particularly at the graduate level, become more accountable for the placement of their graduates in jobs, art therapy educators may have to deal directly with exactly how they are educating their students to find viable employment after graduation.

In terms of employment outcome, licensure has had a dramatic impact on education, particularly in states where licensure is a necessity to practice privately, to make a livable wage, or to obtain or retain a position in a mental health facility. In states where licensure in a related mental health field is available, training programs perform a dual task: educating an individual to be an art therapist while preparing him/her for licensure as a counselor or marriage and family therapist. Although this is a practicality for many art therapy training programs, it does impact the field by placing a significant amount of attention on related coursework other than pure art therapy. Add to this the necessary infusion of the diverse requirements of the AATA guidelines for training (1993), such as research, multicultural issues, and the like, and the task of designing effective art therapy curricula seems daunting at best.

Art Therapy Educators: A Strength or a Weakness?

Art therapy educators are, in essence, an elite group; when compared to other professional groups, they are extremely small in number. This has had an impact on art therapy education in a variety of ways, some of which are problematic. First, although there are very few job openings at any given time in higher education for art therapy educators, often there are also very few applicants from which to choose. In comparison to an opening for an assistant professor in visual art or psychology which, depending on the college or university, may draw hundreds of qualified applicants, art therapy training programs in need of an instructor may attract less than 20 applicants, many of whom are not qualified for the position because they lack the appropriate degree, registration, or previous experience. Although the applicant pool may contain several good candidates with solid records in teaching and/or administration, the pool is nonetheless limited in scope and dimension.

When a job offer is made to a good candidate, the candidate may not take the position for one of several reasons. First, the position may offer no advantage over the teaching/administrative assignment that s/he already has. Also, gender becomes an issue as most art therapy educators (and art therapists) are female; it is still the norm in our society that a male is more likely to relocate himself and his family for a career change than a female. A single female without children may make the move, but a married female or a single parent with concerns about moving children may not be as adaptable to relocation. Many programs, therefore, end up hiring a local individual who minimally fills job requirements such as a Master’s degree and an A.T.R. This person is often entry level, with little teaching experience and has little or no experience in the overall development or knowledge of the field. Also, the individual may not really have the optimal qualifications for the position nor the depth necessary to perform the wide continuum of tasks (academic advising, administration, research, clinical supervision, as well as teaching) required to keep the program viable over the long haul.

In some cases, it is more important that the potential applicant for an art therapy educator position have a clinical license in the state where the position exists. In the final analysis, a lack of licensure can override the other aspects of an applicant’s résumé, as stellar as it may be in terms of past teaching records, presentations, research, or scholarly publications. Although it may be vital to the institution and the program’s existence to hire someone with the required state licensure, this practice does bring up the question of how such hiring affects the vitality of the field of art therapy. Because of such practice, the candidate with the most commitment to art therapy—an individual who has chosen to follow a path involving commitment to the development and practice of art therapy rather than pursuing a license or related clinical track—may not be hired.

Lastly, the type of terminal degree an applicant holds may affect possible hiring. Doctoral degrees are often required if the academic position also involves administration. With very few traditional aca-
ademic settings offering doctoral studies in art therapy, many individuals choose a nontraditional or external degree program to obtain a doctorate degree. These programs allow for in-depth study of a field of interest not available at most colleges and universities; thus, an individual can pursue advanced study specifically in art therapy. However, as several educators observed, some colleges and universities may be unwilling to hire someone with an external degree. One educator noted that in one instance an art therapy educator was denied tenure because her doctorate was from a nontraditional training program.

The Superwoman/man as Art Therapy Educator

There is another phenomenon intrinsic to the art therapy educator that can be potentially problematic. It seems that in order to be an art therapy educator and/or program director, one must literally have superhuman skills and capabilities. Within art therapy educational programs, there are many of these superhumans who singlehandedly carry out all the necessary functions of the training program: teach, advise, administrate, supervise both clinical internships and research, and do much of their own secretarial work.

Frances Anderson, EdD, A.T.R., HLM, shared the following “job description” with colleagues at the 1990 Art Therapy Educators Convocation:

Wanted: Art therapy educator to direct art therapy program. Responsibilities include, but are not limited to: Administration of graduate program, fundraising including grants and scholarships and financial aid for students, directing master’s theses, teaching four art therapy courses per semester, practice site development and supervision. As director you will serve on all major department and university-wide committees and author the upcoming National Association of Schools of Art and Design 7-year self-study document and the AATA Education and Training Program Approval document. Applicant qualifications include: doctorate in art therapy or closely related field; A.T.R. status; 7 years clinical work, including work with special populations, geriatrics, and clients with eating disorders, chemical dependence, physical and sexual abuse; 5 years administrative experience; publications sufficient to qualify for university graduate faculty status; and an exhibition record as an artist. Also needed is more energy than a speeding locomotive, ability to leap tall buildings with a single bound, ability to repel bullets and colleagues’ slings and arrows, x-ray vision, mind reading capacity for dealing with academic administration and students, ability to walk on water, live with no sleep, write like Shakespeare, paint like Picasso, the luck to land grants and pick winning lottery numbers, the political acumen of a Boss Tweed or Richard Daley, the diplomatic skills of a Henry Kissinger. It would also help if the applicant is independently wealthy as we have no resources for student help, secretary or travel, etc. Applicants with no family responsibilities are encouraged to apply (there will be no time for family on this job). This is a 12-month appointment. Salary: $12,000 per year. Timbucto University is located in the beautiful countryside in the far outskirts of Civilization City, the state’s cultural center, which is 2 hours away by airplane or 2 days by mule. (Anderson, 1990)

This description is both simultaneously funny and sad; it is funny because no one person could do all the aspects mentioned and sad because there are many art therapy educators who actually do almost all the things Anderson noted. Most art therapy educators are continuously exhausted by an overwhelming gamut of responsibilities that go beyond mere teaching. In addition to instruction, they are heavily committed to outside activities which support the profession: serving on the AATA Board or Committees, serving on Boards of Affiliate Chapters, participating in governmental affairs in their state, giving in-service presentations to publicize the field, etc. These activities are in addition to the expected clinical work, community service, university service (sitting on various institutional committees, department committees, and ad hoc committees), publication, research, and, in some cases, exhibition of visual art.

The problem with superwoman/man art therapy educators is that many have not been able to keep up the frenetic pace, forcing some to opt for different paths after experiencing academia for a few years. Art therapy education suffers when this happens, because of the potential loss of individuals whose academic work allowed them to contribute to the development of the field through research or writing. Also, Wadeson (1989) noted that some academics leave art therapy education for higher pay, in addition to the burnout experienced on the job.

Programs in Jeopardy: Some Observations

At the start of this editorial, the closure of three AATA-approved, state university programs was mentioned. A fourth program, California State University Sacramento (CSUS), was jeopardized by a series of events earlier this year. The program faced being
phased out due to budgetary restraints within the California system of higher education.

Art therapy training programs in state universities have, in some ways, been considered the profession's flagships. The awarding of graduate degrees in art therapy from state institutions has given the profession a degree of equality with related mental health professions, such as psychology, counseling, and social work, all of which have graduate programs at public universities in most states. Art therapy training programs in state universities have access to more facilities, large libraries, and data bases, and the interactive atmosphere of a diverse academic environment. These advantages can contribute to the learning experiences of students who greatly benefit from the variety and depth of training. The lower tuition also has afforded individuals with limited resources the opportunity to obtain art therapy training at a significantly lower cost; this has been extremely important to single women, single parents, and nontraditional students who may be older and/or have limited financial resources. For these reasons, the closure of state-supported training opportunities hurts the entire field of art therapy, beyond the community and state in which the program was housed.

Before its threatened closure, CSUS's program has had, as many art therapy training programs, a bumpy history. In the 70s, the program was directed by the late Dr. Donald Uhlin, A.T.R., and was housed in the school's Art Department; later, after a series of events, it was placed in the Department of Counselor Education where, until recently, it was directed by Nina Denninger, MA, A.T.R. Denninger further developed the Master's degree program in art therapy at CSUS to enable students to become both registered art therapists and licensed marriage and family therapists in California.

During the 1992–1993 academic year, CSUS’s program became vulnerable to the budgetary problems that have plagued the State of California for the last several years. Higher education was placed in particular jeopardy because public education was greatly subsidized by tax dollars. Cuts were recommended at all state institutions of higher education, pending passage of the state budget. In order to meet these cuts, the Department of Counselor Education and the School of Education (in which Counselor Education is housed) recommended that the Art Therapy program be phased out. The main reason given for phascout was that art therapy did not meet the mission statement of the School of Education. The general mission of the School of Education was to serve school-age children in the public school system and to educate students to work within that system. Although most art therapy graduates from CSUS went on to work primarily with children, the School of Education felt that funds should go first to teacher education rather than art therapy education.

In response, students, faculty, and art therapists in the immediate community and Northern California embarked on a letter-writing campaign; additional help was requested from the AATA and other art therapy educators to provide support. A group of art therapists, faculty, and students went to the state legislature to meet with a prominent legislator who also sent letters to the university administration on behalf of art therapy.

However, the students at CSUS took the process one important step further; they became visible to the rest of the university and to the community in a proactive way. They analyzed the system (e.g., the School of Education and the university) that had told them their program could be phased out and they established a series of strategies to deal with it. They set up booths at both the university and at the state capital to publicize the threat to the art therapy program and to disseminate information on the field; they formulated petitions to solicit signatures in support of the program's retention; they created a media campaign that included talking to local television and radio stations and creating T-shirts (see Figure 1). The students also set up meetings with administrators within the university to express their concerns, ask questions, and become visible. These efforts, created in a very short amount of time, had a substantial effect on the system that sought to phase out their program of study. As a result, the program has been given a reprieve, with attention to moving it to a different department which can financially support it.

One could attribute the situation at CSUS to the budget crisis in California, but that does not explain all the issues involved. The program is robust, having approximately 45 students, and has established a solid reputation in the community. It has an excellent track record for service to the Sacramento area and provides thousands of children, adults, and families with no-cost art therapy services each year. When the phaseout was announced, CSUS was in the middle of review by the AATA Education and Training Board for approval of its training program, a process which was supported by the Department of Counselor Education and the School of Education. It also has the only combined art therapy/marriage and family degree in the state system, making it afford-
able to women and minorities who might not otherwise be able to undertake such training in a private setting. Additionally, there were other programs in the School of Education which have smaller enrollments and have much less impact on the community than does the art therapy program. Yet, the art therapy program became threatened despite its robustness and its contributions to the immediate community and the state system. Such a situation is indicative of the possibility for any art therapy training program to become threatened at any time.

Conclusion:

In this issue of the journal, Junge, Volker, Kellogg and Finn Alvarez call for art therapists to become social activists, with clients and in life. In this spirit, what the students at CSUS, art therapy professionals, and others in the community did concerning the threat to their training program could have far-reaching implications for other programs and for art therapy education in general. Of utmost importance is how the Sacramento students actively handled their situation: they did not roll over and play dead. They formed a network, analyzed the situation, established a plan of action, and pursued it. Most of all, they handled difficult circumstances with a great deal of creativity as well as professionalism.

Like the students at CSUS, we are going through a time in our collective history as a profession and association when we need to reexamine how we can work together. Art therapy educators especially need to consider how to do this, since they are, in many ways, the glue that holds the field together. Unfortunately, this is also a time when art therapy educators are feeling overwhelmed not only by their institutions, but also by our own ranks; many educators are feeling isolated in their schools, unsupported by other educators, and uneasy with the current process of approval by the Education and Training Board (ETB). If we do not honestly confront and deal with these feelings, we most certainly will self-destruct at our own hands before any budgetary or other societal influences reach us.

It is important to remember that when a training program folds, it affects not only the immediate community where the program existed, but the entire professional community of art therapists. When state university programs fold, the problem is critical because these programs are affordable and can support those students who could not otherwise afford to undertake the expense of art therapy education in the United States.
a private college. Also state programs often can support art therapy research, which directly influences, nurtures, and hastens the development of our field. It is also likely that the first successful bid at art therapy licensure (see article by Good in this issue) was partly due to the dynamics of having a program of study at the major public university in that state.

Many of the topics discussed in this editorial are not new to the field, but they are important to both art therapy educators and art therapists if art therapy is to survive in the coming years. In the light of what is happening both in higher education and society in general, it is important to revisit these issues and to reconsider their effect on the overall health of the field of art therapy.

This editorial is dedicated to the graduate students in the Art Therapy/Marriage and Family Counseling Master's Degree program at CSUS who demonstrated a great deal of intelligence, integrity, courage, and professionalism in response to a difficult situation.

Letter to Editor

Dear Ms. Malchiodi:

After reading the recent review by Vija Lusebrink of Shaun McNiff’s *Art as Medicine*, I wondered if she and I had read the same book. The image of a waspish schoolmarm, lips pursed, ruler at the ready, formed in my mind while reading the first page-and-a-half of the review. I plowed through the workmanlike dissertation of what I had found to be a text of rather passionate scholarship, full of literary and philosophical allusions which enlarge the context of art therapy.

On page three, the ruler comes down. Dr. Lusebrink complains about McNiff’s unattributed characterization of art therapists as “interpreters and diagnostic labelers” as she labels him ego-inflated and archetype-identified, “in a number of instances,” none named. Far more damning and personal criticisms, these. She unwittingly supports his point by continually labeling him a Jungian, a claim he never makes, for using the method of dialoguing with an image, a method that predates Jung by many centuries. Barbara Hannah, in *Encounters with the Soul: Active Imagination as Developed by C. G. Jung* (1981), tells us that this method has been in use since the dawn of history. The oldest example she cites is of Egyptian origin, a 4,000-year-old text whose title translates as “The world-weary man and his soul.”

Not content to complain about art therapists supposedly getting short shrift from McNiff, Dr. Lusebrink complains on behalf of James Hillman. Judging from Hillman’s comments printed on the book jacket, he read a pre-publication copy of the manuscript and could have raised concerns himself, if he had any. In any event, Hillman didn’t create the concept of “daimons” any more than Jung created active imagination.

In getting mired in measuring imaginary violations of intellectual property rights, Dr. Lusebrink has taken, in my opinion, a decidedly low road. I would like to focus on the fact that *Art as Medicine* is a lively and inspirational work illustrated with rich paintings that, even in black and white reproductions, show that at least one art therapist remains committed to his art. Additionally, this book, issued in trade paperback and distributed worldwide, appears on the shelves of more bookstores than any other recent art therapy publication.

One of Margaret Naumburg’s last and unfortunately unrealized wishes was to write a book about art therapy that would bring its ideas into the mainstream. Shaun McNiff has accomplished this and I think we ought to be grateful. The exposure of this book benefits all art therapists.

I must take issue with another point regarding the art studio approach. Dr. Lusebrink claims that:

Application of McNiff’s approach appears to be most appropriate to a clientele similar to himself—intelligent, functional individuals who have the personal means to attend international self-exploratory workshops. This approach is less useful to art therapists who work with individuals who have serious impairments and psychopathology, given constraints of time and reimbursement through insurance.

In my experience I have found that one thing the art studio approach has taught me unequivocally is that all people are “like myself,” regardless of their income, I.Q., or social status. When I make art alongside another person, it is our common humanity that is revealed. It is when we sit apart from and judge that our eyes focus on psychopathology or other categories of difference.

In recent years, my students, inspired by McNiff’s ideas among others, have created art studio programs in the most unlikely places. Deborah Gadiel’s open studio work with poor Hispanic outpatient clients continues; Denise Colletti, a 1993 grad of the School of the Art Institute, carried out collaborative studio work with chronic schizophrenics in a sterile state hospital. Carol Kiendl-Binger, also a 1993 grad, created a studio program with inner city adolescents in a day hospital under terrible conditions. These students have consistently taken the powerful idea of art making beyond my wildest dreams. In every case it has been students whose own art making is central to themselves who have been able to move beyond what most would see as insurmountable roadblocks and creatively see and effect new and exciting solutions to problems inherent in the practice of art therapy.

The waspish schoolmarm is an archetype that lurks within each of us, especially tender perhaps in those concerned about establishing the validity of the clinical approach to art therapy, those fearful of wholly trusting the art. McNiff, who seems to have worked out an enviable balance in his life as global ambassador of art therapy, prolific writer, and accomplished painter, may easily evoke the scold in art therapists who perceive their livelihood eroding day by day. To those art therapists I would suggest putting down the ruler and taking up the paintbrush, even if only for a few moments a day. It is in the exercise of our creativity, which is after all our spiritual force, that answers can be found, even to seemingly pragmatic questions. There is nowhere more than within our own profession that art as medicine is desperately needed.

Sincerely,
Pat B. Allen, PhD, A.T.R.

Editor’s note: Another response to Dr. Lusebrink’s review of *Art as Medicine* appears in the Book Review section of this issue.
Ethical Considerations in a Supervisory Relationship: A Synthesis

Jeanne Carrigan, OSF, PhD, A.T.R., Tucson, AZ

Abstract

Some of the most prominent ethical concerns presently being reviewed by psychologists, counselors, and other helping professionals focus on issues related to supervision and training of interns in clinical professions (American Association for Counseling and Development, 1991; Kitchener, 1988; Stadler & Paul, 1986). This movement stems from the increasing number of formal complaints interns have filed with their respective professional organizations (Slovenko, 1980). These claims range from sexual harassment to supervisors acting in dual or multiple roles with interns. The art therapy profession has not been exempt from such complaints. During the past years, the Committee on Ethical and Professional Practices has dealt with similar supervision-related issues.

The purpose of this paper is to examine the nature of the supervisory relationship and the roles of each participating member as they are discussed by theorists from other mental health professions. It is hoped that the following ideas will be of interest and assistance to both interns and supervisors.

Introduction

Some of the most prominent ethical concerns presently being reviewed by psychologists, counselors, and other helping professionals focus on issues related to supervision and training of interns in clinical professions (Kitchener, 1988; Stadler & Paul, 1986). This paper will attempt to synthesize important elements of the supervisory relationship as described in studies and codes of professional conduct from: the American Association for Counseling and Development (AACD), the American Psychological Association (APA), the American Association for Marriage and Family Therapy (AAMFT), and the National Association of Social Workers (NASW).

Increasing interest in the supervisory relationship stems from the growing number of formal complaints filed by interns with their respective professional organizations (Slovenko, 1980). These claims range from sexual harassment to supervisors acting in dual or multiple roles with interns. The art therapy profession has not been exempt from such complaints. During the past years the Committee on Ethical and Professional Practice has dealt with similar supervision-related issues.

These issues are not to be confused with the violation of an educational institution’s code of academic integrity. Matters concerning grades, academic performance, cheating, and/or the quality or content of lectures are concerns that can be addressed directly to the professor teaching the class, to the department head of the academic unit, or to a higher administrative body by means of a formal grievance. The ethical conduct examined in this paper does not necessarily occur in the classroom, but rather lies within relationships formed between interns and supervisors.

The purpose of this paper is to examine the nature of the supervisory relationship, and the roles of each participating member as they are discussed by theorists from other mental health professions. It is hoped that the following ideas will be of interest to members of the American Art Therapy Association as well as be of assistance to both interns and supervisors during the difficult time of internship.

The Nature of the Relationship

The supervisory relationship is best described as complex (Whiston & Emerson, 1989). It is “... an intensive, interpersonally focused, one-to-one relationship in which one person is designated to facili-
tate the development of therapeutic competence in the other person” (Loganbill, Hardy & Delwork, 1982, p. 14). Although it is therapy-like in character, clinical supervision must remain focused on the professional growth of the interns and not become involved in providing counseling to them (Corey, Corey, & Callanan, 1987; NASW, Standard III-9, 1980; AAMFT, Standard 6.3, 1985; APA, Principle 7-C, 1992; AACD, Section B-11, 1981; Kurpius, Gibson, Lewis, & Corbet, 1991). At first, the novice supervisor may believe this is a reasonable expectation, but soon discovers how difficult it is to keep counseling out of supervision. In fact, some theorists believe that this kind of separation is impossible (Ryder & Hepworth, 1990).

Why are Clinical Supervisors Tempted to Counsel Their Interns?

In part, the answer may lie within the very nature of the relationship, for it is both a personal and an intensive experience. It requires an in-depth level of communication between both parties at frequent intervals, resembling counseling sessions (Sherry, 1991). To further confuse matters, many supervisors are therapists, and that is what they do best. Some supervisors simply want to counsel and believe it is their role as a supervisor to do so, while others turn to counseling because they need to “fall back on training as a counselor” due to their lack of training in supervisory methods (Whiston & Emerson, 1989). Also, interns may unknowingly elicit counseling by presenting unresolved personal problems while being supervised, thus introducing the opportunity for a supervisor’s therapeutic intervention.

What do Professional Codes of Ethics Recommend Concerning the Supervisory Relationship?

The following excerpts are taken directly from the professional codes of ethics of four associations (AACD, APA, AAMFT, and NASW). These excerpts provide guidelines concerning the professional conduct of association members while in a supervisory role.

The American Association of Counseling and Development—“When the member has other relationships, particularly of an administrative, supervisory, and/or evaluative nature, with an individual seeking counseling services, the member must not serve as the counselor but should refer the individual to another professional” (AACD, B-11, 1981).

The American Psychological Association—“Psychologists who employ or supervise other professionals or professionals in training accept the obligation to facilitate the further professional development of these individuals. They provide appropriate working conditions, timely evaluations, constructive consultation, and experience opportunities” (APA, 7-C, 1992).

“Psychologists do not exploit their professional relationships with clients, supervisees, students, employees or research participants, sexually or otherwise” (APA, 7-D, 1992).

The American Association for Marriage and Family Therapy—“Family therapists who provide supervision assume responsibility for defining the relationship as ‘supervisor-supervisee’ and for clearly defining and separating supervising and therapeutic roles and relationships” (AAMFT, 6-3, 1985).

The National Association of Social Workers—“The social worker who serves as an employer, supervisor, or mentor to colleagues should make orderly and explicit arrangements regarding the conditions of their continuing professional relationship” (NASW, III-9, 1980).

Why Is Counseling Interns Not Recommended by Most Codes of Ethical Conduct?

First, supervision is an unequal relationship in which interns have little freedom to make choices. It is a relationship in which one member has all the status, power, and expertise, while the other member has little or none (Stoltenberg & Delworth, 1987). Difficulty arises from this imbalance of power. Upchurch (1985) cautions supervisors to beware of potential enticements such as: the misuse of power and authority; the creation of a relationship where the trainee becomes overdependent; the possibility of negative transference and countertransference; and the development of intensive emotional reactions both positive and negative toward the supervisor. In short, supervisors must be alert to the inequity of the supervisor-intern relationship and provide means to compensate for it. It is also suggested that interns be responsible for choosing their own practicum sites and supervisors (Sherry, 1991).
These choices are incidental, however, compared to the choice made by the supervisor to engage in counseling the intern. If this occurs, interns, because of the inequity of the relationship, often have little choice but to participate, even though they did not contract for counseling. If they choose not to participate, their supervision could be discontinued. Placing an intern in a situation of “diminished consent” or “lack of consent” may have ethical ramifications. Of course, this situation is not to be confused with those times when interns need to periodically articulate “What is going on with them?” Lack of consent occurs when the focus during supervision is primarily on the well-being of an intern rather than his/her professional development (Corey, Corey, & Callanan, 1988).

Second, the addition of the counselor role to the supervisor’s job expectations only complicates a relationship that already involves multiple roles. In most instances, supervisors are expected to teach, evaluate, consult, monitor client welfare, and facilitate the intern’s self-awareness (Sherry, 1991). Conflict emerges when the roles become incompatible, such as that of the counselor and teacher (Kitchener, 1988). This conflict can develop into a dual relationship problem if the supervisor “explicitly” conducts two different relationships with an intern over a prolonged period of time (Cormier & Bernard, 1982). An example of a problem arising from a dual relationship is illustrated by Ryder and Hepworth’s observations: “We ask supervisees . . . to be open and relatively undefended with us, and may assure them of our benevolence; but then we grade their performance. A student who is too open with us may live to regret it” (1990, p. 130). This can happen when the classroom instructor also serves as the clinical supervisor. Supervisors need to be aware that there is a difference between the style and rapport of supervision versus the “control-oriented” quality of a classroom. Even with this knowledge, it is difficult to be objective while evaluating interns’ performances when the supervisor is engaged in two distinctly different roles.

Finally, there is a third person involved in all supervisory relationships—the client. The welfare of the client is paramount and no aspect of the supervisory process should jeopardize it (Pope & Vasquez, 1991). Unfortunately, a popular grievance made in malpractice suits today deals with the failure of supervisors to adequately supervise the work of their interns (Sherry, 1991). It is the supervisor who is ultimately responsible for the treatment of the client, and therefore must sometimes make difficult decisions when an intern is not competent or skilled in handling a therapeutic situation. When interns are engaged in therapy with their supervisors, decisions concerning the interns’ competence may become awkward and blurred, leaving the client in a precarious and perhaps dangerous situation.

Even with all the difficulties inherent in the supervisory relationship, internships can provide experiences that are growth-producing for interns as well as opportunities for professional development for supervisors (Corey, Corey, & Callanan, 1987). According to Stoltenberg and Delworth (1987), the success of this relationship depends on the presence of a competently trained supervisor, well-defined roles in the supervisory relationship, the delineation of the intern’s rights, professional expectations and training objectives, and respect for interns. These components are referred to as “due process” or the rights of supervisees. In the remaining paragraphs these components will be discussed in relation to the roles played by each participant.

What is the Role of the Supervisor?

The ideal supervisor is a competent clinician who has taken advantage of continuing educational opportunities on an ongoing basis and has been trained in supervisory techniques (Corey, Corey, & Callanan, 1987; Pope & Vasquez, 1991). Besides possessing these prerequisites, the supervisor is able and willing to formulate and define the supervisory relationship.

This delineation of the supervisory process is extremely important for it provides the intern with a clear understanding of the nature of the supervisory relationship, the expectations of the internship, and the criteria for evaluation (Cormier & Bernard, 1982). Although each internship site will have varying expectations of its interns, some common factors may include fees, internship objectives, assessment criteria, confidentiality, choices of internship supervisors, and grievance procedures (Upchurch, 1985). Interns also need to be informed early in the internship that it is the responsibility of the supervisor to ensure work performed by the intern meets the standards of the profession. If these standards are not met, then it is the responsibility of the supervisor to request that the intern seek counseling or possibly discontinue the internship.

After establishing parameters of the supervisory relationship, the single most important task of the supervisor is timely feedback. Communication between intern and supervisor needs to take place on a
regularly scheduled basis. During these sessions, interns are encouraged to express their professional concerns, while supervisors can “clearly, frankly, and promptly communicate” their observations of the intern’s development (Pope & Vasquez, 1991). Serious matters that involve the intern’s professional and/or clinical abilities need to be brought to the attention of the intern early in the supervisory process. After discussing the problems, the content of the conversations needs to be documented in writing by the intern as well as the supervisor. This kind of early intervention can prevent further complications in the supervisory process. According to Keith-Spiegel and Koocher, “Lack of timely feedback is the most common basis of ethics complaints regarding supervision” (1985, p. 172). When there is cause for questioning the possible fairness of a particular resolution, the supervisor should seek consultation from others (Upchurch, 1985).

What is the Role of the Intern?

Interns must be theoretically and experientially prepared to participate in particular internships (Sherry, 1991). Just as supervisors are ethically obligated to recognize their own limitations and areas of competence (APA, Principle 2-a), it is the intern’s responsibility to select an internship site that is in keeping with the individual’s academic background and abilities. This takes some introspection and honesty on the part of the intern. If this factor is ignored, frustration may follow for all parties involved: supervisor, intern, and client. For instance, an intern who has no knowledge of special populations should not be interning in a school setting where planning and providing appropriate interventions for students with disabilities is a priority. This is unfair to the intern and certainly may place students with disabilities in emotional jeopardy.

As previously mentioned, it is the right of the intern to receive clear expectations of the internship before or early in the supervisory relationship. For many interns these expectations come in written form in a contractual agreement followed by a detailed verbal orientation by the supervisor. In all the excitement of beginning a new job, sometimes these expectations become blurred. The phrase “I didn’t know that” then becomes a common expression. Taking notes during the orientation, reviewing all written documentation, and then asking clarifying questions are the responsibility of the intern.

Interns who are aware of personal problems that may affect the quality of their work performance should seriously consider obtaining counseling. As in the case of academic readiness, emotional health is a crucial factor in the mental health professions. When interns are simultaneously coping with their own problems while involved in an internship, many times the only manifestations of that experience are stress and confusion.

Also, interns often act as extensions of their supervisors in various professional capacities. In many cases, interns may replace the supervisor in providing services to particular clients, may interface with other professionals as a representative of the supervisor, and may participate in various clinical meetings where they are asked to speak on behalf of the supervisor. In all these circumstances, interns should demonstrate respect and consideration for their supervisors (Stoltenberg & Delworth, 1987).

What are Some of the Views of Art Therapy Educators Regarding the Supervisory Relationship?

Before providing art therapists’ viewpoints on this question, it is important to consider what the present Code of Ethics for Art Therapists (1992) states concerning the supervisory relationship adapted from the American Psychological Association (APA, 7-c):

“Art therapists do not exploit their professional relationships with clients, supervisees, students, employees, or research participants sexually or otherwise.”

This statement provides minimal direction to clinical supervisors, who, over the past decade have been requesting more formal guidelines. In response, Wilson, Riley, and Wadeson (1984) wrote a “mini-manual” on art therapy supervision. The article defines and develops the three stages of art therapy supervision by providing detailed descriptions of students’ skill development, by giving examples of how theory and practice are integrated during internship, and by describing the changing nature of the supervisory relationship throughout the different stages of supervision.

In the first section, called “Beginning Phase,” Wilson discusses the importance of well-defined roles for both members of the supervisory relationship. She states that the supervisor’s role is one of “teaching students how to ask questions.” These questions serve as a form of self-examination whereby students can delve into the changing dynamics of the therapeutic process. On a cautionary note, Wilson clearly distinguishes the self-examination of
the art process from the self-examination that transpires in one’s own personal therapy. It is her belief that the role of the supervisor is to assist the supervisee in identifying personal difficulties which may later become obstacles in his or her clinical work. It is not, however, the role of the supervisor to engage in a therapeutic relationship while in the supervisory setting.

Five years later Calisch (1989) created a supervisory model which she labeled “eclectic blending.” In this approach, Calisch attempts to integrate four clinical models of supervision: psychodynamic, interpersonal, person-centered, and behavioral. Her rationale for this new formulation stems from the unique nature of art therapy. Since art therapy includes a variety of theoretical orientations, a model for supervision needed to be created which would “fit its multiple parts.” As Calisch defines the nature of supervision, she describes a different kind of supervisory relationship:

From the very start the supervisor must communicate that attention to interpersonal issues is not only permissible but is a very important component of the supervisory relationship. (p. 41)

She admits that this position is nontraditional, but after personally experiencing positive results from this approach, Calisch believes that fostering a collaborative spirit through interpersonal explorations can be profitable to both supervisor and supervisee.

Lastly, a third model, described by Durkin, Perach, Ramseyer, and Sontag (1989), again addresses the unique needs of the art therapy supervisory relationship. It employs art making and journal writing as a means of communication throughout the supervisory process. Bringing “…the tools of the trade into the supervisory relationship…” (p. 391) is the essence of this model. In it, supervisory sessions become opportunities where both the supervisor and supervisee exchange insights and ideas as they create art and prose describing their supervisory relationship. Art therapy supervisors who have used this model state that it enables both parties to “zero in on issues” before they are consciously formulated. They assert it assists in fostering better understanding of the dynamics of their relationship, providing a visual format in which there can be an exchange of ideas on issues. They also credit this model for promoting integration of cognitive theory into the affective domain. However, the authors admit it is personally risky, crossing over the boundaries of traditional supervision and closely paralleling the therapeutic relationship.

**Conclusion**

Supervision is a relationship full of complexities and ambiguities that does not offer professional counseling to the intern even though one of its primary goals is to promote self-awareness in the intern. It is an intensive personal relationship, yet communication between the two parties must remain on a supervisory level which sometimes results in an unequal relationship that allocates most of the responsibilities and power to the supervisor, while the intern may be in danger of being disempowered. Because of these seemingly paradoxical characteristics, supervisors must be either experienced or seek instruction on how to supervise effectively.

Counseling educators are finding that supervision requires different skills than teaching or counseling (Ellis, 1991; Kurpius, Gibson, Lewis, & Corbet, 1991). For this reason they are beginning to create special training programs for supervisors, and many of them foresee establishing a certification for supervisors. The reader may believe that this additional process is not appropriate for art therapists. However, unless art therapy supervisors are knowledgeable about the ethical and legal issues involved in supervision, their interns will experience poor quality supervision while the supervisors become prime targets for unpleasant legal confrontation.

It is now time for our profession to closely examine how interns are being supervised and later mentored. We need to support those persons willing to supervise by providing regularly scheduled workshops that specialize in supervisory techniques. As a profession, we must assure our students that we are doing everything possible to provide them with opportunities for quality supervision.

CALL FOR PAPERS

Art Therapy is calling for papers on Multicultural Issues in the Theory and Practice of Art Therapy.

Authors are encouraged to submit full-length articles, brief reports, viewpoints, and book reviews which relate to or discuss the interface of multicultural issues with the theory and/or practice of art therapy. Also, submissions which discuss multiculturalism with regard to ethical and professional issues, gender issues, and education/supervision are encouraged.

Please send all submissions to:

Cathy Malchiodi, MA, A.T.R.
Editor, Art Therapy
1202 Allanson Road / Mundelein, IL 60060

Deadline for submissions for this special issue is October 15, 1993. Please read the Guidelines for Authors published in each issue of Art Therapy regarding the specifics of format and style.
The History of Art Therapy Licensure in New Mexico

Deborah A. Good, MA, A.T.R., Albuquerque, NM

Introduction

New Mexico is a state of diverse cultural backgrounds. The people enjoy the idea of getting things done "mañana," tomorrow. The pace is slow, and people take their time to adapt to change.

Paula Banek, A.T.R., was the first registered art therapist to move to the state in 1978 and was active in educating people about art therapy. For this reason, it is not surprising that Paula became the first Governmental Affairs Chair (GAC) for the New Mexico Art Therapy Association (NMATA). During the early 1980s, Paula worked on the development of a state job description. She met with local legislators and set the groundwork for what would become the first art therapy licensure bill in the United States.

While interning under Paula's supervision, I became aware of her determination and admired her dedication to the field. We discussed the needs of our profession and agreed that there was a need for a state job description. I was sure that the political scene was boring and not of interest to me, so through the next few years, Paula continued to meet with state committees and individuals who might support the need for a job description as an art therapist.

In 1987 the governmental affairs position was passed on to me. It seemed fitting that when Paula declined to be NMATA's GAC that someone who had worked with her behind the scenes should take over. I began attending to the AATA Governmental Affairs meetings at the national conferences to find out what other people were doing around the country. The central theme seemed to be that art therapists needed licensure. At that time there was no model licensure bill for art therapists available. The National Coalition of Creative Art Therapists had created a legislative packet, but it was not specifical-

Rep. McSorley followed it into the Senate with the support of Sen. Shannon Robinson, a life member of the New Mexico Art Therapy Association. Sen. Robinson was a freshman in the Senate that year. He had an impressive understanding of art therapy because his legal secretary, Gail Bell, A.T.R., was studying to be an art therapist at the University of New Mexico. He also donated time on his computer for NMATA usage and willingly supported our licensure efforts.

On March 14, 1989, HB184 successfully passed both Senate committees. During this time I wrote guidelines for legal testimony which later became part of the legislative packet created by AATA GAC Robin Gabriels, A.T.R.

As the 60-day session came to a close, HB184 was heard on the floor of the Senate, passing 32–8, on March 17, 1989. It then made its way to the Governor's office for his approval or veto. Cay Drachnik, A.T.R., then president of the American Art Therapy Association, made a special visit to New Mexico upon my request. We tried to speak with the Governor but were unable to do so. However, it was a good feeling to be supported by the AATA on the state level, and it was that kind of support that encouraged me to reach for this dream. I was an unknown art therapist in New Mexico. What an honor for the president of AATA to personally visit and try to help me! I am eternally grateful for Cay’s vision and her ability to see mine.

The politics at this point became particularly interesting. New Mexico had a predominately Democratic House and Senate; but, the Governor was a Republican. He vetoed HB184 30 days later, stating that the penalty section was too broad; he also vetoed the counselors bill.

It is the right of all concerned to discuss with the Governor's attorney the reasons for a veto, so I scheduled an appointment and met with him weeks later. It is also a right to be able to see the file that went with HB184 to the Governor's desk. The NMATA had implemented a forceful letter-writing campaign from art therapists, employers of art therapists, and concerned citizens. We knew that we should have approximately a hundred letters in our file, but there were only three. When I asked the Governor's attorney what the real reason for the veto was, he replied, "The Governor was tired. Your bill happened to reach him within the last 24 hours that he had to sign or veto all bills."

There were many lessons to be learned from this brief interchange. We needed to keep a master file of all letters sent to all legislators and the Governor. We needed to find a way to get our bill to the Governor’s office more quickly after passage on the floor of the Senate. It was difficult to have this kind of momentum and have to wait two years to try again.

House Bill 641

During the rest of 1989 and 1990, we continued to educate legislators on the art therapy profession. The necessity for licensure was not felt as strongly by some art therapists as it was by those who were aware of the preference in employment that was granted to those professionals who could hold a state license. It was with this in mind that we worked toward the 1991 legislative session. The original licensure bill had now gone through many hands in the AATA. Suggestions for revisions were included, and strategies formulated.

With the legislative session approaching in mid-January 1991, we were informed that the counselors were also returning with their licensure bill. The marriage and family therapists had joined efforts with the counselors, and they were working on a bill to license both professions individually. The question was put to the NMATA members whether or not they wanted to join efforts with the counselors and marriage and family therapists. The pros and cons were weighed and a decision was made to unite in a way that would make all of us stronger and still maintain our original goals. Knowing that the decision for the marriage and family therapists to join with the counselors had already been made, we realized the strength in numbers of professionals who could be licensed through their bill would outweigh ours. An argument could be made that the state of New Mexico would save money licensing three to four separate disciplines under one board. We began to work with the Legislative Council Services to combine our bills into what we called the Counselors and Therapists Practice Act.

Historically, the counselors in New Mexico had made attempts at licensure for approximately 15 years. The title "counselor" stirs up conflict when dealing with state agencies, group home situations, dorm counselors, etc. Questions were asked about how we define our professions and still allow job descriptions to exist that do not equal our specifications. Licensure's main consideration always must be "to protect the public." Therefore, a licensure bill must appear to alleviate harm and not produce additional stress on the existing systems in place. These are issues that we continued to battle for the three
years that art therapists joined with counselors and marriage and family therapists.

The 1991 legislative session with opposition from a group of counselors in the northern part of the state. They threatened to openly oppose the bill unless there were changes made in the language. It seemed that some of their requests could be dealt with easily, while others would sacrifice the integrity of the projected law. Negotiations ensued and our bill was not introduced due to compromises that continued to develop. However, the art therapy and marriage and family therapy sections of the bill remained untouched. Finally, 30 days into the session HB641 was introduced in the New Mexico House of Representatives. We were getting a late start and timing was crucial.

Two main differences in support occurred during the 1991 session. An art therapist who worked for a state agency, Aviva Ariel, offered to maintain direct computer contact with the legislative tracking of HB641; this was an incredible help. It eliminated my daily long-distance phone calls at 7 a.m. Also, the three professions raised money to hire a lobbyist to help the bill get through the legislature.

HB641 was assigned to three committees in the House of Representatives: Consumer and Public Affairs, Judiciary, and Appropriations and Finance. Not only were we cut to 30 days, but now we had an extra committee hearing to go through. Fortunately, Rep. Cisco McSorley was Vice Chairman of the Judiciary Committee. As the state GACs from all three professions waited to be heard in committee, I began to work on the members of the Judiciary Committee to see if our bill could be given a due pass without a hearing. After HB641 passed Consumer and Public Affairs, we headed for Judiciary. Our due pass was granted, and HB641 moved to the House Appropriations and Finance Committee.

At this point each committee was overloaded with bills to be heard; hearings were going on into the middle of the night, and starting again at 7 a.m. before the floor session. No time could be lost. We decided to remove the request for appropriations from the bill and passed Appropriations and Finance. Then HB641 moved to a full floor vote of the House of Representatives. Again, our bill split party lines and with a Democratic majority we passed the House and entered the Senate. At this point, there were less than 10 days left in the session.

In the Senate, HB641 was assigned to two committees: Consumer and Public Affairs and Corporations. Sen. Robinson helped us again in the Consumer and Public Affairs Committee. We were heard, passed, and sent to the Corporations Committee where the insurance lobbyists came out in full force. Another compromise had to be made: The mandatory third-party reimbursement was taken out of the bill. Actually, we were surprised that we had gotten so far without more opposition in this area. Originally, the bill had been written with prioritized components that could be eliminated in committee hearings, if necessary. We wrote the bill asking for everything, and then tailored it as we went from hearing to hearing, knowing that we would maintain the priorities of the bill even if we had to sacrifice the frills.

HB641 waited until the last three days of the session to be brought up on the Senate floor for a full, and final, vote. The last day of the legislative session is always a Saturday and the session officially closes at noon. What bills remain unheard, die. After Friday night HB641 still had not been heard. The Senate was working through the night to make its way through the backlog of bills that remained. I got up at 3 a.m. and made my way to Santa Fe, 60 miles in a snow storm. I found my GAC colleagues in the gallery above the New Mexico Senate. The Senate was in the midst of a filibuster and HB641 was behind the filibuster. We sat and watched as the time ran out; there was nothing that could be done.

This 1991 legislative session left us all drained. I questioned the decision to join the counselors. After all, weren’t they the reason for the majority of opposition? Why didn’t they work out their conflicts prior to the session? If only we had started earlier. Working with two other GACs seemed to be slowing us down, rather than helping.

I devoted my energy to negotiating a reduction of the final lobbying fee. The three state associations hadn’t received much for the large sum of money that we were paying. We confronted the lobbyist who said that he tried hard. He told us of all his conquests and said that we were one of the unfortunate losses. I held my ground and recounted the lack of professionalism with which we were treated. In response, he reduced our final fee. The following year, before the 1992 30-day session, I received a letter from this lobbyist granting the NMATA fee lobbying for any concern that came up during that session. Of course, we had to wait another year to introduce our bill again, but this was an interesting turn of events.

The loss of HB641 was felt deeply by many professionals in New Mexico. The consensus of support became unified throughout the art therapy community. The art therapists in New Mexico used this
time to unite their efforts and begin to look at licensure as a plan, rather than a possibility.

House Bill 234

During the summer of 1992, the GAGs met again. Janice Havlena, MA, A.T.R., 1992 president of NMATA, joined in those meetings. As Janice left the presidency, Elaine Giovando, MA, the NMATA 1993 president became a major supporter. The decision was made to stay with the counselors and marriage and family therapists due to the number of professionals who would benefit from licensure and the positive effect those numbers on committee hearing votes. Money was raised for a lobbyist, who was carefully selected. We were not going to go through the same scenario a second time.

HB234 was introduced into the House of Representatives on January 28, 1993, by Rep. Cisco McSorley. The counselors still maintained their opposition in committee hearings. I decided to take a firmer role and work with the lobbyist, proactively confronting opposition. Elaine Giovando, Dr. Robert Waterman, and I spent a considerable amount of time meeting with the counselors who expressed opposition and the legislators. Since this was the third session in which I had played an active role, legislators knew me, spoke to me openly, and mentioned ideas that might help to get our bill passed.

HB234 successfully passed the House Business and Industry Committee on February 16 (unanimously), the House Finance and Appropriations Committee on March 1 (unanimously), and a full House floor vote on March 4 (58-1). House Bill 234 arrived in the New Mexico Senate on Friday, March 5. Sen. Shannon Robinson, chairman of the Senate Public Affairs Committee, heard HB234 on Monday, March 8. Again we passed committee with a unanimous vote. Sen. Robinson carried HB234 to the floor of the Senate on Wednesday, March 10, where it passed the full Senate by a vote of 26-4. After a final concurrence in the House of Representatives the next day, HB234 made its way to the Governor's office.

On Thursday, March 18, 1993 at 3:00 p.m., Governor Bruce King signed the Counselors and Thera-

pists Practice Act into law creating the first state licensure for art therapists. Officially, HB234 became law on July 1, 1993. Between July 1, 1993 and July 1, 1994, the Counselor and Therapists Practice Act Board will be developing application forms, accepting A.T.R.s for grandparenting into licensure, and creating all the necessary documents and rules from which the Board will operate. Governor King will appoint one art therapist, one marriage and family therapist, one mental health counselor, one clinical counselor, and four public members to the Board. By July 1, 1994, licensing of art therapists will be a reality in New Mexico.

Reflections

I believe that the most important thing that I learned from this adventure is that all things really are possible. If you have a vision, you can bring it to maturation. It is easy to become discouraged, but determination and perseverance are worth all their effort and energy to achieve a successful end result.

I matured during this process too. Before I began working toward art therapy licensure, I had no concept of how effective one person could be with regard to state regulations. I had no idea that the government was really here to serve me. As a voting member of my community, I have a right and an obligation to monitor legislation that affects me and my environment. The elected officials are here to serve the public; that concept totally negates the idea that legislative figures are untouchable or unreachable. Now, I look differently on my rights as a citizen and carefully consider whom I vote into public office. As new candidates show up at my door requesting signatures of support, I speak to them about art therapy and my needs as a voter.

Art therapy licensure in New Mexico is only the beginning. I have no doubt that many states will follow and that art therapy will grow in recognition because of these efforts.

Deborah A. Good, MA, A.T.R., is in private practice and directs the Art Therapy degree program at Southwestern College in Santa Fe, NM. Ms. Good has served both on the AATA Board of Directors and on the interim Art Therapy Credentialing Board. The Art Therapist as Exhibiting Artist: Messages from Joseph Beuys, Suzi Gablik, and Donald Kuspit

Mildred Lachman-Chapin, MEd, A.T.R., Chicago, IL

Abstract

The inquiry begins with questions arising from an attempt to integrate the identities of the art therapist and the exhibiting artist. Are they fundamentally opposite: the art therapist functioning to serve others and the exhibiting artist functioning to serve or express himself/herself? This discussion deals with the views of Suzi Gablik, an art historian, Joseph Beuys, an artist, and Donald Kuspit, an art critic.

The art world is talking about a new identity for the artist, one of healing and relationship. This paper examines the implications of the art therapist’s message for the art world of today. Until now we have addressed ourselves almost exclusively to the mental health world. Now it may be time to address the art world from which we came.

Several years ago Mari Fleming and I spoke at the AATA conference about our concerns about being both art therapists and exhibiting artists (Fleming, 1993; Lachman-Chapin, 1993). Afterwards, I was propelled to continue to integrate these two identities, finding in the writings of Suzi Gablik and Donald Kuspit and in the artwork and theories of Joseph Beuys one of the great art debates of our time: How do we value the aesthetic in art as opposed to social activism?

After 20 years as an art therapist, I was pretty clear about my identity, goals, and aspirations. As an exhibiting artist, however, I was not so clear, so I asked myself some questions. As an artist what can I accomplish—money, fame, the love of men? These are the motivations Freud listed. Or can the artist accomplish healing or teaching—something closer to what motivated me as an art therapist? Or, can the artist expect to accomplish social change?

Also, what is driving me as an artist—my unresolved psychic conflicts, a narcissistic wish for fame, a wish for money? (Fat chance!) Am I driven by wanting to help individuals or to change society?

And lastly, what does success as an artist mean to me? This is, in fact, the question that Suzi Gablik in her recent book, The Reenchantment of Art (1991), starts with, as she examines the present state of art and makes her own impassioned pitch for change.

Suzi Gablik

As I tackle these questions, my more familiar identity as an art therapist is what I keep referring to. Thus, this was the basis for my initial response to Gablik’s ideas when I heard her speak two years ago and later when I read her book. I wasn’t so much interested in seeing if I could agree with her ideas about the function of art, as I was in justifying the role of art therapy to the art world. This would, in a personal sense, help integrate my two identities. I was also looking for a new way for our field to be viewed.

Following up on her earlier book, Has Modernism Failed? (1988), which criticizes the aesthetics, intentions, and morals of modern art, Gablik tries in this current book to prescribe a treatment. She rails against the material, object-oriented, aggressive, cold, confrontational, expensive, imposing nature of the present art world, looking instead to return art to its rightful place in the realm of magic, enchantment, and social usefulness. To accomplish this she envisions an art world in which compassion, nur-
turiance, dialogue, and giving primacy to relationship and interaction are paramount. She wants artists to create a meaningful connection between art and society and is especially concerned with caring for the environment. What captured my attention was that in talking about art as interaction, healing, dialogue, and helping, Gablik was describing some of the essential and inherent qualities of art therapy.

Gablik goes on to equate these qualities of art with the feminine, describing the present art scene as masculine, with patriarchal, destructive, deconstructive, rational, and inhumane elements. She says the present patriarchal art world is a “dominator system” in which the self is central.

Power is associated with authority, mastery, invulnerability and a strong affirmation of ego-boundaries—which is precisely what the modern artist’s ‘self’ came to convey. Autonomy disregards relationships, however; it connotes a radical independence from others. By contrast, in the partnership model, relationships are central, and nothing stands alone, under its own power, or exists in isolation, independent of the larger framework, or process, in which it exists. Within the dominator system, art has been organized around the primacy of objects rather than relationships, and has been set apart from reciprocal or participative interactions. What I shall argue is that it has become trapped within a rigid model of insular individuality. To reverse this priority, giving primacy to relationships and interaction, is also to reverse the way that artists see their role, and implies a radical deconstruction of the aesthetic mode itself. (1991, p. 62)

While Gablik seems to be describing the kind of art making that we do as art therapists, she goes further in two important ways. It is these ways I question. First, she clearly wants the artist to become involved, not especially with individuals as we do, but with social change. She is saying that through art we should attempt to correct threatening social evils (threats to the environment in particular). Second, she strongly suggests that we can effect such change. This implies giving up the essentially self-centered, aesthetic approach that has been developing throughout much of art history since the Renaissance: that we each make art to express our own vision and that we try to make it as aesthetically “good” as we can.

As examples of what Gablik would have us do instead, she notes various artists and their projects: Dominique Mazeaud, cleaning up the Rio Grande River; Mierle Laderman Ukeles, shaking hands with garbage men in the five boroughs of New York City; and Krzysztof Wodiczko, making mobile homes for the homeless. She also praises Tim Rollins for his work with learning disabled children in New York City, inspiring collaborative projects derived from classic works of literature. She claims that all these art projects involve actions, sometimes ritualized, which give a spiritual dimension to the artists’ works.

Certainly, the art world has witnessed a great burst of social activism in recent years. Caught in the attacks against the art world by the fight against funding for the National Endowment for the Arts, artists have left their isolated studios to join in concerted political action. But aside from these self-defense activities, the rise in earth works, conceptual, performance, and installation art is a clear indication of the trend away from the object-oriented and commercialized art world.

This year’s Whitney Bienniel, which features artists whose works have been shaped by social, cultural, and political concerns, is further evidence that these concerns have emerged. As Szozianski reports in a recent article in the Chicago Tribune, “This year’s edition (of the Whitney Bienniel) can certainly be considered ‘au courant’ for the way it engages socio-political issues that have emerged at the forefront of current art-making... Its premise—that the politics of individual and group identity define the current zeitgeist and thus should be a primary concern of art—might be challenged” (1993, p. 12). These kinds of problems, he goes on to say, “artists are well-equipped by experience and temperament to illuminate. If they don’t, who else will?” (1993, p. 12)

Joseph Beuys

As I began to examine the question of artist as social healer, I came across Donald Kuspit’s article entitled “Joseph Beuys: the Body of the Artist” (1991b). Kuspit is a distinguished art critic, professor of art history and philosophy at the State University of New York at Stony Brook and A. D. White professor at large at Cornell University. He is the author of many articles and books, as well as a regular contributor to Art in America and Artforum. He is extremely knowledgeable about psychoanalysis and self-psychology and, for this reason, his art criticism is often enriched by his psychological insight.

Joseph Beuys, born in 1921, was a member of the Hitler youth and served as a combat flyer during the war. Shot down over Russia, he was rescued by Tartars who brought his nearly frozen body back to
life by wrapping him in fat and felt. Later, these two materials became very prevalent in his sculpture works. "In 1947, he turned to art as part of his healing process, enrolling in the Dusseldorf Academy of Art. He not only became a professor at the Academy but became known as one of the pre-eminent figures in postwar German art" (Killian, 1993, p. 11). In 1979, he was given a show at the Guggenheim Museum in New York City. He died in 1986, after his sculptures, drawings, and especially his performances brought him international fame. Presently, New York's Museum of Modern Art is having a major exhibition of his drawings, to be shown later in Los Angeles, Philadelphia, and Chicago.

In many of his writings and interviews, Beuys spoke of his intent to help cure the sickness of the German people through his art and his theories about creativity. Kuspit observes that Beuys' narcissistic traumas in early childhood resulted in an art that was essentially psychosocial, that is, "it derived as much from his unhappy childhood experience and fantasy" as from the psychological needs of the German people. "His art," Kuspit says, "was a dialectic between childhood dream and adult social healing" (1991b, p. 82). He did this by "using art to undo the life-denying traumas that had been inflicted on him, without denying their reality (it is this kind of activity that constitutes art's so-called 'spiritualization of life,' its fundamentally reparative task") (Ibid, p. 84).

Beuys was a teacher and a healer. He attempted to "teach other sufferers the lesson of his wound and its cure by warmth." . . . "He understood that the personal is, indeed, the political, that is, one's attitude to other people profoundly informs, even creates, sociopolitical reality" (Ibid, 1991b, p. 86). "The idea that individual and social health are inseparable is crucial to this concept. For Beuys, art was a process of simultaneous self- and social healing" (Ibid, 1991b, p. 82). He felt that every man had creative possibilities. He was reaching to connect with every man, to hold out hope for him to express himself through art (as Beuys conceived art to be), and to make social changes through his art. Beuys made exhibition "a sacred social service rather than simply self-serving. . . . Beuys' exhibition of himself and his art—of his body self as art—was a profound act of giving" (Ibid, 1991b, p. 86).

In a recent lecture Kuspit referred to Beuys as being "the last gasp" of the idea of the artist as healer. Kuspit, in his recent book, The Cult of the Avant Garde (1993a), also speaks at length about Beuys as shaman. "Beuys represents the most strenuous avant garde attempt to reconcile the roles of artist and healer, to make art a kind of healing and to make healing artistic" (1993a, p. 97).

I was happy to have found many similarities between art therapy and the goals of Gablik and Beuys. I rejoiced that the art world, like Moliere's character discovering "prose," might be about to rediscover art's healing function—so fundamental to our role as art therapists. But as I read more and thought more carefully about some of the issues raised by both Gablik and Beuys, further questions arose.

**Activist and Aesthetic Modes**

Ortega y Gasset wrote a famous essay back in 1925 called The Dehumanization of Art. He talked about what he saw as the essential difference between the new, modern, "unpopular" art, and the art of the past. The essential difference, as he saw it, was that art of the past dealt with lived, human reality, while modern art was distanced, objective, stylized, aesthetic, and dehumanized. In talking about the new arts of the period he said, "Wherever we look we see the same thing: flight from the human person" (1956, p. 30). The new artist, he says, repudiates reality, places himself above it. "Being an artist means ceasing to take seriously that very serious person we are when we are not an artist" (Ibid, p. 45). He characterizes this modern artist's stance as self-mockery and distancing.

Shusterman (1992) expresses similar statements by redefining aesthetics as basic to the practical concerns of everyday experience as it must reach out to a broad audience. In effect Beuys says the same thing. In a 1980 video interview, in connection with his show at the Guggenheim Museum, Beuys explains that for him art is a social tool. He says, "aesthetics doesn't exist for me. . . . the human being is aesthetics in itself." Beuys goes on to talk about "social sculpture," saying that the essential qualities of this sculpture are thought and feeling embedded in the materiality of the human body. He speaks of language and thinking as more important to sculpture than the end product. Transcendence in the invisible world is what he is after, "not just material beings." He talks about the joy for life, related to everyone's needs in society, as a molding power of the soul which will not necessarily lead to any physical form in art.

These writers ask that art become meaningful and relevant to human concerns. But in Gablik's writings there is an additional moral and ethical imperative. She, like Beuys, is saying, in effect, that
we as artists should devote ourselves to being activists for change. And much as we may agree with her wish to develop an art world that is more compassionate, relational, spiritual, etc., and to prevent through our work the continued destruction of our ecosystem, must we make the choice to give up our aesthetic strivings? Should we commit ourselves to an active moral and aesthetic program following Beuys’ example?

Kusmit (1991a) spells out what he sees as the essential difference between two kinds of art making. The activist artist, he says, is not only careless about producing aesthetically “good” art, but is also morally against art that is not socially oriented. He goes on to make a psychological differentiation between the two: The activist artist is tied to a super-ego moral stance, seeking to confront and overthrow the existing authority, while “the aesthetically oriented artist experiences the world as disappointing but desirable . . . a hopeful if realistically difficult place” (1991a, p. 22). The aesthetically oriented artist, Kusmit says, is motivated by “desire,” a mysterious life force that revitalizes art, history, and the self; the moralizing artist, he says, is motivated by a wish to overthrow the “parental” status quo, deeming the aesthetic promise of pleasure a seductive illusion.

Others speak out for the importance of the aesthetic quest. Weins says, “While art’s social and political functions are gaining the limelight, however, we must also keep in mind such (currently dubious) things as mystery and beauty—the things that make art art . . . A wholesale dismissal of aesthetic, philosophical, and formal issues which have been built over time would be detrimental. It is often through such elusive constructs as beauty and mystery that art attains its impact, its ability to profoundly inform us about who we are and what we feel” (1993, p. 7).

Carol Becker, associate dean of the Art Institute of Chicago, speaks about the despair of post-modernism and the new emphasis on extending art to a larger audience. She calls this “community based” art. She examines Marcuse’s work, expecting to find support for political activism, but finds instead that he wrote that “the political potential of art lies only in its own aesthetic dimensions” (1978, pp. xii–xiii). Becker says, “For Marcuse the need to make formally effective work is more than an abstract idea . . . Within his system, it is the idea essential to the meaning of art itself” (1993, p. 26). It becomes, in Marcuse’s words, “the cosmos of hope” (1978, p. 52). “Art challenges the monopoly of the established reality,” Marcuse writes, by creating fictitious worlds in which one can see mirrored that range of human emotion and experience that does not find an outlet in the present reality” (1978, p. 66).

Johnston, in reviewing Gablik’s latest book, says that she proposes that artists give up “the most important thing they possess—their individuality, their power to define themselves” (1993, p. 41). She goes on to say, “The artist as child, a figure who transcends the childhood abuse endemic to the modern family, has been a hallowed entity in our culture. The artist as dissident remains a valuable model” (1993, p. 41). She urges more autobiographies—in fact shared autobiographies—“uncovering in greater detail, with more piercing scrutiny, the actual sources of dissent in society” (1993, p. 41).

Another question emerges: Can we, as artists, actually effect change to any important degree by being activists in our art? This has not been the case historically. Can’t our searches in the realms of self and style make an important statement about society? I think of the imprint of Cubism, Dada, Impressionism, Abstraction, the array of recent fads such as Pop, Appropriation, Deconstruction, Minimalism. Each helped us look around and see the world differently. Becker says, “Those who actually desire a revolutionary message cannot grasp the degree to which innovations in form can also be radical in terms of how they change the scope of what people are able to see” (1993, p. 26).

There are certain things that motivate people to become artists in the first place. First, there is often some need to express and exhibit the self in an attempt at self-healing. Like Beuys, some area of hurt calls for attention in those of us who choose to devote ourselves to art making. Beuys clearly wanted his exhibitionism to heal himself as well as society.

I do question whether it is possible for artists to forego our expression of “desire” for the sake of promoting changes in society. Kusmit would say that the activist artist does forego this, having given up on the hope of achieving this “desire.” Instead, the activist artist would adopt an optimistic guise of hope for social progress. Kusmit (1993a) is in fact dubious about Beuys’ attempts to be of “reparative service to pathological society” (p. 96), post-war Germany in particular. He says that Beuys’ performances, in fact, lost their meaning as healing events. He was, in Kusmit’s view, solving his own narcissistic problems rather than giving to or healing his audience.

**Personal Conclusions**

For myself, I chose the aesthetic artist alternative, much as I would like to further the kind of
art world environment and goals to which Gablik exhort us. I have a need to teach, to heal; this is clear from my long career as an art therapist. The art I am driven to make, though, must come from my own inner needs, from the impact of the world on my sensibilities, and from my need to dialogue with my audience. I contribute my art to causes I believe in. I am active socially and politically, but not essentially through my art. Like Beuys, but in a very different way, for me the personal is the political. As Goldberg (1986) says in her book on writing, painting is my way of "facing the world. It is a deeply political act, because you are not just staying in the heat of your own emotions. You are offering up some good solid bread for the hungry" (1986, p. 47).

My personal art may not affect many people. If it were “better” (whatever that means), perhaps it would have more soul shaking responses from others; I would wish it so. But unless I exhibit it, this cannot happen at all. So an important element of what motivates me is this vague, but strong, wish to express, but also to share my own traumas with others, affecting them in some way. Kuspit says, "More than is realized, the artist’s attitude toward his audience, emblematic of the kind of reciprocity he wants to establish with it, is the fundament of his art" (1993, p. 83). He goes on to say, "... the art will not be compelling unless the audience believes it is deliberately addressed to it, the audience, rather than made for the artist’s narcissistic edification as a sign and proof of his creativity. In short, the audience must feel the artist’s will to relate to it in order to find elementary value in his art" (1993, p. 84).

Is my work political? That is a question of numbers—how many people I can affect. It is also a question of relevance to current, deeply felt cultural issues. For me these include loneliness and alienation, deconstruction of a feeling of personal wholeness, and fear of destruction, both personal and environmental. Gablik points out that "for the first time in recorded history, the certainty that there will be a future has been lost; this is the pivotal psychological reality of our time" (1991, p. 19). Gablik also observes that a new way of seeing or understanding brings a new way of acting. Forces of idea and spirit do produce action; any study of history demonstrates this. The material world—economics, geography, technology, the chronology of events—is not the only decisive factor in change. So therefore the personal can be political.

We need hope in this threatening and cynical world. Perhaps my art, in a small way, can give hope to others and encourage them to speak from their own creativity. Perhaps my art can speak of the kind of relationships, the magic and enchantment of connection which Gablik refers to. Perhaps I can bring the outer world—other people touched by my art—to my inner world, making me more whole. Gablik says, "Healing is the most powerful aspect of reconstructive modernism" (what she is urging) (1991, p. 25). She contrasts this with current artists who would have us believe that art can only deconstruct. She also refers to Heinz Kohut, the psychoanalyst and originator of self-psychology, who wrote that "those artists who are in touch with the necessary psychological tasks of a culture prepare the way for the culturally supported solution to a conflict to emerge, or for the healing of a psychological defect" (1991, p. 24).

There has been a considerable movement in the art world to counter the object-oriented and commercial system. Most of this work is indeed social activist in intent. However, this will never replace the individual’s yearning for the vague and diffuse desires for the aesthetic which fires the artist. Perhaps this is the “image of humanness... the liberated human psyche” which art can communicate (Becker, 1993, p. 25). Also, social goals can be equally or better served by the artist who digs deeply into the human condition as she or he knows it from his or her own experience. Becker speaks of this need to “reclaim the importance of subjectivity—not as an end in itself, but as a way to understand the particularities of individuals, and therefore of the collective” (1993, p. 27).

Ramifications for the Field of Art Therapy

What are some of the ramifications for our field? First, we have to acknowledge how we are viewed by the art world, and how we see ourselves vis-à-vis them. I work in an art school, the Art Institute of Chicago. My experience has been that we (both faculty and graduate students) as art therapists are seen as lesser—or not quite real—artists. This is evidenced, in one way, by our struggle to have our graduate students’ artwork included in the school’s graduate show at the end of the year. Not being “studio artists,” our students are sometimes deemed not as qualified as graduate level artists. Happily, we usually succeed.

In many other more subtle ways we also get the message that because we use our art for something, because we “interpret” art, we are in a different category. This undercurrent exists, despite the fact that our art therapy graduate students’ portfolios have to
pass muster with the faculty for entrance, and that nine credits of studio courses in classes with art students are required in the Art Institute art therapy program. Perhaps this reflects the art world’s rejecting response to artist-as-healer. Beuys may be the “last gasp”—accepted and revered—but art therapists are no Beuys.

Is it about time that we, as art therapists, reach more directly into the current dialogue in the art world? We need to discuss the issues raised by Gablik and Kuspit, explaining that our art involvement is indeed activist within our own parameters. That is, we are being all the things that Gablik asks of artists. We do it not to change society directly, but to help change the people with whom we work. This is an essential difference. We work, as did Beuys, with the personal, spreading the effect through society as good teachers and shamans do.

As artists, art therapists enter the arena of artists as equals. This means that we compete and are willing, therefore, to be judged in some aesthetic way. I was surprised and chagrined recently to see that in two shows of artwork by art therapists, there was a real resistance to being judged or juried. In both cases the final decision was to accept all submitting artists. In a discussion afterwards at one show, most of the audience of art therapists expressed strong opposition to exhibiting their work in “commercial galleries.” They talked with disdain about the terrible art world and about being judged.

Is there a three-way split between (1) being an art therapist: (2) making art for self-expression just for oneself; and (3) making art as part of the art world, seeking exhibition, dialogue with a broad audience, and recognition? As I have moved more into being an exhibiting artist, while continuing to be an art therapist, I sense an uncomfortable hostility from some of my colleagues. Is it envy? Are art therapists disappointed artists? (Agell, 1986) Is it because there is a vague feeling that by emphasizing exhibiting, we are giving up some of the ideals of the quiet, interpersonal creativity of art therapists? Is there a pejorative, moral stance relating to what is seen as the narcissism of exhibition? I don’t know the answers to these questions, but I think they are worth thinking about by our profession. This analysis has led to what seems to be an opposition between the human, subjective, healing kind of artist—Beuys, Gablik’s artists, we art therapists on the one hand—and the aesthetic, object-oriented, desire-driven ones on the other. As art therapists, we are clearly both. As artists, we must find our own way in an art world earnestly searching for answers.

I think it is time to address the art world with a statement about who we are and where we stand with regard to the dialogue I have been describing. I see us as being both activist and aesthetic artists. We help, therefore we act. But we also deeply value the aesthetic concerns that make us artists, and which we can impart in our activist role to our clients. We can also substantiate and confirm the roots of art activity in the primal psychological and spiritual well-springs of the mind and soul, thereby making clear that one of the functions of art is to heal. Perhaps it can only be to heal oneself, to help others to heal themselves. Perhaps we can, by “reaching out to an audience greater than the art world . . . offer some vision for developing a less alienated future” (Becker, 1990, p. 26).

Finally, we can hope that our clarified identity and our activities both as therapists and exhibiting fine artists—joined with other artists in the art world—will have some power to effect some of the social changes we want. Until now we have related almost exclusively to other mental health fields. That is where our jobs have been. Now we need to build bridges to the art world. That is where we came from.

 Mildred Lachman-Chapin, M.Ed. A.T.R., is an art therapist in private practice, a member of the adjunct faculty at the Art Institute of Chicago, and an exhibiting artist.

The Art Therapist as Social Activist: Reflections and Visions

Abstract

From a systems perspective, the role of the art therapist as social activist at a time of deep and crucial change for our clients, mental health systems, our country, and the world is discussed. Despite the fact that art therapists, through our artists' identities, are natural agents of change, our education and strivings for professional acceptance mediate against our natural proclivities in this direction. Case examples of their experiences as change agents are presented by three art therapists: two write in dialogue about their participatory research project with Central American refugees, and another writes about her work as a trade union activist.

Maxine Junge: Art Therapists and the Paradoxical Gift of Sight

Art therapists are particularly talented at seeing; it is our stock in trade. As the dictionary states, seeing is "perceiving, coming to know, forming a mental picture of, and understanding the meaning of something."* Seeing, we come to profoundly understand our clients. Visible in their art expression are the depths of their terrors, the joys of their inner worlds, and their efforts to change these worlds. The art therapist's and the client's engagement with the process of creativity as a method of inquiry and a way of knowing, pictorially reveals and externalizes reservoirs of memory and deeply felt implicit and tacit awarenesses hidden from consciousness.

Art expression takes us to unknown places beneath the silences of words and brings the terrors of the dark into the light where they may be tamed. All human beings are paradoxically both cursed and blessed by the darkness of not seeing. What do we look at when we see? We cannot bear to look upon mountains of corpses, faces from the Holocaust, or images of the evil of African-American slavery and oppression. Such imagery assaults our eyes and threatens to burn them out. By seeing too much we go blind; we close our eyes to defend against our own powerlessness in the face of horror. But by closing our eyes to shut off what is too terrible to know, we may go blind to what is before us.

What do we see when we look? Thirty-five thousand people die of starvation each day; the majority are children. The images of Somalia haunt us and, finally, led to United Nations' and American intervention, but many died and will still die before help arrives. The great plague of AIDS confronts us daily; there are two or three listings each day in the Los Angeles obituaries. Already lost are many of our best and our brightest. The violence of the cities explodes daily, in particular against and within minority groups. Recently, we rejected as President a man who advocated a "kinder, gentler world" and in a condition of astounding denial refused until the end to see beyond his office walls to the desperate realities in which many people live.

What do we see when we look? A decade of denial when we allowed ourselves to be lulled to sleep by a handsome, forgetful Hollywood actor and his

successor. We see a country where in most places the sale of fireworks is illegal, but the sale of machine guns is not. In the Los Angeles rebellion or “riot” (as you may choose to call it), we saw the faces of despair and desperate, encroaching poverty and racism. We saw the logic of pain unraveling identity. In the year since that cataclysmic event which altered the consciousness of our nation, not much of a concrete nature has happened to “rebuild L.A.” How can we come to know the truth in Krishnamurti’s words: “You are the world and the world is on fire”? This image that lies before us is what we must see.

Artists as Those Who Help People See

We who come to the profession of art therapy embrace the tradition of artists as those who help people see. We resonate with the idea of the artist as outsider, observer, social critic. Imagine the images of Bosch, Goya, Daumier, Ben Shahn, Picasso’s “Guernica,” Maya Lin’s Vietnam memorial in Washington, her civil rights memorial in Montgomery, Alabama with Martin Luther King’s words on it, “Until justice rolls down like water and righteousness like a mighty stream,” and the AIDS quilt. Let these images glide through your mind and speak their truths to your heart.

As these images move through your mind, you cannot avoid feeling the sweeping power of the arts for change . . . you feel. And it is that word—“feeling”—that is the problem. Feeling requires that we open our eyes to break through our denial. It leads to deep questioning about ourselves and our world, intense discomfort, possibly despair and possibly joy. Feeling lets us know what we try hard not to see: that we do not have control over much. Feeling leads to opening the windows so that the unknown comes in and the winds of change blow through, so that we can see.

The Role of Imagination

The great painter Goya told us that “the sleep of reason produces monsters.” The key to sight and, beyond it, to change is the power of the imagination. To paraphrase Goya: The sleep of the imagination produces, even in life, death. Imagination is the essence of hope—and of the potentialities of the creative process. However, the word “imagination” does not appear in the indices of many of the books about creativity written in the last 20 years. Additionally, dictionary definitions hold within them the intriguing duality of imagination as creativity and change on the one hand, and, on the other, as something not real, devoid of truth, as in “imaginary.” But it is the act of imagination that offers a vision of something different, better, and the resulting hope that can impel us to action. The power of the imagination gave rise to the dream of democracy, in China for example, and the tumbling of the Berlin wall and the national boundaries which have tossed Eastern Europe into so much chaos. These examples prove that change seldom comes when or as we expect it to, nor in a necessarily orderly or predictable fashion. The concept of planned change is, indeed, an oxymoron.

Psychotherapists, Art Therapists, and Social Change

Psychotherapists, unlike artists, have not tended to be activists, but rather agents of social control. As the mental health system has crumbled around us and our clients in the last 10 years, we must wonder if our twin identities of artist/therapist—the artist awake to change and the therapist holding on to containment—force us into some impossible double bind.

At first therapists saw the individual and his or her intrapsychic problems, but not beyond the boundaries of the person’s psychic skin. Most therapists sat in the protected havens of their offices and waited for clients. A powerful conceptual leap occurred when we widened our view of the individual’s struggles to also include the family system. However, most therapists have not yet taken to the streets or viewed our territory to include the community, society, and the larger world environment. All too often therapists heal what is already wounded and do not attend to the milieu which wounds and re-wounds again and more deeply.

Suggested by Jung, Bank, and others, people project outwardly the dark sides that cannot be tolerated within. For example, in the 12th and 13th centuries, at a time of denial of the body, leprosariums isolated lepers so that they would not have to be seen, to infect others with the awareness of bodily reality and mortality. At the beginning of the Renaissance, a time of renewed worldly sensuality and the birth of rationality, leprosy died out and the leprosarium buildings became insane asylums. Insanity, thus, became the disavowed projection of the age of science and rationality—insanity which must be locked away from view.

In more recent times psychotherapists have embraced the notion of themselves as scientists, objec-
tivists, rationalists of the psyche. They focused on examination of the individual mind, with social adaption as a goal—let us not forget the era of lobotomies. The value of conformity to the culture was, and to a large extent still is, the norm within the white male medical hierarchy; the labeling of deviance as psychopathology had as its intention the reification of control. If deviance and irrationality are incarcerated, they become invisible, and safety of the status quo can be maintained.

That our ideas are culturally and socially constructed is not news. Even in the short 20 years I have been in the mental health field I can remember when mothers were blamed for all problems in their children, particularly boys. (This mother-blaming era, of course, is not over yet!) Schizophrenia was thought to be caused by families, particularly schizophrenic parents. Autistic children were a result of "ice box" or very distant parents. Father/daughter incest was not all that bad and could even be helpful for a girl. The dominance of women in single-parent black families was destroying black men and children, and a patient who was unable to get to the clinic with her six children because she could not afford the bus fare was considered resistant to change. Although paradigms and pendulums shift, we retain within the new, habits of the old. Thus, many of these ideas remain today in barely disguised forms.

O'Connor, in his article "Therapy for a Dying Planet" (1989), writes of an incident which occurred in Frieda Fromm-Reichmann's practice before she left Germany to come to the United States:

A young woman with numerous irrational fears came to her for help. During the course of psychoanalysis, the patient gradually overcame her fears, and after three years, the therapy was successfully ended. A few weeks later the young woman, who was Jewish, was picked up by the Gestapo and sent to a concentration camp. (p. 70)

The message is obvious: In the words of a social psychologist friend, "Are we missing the forest for the clouds?" As art therapists are we too often helping people adjust to a destructive society? Are we ourselves co-opted by the status quo and, understandably, yearning to be inside, adapt, make do, and continue to cope with a fatally injured mental health system?

Art Therapy Education and Activism

What about the art therapist's education as education for activism? Does our education help us see? A part of our history as art therapists that may impede us is that we have been trained as "appreciators" of art, as reflectors, supporters, explorers of the intrapsychic landscape rather than pro-activists, co-creators engaged together with our clients in their struggle, which is ultimately also our own. Typically, we are not trained as advocates or revolutionaries, not as social and cultural analysts or critics, but as those who through the art therapy process help people cope and adapt.

As the director of a masters program, I confess to you my belief that all too often education is not authentically based. The process of professionalization itself initiates the student into the community through a series of formalistic rituals which deaden the senses and overinflate the thinking processes to the exclusion of feeling and imagination. As art therapists, we learn many unforgettable lessons about change. Unfortunately, when student therapists graduate into the professional world and seek to enter the ranks of employed and respected practitioners, in the words of Pogo, "They see the enemy and the enemy they are us." Quite naturally, with student loans on our backs, we embrace the status quo, strive to climb the hierarchical ladder, and forget everything we ever knew about the artist's mission to make waves.

As example, a few years ago our masters program engaged in deep changes in the system which included not only the department, but also the university, the mental health community, and the state. On the face of it, a simple issue of licensing was at the core. We all are aware that there are political and economic tides that arise out of complex struggles and exert enormous pressures on our lives. In addition, themes of the artist, the arts, and therapy as outsiders in the academy and in the mental health professions were apparent along with art therapy emerging as the projected dark side of rational, scientific, behavioral psychology.

In this circumstance, people, particularly students, refused to accept the status quo. They found that the answers were in themselves and empowered them to action. Touching the strength in themselves was education at its best, and in an extraordinary way helped them understand the meaning of empowering their clients as human beings. In our profession we need this kind of systems observation, reflection, and social change, and must undertake this willingly, with our eyes wide open.

I propose that it is time for art therapists to take another conceptual leap—an activist leap. To begin, we must recognize ourselves and those with whom we do therapy as deeply interrelated. Next, we must
acknowledge that we and our clients are part of larger systems in which life and work can go on or may end in despair. And we must see that struggle clearly and engage in it strategically and effectively beyond the boundaries of office walls and the psychic limitations of our own consciousness and denial.

Art Therapists as Activists: Three Stories

Following are the experiences of three art therapist/activists. Christine Volker and Anne Kellogg speak in a dialogue about their participatory research project with Central American refugees. Janise Finn Alvarez was also part of the work. She writes about her participation and work as a trade union activist.

Christine Volker and Anne Kellogg: A Dialogue

Christine Volker:

I come from the tradition of the artist/activist. In art school I found myself drawn to the work of Kathe Kollwitz, the German Expressionist artist. Although Kollwitz’s work was inspired by a great spirit of social activism, I could never make that leap in my own artwork. An axiom of the formalist school of painting prevalent in my art education strictly stated that one did not mix politics with art. As a result, I kept my political activism and my art separate throughout the 1980s.

New political activism eventually led me to Nicaragua in 1986. I celebrated New Year’s Eve with the campesinos of the state-run coffee farm cooperative where we had been picking coffee beans high up in the mountains. Later, I drank a toast with Luis, a Commandante of Sandanista troops stationed there to guard us from Contra attack. Our four-mile radius was protected, but nightly I heard the shooting and saw the helicopters flying the wounded to the hospital in nearby Matagalpa. As a result, I returned to the United States a changed person.

In 1987, I enrolled in the art therapy program at Loyola, where I was astonished to meet another social activist, Maxine Junge, who also happened to be the director of the program. In my first semester when I talked about my trip to Nicaragua, a fellow student, Anne Kellogg, stated, “I feel very connected to you.” From this connection began our joint clinical research project.

Anne Kellogg:

When Chris and I discovered each other, we realized we had both been previously active in social justice work with the Central American community.

We decided to integrate our past and our present, developing a project we called “Going Through the Journey with Central American Refugees” which explored the conditions of uprooting, migration, and relocation through family art therapy.

Our project examined the family drawings and dynamics of Salvadoran and Guatemalan refugees who migrated to the Los Angeles area. Particular attention was paid to the psychological effects of pre-migration conditions, the migration process, and post-migration relocation in the United States.

CV: This work with refugees from El Salvador and Guatemala provided us an integration of activism, art, and psychology. Our multiple personas have finally become one. This is partly what we hoped to accomplish with our interventions with the refugees: An integration of their past identity in their country of origin with their present reality as they adjusted to a new culture and country—an integration which involved an acceptance of self. For only in realizing our pain, can we heal.

AK: In the early ’80s I became involved in housing Central American refugees as part of what was called “The Underground Railway.” This movement helped to shelter, feed, and find work for Central Americans. As part of a church peace group, I became active in educating my parish about U.S. involvement in Central America and the conditions refugees experience after their arrival in the United States. My parish supports a sanctuary house in Los Angeles called Casa Grande which gives short-term shelter to arriving Central Americans. One million Central American refugees have arrived in the United States in the last 10 years, largely due to increasing violence and oppression in their countries. While many of these people now receive amnesty under the 1986 Immigration Control and Reform Act, hundreds of thousands have illegal status and, if returned to their country of origin, could be subject to political reprisal, torture, or death.

CV: Our art therapy project was accepted by the committee at Casa Grande. The house is a temporary shelter which provides a safe haven and community for Central American refugees who have arrived in this country in the last one to five months. While staying in the house, refugees may apply for political asylum and search for work and more permanent living conditions.

AK: We hoped artwork would provide a safe place for containment of the multiple traumas experienced by these people during their uprooting, migration, and relocation. It was thought that the art process could facilitate grief and mourning, capitalize
on family strengths, and begin to integrate past experiences with present reality. Perhaps most importantly the art product could create an historical document to be used as a touchstone marker in the defense of these peoples’ human rights.

CV: We held two preession meetings with the families in the house before obtaining permission to do the therapy. We found our values as “gringo” psychotherapists challenged. We were questioned and rightly so. “How could drawing pictures possibly help?” they asked. “Didn’t we realize that these were painful issues better left alone?”

AK: As we attempted to address these questions, we felt an overwhelming respect for these people who had gone through so many traumatic experiences to reach our country. We also knew that our own country was responsible for fueling much of the violence with our military aid to El Salvador. We realized that this project was as much for our own healing as theirs. While it was difficult to establish trust and respect under these circumstances, we received approval to proceed with the group.

CV: The multifamily group consisted of 12 people, including two intact families. The others were single members of families who had come to the United States hoping to bring other members of their families later. Since families usually arrived in stages, many felt fragmented and experienced grief for absent members. Following are case examples of representative themes or issues which came up during group therapy.

The Chibarras were a reconstituted family consisting of Father, Esteban, Mother, Ana, two sons, Gustavo, 9 and René, 7, and one daughter, Estralita, 3.

Esteban fled to a refugee camp in Honduras when his village in El Salvador was ambushed by government soldiers. The soldiers would often come to the village looking for evidence of guerilla activity. When the soldiers came, the villagers would flee, taking specially prepared boxes of provisions which would sustain them in their hiding places until a scout informed them that the soldiers were gone. On one such occasion the returning villagers were met by a surprise ambush attack. A massacre ensued. Esteban was one of the returning villagers. He escaped the soldiers by diving into a lake and emerging behind a bush with just his nose and eyes above water. He watched while his village was burned and his neighbors slaughtered. He watched while his four children were butchered. He watched while his wife was raped and then shot to death.

After the soldiers left, Esteban ran to the nearest refugee camp. There he met Ana who had lost her husband in similar circumstances. Together they re-

constituted a family, migrated to the United States, and found sanctuary at Casa Grande.

The artwork of this family depicted various intrusive themes—the bombs, soldiers with guns, helicopters flying overhead machine-gunning the people below. One drawing showed four children and a wife sitting at a table eating. The father, Esteban, is standing in the corner of the page. Esteban explained that he had returned to the village from the refugee camp in Honduras to get a table which had been left behind when he fled. Esteban had built this table for his family and retrieving it was important to him; it served as his transitional object. A border was drawn encircling the family, symbolically containing the anxiety stirred by this memory. Esteban said that the border represented a map of Honduras, yet he placed himself outside the family. Esteban’s present family with his new wife Ana had only three children, yet here were drawn four children. Could Esteban have unconsciously drawn the family he had lost in the massacre?

In his drawing, René, age 7, showed two helicopters. One was black signifying the death helicopter shooting people on the ground below. A person was shown lying on the ground dead. Two donkeys looked on, one with a black death head. Three trees were drawn, all uprooted from the ground. One of the trees, like the person, is lying on its side, perhaps also dead, signifying that the life force itself was also dying. The house was depicted with people standing in the doorway, seen through the walls. The rendered Coca-Cola machine was a visible reminder of American involvement in El Salvador. René spoke about his drawing: “Here’s the helicopter, here’s the dead person, here’s a fallen tree.”

René was asked to draw something about the United States. He drew a helicopter shooting a figure holding a machine gun pointed upward outside Casa Grande in Los Angeles. People were inside the house, sitting at the table and two figures stood at the entrance. The recurring theme of the shooting helicopter was seen in many of the children’s drawings and seemed to symbolize the common trauma of war they experienced. The children were also aware of helicopters in the skies over Los Angeles since on many evenings a helicopter could be heard flying over Casa Grande. For René the black image of the shooting helicopter represented a threat not only from the past but also in the present. This is an example of the intrusion of thoughts and feelings associated with past traumas which are symptoms of post-traumatic stress disorder.

Esteban’s and Ana’s 3-year-old daughter Estralita used glue, pen, masking tape, and collage as she created what she called “La Bonita.” She and the two other young boys in the group were the only ones who mentioned bombs. The adults did not respond to this or talk about it. The children seemed to have more direct access to their memories of the traumas of
war. The adults seldom referred directly to the conditions of the war relevant to their uprooting.

A collage by Esteban illustrated the conditions in El Salvador. There were four images: two men riding horses signifying life in the country; a scene of the desert representing the crisis in El Salvador; an old woman and her granddaughter, symbolizing love and respect for the elderly; and a perspiring boy with a thermometer in his mouth, representing the sick ones and the sickness of the country.

Predominant in the children's drawings were destructive weapons of warfare. The helicopters firing down, the man with the machine gun, and the bomb. These represented intrusion into their present reality of the past traumas of war. The floating houses, which we found in many of the drawings, symbolized the loss of home and country and current rootlessness. Casa Grande is only a temporary shelter. Floating houses without any baseline represented the insecure existence of these refugees in a foreign country.

The floating house, the uprooted tree, and the running man occurred repeatedly in the artwork and seemed to symbolize the trauma of the uprooting, the migration, and the relocation. The multi-family art therapy was brief crisis intervention work and did not allow for addressing the many losses in depth. But the project was a gesture of healing in the context of incomprehensible wounds.

AK: During our work at Casa Grande, we came to admire and respect the strength and courage of the men, women, and children we met. Through the art process and product we tried to validate this strength and normalize the natural responses that come from going through such out-of-the-ordinary experiences, to contain the pain in the context of the art.

CV: From individual statements presented by the refugees at the final evaluation meeting, the art therapy process helped more than any other kind of therapy that had been done at Casa Grande. Visual imagery allowed for the confrontation of painful past events. The refugees told us that this was not easy for them, but they said it was necessary.

AK: The creation of symbols to explore the uprooting, the migration, and the relocation offered the people the opportunity to address their traumas and to integrate them. But monumental wounds continue. People arrive with images of murder, rape, torture, and the loss of loved ones. When they first arrive, they are preoccupied with survival, but as time goes on the images return as nightmares. How can we provide healing in this overwhelming context? We believe the art helps; the people we have worked with say that it does.

Janise Finn Alvarez:

I was fortunate to have the opportunity to be the translator and the art therapist for the project described by Christine Volker and Anne Kellogg. The experience of working with the refugees was as empowering in its own way and as moving as anything that I have done. These people have courage and have been through things that even speaking of cannot give them their full weight.

I am Central American in heritage—Central American and Irish. My mother comes from Nicaragua, and my father comes from Ireland. There aren't too many Central American art therapists around. And I am bi-lingual—I was born in Los Angeles, but Spanish was my first language. I learned English in school.

Also I feel a kinship to many of the Salvadorans since one of the groups most persecuted there are trade unionists. It's up there with being a Jesuit priest in terms of the mortality rate. As disheartened as I often am by the attitude in the United States toward labor unions, I think most people have been successfully brainwashed by the forces of major business which Ronald Reagan personified and to which George Bush was handmaiden. It is powerful and deeply moving when I think of my trade unionist counterparts in El Salvador who are killed.

When I graduated from a masters program in art therapy, I was thrilled and grateful to have a job, especially the job I wanted working with families in the Hispanic community in East Los Angeles. But I started to get a little uncomfortable about the fact that art therapists and dance therapists were paid less than other M.A.-level therapists. Being an activist is first having pride. When you're a trade unionist, you have pride in your work. You feel you must be taken seriously and be listened to. I had a good sense of what I was and felt my training was good. I also believed that my specialty as an art therapist was very important and that I should actually be paid more than other therapists. But at first I didn't even try to get that across to others.

I mentioned my sense of injustice about the situation to people, and someone suggested that I run for the union negotiating team because we had a contract coming up in the agency. So I did. It was an empowering experience to achieve what I wanted, which was parity. The sense of sitting down across the table from your employer as an equal was also empowering.

Suddenly, I had changed the job. I didn't beg for it; I didn't plead for it. We just sat down and got
what we asked for. I thought this was really wonderful: People's lives change this way. I helped myself, but I was also helping others. My dance therapist sisters on the staff were crying they were so excited with our success. They had been beaten down with the idea that we're just lucky to have a job. "Creative arts therapy—what is that? You're so lucky to get what you can get—whatever little crumb...five dollars an hour...ten dollars an hour...hey, you're doing well!"

That experience changed me. I went on and ran for president of the union chapter, and I continued to inform myself about labor history. It certainly dispelled a lot of the myths that I had heard over the years. I became the treasurer of the Local, which is a state-wide Local, representing social service workers throughout the state of California.

I also had a wonderful experience when I attended a women's conference. For one week I was surrounded by other union women from all over the western United States—rural women, urban women, professional, highly degreed women, and also sheet metal workers—all different colors, all different shapes. I'd never seen a less racist situation in my life. And we were all representing workers.

The strike that occurred at my agency was remarkable for me. After we resolved the strike, I went back to work at the clinic, and it was tough. I had to go back and deal with harrassment and the things that make people afraid of being in a union. One of the most effective methods that employers have when they wage a campaign against a union organizing drive is to say that it's going to be different—it's going to be nonadversarial. It is adversarial. It's not a question of morality. It's a question of each person looking out for his or her own interests, and if you're not looking out for yours and you're thinking that your boss is doing it for you, you're really in a dangerous, victimized situation. If you're leading your clients to believe that the world is basically okay and it will always take care of you, because you believe that, you're leading them into some dangerous situations.

A strike is, of course, the most adversarial of situations. We went out on strike and stayed out for 12 weeks. Even though the economic issues were settled in a week, management wanted to keep every scab they'd hired. If we had accepted that contract and gone back to work at that time, that would have been selling out so we stayed out for 12 weeks in solidarity. We were able to triumph. I'm very proud of that. It's a special moment in my life, though it was painful being without a paycheck for 12 weeks.

I am an artist and a labor activist, and I think there's a connection. An important social realist art tradition most of us are familiar with is the WPA work that came out in the '30s and how strong that was. It was the artists' responsibility then and now to speak out. As an art therapist/activist, I believe I have a responsibility to take what my clients are telling me and discern what is theirs and what is the chaos and injustice of the world they live in. If I say the responsibility is mainly the client's, then I am doing something that is not unlike what a bad boss does to her or his employee. I am causing the client to be weakened. A therapist may even wrongly think she or he is empowering the client by giving him or her a sense of an unrealistic idea of what the world is—the sense that it's all their doing. It is not. Children in Central America saw bombs dropping. They didn't imagine that. The devastation that occurred in their lives wasn't their choice. It was die or leave—it was that simple. And so they did leave. Now they are in pain, and there's a realistic reason for that. They should be in pain and they should be angry as hell. And we should be angry as hell, too.

I see my roles as an art therapist and activist intertwined. I can't just think of that person in front of me as my client for one hour. I must consider what that person goes home to, what that person's life is about. If I am not doing something to rectify the injustice that's creating the problem in that person, then I'm just hand-holding and frankly I don't want to be a part of it. If you do not act, you become accepting of all that happens to you.

The Challenge: Toward Community

The art therapist has had a proud tradition as a pioneering individualist. But we believe the time is now to move away from individualism toward community, to break through and look at the world we and our clients live in, and to work to change it. A colleague, a Korean who grew up in this country, went back to Korea recently. The Koreans he met said to him, "Do not come to help us. Come in solidarity. We do not need your help. We need community with you." We must look to each other, to other creative arts therapists, to other people to form a community—a global community in which human growth is prized. Together we must find the courage to take the actions to ensure this vision.

Joanna Rogers Macy, a peace activist, has written:

When we face the darkness of our time openly and together, we tap deep reserves of strength within us.
Many of us fear that confrontation with despair will bring loneliness and isolation. But—on the contrary—in the letting go of old defenses and our denial, truer community is found. In the synergy of sharing comes power. (1983, p. 76)

With our eyes wide open, as art therapists/activists in the human community we must cherish the transcendent dream of a just and creative society and using our imaginative hopes, nurture it into being by our actions. As art therapists we have unique talents to offer in this regard.

In Maya Angelou’s words from her inaugural poem (1993) for President Bill Clinton:

History, despite its wrenching pain,
Cannot be unlived, and if faced
With courage, need not be lived again . . .
The horizon leans forward
Offering you space to place new steps of change.
Here, on the pulse of this fine day
You may have the courage
To look up and out . . .

Finally the challenge:
Lift up your eyes upon
This day breaking for you.
Give birth again
To the dream . . .
Lift up your hearts
Each new hour holds new chances . . .

Dwight Mackintosh: The Boy Who Time Forgot

by John MacGregor, Ph.D.

About the book
Dwight Mackintosh: The Boy Who Time Forgot is the result of a unique collaboration between author/scholar John MacGregor, Ph.D.; Creative Growth Art Center, a studio and gallery for mentally and physically disabled adults; and Coleman Souter, a San Francisco design firm.

The book follows a 15-year obsession with image making by elder Dwight Mackintosh, working a remarkable artistic environment in downtown Oakland, California. The inner world of an Outsider artist is revealed in Mackintosh’s exquisite drawings, and made accessible to the reader by the poetic prose of author John MacGregor.
Brief Reports

Art Therapy Faculty Survey

Vija B. Lusebrink, PhD, A.T.R., Louisville, KY

Abstract

A survey of 29 graduate and undergraduate faculty in art therapy showed that both graduate and undergraduate programs rely heavily on part-time faculty. The part-time faculty do only teaching and do not receive any benefits, except for a couple of instances. The full-time faculty’s duties, in addition to teaching, include research and service requirements which range from 0–25%. They all receive medical insurance, but only two-thirds of the programs offer retirement benefits for their full-time faculty.

As Chair of the 1992 Research Committee, I conducted a survey of art therapy faculty in different institutions of higher learning. The survey focused on the following areas: number of full- or part-time faculty, salary range, teaching load and other job-related assignments, benefits, and whether a doctoral degree was necessary for the position. In addition, information was collected in regard to the necessity for doctoral degrees and programs in art therapy in the future.

A total of 73 survey forms were mailed to different graduate-level and undergraduate programs, including those offering only some courses in art therapy. This information was based on the AATA 1990 brochure on programs in art therapy. Of the 29 replies received, 10 were from accredited graduate programs, two from graduate institutes, and two from clinical training programs. Other replies received were from the following: a program offering an area of concentration in art therapy for doctoral studies; two programs in graduate studies with 21 credit-hours in art therapy; one program offering both an undergraduate and graduate program; an Extension program offering both a post-master's certificate and an External Degree program option in art therapy; one graduate program offering a survey course in art therapy.

Of the eight replies received from undergraduate programs, three stated that their respective programs were either terminated or not in existence.

Faculty Status

One of the outstanding features of both graduate and undergraduate programs is the reliance on part-time faculty.

Of 10 approved graduate programs:

• 1 program has four full-time faculty;
• 3 programs have three full-time faculty;
• 2 programs have two full-time faculty;
• 4 programs have one full-time faculty.

The number of part-time faculty in the graduate programs ranged from 2 to 16 with a mean of 7.4 part-time faculty. For the undergraduate programs only one program had three full-time faculty; two programs had full-time directors; the number of part-time faculty in the undergraduate programs ranged from none to four.

Salary

The salary ranges of graduate university-based programs are represented in Table 1.
Institute faculty were paid by the number of students enrolled in classes. Clinical internship program directors' salaries ranged from $30,000–$40,000, with the mean of $37,000. The salary ranges for part-time faculty in graduate programs are represented in Table 2.

In all the undergraduate programs, the directors' salary range was $30,000–$40,000, with a mean of $32,500. As already indicated, only one undergraduate program had two full-time faculty members, in addition to the director, at the assistant professor level; their salary was $25,000.

The pay for undergraduate instructors for a three credit-hour course ranged from $1,160–$1,200.

### Duties

The survey questionnaire specified the following categories for faculty duties: teaching, administration, research, and service. The duties of the full-time faculty of approved programs are represented in Table 3.

The part-time faculty did only teaching, except in a couple of instances where they had some administrative, service, or research duties. The number of courses taught by part-time faculty ranged from one to three.

The duties of the directors of institutes and clinical internship programs are represented in Table 4 and undergraduate programs in Table 5.

Benefits  
In all university-based programs, full-time faculty received medical insurance, as did those in one institute program and in one clinical internship program.

Other benefits received by full-time faculty were:

- Retirement (10 out of 16 reported data);
- Free tuition for course(s) (7 out of 16 reported data);
- Life insurance (6) and disability insurance (6).

One of the institute programs offered its faculty medical insurance, and the other tuition remission. Of the clinical internship programs, both offered retirement, and one also offered medical insurance and tuition remission.

The biggest difference between full-time faculty and part-time faculty was the fact that part-time faculty did not receive any benefits, except for one program which offered medical insurance and tuition remission, and another program which offered tuition remission.

Faculty with Doctoral Degrees  
All or part of the faculty (12 out of 19) in university-based programs or departments offering art therapy courses have doctoral degrees. Seven of the universities which either have graduate programs or offer courses in art therapy already require their faculty to have doctoral degrees, and five will require a doctoral degree in the future.

Presently, only one university offers a doctoral program, which is in art education with the option of an area of concentration in art therapy. Five programs are planning to start doctoral programs within 5 to 10 years.

Of the 19 university-based responders, 12 indicated the need for doctoral-level programs in art therapy especially to prepare individuals for teaching positions and to obtain a base of knowledge in art therapy. One respondent pointed out that "art therapy disparately needs systematic research, and doctoral research is a way or means to extend the knowledge base of art therapy." Five other respondents were undecided about this need. One respondent did not see a need for doctoral degrees for researchers/pr. ctioners and clinicians.

Conclusion  
The present sample of the surveyed programs in art therapy reiterates the fact that most of the graduate and undergraduate programs depend to a large extent on part-time faculty. This necessity provides some benefits to students, such as offering a wide range of approaches to art therapy, especially in the clinical area. The benefits to institutions of higher learning are obvious since part-time faculty are less expensive, they draw lower salaries, and do not receive benefits. Unfortunately, relying on part-time faculty can be detrimental to the field of art therapy in the long-range view, since part-time faculty are not involved in research.

The difference in salary of the various levels of graduate faculty range from $10,000–$18,000. The present survey did not ask for the length of employment, which would account for some of the differences. The salary for the undergraduate faculty is low, especially at the assistant professor level. Hopefully, the present survey will provide some supportive data for the AATA in this area.

In regard to research, the percentage of time devoted to research by the faculty is low. Development of doctoral programs would not only prepare art therapists for teaching, but also offer them the opportunity to engage in systematic research. As pointed out by several respondents, the field of art therapy needs to increase its base of knowledge.
Age and Gender Differences Expressed Through Drawings: A Study of Attitudes Toward Self and Others

Rawley Silver, EdD, A.T.R., HLM, Sarasota, FL

Abstract

This study investigated gender and age differences in attitudes expressed in response to a drawing task. Subjects included 531 respondents in five age groups: children ages 7–10, younger adolescents ages 13–16, older adolescents ages 17–19, younger adults ages 20–50, older adults ages 65 and older.

Although proportionally more females than males drew pictures about relationships, and more males than females drew pictures about solitary subjects, these differences did not reach statistical significance. However, when the attitudes expressed toward self and others were taken into account, significant differences were found.

1. Respondents tended to choose and draw subjects the same gender as themselves to a highly significant degree.
2. Males expressed positive attitudes toward solitary subjects, negative attitudes toward relationships to a highly significant degree.
3. Females expressed positive attitudes toward solitary subjects, both positive and negative attitudes toward relationships to a highly significant degree.
4. Males showed significantly higher frequency than females in drawing about assaultive relationships. However, age and gender differences interacted resulting in a significant age variability in assaultiveness for females but not for males. The proportion of older women who drew pictures about assaultive fantasies exceeded the proportion of older men who did so, as well as the proportion of all other female age groups.
5. A converse age and gender interaction was found for caring relationships. Males showed significant age variability whereas females had significant frequency of caring relationships across all age groups. The proportion of younger men who drew pictures about caring relationships exceeded the proportion of younger women who did so, as well as the proportion of all other male age groups.

Introduction

This study asked whether responses to a drawing task can express attitudes toward self and others, whether males and females have characteristically different attitudes, and if so, whether attitudes change from youth to maturity to old age.

Although these questions are not usually asked by art therapists, answers may provide useful norms for evaluating emotional needs as well as more accurate expectations. For example, several studies have found that males focus on independence and competition, that females focus on connectedness and caring for others, and that our school systems favor the male point of view (Gilligan, Ward, & Taylor, 1988; Tannen, 1991; The American Association of University Women Report, 1992). These studies based their findings on academic achievement and verbal communication.

Editor's note: This research study received the 1992 Research Award of the American Art Therapy Association. It is included in this special issue of Art Therapy to highlight Dr. Silver's professionalism and commitment to art therapy research.
This paper presents an expansion of a study of gender differences in drawings by children (Silver, 1992). It considers the same questions but expands the inquiry and includes adolescents and adults. The underlying theory—that drawings can yield information about differences between genders and age groups—received some support in another previous study (Silver, 1987). Differences between genders were found in the emotional content of drawings across four age groups: third graders, high school seniors, younger adults, and older adults. The male groups consistently portrayed more negative environments inhabited by positively seen subjects; female groups seemed to relate subjects to environments, portraying fortunate subjects in pleasant worlds and unfortunate subjects in unpleasant worlds. These differences were significant across the four age groups. To the extent that the principal subject of a drawing reflects the self-image of the person who draws it, and the environment reflects the way that person perceives the world, the findings suggested that boys and men tend to see themselves as fighting in a dangerous world, while women and girls tend to see themselves as part of the world rather than opposing it.

The case for unconscious representation of the self in human figure drawings has not been firmly established, according to Harris (1963). He suggests that the concept defies objective validation and questions the theories of Machover (1949) and Buck (1948). Harris also cites studies of gender differences by Jolles (1952) who found that 80% of children ages five to eight drew their own sex first, and by Schubert and Wagner (1954) who found that a smaller proportion of women drew the female figure first than the proportion of men who drew the male figure first.

The present study is an attempt to clarify previous findings by asking three questions:

1. Do respondents to a specific drawing task choose same-gender subjects to a significant degree, supporting the view that the subjects of drawings reflect self-images?
2. Do women and girls respond to a specific drawing task with drawings about interpersonal relationships, while men and boys respond with drawings about solitary subjects?
3. Can responses to a drawing task provide information about age and/or gender differences in expressing attitudes toward solitary subjects and relationships, and if so, can this information clarify expectations and identify emotional strengths and weaknesses?

Methodology

In response to the first question, the genders of respondents were compared with the genders of principal subjects in their drawings. For answers to the second question, genders were compared after dividing responses into two groups: those portraying solitary subjects and those portraying relationships. For answers to the third question, responses were assessed on a five-point rating scale (see Figure 1).

**Attitudes Toward Solitary Subjects**

1 point: Strongly negative: for example, solitary subjects who are sad, helpless, or dead; the future seems hopeless.
2 points: Moderately negative: for example, solitary subjects who are angry, frightened, dissatisfied, or unfortunate.
3 points: Intermediate level: neither negative nor positive (unemotional) or both negative and positive (ambivalent or ambiguous).
4 points: Moderately positive: solitary subjects associated with passive enjoyment, for example, watching TV or being rescued.
5 points: Strongly positive: solitary subjects associated with active enjoyment, accomplishment, for example, drinking soda or escaping.

**Attitudes Toward Relationships**

1 point: Strongly negative: for example, life-threatening or assaultive relationships.
2 points: Moderately negative: for example, stressful, hostile, confrontational, or unpleasant relationships.
3 points: Intermediate level: neither negative nor positive (unemotional) or both negative and positive (ambivalent or ambiguous).
4 points: Moderately positive: for example, friendly or pleasurable relationships.
5 points: Strongly positive: for example, caring or loving relationships.

**Figure 1. Rating Scale for Assessing Attitudes Toward Solitary Subjects and Relationships Expressed in Response to the Drawing Task**
Age and gender groups were then compared in terms of percentages and mean scores.

Subjects

Subjects for the study included 531 children and adults, 257 male, 274 female. Five age groups were sampled: children ages 7 to 10, young adolescents ages 13 to 16, older adolescents ages 17 to 19, younger adults aged 20 to 50, and older adults ages 65 and older.

The children included 116 girls and 145 boys attending grades 2, 3, and 4 in urban and suburban elementary schools in New Jersey, New York, Pennsylvania, and Ontario, Canada. Seven schools were public and one was parochial. The young adolescents included 28 females and 37 males attending grades 8 to 10 in three public urban and suburban schools in Pennsylvania and New York. The older adolescents included 38 females and 22 males attending 12th grade classes in New York urban and suburban public high schools, as well as a class of college freshman in Nebraska.

The sample of younger adults included 61 women and 25 men who attended lectures or workshops and responded to the drawing task anonymously. The older adults included 28 men and 31 women over the age of 65 who lived independently in their communities and responded anonymously to the drawing task while attending recreational programs or social occasions.

The Drawing Task

Respondents were asked to choose two drawings from the array of Silver Drawing Test (SDT) stimulus drawings, imagine something happening between the subjects they chose, then draw a picture of what they imagined. They were encouraged to change the stimulus drawings and to add their own ideas. When drawings were finished, they were given titles and discussed, whenever possible, so that meanings could be clarified. Examples of stimulus drawings are shown in Figure 2.

The Assessment Instrument

The assessment instrument (Figure 1) was adapted in part from a scale in the Silver Drawing Test (SDT, Silver, 1990), a five-point continuum ranging between strongly negative and strongly positive themes. It was also adapted from the scale in Stimulus Drawings and Techniques (Silver, 1991) which was used in the 1987 study. Relationships between the two previous scales have been examined in a study of interscorer reliability in which 12 of the 24 scored drawings were responses to the Stimulus Drawing task and 12 were responses to the SDT task. No significant differences in mean ratings were found (t(22) = .8). Thus, there appears to be consistency of measurement between the scales. In addition, the new scale was developed from the scale used in the 1992 study (which was based on the two previous scales), but, in addition, distinguished between autonomous subjects and relationships.

Procedures

Responses were divided into two groups: drawings about solitary subjects and drawings about relationships between subjects. These were then examined for gender differences and similarities. It was theorized that respondents who drew solitary subjects thought of themselves as alone while those who drew relationships thought of themselves as part of a group. A solitary principal subject was defined as a person or animal acting autonomously, either the only living subject of a drawing or, if several living subjects are portrayed, they act independently or appear indifferent to one another. Drawings about relationships were defined as drawings of people or animals interacting with one another. The relationships may be visible in the drawing, verbalized in the story, or else implied.
Because the sample of children was considerably larger than any other sample, it was felt that an additional perspective on gender differences would be gained by equalizing the number of subjects in each group and obtaining mean scores on the five-point rating scale. With this in mind, 20 subjects from each of the age and sex groups were selected at random (N = 200) and mean scores of the 100 males and 100 females were compared. Although these numbers are too small for a reliable statistical analysis, they provided interesting information and raised questions for further research.

Results

**Question 1. Do respondents to a specific drawing task choose same-gender subjects to a significant degree, supporting the view that the subjects of drawings reflect self-images?**

Most respondents chose same-gender subjects. Among the 257 males in our sample, 54% chose male principal subjects, 11% chose female subjects, as shown in Table 1. Among the 274 females, 52% chose female subjects, 11% chose male subjects, as shown in Table 2. To determine whether they drew same-gender subjects to a significant degree, a 2 × 2 chi square (X²) was calculated utilizing those males and females who clearly drew human subjects in their response drawings (N = 338). Results indicated that respondents who drew human subjects, drew same-gender subjects to a degree significant at the .001 level of probability (X² = 145.839 p < .001; ð = .657). The phi coefficient (ð) was calculated on the chi square to determine the strength of the relationship. The phi coefficient ranges from ð, a weak or nonexistent relationship, to 1, a very strong, definitive relationship.) This finding seems to support the assumption that responses to projective drawing tasks tend to be self-gender images.

Another similarity between genders was found in the choice of animal subjects (34% males, 31% females) which seemed to serve as human symbols, consciously or unconsciously disguised. This observation was illustrated in the response of an older man who apparently drew an analogy: man chases women as dog chases cats (Figure 3).

The tendency to choose same-gender subjects peaked in childhood (63% girls, 59% boys) and reached its lowest level among adults. A surprising difference between genders also appeared. Among younger adults, the tendency to choose same-gender subjects declined to virtually the same level (40% men, 39% women). Among older adults, however, the decline continued among older women, but reversed among the older men, most of whom, like the sample of boys, chose male subjects (boys 59%, older men 54%).

Only 19% of the older women chose same-gen-

tend to focus on self-sufficiency and females on responsibility and care, but when attitudes were taken into account, as in the third question, significant differences were found.

Question 3. Can responses to a drawing task provide information about age and/or gender differences in expressing attitudes toward solitary subjects and relationships, and if so, can this information clarify expectations and identify emotional strengths and weaknesses?

Proportionally more men and boys expressed positive attitudes toward solitary subjects (63% positive, 17% negative), negative attitudes toward relationships (57% negative, 26% positive) as shown in Tables 4 and 5. These differences were significant at the .001 level of probability ($X^2 = 46.971$, $p < .001$; $\phi = .474$).

Proportionally more women and girls also expressed positive attitudes toward solitary subjects (68% positive, 17% negative) as shown in Table 6. Their drawings about relationships, however, were both positive and negative (46% negative; 41% positive, as shown in Table 7. These findings, too, were significant at the .001 level of probability ($X^2 = 25.32$, $p < .001$; $\phi = .327$).

In addition, chi-square analyses were conducted on the frequency of particular attitudes expressed by males and females in the five age groups. The data on this analysis were limited to the frequencies of four attitudes: assaultive relationships, caring relationships, active solitary pleasures, and passive solitary pleasures.

Males showed a significantly higher frequency than females of drawings about assaultive relationships ($X^2 (1) = 9.38$, $p = <.01$). However, gender and age differences interact ($X^2(4) = 13.07$, $p < .05$), resulting in a significant age variability in assaultiveness for females ($X^2(4) = 11.89$, $p < .05$), but

Positive: 37 (26%)

not males. In other words, female assaultiveness appeared to change with age, whereas male assaultiveness remained stable.

The converse age and gender interaction was found for caring relationships (X²(4) = 12.52, p < .05). Males showed significant age variability (X²(4) = 13.10, p < .05), whereas females had similar frequency of caring relationships across age groups.

No significant age or gender effects occurred for passive and active pleasures.

When attitudes toward relationships and solitary subjects were examined in greater detail some intriguing differences appeared:

1. Negative Attitudes Toward Relationships

   Strongly negative (assaultive, 1 point). Proportionally more older women than older men responded with fantasies about aggressiveness (27% females, 21% males), the only age group in which females surpassed males, as shown in Tables 5 and 7. The least difference between genders was found among older adults; the greatest difference was found among children and younger adults. Five times as many younger men as younger women drew pictures about assaultive relationships (15% men, 3% women) and approximately four times as many boys as girls (19% boys, 5% girls). In both adolescent groups, about twice as many males as females drew pictures about assaultive relationships. The fantasies about assaultive relationships followed similar patterns with both genders, increasing with age from third graders to younger adolescents and to older adolescents, dropping to their lowest levels with younger adults, and rising with older adults.

   Moderately negative (stressful relationships, 2 points). Although little difference between genders was found in drawing about stressful relationships (males 32%, females 36%), noteworthy differences appeared when age groups were examined.

   Proportionally more older men expressed fantasies about stressful relationships (64%), than any other age or gender group. Also high was the proportion of younger adolescent girls (53%). An example is shown in Figure 4. The smallest proportion (14%) was found among older adolescent girls.
Strongly positive (caring relationships, 5 points). Almost no gender differences were found in drawings about caring relationships (15% females, 14% males); age differences, however, were found. The younger men produced the largest proportion of drawings about caring relationships (46%), a proportion surpassing all other male and female age groups (Figure 5). By comparison, only 10% of the younger women drew pictures about caring relationships. Among female age groups, the greatest disparities were found among adolescents (27% older adolescents, 5% younger). Among male age groups, the

smallest proportion was found among younger adolescents (4%).

*Moderately positive (friendly relationships, 4 points).* Approximately twice as many females as males drew pictures about friendly relationships (26% females, 12% males), and all age groups followed this pattern of gender differences.

3. Negative Attitudes Toward Solitary Principal Subjects

When strongly and moderately negative attitudes were combined, no gender differences were found (17% of both males and females). When they were separated, however, differences again appeared.

*Strongly negative (sad or helpless, 1 point).* Although few respondents drew pictures about sad or helpless principal subjects, the proportion of females doubled the proportion of males (6% females, 3% males) as shown in Tables 4 and 6. When age groups were examined, the largest proportions were produced by the sample of older women (13%) and younger adolescent girls (11%) (Figure 6). None of the older adolescent girls and only 5% of the children and younger women drew sad or helpless solitary subjects. Only three of the 114 male respondents drew sad or helpless solitary subjects, and all three were boys ages 7 to 10.

*Moderately negative (frustrated or frightened, 2 points).* A larger proportion of males than females drew angry or frightened solitary subjects (14% males, 11% females).

4. Positive Attitudes Toward Solitary Subjects

*Strongly positive (active pleasures, 5 points).* Larger proportions of males than females associated solitary subjects with active pleasures (29% males, 21% females), except for the older women who reversed the tendency. A large proportion of older women than older men associated solitary subjects with active pleasures (31% women, 21% men).

*Moderately positive (passive pleasures, 4 points).* Larger proportions of females than males associated solitary subjects with passive pleasures (47% females, 34% males). The largest proportion was found among younger adolescent girls (67%); the largest male proportion among boys (43%).

In comparing mean scores, the females expressed more positive attitudes toward relationships than did males; males expressed more positive attitudes toward solitary subjects than did females, as shown in Table 8. Except for the sample of younger men, age groups among both genders had higher mean scores for solitary subjects than for relationships. The spread was greater for males than for females. The younger men received mean scores of 3.70 in both categories.

In attitude toward relationships, the younger men received a higher mean score, expressing more

positive attitudes than any other age or gender group. The older men received a lower mean score, expressing more negative attitudes than any other age or gender group.

In attitudes toward solitary subjects, the younger male adolescents received a higher mean score expressing more positive attitudes than any other age or gender group. The older women received a lower mean score, expressing more negative attitudes than any other age or gender group.

**Discussion and Summary**

The findings of this study, built on previous findings, seem to support the assumption that the principal subjects of projective drawings tend to represent self-images. Respondents who drew human subjects, drew same-gender subjects to a degree that was highly significant at the .001 level of probability. For art therapists, this finding provides evidence that looking for overt and covert self-images in projective drawings is appropriate and productive. It should be noted, however, that even though comparatively few respondents drew principal subjects of the opposite sex, this finding may also have useful implications. These respondents, particularly the adults, tended to express negative attitudes toward opposite-gender subjects. Although the numbers were too small for statistical analysis, this observation suggests that further study with additional respondents would be worthwhile.

The study did not find that females draw pictures about relationships and that males draw pictures about independent solitary subjects. Although proportionally more females than males drew relationships, and more males than females drew solitary subjects, these differences were not statistically significant.

When responses were examined for particular attitudes, significant differences were found between age groups as well as gender groups. Males showed a stable and significantly higher frequency of drawings about assaulitve relationships, as might be expected. It was surprising, however, to find that females showed significant age variability in drawings about assaulitiveness. Female fantasies about being assaulitive appeared to change with age. The proportion of women age 65 and older not only surpassed the proportion of older men as well as all other female age groups, but also surpassed the proportion of all male age groups combined.

When drawings about caring relationships were evaluated, it was surprising to find that males showed significant age variability. The proportion of younger men ages 20 to 50 not only surpassed the proportion of younger women as well as all other male age groups, but also surpassed the proportion of all female age groups combined. Again, the numbers were too small for statistical analysis, but hold promise for future studies.

The findings of this study raise questions about traditional expectations regarding ages and genders. It is usually expected that males are more aggressive and that females are more caring. Some investigators attribute these differences to social pressures and the way children are raised. Others look to biological causes, such as hormones which program males for aggression and competitiveness and females for caring and nurturing. One explanation for the finding about men age 20 to 50 fantasizing about caring relationships could be that they are biologically programmed to protect and care for their families. An explanation for the finding about older women fantasizing about aggression could be the effect of menopause on the production of estrogen and progesterone.

In any event, the findings seem to suggest that drawings can serve to identify age/gender differences in attitudes. If expanded, the findings may eventually provide norms on which to base more accurate expectations as well as information about emotional needs. For example, the older adults expressed more negative attitudes than any other age group. These findings suggest a need for thorough follow-up when drawings about sad, solitary subjects or stressful relationships are found.

On the other hand, it is important to note that many of the negative responses by older adults were characterized by sarcasm: self-disparaging humor. The implication seems to be that art therapists who work with the elderly can expect to find not only frailties, but also wit and resilience.

I hope some readers will be interested in joining this ongoing study by presenting the drawing task to additional respondents. If the sample populations can be expanded, some of the tentative findings reported here could be clarified.

Art Therapy in Private Practice: Legal and Insurance Issues

Gail Wirtz, MAT, MPS, A.T.R., Chicago, IL

Unforeseen issues of litigation and insurability pose a potential threat to art therapists in private practice. Unlike social workers or psychologists, art therapists are not licensed by the state. This lack of certification jeopardizes our legal credibility and insurability. Frequently, art therapists must fight for any rights they might expect from the judicial system. We should be aware that this may be costly. Current association-sponsored insurance coverage falls far short of the needs of the art therapist in private practice.

For 10 years I have owned and operated an art therapy-art education business with a staff of six and an exposure of approximately 100 clients weekly. The center serves families within a Chicago middle-to-upper-class community. Creative development classes serve parents and children, and individual art therapy is provided for children. Because of volume, I have had greater contact with the public, leaving me more exposed to legal and insurance issues than many art therapists.

During its operation, the center has been a viable and valuable asset, both to me and the community. However, several events caused me to reexamine the role of art therapy within the framework of legal and insurance issues. During the past three years, I have twice been involved in legal matters. Although different issues were addressed, the combined financial and professional impact led me to question the viability of private practice for art therapists.

The first case concerned a child who was allegedly abused by a janitor at her school. I worked with the child for three years. Ten years later I was subpoenaed to testify in the case as the child’s therapist. Providing therapy for the child was not the most difficult aspect of the case; the difficulty arose in going to court as her therapist. I was not trained to give depositions, nor was I knowledgeable about my own malpractice liability, had I unknowingly crossed the defined role of art therapist. Aware of my lack of training in these areas, I chose to have a lawyer present in the deposition, for support and to assure that I would be defended.

I was informed that I would be an expert witness, compensated for the numerous hours of preparation and days of deposition. After two days of deposition, however, it became evident that the judicial system did not recognize art therapists as professionals and, therefore, I was not eligible for compensation. At my lawyer’s request, the judge clarified my status as an expert witness and my right to payment. The judge also reinstated my legal right to have written questions in advance for review with my attorney. Prior to this point, however, I was not paid for my work.

The intricacies of the sexual abuse case alerted me to examine my own vulnerability to sexual abuse charges. Now concerned with liability, I began investigating my own insurance policy which was through the association-sponsored company furnishing group rates for art therapists. An insurance broker who reviewed it was unable to get a clear answer regarding coverage for sexual abuse. The policy offered no obvious coverage for sexual abuse; it stat-
ed that abuse is excluded if an adverse judgment were found against the insured. The underlying message appeared to be: "We will not insure you, but we might if you are found not guilty."

My second legal exchange concerned a lawsuit in which I was sued by an employee for discrimination. The before-trial costs were great; I followed my lawyer's advice to settle with no admission of guilt. This painful learning experience took valuable time from my business and family. Again, I looked to my insurance carrier for help, but discovered that discrimination is a separate policy which it does not offer.

Many art therapists in private practice may be under the misconception that they are covered by insurance. My experience has been that this is not the case. Lawyer's fees for protecting our rights in court frequently are not paid by insurance companies, nor are many additional costs. The obtuse language used in the policy can allow insurance companies to withhold payment while unsuspecting art therapists believe they have coverage. Art therapists can avoid problems through careful preparation in several specific areas:

1. **Malpractice and the boundaries of the art therapist.** Going beyond the boundaries of the job description for art therapists can result in charges of malpractice. This can precipitate lack of coverage through the association-sponsored company and other carriers. A review of the literature reveals that 13.2% of the "total claims against psychologists [are for] psychologists undertaking work in areas for which they are not qualified by education, training, and experience" (Pope & Vasquez, 1991, p. 28).

2. **Alleged sexual abuse.** Accusations of alleged sexual abuse can rob an art therapist of professional and personal integrity and impose economic hardship. At this time the association-sponsored insurance company states they do not cover allegations of sexual abuse, particularly if the court rules against the insured. The literature reveals that "53.2% of the costs of malpractice are for sexual impropriety" (Ibid.). More insurance money is paid for sexual abuse allegations than any other area. This is a high-risk area that warrants genuine concern for coverage.

3. **The definition of art therapist.** The insurance company I now use defines an art therapist "like the state." The state, I informed them, has no definition. However, nothing in writing elucidates the company position; yet, they were unwilling to assist me in clarifying who could be hired under the job title "art therapist."

To address this dilemma, I am seeking a new policy. My insurance broker recommended changing the corporation to not-for-profit, thereby increasing eligibility with insurance companies that deal with not-for-profit agencies. One carrier has been found who uses clear language, particularly in the areas discussed above; sexual abuse coverage is clearly stated within the policy, giving me greater confidence.

My experience highlights many legal concerns facing the art therapist in private practice. For example:

1. Is it safe for Registered Art Therapists (A.T.R.'s), with no other professional affiliation, to be in private practice?

2. What are the specific guidelines for art therapy practice that state the limitation of our training? In our work, boundaries frequently overlap with duties commonly attributed to social workers and other therapeutic professionals, for example home visits or recreational work. Do we need to clarify our professional boundaries and limit our practice to art therapy only?

3. If the association-sponsored insurance carrier knew that we were not state-recognized, would it continue to insure us?

4. Could the association set up private practice guidelines or offer a legal ethics course that would be available to art therapists?

I believe we need to tread very carefully, acting before we must react. Legal issues are easier to prevent than to fight. Faced with our litigious society, these issues are critical to the future of our field. Clarity in defining our legal rights may be dependent on state recognition. We need education concerning liability. Perhaps most importantly, we need to be supported by insurance companies that will defend our rights as policyholders, without leaving us with unanswered questions when litigation rears its ugly head.

Full Circle

Mury Rabin, PhD, A.T.R., Hastings-on-Hudson, NY

Fifteen years of observing the effects of their artwork on patients in treatment has convinced me of the authentic power of art therapy. Without doubt, it helps the sick get well, certainly healthier. It confronts the patient with truth, both the dark and light sides. Also, it addresses the intellect from another perspective: Patients' drawings depict conscious thoughts in the manifest quality of expressive work. Simultaneously, latent qualities that seem to emerge mysteriously from the unconscious are revealed in the artwork. On paper, patients present their dreams to themselves.

Art therapy works. The therapy of art therapy works. Yet, the mechanism of how the unconscious and conscious become visible remains elusive. Why particular colors have meaning to the individual, why the patient chooses a particular image as most significant, why the art may predict future happenings—getting healthier, sicker, suicidal thoughts and actions, playing it out in images, aggressive and abusive actions, feeling sad, joyous, angry, depressed, empty and full—these questions still intrigue us. Like the template of a bird's song, art therapy is awesome. It is potent; it is always authentic. The patient always knows it is truth (Rabin, 1987).

Art can help well people be healthier. Art can invite passions to yield to their highest potentials. Art can be beautiful, soothing, inspiring. However, it is just as often the catalyst for disturbing feelings. It can evoke compassion, revulsion, anger, depression, love, and despair. The artist may succeed in conveying his/her intent to the viewer. Art speaks to the viewer, often evoking a personal response different from the artist's intentions.

Given time, nonverbal communication through art has an impact on the healthy person much the same as art produced in therapy. For the patient struggling to regain health, art serves to complete that process of healing and growth. For the well person who either produces his/her own art or views that of others, the effect is one of reaching a higher level of wellness, of activating his or her creativity. As an exercise in assisting the communicating functions of both brain hemispheres, it increases intellectual activity (Taylor, 1960).

The functioning person bears the stresses of life in a verbal culture. Nonverbal symbolic messages support the well person in efforts to bear responsibilities in a society that suffers from creative malaise. It is not enough to smell the roses; we need to stop and feel them, study them, find the differences within the flower and its leaves, and acknowledge the thorns. What is its neighboring plant, the earth beneath, the effect of weather on its color and stability? Does it smell different from time to time?

Art has to become a passion that is pursued daily, through nature as well as through formal art productions. We can develop a respect for and an unconscious attitude toward art. Childlike activities inviting creativity should not be confused with childish busyness.

Creative people make creative societies. make smarter societies, make better places, make ethical societies. Kramer (1971) writes:

There is, in my opinion, evidence that the lack of active art experiences and the concomitant saturation with pseudo-art among large segments of the population constitute a pathogenic condition. (p. 5)

Henri (1960) observes:

Art when really understood is the province of every human being. . . . When the artist is alive in any person, whatever his kind of work may be, he becomes an inventive, searching, daring, self-expressing creature. He becomes interesting to other people. He disturbs, upsets, enlightens, and he opens ways for a better understanding. Where those who are not artists are trying to close the book, he opens it, shows there are still more pages possible. The world would stagnate without him. . . . Museums of art will not make a country an art country. But where there is the art spirit there will be precious works to fill museums. Better still, there will be the happiness that is in the making. Art tends toward balance, order, judgment,
of relative values, the laws of growth, the economy of living—very good things for anyone to be interested in. (p. 15)

A culture hospitable to art will be more likely to receive art therapy as a serious profession and provide equal status with other therapeutic disciplines. I look forward to a time when art therapists will finally have an identity. We are still reading news articles about pictures used in treatment by a variety of health professionals without a single mention of art therapy or art therapists. An example follows:

Prosecutors in the Glen Ridge sex assault case today used drawings made by a mildly retarded young woman to press their argument that the four young men on trial here forced her to perform sex acts. . . . The witness, Ann Burgess, a psychiatric nurse and researcher with expertise in sexual assault cases, asked the young woman to do the drawings, a standard psychological testing tool. . . . Twelve weeks into the trial, the drawings could well be the last impression the jury receives of the prosecution's case. . . . (Sullivan, January 8, 1983, p. 43)

Art therapy has been the best kept secret in the therapeutic community. Art therapists often do the work but seldom receive recognition for accomplishments. When I was hired to head a section of a psychiatric unit of a hospital, I was told the psychiatrist agreed to hire me “because she has her PhD, and in spite of the fact that she is an art therapist.” My training and skills were, of course, used and welcomed, indeed considered to be essential to treatment.

I know many credentialed art therapists and other creative art therapists who have had to continue their academic training after completing degrees and credential procedures. Only by acquiring a more acceptable credential, i.e., social worker, psychologist, family counselor, could they be assured employment at a decent economic level. There is still little chance of moving up in the hospital setting. One student, prior to graduation, was offered the same position at the same salary I was receiving. So much for my master’s and doctoral degrees and the coveted A.T.R.!

Cross-fertilization with other therapies may be needed to promote art therapy as a profession whose standards match other disciplines. Research following traditional methodologies will bring recognition among professions that acknowledge only scientific approaches. More training in accepted research methodologies would benefit the cause of art therapy. It is no more difficult to design a study that will yield results that have meaning across disciplines.

Single case studies that do not provide some means of assessment will no longer be useful for the purposes of increasing the credibility of art therapy.

When art is nurtured and valued by our society, when it is respected and even revered, art therapists may then be able to flourish in their own right. Many art therapists are artists, indeed were artists before becoming art therapists. A portfolio of quality art is required for admission to many art therapy programs. It is important for art therapists to continue to work at their art and allow their art to develop as they grow as an individual. The artist-therapist must become one. Just as one works to increase health in clients, one must find a way also to keep an identity as an artist. S/he must plant art seeds everywhere. Working to help the well person develop creativity may be an avenue to explore, where art therapy will be honored and its influence widened.

Who is Art Therapy?

She’s a stroke of paint from a loaded brush
She’s clay pounded and staged
Graphite caressing the page
She’s paper scrolled i. a hush
Never revealing too much
She’s the revealer of secrets
A painter of terrors and fears
And of dreams buried in years
Captive her spirit frees
Releasing the bars within me
She’s a sculptor of hearts
A magic touch of a collage
A mandala of new starts
Emancipating the lodged

Essentials of Art Therapy Training and Practice

188 pp., 21 black & white illustrations. $35.75 cloth. ISBN 0-398-05794-X.

Bruce Moon presents us with a text generously filled with poems, dialogue, and illustrations. Moon writes eloquently and comments on a variety of topics: image, metaphor, creative encounters, intern/supervisor relationships, love, work, assessment, and language. His pieced-together sequence of chapters reads like separate notes, articles, essays, and commentaries.

The title of this book is somewhat misleading; it probably should be retitled Essentials of Existential Art Therapy Training and Practice. Moon offers art therapy educators at least 25 "essentials" of art therapy training and practice. These are based on his own approach to art therapy and his internship and training program at Harding Hospital, both of which are based on existentialism and humanistic psychology. The book effectively serves as a sequel to Moon's previous book Existential Art Therapy: The Canvas Mirror (1990), and not as an overview of the current diverse approaches to art therapy training and practice.

Despite the existential orientation of the book, many ideas presented are useful to all training programs regardless of theoretical approach. Moon's description of the art therapy student's process is right on target and worthwhile as it reflects an educator's journey with students. Chapter III, "Beginner's Chaos," is designed to decrease the anxiety and overwhelming feelings of the entering student. Chapter IV, "The Journey Metaphor in Training," demonstrates the struggles and risks taken by the art therapy intern. Chapter XI, "Gifts of the Young," and Chapter XII, "Gifts of the Male and Female Student," remind us to be aware of the differences among our students and to appreciate and honor these differences as gifts to training and to the profession.

However, we disagree with Moon's apparent "loose" approach with students, described in Chapter V, "The Mentor Supervisor." Here it appears the supervisor should allow students to discover proper/appropriate expectations at the clinical site. A structure, or at least a boundary, sets out the path of acceptable codes of conduct, ethics, and proper attire for the student. The student must still struggle to assert his/her own individuality and, angrily or sadly, discover himself/herself in the midst of overwhelming expectations. Expectations, clearly expressed, can avoid needless wounding of the novice interns already delicate sense of themselves as they enter into the profession of art therapy.

Moon discusses imagery, symbolism, and
assessment. He criticizes "cookbook" approaches to interpretation of artwork, and encourages art therapists not to attempt to use formulas or systems to analyze images. He encourages us to "regard images as living things" (p. 4), and states that "the image cannot be measured or verified" (p. 9). He describes his humanistic approach of mutual exploration of meaning in art and the art-making process.

On the topic of professional identity, Moon believes "our professional prestige must come from our own profession" (p. 56). He cautions educators not to train students to be "as-if psychologists or pseudo psychiatrists" (Ibid).

Moon presents strong opinions about the essentials of the core curriculum in art therapy training. Although he states that creative arts therapies professions "must develop standards of education that are both meaningful and diverse" (p. 21), he clearly describes and supports training and practice based in existentialism and humanistic approaches. He believes the core curriculum should include the humanities such as philosophy, theology, and literature, in addition to the "arts processes" (p. 154), "relationship skills, communication skills and psychotherapeutic techniques" (Ibid). Throughout the book he is most adamant that studio art coursework be included in training programs and he attacks the AATA educational guidelines for "not support[ing] continued engagement in studio art coursework" (p. 49). He expresses his belief that "arts-making is soul-making" (p. 66), and that in order to be art therapists we "must engage in the art process at a deep level" (Ibid) or else "we art therapists will eventually dry up and be blown away like dust" (p. 52). We question his description of his course "Studio Methods Seminar" which sounds like group art therapy.

Moon criticizes the AATA training guidelines and current art therapy training programs, methods, and philosophies. At times his attacks on the AATA guidelines sound more like the whining school boy who is angry at his teacher about a grade, as though the AATA has wronged him and/or his training program in some way. An example is his attack on guidelines for 600 hours of practicum. Reasoning that, spread over the course of training, the practicum amounts to only two hours per day, he complains that learning can not "be done in brief, inconsistent clinical exposures" (p. 64). He "urge[s] that clinical field work experiences be enriched by class-

room instruction" (p. 63). Has he done his homework? Research into curricula of other programs would reveal that some do include enrichment and exposure to other disciplines, milieu, and various skills through coursework, group supervision, and the practicum experience itself.

We note that in 1989, the AATA members voted not to "alter" but to step forward with requiring a master's degree as the clear path for registration. To join our ranks, other paths to registration must demonstrate rigorous study and internship. We do not perceive the AATA to have taken away our creativity nor the "art-part" of us. Preserving it is the responsibility of art therapy educational programs and the student.

We applaud Moon's admonitions to educators to continue in their own art and clinical work in order to practice what we preach. Moon's mixture of teacher, supervisor, clinician, and artist, is a strong role model that is, we think, common to most art therapy educators. It keeps us in touch, and thus we are most useful to our students and clients.

Moon continually stimulates us to think about how we train our students. As educators we owe it to our students to require a diverse theoretical clinical and creative experience. It is our job to foster their growth to become self-actualized therapists by nourishing their creativity, challenging these notions through experientsals, and actively encouraging them to explore their issues in therapy (outside of the educational program). Our students also need to know the language, not the job, of the psychiatrist and psychologist to carve out their unique piece of the job market as professional art therapists.

In the practical world, art therapists need to be similar to other mental health professionals as much as they need to be different. Just as Bruce Moon cautions us not to over analyze or project onto the art creation, we ask him not to pigeon-hole each "master's degree" program and other art therapy training methodologies. We, as art therapists, use different media, different "language," and different metaphors. It is the diversity we all bring to the field of art therapy that is truly creative.

Reference

Respectful of the healthy ego that is in pain, Joyce Houser Ward outlines the sequential stages of the therapeutic process. She speaks to the myriad of people who have sought therapeutic help because it was the healthy choice.

As therapists we often forget how mysterious and sometimes frightening the world of the psyche is to the novice client. Ward has not forgotten. She writes to the client, supporting his or her courage and determination to be in therapy. Her words are empathetic:

This healing process is a journey chosen by relatively few people. If you are one of those, credit yourself as courageous, wise, and fortunate. You’ll never regret the choice. The beginning might be frightening and arduous, but it gets easier as you go along. (p. 183)

Ward is to the therapeutic process what Kubler-Ross has been to the grieving process. She has clarified the pattern of therapy. Her chapter titles chart the steps of therapy: Facing the Unknown, Pain’s Purpose, Fears and Feelings, Resisting Change: Fight or Flight, Shame and Self-exposure, Becoming Real: Opening the Emotional Floodgates. From Despair to Hope. Therapy in Recovery, The Healing Relationship, Rebirth, and Transformation. She sets goals and gives hope by describing what life can be like after therapy ends. “Healing emotionally frees you to be more of who you want to be and to do” (p. 181). The end of therapy is “a place where you meet yourself free of masks; where you touch the spiritual skin of life, taste its flavor, and breathe its breath” (p. 182). She continues:

You can never return to the place of not knowing, to the unconsciousness of earlier days. Sometimes you may wish you could return, because the journey gets painful and the old days seem simpler in your memory. But you can’t go back, and even if you could, ultimately you wouldn’t choose to. It’s like having been blind all your life; suddenly you’re able to see: movement, colors, and shapes pour in, more than you ever imagined. Much of what fills your vision is beautiful and miraculous, but ugliness enters in too, uninvited, along with the grotesque and horrifying. You don’t like everything in life’s mixture of joy and pain, yet having experienced it, you wouldn’t want to go back to blindness. (pp. 183-184)

Ward emphasizes, encourages, cultivates, and enlists the strengths of the client. For clients who range from grandiose to battered, from self-sufficient to fearful, for all those “normal neurotics” who come to therapy in emotional pain, or at the point where they have just begun to see unpleasant or disruptive patterns in their lives, this is the book of choice. Therapists will want to have this book in their lending libraries.

An artful therapist, Ward clothes hard reality in poetically attractive language; her words are easily quoted. She is a mentor to us all.
A Child's Story: Recovering Through Creativity

Pat Harris with Jeanette Batz, St. Louis, MO: Cracom Corporation, 1993.
154 pp., 33 color illustrations, $29.95 hardcover. ISBN 0-9633555-2-X.
Reviewed by Margaret L. Smart, MSW, LCSW, A.T.R., Palo Alto, CA

A Child's Story is two books in one. First, it is a primer of child abuse, including definitions, theories of cause, and the consequences and requirements for recovery. Embedded within the first book is Harris' story of abuse and, more importantly, her path to recovery. The author shares excerpts from her journal, poetry, and art. The two books are interwoven, alternating between informational material and her story. This format, however, detracts from the important message of the book.

Designed for a newcomer to the field of abuse, much of the current thinking on causes and consequences of abuse is presented in straightforward, simple language. However, Harris does not inform us that this material is only an introduction to an extremely broad and most complicated subject. An example is found in her discussion about perpetrators. Many theories have been raised regarding cause of abuse, motivations of perpetrators, and classes of perpetrators. Harris offers only limited coverage on these topics and draws conclusions too quickly. At this point in our knowledge about child abuse a presentation of the many questions we need to address would have been preferable.

Harris is sometimes glib and one-sided. When she discusses the role of the survivor's partner she misses the point that the partner is also a victim who requires support to withstand living with the survivor's pain. While survivors can learn to give and take within the now healthy, nonabusing relationship, it is not realistic to expect that the nonabused partner will always provide strength and understanding.

No book on abuse is complete without a discussion about treating children of suspected abuse. Behavior, previously thought to be conclusive evidence of abuse, is now open to question. Specific physical evidence previously connected with physical abuse is now seen as normal for children of certain ages. In some cases, suspicions have been raised that therapists may unwittingly influence what the child tells them. None of these issues are addressed.

The true power of this book is in the author's own story of abuse and recovery. Her engrossing journal entries provide a chronology of pain, conflict, and discovery. She has the courage to seek information and confront those who might help her find the truth. In the face of disappointment, she struggles on. Her perseverance and unshakable faith in the outcome are awe-inspiring. She expresses the experience of the abused child and speaks authoritatively on coping with the terror of abuse.

Poetry and art enable her to reach inner pain. Poetry opens the door to her child. The adult forms the words, but we hear, clearly, the child's voice, allowing us to experience her pain. Her deepening understanding about the consequences of abuse moves from theoretical material to written thoughts of the survivor, and from poetic expressions of memories and feelings to the ugliness of pain in her artwork. She found increasingly more potent vehicles to release her pain. Of these, art is the most potent. As she journeys through these levels, she is healed by her own process and by allowing others to join her.

If ever there was a book that validated the use
of art as therapy, this is it. Harris, whether knowingly or not, demonstrates what art therapists have long known: Art enables the abuse survivor to reach the depths of hidden pain and bring it to the surface to be viewed, understood, and, eventually, mastered. Art taps the strengths of the abused, assisting in healing the wounds. For this reason, I highly recommend this book.

A Child’s Story: Recovering Through Creativity

Reviewed by P. Gussie Klorer, MA, A.T.R., Edwardsville, IL

If a book about incest can be considered beautiful, this one is in its physical appearance and in the message it conveys to therapists and their survivors. Written from the perspective of an incest survivor, Pat Harris speaks powerfully about pain and healing. Her raw honesty about her abusive past is illustrated through art and journal entries. Sensitive questioning, relentless searching, and her strong need to survive are apparent throughout.

This is not art produced in the context of art therapy. Harris is a professional artist who never intended to put her story in her art, but found the images “interrupted work I was preparing for a one-person show and startled me with their revelations” (p. 3). The reader is privy to the process of uncovering many layers of memories which did not emerge until Harris was in her thirties and had run the gamut of somatic symptoms and therapy. Psychoanalysis was integral to her (the book is dedicated to her therapist), but it goes far beyond merely recording the process of expressing her pain. The issue of pain is approached through three “voices”: the wounded survivor struggling to heal, the nonverbal voice of her art, and a strong voice of knowledge and insight gained through research. Ms. Harris’ purpose was not only for her own self-empowerment but also to help other survivors gather the courage, patience, and energy needed to heal.

She organizes the book into chapters interfac ing her art and journal entries with information about child abuse, perpetrators, survivors, consequences of abuse, the recovery process, and a section on expressive therapies. Harris has researched her topic well and is able to juxtapose and balance emotionally laden material with intellectual discussion. She has relied on experts for documentation and does not pretend to be an authority on anything other than her own process. Consequently, the reader senses her as a generous and humble, yet immensely courageous and talented woman.

In the section on expressive therapies, Harris interviewed two St. Louis art therapists, Carol Lark and Sharyl Thode Parashak. She gives examples of how art therapy might be used with adult and child survivors and makes a strong case for survivors to seek professional help rather than trying to self-heal. Harris asks,

Why not just sit home with some Crayolas? Because you need a witness, someone to help you maintain some structure while your whole emotional world is
A CHILD’S STORY: RECOVERING THROUGH CREATIVITY

falling apart and coming back together in new ways. This other person makes things safe and proves to you that your view of reality is valid. (p. 143)

Harris makes another strong case for the importance of looking at one’s imagery and thinking about possible meanings. As she gains new insights, meanings change over time. Therapists who believe they can interpret art and assign diagnostic assessments to pictures without understanding the artist or client’s own interpretations should reconsider their methods.

A Child’s Story can help survivors understand some dynamics of the recovery process. Placed in the waiting rooms of art therapists, the book can serve as a quiet inspiration to clients who are struggling with their own imagery. I have lent my copy to clients when I felt they needed to feel less alone in their struggles.

Concurrent to the publication of the book, Harris exhibited her paintings at the St. Louis Design Center, a gallery in St. Louis. The exhibit included all the paintings in the book along with sculpture and an installation of a child’s room. Viewer participation and feedback were invited by providing mural paper for graffiti commentaries. To further educate the public, statistics and factual information about child abuse are provided. Harris appears to be making a bridge between fine art and therapy, a bridge not always welcomed in the fine arts community. Perhaps recognizing this, Harris embraced the art therapy community by providing a special viewing and gallery talks for area art therapists. It is difficult to review this book without including insights gleaned from the gallery talk and discussion.

The exhibit raises many questions for artists and art therapists: Is this art? Or is this too similar to that which is produced in therapy? Ulman (1975) addressed this issue years ago when she reminded us that the definition of art therapy is closely intertwined with the definition of art. Ulman stated, “The spontaneous projections encouraged in therapy-oriented art therapy are not art in the complete sense, but neither are they anti-art. They are vital fragments of the essential raw material from which art may evolve” (Ibid, p. 13). Ms. Harris considers her art not only a documentation of her healing process, but valid as art objects. Some images, particularly a book of drawings titled “A Child’s Story,” appear raw and unresolved as art objects. Yet other series of paintings, such as the “Wounded Women” and “Self-Bound Women,” classify as art objects. Her work represents a necessary challenge to the fine arts community who historically perceive fine art and art therapy as separate entities. Throughout art history, however, there has been an overlap between the two. The difference appears to be that Harris is talking about it.

Ms. Harris relates an incident when a former teacher from art school came to her studio and criticized her use of art to express troubles. The instructor “suggested that I start over and draw things in my studio. She said the windows with the heart mobile in front of them seemed more like me” (p. 82). Later, Harris resolves this issue for herself when she writes in her journal.

The teacher who told me to paint things in my studio and that art was not therapeutic was wrong. Art can be therapeutic for both the creator and the viewer. Political art disturbs and moves people. When an artist has something to say and does not wish to entertain, then she must not follow those rules of pleasing by subverting the emotions into a still life. I don’t wish to paint life the way people want to see it. I want my art to tell people how life is. (p. 127)

Clearly, Harris’ intention is to be educational; she writes to heighten awareness about abuse and to help other abuse survivors heal. Her role is one of an advocate. By choosing to exhibit this work, she confronts the fine arts community who resist and dismiss this bridge between art and therapy. She has demonstrated that the art community do not know what to do with her work, and consequently they ignore it.

As an educational tool this is a potent book both for therapists and survivors of incest who will be moved by the blunt emotionality of her art. Readers who have not been abused will gain greater understanding of the complexities of abuse cycles. Artists may have difficulty with the distraction of explanations and rationalizations and may dismiss the art because of the dual intent of education and expression.

This book should be a welcome addition to art therapists’ libraries. Harris has put her soul into this book, and it is a beautiful testament to the strength she has gained through her creative outlets.

Book Review Response

Dear Book Editor:

I have just finished reading Dr. Lusebrink's review of Shaun McNiff's most recent book, Art as Medicine. As I put the review aside, I couldn't help but wonder if Vija and I had read the same text. I feel compelled to write to you and offer an alternative view.

I regard Art as Medicine as one of the most significant works ever to emerge from the profession of art therapy. While each of McNiff’s previous books has made articulate and thought-provoking philosophical and theoretical contributions to our body of knowledge, this new effort exhibits a depth and existential integrity that surpass the earlier texts. Contrary to Lusebrink's pronouncement that “quotes from various sources, including a number of poems...result in an uneven text,” I found the interweaving of ideas from Corbin, Hillman, Nietzsche, Ferrini, Magritte, and D. H. Lawrence to be evocative and absorbing reading.

I was troubled by Lusebrink's implication that McNiff's approach to art therapy is "in opposition to science." In fact, McNiff states, "...my mission has not been in opposition to science." He does express displeasure with what he terms "scientism." This is an idea akin to the "Clinification Syndrome" described by Pat Allen, PhD, A.T.R., in Volume 9, Number 1, of this journal. There are many art therapists who are equally concerned with this aspect of the profession.

As I read the image dialogues section of the book, I was engrossed by the passion and artistic commitment conveyed in Shaun's reflections on his paintings. In my view this book works because of its unique blend of imagination, intimacy, and solid intellectual inquiry.

Lusebrink cites as one of the biggest shortcomings of the book its "frequent, derogatory, inaccurate, and undocumented statements about art therapy." I found McNiff's references to the profession to be provocative, insightful, and deeply respectful. I have heard many presentations at conferences which validate his concern with those in the field who analyze and dissect the life out of images, in effect committing "imagicide." McNiff attributes 14 art therapy colleagues as having intimately collaborated in the development of the book. I suspect they, and many more, share his concerns with the directions of the profession.

Dr. Lusebrink asserts that "this [McNiff's] approach is less useful to art therapists who work with individuals who have serious impairments and psychopathology, given the constraints of time limits and reimbursement through insurance." At one level Vija may be correct. At a deeper level, however, Art as Medicine has been of great use to me in the clinical setting in which I work. I treat individuals who have severe emotional and mental disturbances and limited resources. The reading of McNiff's book has served to refresh my faith in the art process. It has fed my soul and, thus, has been of immeasurable help to the patients I serve.

Shaun McNiff serves our profession as a mentor therapist whose primary mission at this time is to take care of us art therapists. I believe that this book should be welcomed as a terribly important and positive contribution to a field desperately in search of grounding theory and philosophy.

An Exhibition of Art
by Edith Kramer

Edith Kramer, noted artist/art therapist, exhibited paintings and sculptures at the College of Notre Dame Weigant Gallery, Belmont, CA, June 5–9, 1993. The exhibit was arranged through the joint efforts of Marilyn Halevi, A.T.R., Annette McGarr, Rebecca Ratekin, Doris Arrington, EdD, A.T.R., the CND Graduate Student association, and college staff.

Edith Kramer was born in 1916 in Vienna, Austria. She was educated in Vienna and studied drawing and painting in Prague from recognized members of the Bauhaus. She emigrated to the United States in 1938 and became a citizen in 1944. She practiced and taught art until 1950 when she began her work as an art therapist with emotionally disturbed and economically deprived children in the New York area. Since 1959 Kramer has taught in art therapy training programs and presently serves as an Adjunct Professor at New York University. She has authored three books: Art Therapy in a Children's Community, Art as Therapy with Children, and Childhood and Art Therapy: Notes on Theory and Application.

Dwight Mackintosh and the Creative Growth Center

The Creative Growth Center in Oakland, CA, provides creative art programs, educational and independent living training, and counseling and vocational opportunities for adults who are physically, mentally, and emotionally disabled. A professional art studio has been developed for clients who are especially gifted and who have the potential for becoming partially or fully self-supporting through their art. Drawing, painting, printmaking, graphic arts, and ceramic sculpture are included in a program designed to suit the talents and needs of individual clients. The program is further enriched by field trips to museums, art galleries, and artists' studios. Whenever possible, clients are taken "on site" for drawing and painting experiences. The Creative Growth Gallery professionally exhibits the work of Creative Growth clients, as well as the art of emerging and well-known artists.

Someone who has benefited from this remarkable program is Creative Growth artist Dwight Mackintosh. More than 10 years ago, Mackintosh began coming to the Creative Growth Art Center, spending his days churning out work after work, many of which consisted entirely of wavy lines that resembled secret writing or elaborate scribbles. Irene Ward Brydon, A.T.R., director of the center, observes that "drawing is a compulsion for him... from the first day he came here, we knew he was a significant artist."

Noted scholar John McGregor has recently published a book on Dwight Mackintosh titled Dwight Mackintosh: The Boy Who Time Forgot. The book follows the artist's 15-year obsession with image-making while working in the Creative Growth Center. The compelling inner world of this outsider artist is revealed in both Mackintosh's exquisite drawings and John McGregor's poetic prose about the artist.

CODE OF ETHICS

THE AMERICAN ART THERAPY ASSOCIATION, INC.

CODE OF ETHICS FOR ART THERAPISTS
APPROVED BY MEMBERSHIP BALLOT
September 1990

Art therapists are members of a larger community of professionals providing services in the mental health field. As such members, art therapists subscribe to the basic ethical standards accepted by other organizations representing such professionals. With due respect and where applicable, part of the following ethical standards is based upon those developed and adopted by the American Psychological Association Ethics Committee.

Art therapists believe in the dignity and worth of the individual human being. While demanding for themselves freedom of inquiry and communication, art therapists accept the responsibility this freedom confers: objectivity in reporting findings, high standards of competence, and consideration for the best interests of all persons for whom services are rendered.

Responsibility

Art therapists place high values on objectivity and integrity, maintain high standards of professional competence and service, and are responsible for the consequences of their actions.

A. Art therapists have the responsibility to attempt to prevent distortion, misuse, or suppression of art therapy findings by the institution or agency of which they are employees.
B. As members of governmental or other organizational bodies, art therapists remain accountable as individuals to the highest standards of their profession.
C. As art therapist educators, art therapists recognize their primary obligation to help others acquire knowledge and skill and maintain high standards of scholarship.
D. As practitioners, art therapists know that they bear a heavy social responsibility because their recommendations and actions may alter the lives of others. They are alert to personal, social, organizational, financial, or political situations or pressures that might lead to misuse of their influence.
E. Art therapists recognize that personal problems and conflicts may interfere with professional effectiveness. They refrain from undertaking any activity in which their personal problems are likely to lead to inadequate performance or harm to a client, student, colleague, or research participant.

If engaged in such activity when they become aware of personal problems, art therapists seek professional assistance to determine whether they should suspend, terminate, or limit the scope of their professional activity.

Competence

The maintenance of high standards of competence is a responsibility shared by all art therapists in the interest of the public and the profession as a whole. Art therapists recognize the boundaries of their competence and the limitations of their techniques. They provide only services and use only techniques for which they are qualified by training and experience. In those areas in which recognized standards do not yet exist, art therapists take whatever precautions are necessary to protect the welfare of their clients. They maintain knowledge of current professional information related to the services they render.

A. Art therapists accurately represent their competence, education, training, and experience. The AATA recognizes that individuals who have achieved Professional Membership status in the Association may call themselves art therapists. Those members who have met the additional criteria as set forth in the Standards of Registration of the AATA may call themselves Registered Art Therapists and may utilize the initials A.T.R.
B. As art therapy educators, art therapists provide instruction based upon careful preparation and are accurate, current, and scholarly.
C. Art therapists recognize the need for continuing education and are open to new procedures and changes in expectations and values over time.
D. Art therapists recognize differences among people, such as those that may be associated with age, gender, socioeconomic, sexual preferences, and religious and ethnic backgrounds. When necessary, they obtain training, experience, or counsel to assure competent service or research relating to such persons.

Moral and Legal Standards

An art therapist's moral and ethical standards of behavior are a personal matter to the same degree as they are for any citizen, except as these may compromise the fulfillment of their professional responsibilities or reduce the public trust in art therapy and art therapists. Regarding their own behavior, art therapists are sensitive to prevailing community
standards and to the possible impact that conformity or deviation from these standards may have upon the quality of their performance as art therapists. Art therapists are also aware of the possible impact of their public behavior upon the ability of colleagues to perform professional duties.

A. As art therapy educators, art therapists are aware of the fact that their personal values may affect the selection and presentation of instructional materials. When dealing with topics that may give offense, they recognize and respect the diverse attitudes that students may have toward such materials.

B. As employees or employers, art therapists do not engage in or condone practices that are inhumane or that result in illegal or unjustifiable actions. Such practices include, but are not limited to, those based upon considerations of race, handicap, age, gender, sexual preference, religion, or national origin in hiring, promotion, or training.

C. In their professional roles, art therapists avoid any action that will violate or diminish the legal and civil rights of clients or of others who may be affected by their actions.

Public Statements

Honesty, caution, and due regard for the limits of present knowledge characterize statements of art therapists who supply information to the public, either directly or indirectly.

Public statements include, but are not limited to, communication by means of a publication, directory, television, radio, or films.

A. When announcing or advertising professional services, art therapists may list the following information to describe themselves and the services they provide: name, relevant academic degrees earned from an accredited institution, date, type and level of certification or licensure, AATA membership status, address, telephone number, office hours, a brief listing of services offered, an appropriate presentation of fee information, and policy with regard to third party payments. Any additional relevant information may be included if not prohibited by other sections of these Ethical Standards.

B. In announcing or advertising the availability of art therapy services or publications, art therapists do not present their affiliation with AATA or any other organization in a manner that falsely implies sponsorship or certification by that organization. Art therapists do not state AATA membership, professional or otherwise, in a way to suggest that such status implies specialized professional competence or qualifications.

C. Public statements made by art therapists do not contain (1) false, misleading, or unfair statement, (2) a misrepresentation of a fact or statement likely to mislead or deceive because it makes only a partial disclosure of relevant facts, (3) a testimonial from a client regarding the quality of the art therapist's services, (4) a statement implying unusual or one-of-a-kind abilities, (5) a statement intended or likely to create false expectations of favorable results, (6) a statement comparing offered services to those of other professionals, (7) a statement likely to appeal to a client's fears, anxieties or other emotions concerning the possible results of failure to obtain the offered services, (8) a statement which directly solicits individual clients.

Confidentiality

Art therapists have a primary responsibility to respect client confidentiality and safeguard verbal and visual information about an individual or family that has been obtained in the course of their practice, investigation, or teaching.

A. Information shall be revealed only to professionals concerned with the case. Written and oral reports only disclose data relevant to the purposes of the inquiry. Every effort is made to avoid undue invasion of privacy.

B. Art therapists are responsible for informing their clients of the limits of confidentiality.

C. Art therapists obtain written permission from clients before any data, visual or verbal, is divulged. All identifying information about the individual is adequately disguised.

D. Art therapists reveal information without the consent of their clients when there is clear and immediate danger to any individual or to society, or as mandated by law. Such information is revealed only to the appropriate professional workers, public authorities, or others designated by law.

E. Art therapists make provisions for maintaining confidentiality in storage and disposal of records and art expressions.

Welfare of the Art Therapy Client

Art therapists respect the integrity and protect the welfare of the person, family, and/or group with whom they work, and they understand that the art expression is the privilege of the client.

A. Art therapists terminate or transfer clients when it is reasonably clear that the client is not benefiting from a therapeutic relationship.

B. Art therapists make financial arrangements that are clearly understood by their clients and that safeguard the best interests of the client and the profession.
C. Art therapists employed by another person or agency suggest clientele of the employer or agency leave to come to their private practice only when there is mutual agreement between the art therapist and the employer or agency. Such a change is made only in the best interest of the client.

Professional Relations

Art therapists act with integrity in regard to colleagues in art therapy and in other professions.

A. Art therapists do not offer professional services to a person receiving art therapy from another therapist except by agreement with the other therapist or after termination of the client’s relationship with the other professional.

B. Art therapists assign credit to those who have contributed to publication and in proportion to their contribution.

C. Art therapists understand areas of competence in related profession and make use of all professional, technical, and administrative resources to best serve their clients.

D. Art therapists secure appropriate authorization when conducting research in institutions and organizations. They ensure that the institution or organization receives adequate information about the research and proper acknowledgement of their contributions.

E. Art therapists do not exploit their professional relationships with clients, supervisees, students, employees, or research participants sexually or otherwise.

F. When art therapists know of ethical violation by another art therapist, they informally attempt to resolve the issue by bringing the matter to the attention of the art therapist in question. If the misconduct is minor in nature, such an informal solution is usually appropriate and is made with sensitivity to any rights of confidentiality involved. If the violation cannot be resolved informally or is of a more serious nature, art therapists bring it to the attention of the Board of Ethics and Professional Practice of the AATA.

Public Use and Reproduction of Client Art Expression

Art therapists are responsible to their clients for any public use and reproduction of client art expression.

A. The identity of the client is protected by withholding the name, address, date of hospitalization or treatment, and other specific information which may disclose the person’s identity to the public. Any part of the art expression which may reveal client identity is disguised.

B. Art therapists display client art expression with the written consent of the client or his/her legal representative. Consent is obtained with the recognition of the client’s freedom of choice and appraisal of conditions that may limit freedom of choice.

C. Art therapists display client art expression in a manner upholding the dignity of both the client and the profession.

D. Art therapists have the responsibility to interpret client art expression fairly and accurately in a manner that minimizes the possibility of misleading the public and other professionals.
ATTENTION AUTHORS

In order to help us process your submission more quickly, please complete the following information and attach one copy to your manuscript:

Guidelines for Submissions

All submissions will be acknowledged upon receipt by the AATA National Office. *Art Therapy* uses a blind peer review procedure for full-length articles and brief reports; final decisions regarding publication are made by the reviewers and the Editor. Decisions regarding submissions to other sections are made by the Editor, Associate Editor and special section editors.

The following are guidelines for developing and submitting a manuscript. Manuscripts that do not conform to these guidelines will be returned to the author without review.

**Manuscript Categories**

1. **Full-length Articles.** Full-length articles may focus on the theory, practice and research in art therapy or related areas. Manuscripts must include an abstract of approximately 75-125 words summarizing the major point of the article.
2. **Brief Reports.** Short articles which focus on the results of research are appropriate for this section. Manuscripts should include information on the research design, methodology and results; an abstract of approximately 75-125 words should also be included.
3. **Viewpoints.** Short articles focusing on personal experiences, poetry or original art may be submitted to this section.
4. **Book Reviews.** Reviews of books of interest to art therapists may be submitted at any time. Books which authors wish to have considered for review may be sent directly to the AATA National Office at the address listed above.
5. **Film/Video Reviews.** Reviews of media (films or videotapes) may be submitted at any time. Media which producers wish to have considered for review may be sent directly to the AATA National Office at the address listed above.
6. **Comments.** Brief comments on articles published in *Art Therapy*, issues critical to the profession and practice of art therapy, or letters to the Editor may be submitted to this section and should conform to the style of all other submissions.

**Other Requirements**

1. Send five (5) clear copies of each manuscript to Cathy A. Malchiodi, A.T.R., Editor, *Art Therapy: Journal of the American Art Therapy Association*, c/o AATA, Inc., 1202 Allanson Road, Mundelein, Illinois 60060. Neither AATA nor the Editor can be responsible for submissions sent to any other address.
2. Only original articles that are not under consideration by another periodical or publisher are acceptable.
3. Manuscripts must be typewritten on 8½” × 11” white paper with margins of at least an inch. The body of the paper, references, tables and quotations must be double-spaced.
5. An abstract of 75-125 words must be included with full-length articles and brief reports.
6. Please avoid footnotes wherever possible.
7. A cover sheet should be prepared to include the full name(s) and degree(s) of the author(s), professional affiliations, and the return mailing address of the author to whom correspondence can be sent. Authors’ names, positions, titles and places of employment should not appear in the body of the paper to assure anonymity and to facilitate blind review.
8. Use tables sparingly and type them on separate pages. Refer to the APA *Publication Manual* for style of tabular presentations. All tables, charts or diagrams must be legible and able to withstand reduction. Include originals and four (4) photocopies.
9. Photographs must be at least 5” × 7” and black and white glossy prints, preferably with high contrast. Photocopies of illustrations or art expressions are not acceptable for publication. Figure numbers and captions should be noted on the back of photographs; captions must be typed and submitted on a separate sheet of paper. Please refer to figures in the text as Figure 1, Figure 2, etc. Include four (4) sets of photocopies of original photographs.
10. Lengthy quotations (300 words or more from one source) or reproduction of works of art (this does not include client art expressions, which is addressed below) require written permission from the copyright holder for reproduction. Adaptation of tables or figures from copyrighted sources also requires approval. It is the author’s responsibility to secure such permission; a copy of the copyright holder’s written permission must be provided to the Editor immediately upon acceptance of the article for publication.
11. Client/patient confidentiality must be protected in the title, abstract, text, photos, illustrations and other accompanying material. Proper releases for use of client art expressions and other client information must be obtained and kept on file by the author.
12. It is expected that any manuscript accepted for publication in *Art Therapy* will go through at least one revision before publication. If authors have prepared their manuscripts on either an IBM, IBM-compatible or Macintosh computer, upon acceptance, they can send a 3.5” diskette containing an electronic copy of the manuscript to the AATA office. This will help speed processing, editing and publication.

**Note:** Authors bear full responsibility for the accuracy of all references, quotations and materials accompanying their manuscripts.
CHARLES C THOMAS • PUBLISHER

- Fryrear, Jerry L. & Irene E. Corbit—PHOTO ART THERAPY: A Jungian Perspective. '92, 220 pp. (7 x 10), 24 ill., $44.75.

PHOTO ART THERAPY: A Jungian Perspective illuminates and guides the reader through new possibilities for art therapy practice, approached by the authors as a creative interaction with different artistic media and therapeutic methods. Although the book is based on Jungian theory and practice, the authors carefully explore cooperation with other therapeutic perspectives, all of which are in keeping with Jung's belief in transcendent universals and multifaceted therapeutic practices. The book is divided into four sections: Self-Understanding, Alleviating Distress and Symptoms, Group Therapy, and Discussion. Wherever possible and practical, photo art therapy is done by clients as illustrations of the concepts included. The text not only demonstrates innovative ways of combining artistic media but allows clients to articulate the inner workings of the therapeutic process through an engaging series of dialogues and narrations. The book establishes a twofold landmark in elucidating art therapy's close and vital connections to both phototherapy and the discipline of Jungian psychotherapy.

- Moon, Bruce L.—ESSENTIALS OF ART THERAPY TRAINING AND PRACTICE. '92, 188 pp. (7 x 10), 21 ill., $35.75.

Central to the author's approach is the manner in which he believes the capacity of the beginning art therapist to come together in their efforts to learn and grow. The author demonstrates the deep, intimate, alive and complex training relationship that can lead to the awareness of meaning in the lives of both. The concern for authentic engagement in the training relationship enhances the beginner's ability to use the self to help clients learn to use art and artistic expression to identify and integrate new insights in their lives. The book is ultimately concerned with the use of art and the artistic relationship to promote personal growth. The author's deep understanding of both art and existentialism makes this book a high point in the evolving fields of existential psychotherapy and art therapy. It is an important contribution to the development of creative, effective psychotherapists who value human growth.

"Don’t tell" was a constant threat, but no one ever said, "Don’t draw a picture."

A Child’s Story: Recovering Through Creativity by Pat Harris is the personal story of an adult child-abuse survivor who finally is able to tell. Using her talent as an artist and with the help of a professional writer/friend, she reveals the steps of her recovery, from victim to survivor to activist.

KEY FEATURES
- Thirty-three full color reproductions of the artists work...
- Personal art, journal entries including poetry...
- Integration of professional insights through background essays on aspects of abuse, recovery and expressive therapies.

REVIEWER’S COMMENT
A Child’s Story provides the reader with an opportunity to view the intense images of sexual abuse and the artists healing journey. The book demonstrates the connection between the imagery of early traumatic memories and the healing power of creative expression. Pat’s discussion of sexual abuse literature provides a frame of reference for the emotional experience of interacting with the images, making it an excellent reference for therapists, educators and survivors.

— Mary N. St. Clair, MA, ATR, LCSE
St. Louis Institute of Art Psychotherapy—Director

BOOK EXCERPT
"What I painted or drew became my voice, my way of speaking those unspeakable feelings. Art is a means in which emotions can be retrieved before the survivor can verbalize the experience. After visual communication is accomplished, the story can be put into words, thus beginning the healing process."

— Pat Harris

STATEMENT OF PURPOSE: Art Therapy: Journal of the American Art Therapy Association is the official journal of the AATA, Inc. The purpose of the journal is to advance the understanding of how visual art functions in the treatment, education, development and enrichment of people. The journal provides a scholarly forum for divergent points of view on art therapy and strives to present a broad spectrum of ideas in therapy, practice, professional issues and research. An emphasis is placed on the use of the visual arts in therapy, but articles in related disciplines of interest to art therapists will be considered for publication.

ART THERAPY: JOURNAL OF THE AMERICAN ART THERAPY ASSOCIATION (ISSN 0742-1656) is published quarterly by the AATA, Inc., 1202 Allanson Road, Mundelein, Illinois, U.S.A. 60060. Telephone (708) 949-6064; FAX (708) 946-4580. Non-members may subscribe at the following annual rates: $40 (U.S.) and $54 (Foreign); Institutions: $57 (U.S.) and $83 (Foreign). AATA members receive the journal as a benefit of membership.

Single issues: For price and ordering information, call or write to AATA, Inc., 1202 Allanson Road, Mundelein, IL 60060 (708) 949-6064.

This Journal is abstracted in: Psychological Abstracts, Innovations & Research, Art Bibliographies Current Titles and Art Bibliographies Modern.

Advertising: Please see advertising rates listed elsewhere in this journal or contact the American Art Therapy Association, Inc., 1202 Allanson Road, Mundelein, Illinois 60060 (708) 949-6064. The publication of any advertisement by the AATA, Inc., is not an endorsement of the advertiser or of the products or services advertised. Art Therapy: Journal of the American Art Therapy Association—The First 10 Years

Cathy A. Malchiodi, MA, A.T.R., Editor

This issue of *Art Therapy: Journal of the American Art Therapy Association* marks an important turning point: Ten years ago, in October 1983, *Art Therapy*, Volume One, Number One was published. The American Art Therapy Association announced in the *AATA Newsletter* early in 1983 that it would “be producing a new professional journal, published solely by the association” (AATA, 1983a, p. 1). At that time, a subcommittee of the Publications Committee was appointed, including the following individuals: Barbara Katz Mandel, Georgiana Jungels, Frances Anderson, Mildred Lachman-Chapin, Linda Gantt, R. th Obernreit, Susan Michal, Judith Rubin, Harriet Wadeson, and Robert Wolf. This subcommittee worked to establish the journal’s first editorial policies, the criteria for selecting an editor, and the style and format for publication.

The first issue of *Art Therapy* was coordinated by Linda Gantt and Mildred Lachman-Chapin, two past AATA Publication Chairs, and Barbara Katz Mandel, 1983 AATA Publications Chair. Linda Gantt served as Interim Editor until a permanent Editor was found. In June 1983, a search committee was formed, consisting of Barbara Katz Mandel, Harriet Wadeson, Vija Lusebrink, Sandra Packard, and a professional consultant, Anita DeVivo, then Director of the American Occupational Therapy Association (AATA, 1983b). A job description for the first Editor of *Art Therapy* was announced (Ibid.); subsequently, Gary Barlow was appointed Editor for a four-year term, and continued in the capacity of Editor until 1991.

The emergence of *Art Therapy* as the official journal of the American Art Therapy Association came at an uneasy time in the organization’s history. The December 1983 issue of the AATA Newsletter reported, among other things, that the association faced a deficit for fiscal year 1983, the executive director had resigned, and the Annual Business Meeting was viewed by many members as less than congenial (AATA, 1983c). Apparently, there was also concern about protecting the journal from political influence within the association, as evidenced by a motion at the Annual Business Meeting that requested the “[AATA] Bylaws be revised to ensure the Journal’s independence from the Publications Committee” (Ibid., p. 2). Members’ rights to express divergent points of view in the *AATA Newsletter* were also reaffirmed through a motion from those in attendance (Ibid.).

Despite the apparent upheaval in the AATA, *Art Therapy* was underway with a spectacular inaugural issue. Not only was the publication of an AATA-sponsored journal impressive in and of itself, but the articles in that first issue also have major significance for the field today. Both Judith Rubin’s and Pat Allen’s observations on the life of Margaret Naumburg (who died earlier that year) provided moving accounts that have become standard readings on the history and foundations of the field. Don Jones’ verbal and visual reflections on being an art therapist also provided another important piece of history from a personal perspective, capturing the institutional world of several decades ago. He also articulately described the isolation experienced while practicing art therapy. Although the AATA has greatly expanded opportunities for communication with other art therapists, many of us can still relate to feeling isolated in the agency or hospital within which we work, just as Jones did in the ’40s.
Readers were also treated to a preview of John MacGregor's forthcoming book, _The Discovery of the Art of the Insane_ (1989), which would later become a highly respected text on psychiatric art. Frances Anderson provided an extensive analysis of the published research literature in arts for the handicapped, giving the reader an invaluable list of research studies related to the visual arts. Rawley Silver wrote the first of many articles for _Art Therapy_ on her investigation of how drawing tests can be useful in identifying and understanding children whose intellectual abilities may not have been apparent in traditional intelligence tests. Both Harriet Wadeson and Shaun McNiff provided personal perspectives on the art in art therapy (Wadeson) and a studio approach to art therapy (McNiff) in the first Viewpoints section of the journal.

Both Mildred Lachman-Chapin and Interim Editor Linda Gantt highlighted the importance of words in our work as art therapists. Lachman-Chapin raised questions about how we communicate with our clients and how we describe our work as art therapists to others, citing the need for articulation in both endeavors. Gantt explored the importance of the written word in another way, calling for a reexamination of the work of early writers and a continuous reevaluation of previously published art therapy literature:

Our Janusian look must not be reserved for the beginning of new projects but must be our customary stance as we take stock of our successes and failures, always with an eye to improving the published literature, the foundation of our field. (1983, p. 3)

In some ways, the profession of art therapy has come a long way since the publication of the first issue of _Art Therapy_; in other ways it has remained the same. The isolation experienced by art therapists in a mental health setting that Jones observed still exists to some extent, although not as acutely as when he first practiced. Anderson's observation that art therapists must begin to utilize research methodology in addition to the traditional case study if they are to expand the field and be accepted by both professionals and political bodies which regulate mental health services, still holds true today. Additionally, the role of art in art therapy explored by both Wadeson and McNiff continues to resurface as art therapists redefine their roles with client populations and with other professionals.

Gantt made the following observation concerning the field of art therapy and the profession in general in the first _Art Therapy_ editorial:

The 1980s will be a critical period in our profession's development. We will be forced to show how art therapy is both distinct from and similar to allied fields, for on such distinctions rests our future, our training programs, our positions, and our prestige. (1983, p. 3)

It seems that the 1990s will provide the profession with challenges similar to those that Gantt spoke of over a decade ago. On this, the tenth anniversary of the first publication of _Art Therapy_, it is fitting to reconsider Gantt's observation with an eye toward improvement not only of our published literature, but our overall profession.

Response to Commentary by Pat Allen, PhD, A.T.R.

In my review of Shaun McNiff’s *Art as Medicine* I tried to give an objective view of the introspective nature and richness of McNiff’s writing and images, while objecting to some of his subjective generalizations about other art therapists and their approaches.

McNiff’s book is a very good example of the heuristic method of inquiry. At the same time it points out the drawbacks of this method, which are further brought into focus by Pat Allen’s commentary in *Art Therapy: Journal of the American Art Therapy Association*, 10(3), p. 129. First, the subjective approach is valid when used to describe the individual’s experiences, but it raises problems if used to address issues pertaining to the public domain, namely in McNiff’s case, to make personal judgments about approaches used by other art therapists. As we can see in Allen’s commentary, the subjective nature of heuristic studies may evoke different perspectives from different readers, depending on the reader’s viewpoint, and render the responses too personal and subjective instead of creating a dialogue.

The second drawback of the heuristic approach is the possible overemphasis on a singular approach. In this case, the emphasis is on a particular view of imagery and the use of art therapy, instead of a more objective recognition of the evolving nature of the latter.

Art therapists have already fought the battle of art as therapy versus art as psychotherapy in the past. Hopefully, the present duality of the art studio approach as emphasized by Allen and the diagnostic and analytical perspectives that presumably dominate all other art therapists’ work as defined by McNiff will not precipitate a conflict repeating the past in regard to the exclusiveness of a particular approach as the only acceptable one.

The sequential duality in the development of concept formation has been eloquently described by Arnheim:

Percepts are generalities from the outset, and it is by the gradual differentiation of those early perceptual concepts that thinking proceeds towards refinement.

However, the mind is just as much in need of the reverse operation. In active thinking, notably in that of the artist or the scientist, wisdom progresses constantly by moving from the more particular to the more general. (1969, p. 186)

Similarly Wolfflin (1950), in his treatise on the development of style in later art, pointed out that in occidental art there were changes from linear, planar, and closed forms to painterly, recessive, and open forms, and from multiplicity and absolute clarity of the subject to unity and relative clarity of the subject. These changes were “recommenced” again around 1800 and replaced by a new “linear” mode of vision.

Wolfflin stated that “a closer inspection certainly soon shows that art even here did not return to the point at which it once stood, but that only a spiral movement would meet the facts” (1950, p. 234).

These descriptions of the development of percepts, concepts, and artistic styles could be taken as similes for the development of art therapy.

The earlier implied duality in this view can be accepted as another evolutionary step in art therapy. Such a larger view does not need to deny the validity of different approaches nor the existence of the multiple components of art therapy.

Letter to Editor

As former chair of AATA’s Publications Committee, I certainly encourage debate in the pages of AATA’s publications and applaud Art Therapy for printing Pat Allen’s disagreement with Vija Lusebrink’s review of Art as Medicine by Shaun McNiff. I was in McNiff’s place a number of years ago, and was appreciative of a reaction letter to a re-
view of one of my books (Arthur Robbins and Donna Bassin. (1980). American Journal of Art Therapy. (20) 78.)

I am writing this letter, however, not to applaud but to decry. Healthy debate is one thing; inflammatory characterization of a colleague is another. I am referring to Pat Allen’s letter’s opening paragraph in which she conjures an image of Lusebrink as “a waspish schoolmarm, lips pursed, ruler at the ready.” In the next paragraph she states, “the ruler comes down” (Art Therapy, 1993, 3(10), 129). Although seven paragraphs later Allen states that “the waspish schoolmarm is an archetype that lurks in each of us,” the characterization of Lusebrink sticks as Allen objects to many of her points throughout the letter. In the same issue, a letter from Bruce Moon offers another reaction to Lusebrink’s review. Moon makes points similar to Allen’s; however, in contrast to Allen, Moon does not couch his arguments in unflattering imagery, but states them in a forthright manner. (It is curious to note that Allen’s letter is placed after the editorial at the beginning of the issue under Commentaries, whereas Moon’s letter is placed near the end of the journal.)

It is ironic that the same issue of the journal contains AATA’s Code of Ethics: “Art therapists act with integrity in regard to colleagues in art therapy” (p. 184). At best Allen’s characterization of Lusebrink is unprofessional. This sort of imagery regarding a colleague perpetuates an ugly aspect of AATA’s history that has been besmirched by inflammatory name-calling. One prominent art therapist called another a Nazi in a widely circulated letter; I was labeled “a true master of double think and newspeak . . . foretold by Orwell in Nineteen Eighty-Four” in the AATA Newsletter, 1984, (XIV); a prominent art therapist accused another of having his hand in AATA’s till in a local publication; and on and on.

I believe it is the responsibility of Art Therapy’s Editor and Editorial Board to urge contributors to write in a professionally responsible manner if their submissions are to be published. Although inflammatory imagery is sure to draw reactions (I doubt this letter will be the only response), it’s a cheap way to inspire debate.

Chicago, Illinois

Letter to Editor

Superlative! Bravo! Timely! Provocative! Honest! Challenging! All these words were on my lips at some time during my reading of the current issue of Art Therapy (Volume 10, Number 3, 1993). I just received the journal in the mail today and all other mail waited as I couldn’t stop until I’d read every word! First time that’s ever happened! The theme—Professionalism—couldn’t be more appropriate at this time and is a topic sorely needed in the ranks of art therapists.

Your Editorial hit the nail on the head making it increasingly difficult to continue to ignore the need for professionalism. Jeanne Carrigan’s article on ethics challenged us further to get our act together. Debbie Good’s history of New Mexico’s licensing was an inspiration and goal to strive for in many other states—one true success story. Millie Lachman-Chapin’s dilemma of the iden’ty conflict between art therapist and exhibiting artist is familiar to us all and seemed to mirror the dilemma of our professional existence and behavior as does Maxine Junge, et al. (although “The Challenge: Toward Community” with which this article concludes reinforced ING’s work in building “. . . a global community in which human growth is prized.” I have just witnessed the most generous sharing and exchange at our conference in Vilnius, Lithuania with plenty of courage and vision to ensure ongoing expansion and growth). Rawley Silver’s research study set a fine example of professional achievement—a model for us all. Gail Wirtz’s cautions to art therapists in private practice definitely needed to be said, more importantly they need to be heeded. This seems to be an area of enormous ignorance and elective blindness among art therapists. Ms. Wirtz gave us a much needed eye-opener!

I appreciated the dual reviews of A Child’s Story: Recovering Through Creativity and found the response to a previously published review of Shaun McNiff’s book to be refreshing in offering an alternative viewpoint.

Congratulations on a job very well done. Don’t lose your looking glass into the future. There will be much more need for it with the issues ahead! Keep up the good work!

Bobbi Stoll, MFCC, A.T.R.
The Effects of Art History-Enriched Art Therapy on Anxiety, Time on Task, and Art Product Quality

Carol L. Miller, MA, A.T.R. Glen Oaks, NY

Abstract

The effects of an art history enrichment art therapy task on anxiety, time on task, and art product quality among chronic adult psychiatric day hospital patients were investigated using a repeated-measures, quasi-experimental design. State-anxiety was measured with the State-Trait Anxiety Inventory (Spielberger, 1983). Art product organization level was assessed with the Art Description Scales (Miller & Miller, 1992). The results indicated the art history enrichment task reduced anxiety (p < .05) and increased time on task (p < .002). Art organization level tended toward a significant increase (p = .075) compared with a control condition. The findings are congruent with the literature concerning supportive art therapy and suggest that the use of art history enrichment in art therapy may be helpful with this population.

Introduction

Chronic psychiatric patients in a long-term day hospital present a number of challenges to the art therapist. Patients in the art group often complain about the difficulty of concentrating on the art task; they frequently lack the motivation to continue, show signs of restlessness, and sometimes express negative feelings about art.

In a research paper written in 1975, Young concluded that supportive art therapy which uses the creative process and instruction in art techniques to enhance self-esteem and self-identity was a successful approach with chronic psychiatric patients, particularly those suffering from schizophrenia, who were short-term inpatients. Using supportive art therapy with a day hospital adult population, what specific kinds of art tasks would be most helpful to reduce anxiety and thereby encourage sustained participation in the art activity?

Art therapists have developed structured art directives found to be therapeutic with schizophrenic patients (Honig & Hanes, 1982; Landgarten, 1981; McNiff, 1976; Moriarty, 1973). I have developed an art directive which seems to engage patients in the creative process—the use of art history as an introduction to the art task. Art history, which includes anecdotal biographical material as well as discussion of the artistic style, seems to validate the art task as an adult activity. The art task presented to the group includes selected elements derived from the art. I have also observed clinically that art history enrichment appears to result in better patient attendance, more sustained participation during art therapy sessions, and higher quality artistic products. The research reported in this article explores this approach quantitatively by examining the effects of art history enrichment before the art task on patients' levels of anxiety, the time they spend on the art task, and the

Editor's Note: The author wishes to thank Frances Kaplan, Coordinator of the Creative Arts Therapy Program at Hofstra University, for her thoughtful help in preparing this manuscript, and the author's husband, Michael, for his assistance with the data analysis and scale construction.

Requests for reprints or inquiries concerning the Art Description Scales should be sent to Carol L. Miller, Department of Psychiatric Rehabilitation, Long Island Jewish Medical Center, Hillside Hospital Division, Glen Oaks, NY 11004.
quality of their artwork. The findings of this study could be helpful to art therapists who wish to reduce patient anxiety among their chronic psychiatric patients, increase patient involvement and participation in the artistic process, and improve the quality of patients' art products (Kramer, 1971).

**Review of Related Research**

A search of the literature revealed no quantitative research in the area of art therapy and anxiety reduction. Young (1975) found, in a primarily observational study of chronic schizophrenic inpatients, that structured, supportive art therapy gave patients "a sense of security in working towards a definite goal—that of improved technique and mastery of art skills" (p. 115). She compared three treatment and control groups and found that the schizophrenic patients "were not able to relate actively to an insight-oriented art therapy program" (p. 101).

Drawing upon Young's work, in two reports about the same experiment, Borchers (1985) and Green, Wehling, and Talisky (1987) explored the effectiveness of supportive art therapy with chronic psychiatric patients attending an aftercare clinic in an experimental, quantitative study. Patients in the art therapy group showed significant improvement on two measures of the Progress Evaluation Scales: "Getting Along with Others" and "Attitude Toward Self" (Ihleivich & Gleser, 1982), with $p < .05$ on both, but not on the Rosenberg Self-Esteem Scale (1965). "Seventy percent of the subjects reported feeling relaxed after the sessions" (Green, Wehling & Talisky, 1987, p. 990).

Honig (1977), writing about her structured work with schizophrenic patients, stated that "the loose, permissive, creative, or spontaneous approach often increased anxiety and confusion" (p. 100). Honig and Hanes (1982) discussed how the art therapist can intervene to alleviate such confusion and fear with a series of tasks that address specific areas of psychopathology. These authors mention relaxation and anxiety reduction as possible benefits from using a structured art therapeutic approach. The research reported here attempts to document in a quantitative study whether this symptom reduction is an objective, observable, therapeutic outcome when art history is used to enrich and structure the art task, as compared with a low-structured control condition. In addition, I observed the art history-enriched condition's effect on the time patients spent on the art task and the level of organization of their art products.

**Hypotheses**

Research groups were formed and data were collected and analyzed to prove or disprove the following hypotheses.

1. There will be a significant reduction of anxiety under the art history experimental condition, while anxiety reduction under the control condition will not be significant.
2. The time spent on the art task under the art history experimental condition will be significantly greater than under the control condition.
3. The level of organization of the artwork will be significantly greater under the experimental art history condition than under the control condition.

**Method**

**Research Participants**

The sample consisted of 13 adult, day hospital patients, eight females (61.54%) and five males (38.46%). Their ages ranged from 24 to 58, with a mean of 35.23 and standard deviation of 9.97. The patients' primary diagnoses included five with Affective Disorder (38.46%), five with Paranoid Schizophrenia (38.46%), and three with Schizoaffective Disorder (23.8%). Patients had been participating in the art therapy group from 1 week to 52 weeks, with a mean of 16.46 weeks and standard deviation of 13.97. All but one patient had been in the group 24 weeks or less.

**Instruments**

The Spielberger Self-Evaluation Questionnaire, also known as the State-Trait Anxiety Inventory (STAI, Form Y-1) (1983), was used to measure participants' anxiety. Form Y-1 is a 20-item scale that evaluates how respondents feel "right now, at this moment," as it was designed to measure the patient's current state of anxiety. The State form (Y-1) is more sensitive to small changes than the Trait form (Y-2), which measures the more enduring trait of anxiety. The S-Anxiety scale has shown high internal consistency: alpha reliability is 0.92. Because it was developed to be sensitive to fluctuations in situational stress, reported test-retest correlations are low, as would be expected. "The S-Anxiety scale has been found to be a sensitive indicator of changes in transitory anxiety experienced by clients and patients in counseling, psychotherapy, and behavior-
THE EFFECTS OF ART HISTORY-ENRICHED ART THERAPY

modification programs” (Spielberger, 1983, p. 2). Spielberger states that “to assess changes in anxiety over time, it is recommended that the S-Anxiety scale be given on each occasion for which the measure is needed” (pp. 3–4). The scale has been shown to have good validity, both with psychiatric and normal populations and has been used in research and clinical practice for over 20 years.

In addition to being psychometrically sound and well-developed, the S-Anxiety scale has the advantage of being brief and easy to administer within 5 or 10 minutes to a group. In addition, the scale does not contain upsetting content, which could have negative effects on disturbed patients.

Time spent on the art task was obtained by observing how long individuals took to complete their artwork. Because I was concurrently involved with art materials, helping patients, giving directions, and administering the anxiety pretests and posttests, time spent on task was estimated to the closest 5-minute interval.

The Art Description Scales (ADS) (Miller & Miller, 1992) were used to assess the quality of the artwork. Arnheim (1950) felt that “a person’s best achievement bears therapeutic fruit, not obtainable from a lesser effort” (p. 249). The ADS were developed for this study to measure the level of organization in the artwork, i.e., use of clear forms, structure, organization, closure, etc. The instrument contains 10, seven-point, semantic-differential scales emphasizing cognitive control and organization. The 10 items are summed to yield a total score which can range from 10 to 70. Internal consistency coefficient alphas range from 0.975 to 0.982 for the three raters: an activities specialist, a PhD counselor, and myself. Inter-rater reliability coefficients ranged from 0.779 to 0.922, with a mean of 0.841. The scales appeared reliable and internally consistent enough to use in research.

Each rater independently assessed the 26 paintings (13 control group, 13 experimental) which were intermixed and presented in the same randomized sequence. To obtain as unbiased a measure as possible, the total scores of the three raters were summed for each painting. Organization level scores for this study could range from 30 to 210.

Procedure

The research design used was a single-group, time series (Cox & West, 1982), which is a quasi-experimental design, similar to Campbell and Stanley’s equivalent time-samples design (1966).

The research took place on two successive Wednesday morning sessions of 1½ hours each. Although I believe a greater separation between group sessions could counteract the "practice effect," time constraints required the experiment to be done in two consecutive weeks.

Seventeen patients (the low-structured control group) were given the Self-Evaluation Questionnaire at the beginning of Session I. The patients were identified by research numbers on the scale, rather than by patient names, to provide anonymity. After collecting the questionnaires, I asked the group to do an art task by saying, "Paint freeform shapes" (the temperas were placed on the work table, 12" × 18" paper was distributed as well as brushes). The patients were therefore given some structure since the present research focuses on art history enrichment rather than unstructured versus structured art tasks.

It was announced at the beginning of the session that patients should not leave before submitting their artwork and receiving another questionnaire. After patients finished work on their paintings, the time spent on the art task was noted, and they received the posttest questionnaire.

At Session II, the art history-enriched experimental group, the same procedure was followed in administering the pretest, this time to 15 patients of whom 13 were in Session I. The same art materials were used, but the art directive included an introductory mini-lecture about Kandinsky, his career, and the beginning of nonobjective art, together with illustrations of his work. In addition, I gave information about how to structure the painting—by drawing three curving lines across the paper that intersected with each other at a few points. At the end of Session II, patients submitted their work and completed the posttest questionnaire. Again, the time patients spent on the art task was noted.

Method of Data Analysis

The anxiety scores, time spent on the art task, and ratings of the art organization level were analyzed by using both paired-comparison t tests and Wilcoxon signed-rank tests (nonparametric tests) since the sample size was only n = 13 and assumptions about normality and equal variances required in the t test may not have been warranted.

For the anxiety data, a comparison of pretest versus posttest scores was made—first, for the control condition, and then for the experimental condition.
Results

Hypothesis 1 stated that there would be a significant reduction in anxiety under the art history experimental condition, while anxiety reduction under the control condition would not be significant. The results of the data analysis for anxiety are shown in Figure 1.

In the low-structured control condition, the mean anxiety score dropped from a pretest of 39.154, \(SD = 12.453\), to a posttest of 36.615, \(SD = 12.790\), \(t(12) = 1.26, p = .1558\) (one-tailed test), or nonsignificant. Although patients’ anxiety levels dropped during the low-structured, control condition, the decrease was not significant.

In the experimental condition, using art history enrichment, the mean anxiety score was reduced from a pretest of 38.846, \(SD = 13.24\), to a posttest of 35.692, \(SD = 11.426\), \(t(12) = 1.814, p = .0474\) (one-tailed test), significant at the .05 level. The observed decrease in patients’ anxiety levels during the experimental condition was significant.

To ensure that these results would remain significant under nonparametric tests, the Wilcoxon signed-rank test showed for the control group \(Z = -1.112\), corrected for ties, \(p = .1331\) (one-tailed test), or nonsignificant. For the experimental group, \(Z = -1.931\), corrected for ties, \(p = .0268\) (one-tailed test), significant at the .05 level. Both the \(t\) tests and Wilcoxon tests support hypothesis 1.

Hypothesis 2 stated that the time spent on the art task under the art history experimental condition would be significantly greater than under the control condition. The results of the data analysis for time spent on the art task are shown in Figure 2.

Figure 2 shows that the mean time spent on the art task during the control condition was 33.077 minutes, \(SD = 17.505\), with the mean time under the experimental condition being 47.692 minutes, \(SD = 9.04\). The \(t\) test showed \(t(12) = 3.916, p = .0011\), significant at the .002 level. The Wilcoxon signed-rank test showed \(Z = -2.675\), corrected for tie, \(p = .0038\) (one-tailed test), significant at the .005 level. Patients working under the experimental condition spent a significantly greater amount of time on the art task than they did under the low-structured, control condition. The results supported hypothesis 2.

Figure 3 shows frequency distributions of the time spent on the art task under the control and experimental conditions and graphically indicates the increase in time spent on the art task when art history introductory enrichment was used compared with the low-structured control condition.

Hypothesis 3 stated that the level of organization of the artwork would be significantly greater under the experimental art history condition than under the control condition. Figure 4 shows the sum of the three raters’ assessments of the art products under the control and experimental conditions using the Art Description Scales.

The mean of the summed ratings of art organization level for the control group was 127.077, \(SD = 48.82\), while the mean rating for the experi-

---

**Figure 1.** Art History Effects on Anxiety.

**Figure 2.** Art History Effects on Time on Task.
mental group was 147.231, \( SD = 40.803, t(12) = 1.546, p = .074 \) (one-tailed) test. A Wilcoxon signed-rank test showed \( Z = -1.433, p = .076 \) (one-tailed test). The mean global ratings of artwork organization level increased under the experimental condition. Since \( p < .10 \), the increase tended toward significance.

Hypothesis 3 received some support: The increase in level of organization from the control to the experimental condition tended toward significance.

**Discussion**

Hypothesis 1 stated that anxiety reduction under the art history experimental condition would be significant, while anxiety reduction under the control condition would not be significant. The results of the data analysis lend support to this hypothesis, as there was a statistically significant reduction observed in the experimental condition. Although the anxiety decreased in the control condition, it did not decrease significantly.

Hypothesis 2 stated that art history enrichment would result in patients becoming more involved in the art task and therefore spend more time on it than under the control condition. This hypothesis was strongly supported by the data. Patients spent an average of 15 minutes more on the art task in the experimental group than in the control.

Hypothesis 3 predicted that the art history enrichment would be associated with higher levels of organization in patient artwork. The results of the ratings on the Art Description Scales tended to support this hypothesis. Although the organizational level of artwork was higher in the experimental condition, it did not quite reach the .05 level of significance (\( p = .074 \)). Even in the control condition, many patients produced art at fairly high levels of organization, possibly because some structure was provided. Also, many of the patients had been in the group for several months and may have increased their art organizational level before the experiment was conducted.

Overall, the hypotheses of this study were generally supported. The use of art history enrichment appears to have a beneficial effect on chronic adult psychiatric day hospital patients’ emotional states (anxiety) and behavior (time spent on the art task, involvement in the art process). Also, there is some suggestion that quality of artistic output may have increased, although this only tended to reach significance. The impact of these observations may be that patients’ self-esteem also increased, although this was not measured.

While Honig and Hanes (1982) have developed a detailed series of art therapy tasks to enhance mental functioning with chronic patients in long-term residential treatment and Young’s use of a teaching approach was beneficial to chronic patients in a short-term psychiatric unit (1975), the art history enrichment of the present study was developed for stabilized, but chronic, day hospital adults who need to build interpersonal skills and strengthen ego devel-
opment over a 6- to 12-month time span. In order to achieve this, they need to become involved with the art activity, as well as the group. Among this population, art history enrichment reduces anxiety and involves the patients with their work so that they are better able to develop skills and improve concentration. As with any therapeutic treatment, the age, socioeconomic class, diagnosis, time in program, and capabilities of the patient (Young, 1975) are factors to be considered when deciding if art history enrichment is an appropriate therapy.

Green, Wehling, and Talsky (1987) reported that patients felt more relaxed after art therapy sessions. The present study supports these authors' observations with a standardized measure of anxiety. A number of writers have discussed the value of the addition of art education to art therapy with particular patient groups (Arnheim, 1980; Erikson, 1979; Kramer, 1971; Talercio, 1986) as being supportive to ego development and a sense of identity by helping the patient focus on his or her strengths and abilities through the "creative problem solving process ... from interactions with art products and processes" (Congdon, 1990, p. 19).

Beyond anxiety reduction and task involvement are broader goals: (a) the creation of a valued art product through which the patient can integrate elements of his/her personality through line, shape, and color; McNiff (1976) and Arnheim (1980) believe that quality of the artwork can help in the healing process; (b) learning to manipulate a variety of art materials that are an "extension of the self" (Erikson, 1979, p. 79); and (c) becoming part of a community with fellow artists when artwork is displayed and discussed, as well as becoming part of the larger community in hospital and community exhibits.

Although the reduction of anxiety in the control condition was not significant, it was observed to decrease somewhat by the end of the session. This may be because some structure, although not a great amount, was provided by the therapist. For some patients, the art activity itself may have had a modest effect on reducing their anxiety.

It was expected that patients would spend more time on the task in the art history enrichment group than the control group, but it was surprising to see how little time patients spent in the low-structured control group. Many patients were uninvolved and eager to leave the art therapy studio. A possible explanation for this observation is that patients may have been used to more structure from previous experience in art therapy groups. It should be noted, however, that art therapists agree that in comparable settings, low task involvement and consequently short time spent on the art task are typical responses from chronic psychiatric patients in an art therapy group.

Questions raised by this study include: (a) Would the art therapy reduction of state-anxiety (Spielberger, 1983) over a longer period of time, i.e., several sessions, result in measurable reductions in trait-anxiety, which is defined to be a more enduring characteristic (Spielberger, 1983)? (b) Does the art history enrichment which improves the quality of the patient's art product then lead to enhanced patient self-esteem? (c) Can the assessment of the art product examined in this study (art organizational level) be used to monitor and assess patients' overall response to the art therapy program?

The findings of this study may contribute to the practice of art therapy by providing empirical support for using an intervention of art history enrichment to promote symptom reduction, patient involvement, and higher quality art products. For this reason, it might be important for art therapists in training to have an art history course in addition to studio work.

As with all research, this study has many limitations: mixed diagnostic categories in the group, which may moderate results, the nonrandomness of the sample (for external validity), the small sample size (n = 13), possible practice effects from frequent test repetitions, and not observing anxiety reduction over a greater period of time, so as to make the findings more useful in treatment planning. Although there was not a separate control group, some researchers feel a group can serve as its own control, ensuring that it is comparable to the control group, thereby reducing error variance (Winer, 1962). Some confounding variables that were not controlled include the number of weeks patients had attended the group and the time patients took their medication in relation to the time the art group met (as some patients get very sleepy from their medication, while others get restless). Since I served both as art therapist and researcher, I may have acted in a way to bias results. Also, a small number of patients asked questions about the meaning of words in the Self-Evaluation Questionnaire. Suggestions for further research include addressing the questions raised and the concerns about the limitations just stated and further developing and refining the Art Description Scales, which could be useful in evaluating other art therapy approaches.
Conclusion

The structured art therapy program with art history enrichment is successful in helping patients who do not respond easily to other art interventions to spend a sustained period of time at a task and to be satisfied and pleased with their art products, according to their verbal accounts. They are observed to be more connected to the group because of the greater time spent in the group and evidence more joy while in the process, when a lack of affect is the norm. Their voluntary attendance usually results in a "full-house," and patients are shown a way to use their time enjoyable and productively by becoming connected to the larger world of artistic traditions and culture generally.

Ulman (1977) correctly forecast: "Looking ahead, it appears that art education therapy, thus far used mainly with younger people, may find a growing currency in work with adults. It has been predicted that what I termed 'the therapeutically oriented art class' may become a part of the treatment offered adults in the growing numbers of community mental health centers" (p. 16).

Finally, an art educative approach seems to communicate to patients that the staff has not given up on them. The very act of teaching information, concepts, skills, and techniques with seriousness and care imparts the unspoken belief and hopefulness that the patient can learn to join the larger world of people and events.

Using Visualization and Art to Promote Ego Development: An Evolving Technique for Groups

Abstract

A technique was devised for promoting specific aspects of ego development in groups. In its current form, this procedure employs two visualization and art experiences and is guided by two therapeutic models, transactional analysis and existential therapy. Loewinger's conception of ego development provides a larger framework in which to place the experiences and their accompanying models and offers a hierarchy of treatment goals. Details of the procedure, along with the supporting rationale—including a description of Loewinger's scheme—are presented. Examples from applications of the procedure are also discussed, and directions for further investigation are indicated.

Introduction

The purpose of this report is to present a group art therapy procedure, our experiences in using this procedure, and a supporting theoretical framework. Designed to promote specific aspects of ego development, the procedure has the primary goals of enhancing self-esteem, improving interpersonal relating, and increasing awareness of personal values. Two therapeutic models, transactional analysis and existential psychotherapy, are used to inform a process that involves two visualizations with accompanying art expressions. Our procedure is in a preliminary form, and conclusions regarding its efficacy should be considered highly tentative. We offer it as work in progress that exemplifies one direction in which the boundaries of art therapy can continue to expand.

The Ego Development Scheme

Our aim is to promote optimum mental health rather than to address psychopathology. We assume that the more mature the individual, the more resources that person will have to deal with life's problems—including mental illness. Marie Jahoda (1958) has discussed how "positive mental health" goes beyond adjustment, normality, or absence of mental illness, and Jane Loewinger (1976) has identified this definition of mental health as consistent with the highest level on her ego development scale. To fully appreciate the benefits of coming as close as possible to this ideal, it is necessary to examine Loewinger's formulation.

Building upon an existing body of developmental theory and informed by empirical study, Loewinger devised both a theory of ego development and a means for measuring this concept (Loewinger, 1976; Loewinger & Wessler, 1970; Loewinger, Wessler, & Redmore, 1970). In her scheme, ego development is defined as a hierarchy of 10 invariant stages and transitional levels. Passage through these stages results in changes in impulse control, moral style, interpersonal relations, conscious preoccupations, and cognitive complexity (see Table 1).

After early childhood, the ego-development

</table>

Note: Beginning with the 1-4 stage, descriptions are cumulative. Content of table based upon material found in Holt (1980), Loevinger (1970), and Loevinger and Wessler (1970).

Stages are relatively independent of age. That is, individuals can cease development at almost any point on the scale, and there is evidence that many do not progress very far. For example, research using Loevinger's sentence completion test of ego development strongly suggests that the Self-Aware (1-\(\frac{1}{4}\)) level is the modal level for adults in our culture (Holt, 1980). Characteristics of this level, such as "painful self-criticism," clearly stand in the way of optimal psychological functioning.

More favorable characteristics are found as we inspect the higher levels. Note that self-respect (1-4), true tolerance (1-\(\frac{3}{4}\)), concern for broad social perspectives (1-5), and being broadly empathic (1-6) are located in succession at the upper end of the scale. This suggests that healthy ego development involves a gradual consolidation of a sense of self along with a progressive decrease in egocentricity and a turn toward altruism. For therapists who wish to promote ego development, a complex approach that includes self-esteem building, interpersonal skills training, and values clarification seems indicated. For art therapists working in this area, visual tools that facilitate psychological differentiation and integration are required. Previous work (Lusebrink, 1990) suggests that mental imagery may well be such a tool.

Visualization as a Tool for Art Therapy

Visualization is the formation of a mental picture. This working definition involves the conscious creation of an image or images. Visualizations have been created for the purpose of healing disease (Epstein, 1989), for the purpose of relaxation and stress...
Visualization was our method of choice because of the powerful results imaging has reportedly produced in recent years (Korn & Johnson, 1983). Epstein (1989) states that research has not examined the phenomenon of healing through imagery in a methodical way, but drawing upon clinical experience, imagery has been found to reinforce healing of both the mind and the body. There are a variety of ways to construct visualizations, which makes them very adaptable to particular needs. One is receptive visualization (Fanning, 1988). After the initial relaxation stage, the participants retrieve their own set of feelings and images. There are minimal prompts, and the participant’s mind is allowed to wander and seek its own place. Another approach is programmed visualization (Fanning, 1988). Here the individual responds to guided imagery—either self-directed or guided by another. Programmed visualization is used to help a person accomplish something specific, such as more effective public speaking, increased assertiveness, or athletic achievements. Our visualizations use a combination of receptive and programmed visualization. This seemed most appropriate for our purposes because we wished to achieve a specific, yet broadly defined, goal.

Visualization and Art Experiences

Practitioners of growth-promoting therapy have recommended use of more than one therapeutic model (Corey, 1985; Wadeson, 1987; Wilber, En- gler, & Brown, 1986). For this reason, we have chosen two models consistent with our philosophies and experience.

Transactional Analysis Visualization

Both transactional analysis (TA) and art therapy use action-oriented techniques which coincide with their respective principles. Often art therapists will use an art directive and then discuss the production (Landgarten, 1981). Therapists using TA are concerned with communication within the patient’s system of relationships. They analyze interactional patterns and teach the principles to the patient (Berne, 1961). Combining the two therapies seemed natural and appropriate for our purposes.

The concept of ego states—adult, parent, child—is the cornerstone of TA theory. Keeping this in mind, we designed the directives and visualization to be given while participants are in the adult, or mature self, state. TA also teaches that people are motivated by the need for “strives.” Thus, we developed an art directive with the intent of creating a positive feeling, a positive image, and eventually a positive stroke. Berne (1961) has proposed that promoting such positive interactions is ego-building. It would appear to follow, then, that this encourages movement toward a higher developmental stage.

A short relaxation is used to prepare for this visualization. This relaxation exercise is given in the style of Epstein (1989), who differentiates between relaxation that induces a semisleep state for the purpose of lowering stress and relaxation in which the participant actively works on the imagery. The directives for the relaxation and visualization are as follows:

This art expression has a few steps to it. For this exercise you will be working with a partner. You will be choosing someone from this group who you do not know and will be spending time conversing together. One of you will begin speaking about anything of interest to you at this time—why you are here, your professional interests, personal goals, personal history—just anything you feel like sharing. Your partner will begin by listening but is invited to ask questions and join you whenever appropriate. Then you will re-verse the process. You will have approximately 3 minutes each. I will alert you when to switch. You may find your partner now.

[Following completion of the conversation] Relax in your chair, and if you feel comfortable, close your eyes while we start with deep breathing. First exhale, with the exhale being long and relaxing. It should be twice as long as the inhale. Now inhale, exhale, inhale, exhale. Now think of the partner you were talking with and think about one of the qualities you noticed that was positive—something you noticed about that person that made you feel good, that you admired, that you recognized as special. Now, still breathing and relaxing, feel that good quality, that trait that you liked, or the positive aspect of your partner’s personality. Take it inside you and feel it while you notice how it looks. Notice the shapes of it, the colors, the lines, if there are patterns. Feel it and notice the special imagery that is coming to mind. Stay with the imagery and feel it as you see it. Still relaxing, enjoy the imagery. When you have that imagery and when you feel it, then, still staying relaxed and seated, you may open your eyes. When you are
ready, you may begin your artwork. Begin to portray the positive quality, trait, aspect of your partner that you just pictured. You will have 15 [or longer] minutes for the artwork.

[Following completion of the artwork] You are going to give your partner the artwork. Give your artwork and describe what the quality is and how it looks to you. When you give it to your partner, your partner will receive it and state the quality by saying "I am . . ." and briefly describe the images using "I am." Then you will receive your partner’s artwork. When you have finished, we will have time for a discussion.

Existential Therapy Visualization

The primary focus of the existential approach to therapy is dealing with ultimate concerns: freedom, isolation, meaning, and death (May, 1983; Yalom, 1980). Assuming responsibility for one’s own existence is of primary importance for this process—as is the development of values. It is through connections with others and with the world that personal values are discovered and refined.

We contend that the tenets of existential therapy offer an orientation for helping clients achieve the ego-transcending traits of the higher levels of the ego-development scale. (It is a paradox of ego development that, in a sense, one has to lose oneself in order to find oneself.) More a philosophy than a set of techniques, the existential approach provides a world view that can guide the art therapist in creating growth-promoting activities (Moon, 1990). It is just such a viewpoint that has inspired the following visualization:

Imagine that you are taking a journey—a journey into space. Imagine the space capsule here in the center of the room. You make your preparations and climb into the capsule. Now the roof is rolling back and the capsule is ready for flight. Now you begin ascending into space. You are seated by a window and, as you ascend, you enjoy the changing view. You see the [school, hospital, workshop setting] getting smaller and smaller. You see the [city, town, surrounding countryside] spread out before you. It is very beautiful. You ascend still further—up and up—until you can see the curvature of the Earth and then the entire earthly sphere that we call home. As you look, images of what means the most to you about our world begin to appear. Slowly, your spacecraft begins to circle the Earth. Slowly the images of what means the most to you become clearer. As you travel, you are entranced as you view the shapes of the continents passing beneath you, and you are struck by the observation that there are no discernable boundaries between countries—that each merges into the other—that each is a part of the whole. As you continue to circle the Earth, you think of the world’s troubles and you begin to see images of how you would like the world to be. As you continue on your journey these images of how you would like the world to be become more and more vivid. Slowly you complete the circle—slowly you begin to descend—slowly you return to this room, bringing with you memories of the beauty of the Earth, bringing with you the images of what means the most to you, bringing with you the images of how you would like the world to be.

When you are ready, make a picture about this experience. You will have 15 [or longer] minutes to complete your artwork. We will then discuss your experiences.

Discussion of Examples

We have applied our procedure in a number of different contexts: a graduate course for art therapy majors; an elective undergraduate art therapy course; a workshop at an art therapy conference; and a treatment setting (TA visualization portion only). But before presenting examples from these applications, a few general observations are in order.

First, although both visualization experiences are highly involving, the TA experience was generally considered more powerful by participants. This might well be due to a sense of increased intimacy and self-esteem evoked by the personal affirmations. Therefore, when the experiences are used together, it appears to feel more satisfying to conclude with the TA activity. (Indeed, feedback recommending this order was given by the graduate students.)

Second, our experience suggests that the TA visualization is appropriate for both patient and non-patient groups. The existential visualization, on the other hand, has not been tried with psychiatric patients and is probably not as appropriate for them— or for those whose development has been arrested at a low level of ego functioning.

Third, we consider collage to be the medium of choice. All kinds of paper, magazine pictures, and materials of various colors and textures can be effectively used. In our opinion, the additional sensory stimulation provided by these materials facilitates the translation of the visualizations into concrete form. Also, collage can result in a satisfying end product even for those with minimal art skills.

Specific Examples

Because the TA visualization offers a “here and now” interpersonal experience, it is suitable for an
inpatient setting where the groups are always changing. One of us used it in the 20-bed psychiatric unit of a community hospital with the goals of increasing interpersonal contact and promoting the feeling of general well-being. Overall, the experience was reported as pleasurable by the group. The patients were generally supportive of each other and, when paired off, became active participants relative to their level of functioning. They remarked how often their focus dwells on negativity and problems, thereby overlooking opportunities to become aware of and nourish positive aspects of themselves and others.

The remaining examples are from our joint session with an undergraduate class in art therapy for which one of us was the instructor. Ten students participated in both the existential and TA experiences, presented in that order. Following the session, the students wrote brief reactions to the experiences in their class journals that supplied us with additional information. We are aware that the student-teacher relationship probably introduced a certain amount of bias. Whether this significantly influenced our conclusions can only be determined by further investigations.

The student artwork provides indications of current levels of ego functioning. Figure 1 depicts the personal goals of a male student that relate to sports and body building. This self-focused response to the first visualization was in marked contrast to the more altruistic responses of the other students. The work of a woman student also departed from the norm—but in a different manner (see Figure 2). Her collage, with complementary images symbolizing balance, represented an attempt “to break from the stereotypical images of peace, love, and happiness” (quote from journal). The narcissism of the one student’s response and the creativity of the other student’s response suggest divergent levels of ego development.

More to the point, there are also hints of ego-advancement in this set of examples. The young man who desired physical strength was able to put aside his self-preoccupation and reflect on the qualities of another as part of the TA experience (see Figure 3). In his journal he remarked, “I drew a sunbeam as a portrayal of the girl I worked with, because I always thought of her as a ‘spaced out’ person, but she really isn’t.” In another instance, a student responding to the existential visualization appeared to reinforce high ego-level values while depicting a frequently occurring theme—respect for nature (see Figure 4). She wrote, “Not only did I show society’s negative characteristics but I also showed the way I wish

Figure 1.

Figure 2.

Figure 3.
things were such as: enjoying nature rather than exploiting it, and enjoying the simpler things in life rather than material possessions.

I should be noted, however, that any steps forward were probably fleeting and may have been little more than normal fluctuations in ego level. Loevinger (1976) has stated, "Ego development is growth, and there is no way to force it. One can only try to open doors" (p. 426). Although we cannot aspire to more, we do assume that each additional "door opening" has value and might, in the long run, produce a lasting cumulative effect.

Finally, the procedure appears to have some general assessment value. Suggestions of typical defense mechanisms—which may or may not be indicative of ego level—were revealed by the artwork and accompanying interactions. For example, one young woman's collage contained a cotton mandala with a silver smiling face labeled a "puffy cloud" (see Figure 5). Her journal indicated that it made her feel good to create this for her male partner. He, however, expressed feeling puzzled as to what it meant. It is possible that the puffy cloud represents the artist's projection of her own internal world. On the other hand, her partner may have been denying that, as a male, he could be associated with an image of "feminine" softness. In any case, possibilities for further exploration were presented.

As a concluding example, another young woman's description of the same visualization experience revealed the defense of healthy narcissism. She wrote, "It felt good to give someone something that

Figure 5.

I had made myself and was my creation and I felt special having something presented to me about myself. That is the best gift that you can give someone else." With this statement, she also gave evidence of nonmaterialistic values worthy of emulation and provided an endorsement for the art therapy process in general.

Conclusion

The examples presented in this article exhibit some emerging patterns relevant to ego develop-
ment. We believe these are sufficiently supportive to warrant the expenditure of effort needed to conduct objective studies. Quantitative research using Loewinger's ego-development measure in a pretest/posttest design is a logical next step. Positive findings from this research would, in turn, provide encouragement for the development of companion procedures. As a consequence, a therapeutic program of several sessions could be put together with the aim of promoting the enduring increases in ego level that are unlikely to result from a single exposure. Our study, then, represents only an initial step down a long road—but suggests that the journey is worth undertaking.

Resistance in Art Therapy: A Multi-Model Approach to Treatment

Abstract

Four treatment models are discussed with reference to working with resistance in art therapy—drive psychology, object relations theory, self psychology, and ego psychology. Each of these models imagines resistance in its own way. Working with these four models of treatment, art diagnosis, therapeutic interventions, and the transference/countertransference relationship are considered with particular attention to resistance issues. Four cases are presented.

Introduction

Therapeutic models of treatment roughly fall into four major categories (Pine, 1990): drive psychology, object relations, self psychology, and ego psychology. Each theory attempts to organize therapeutic data under a central principle that not only helps therapists understand each case but also offers a methodology of interaction with patients. If therapeutic communications stall into a period of stagnation characterized by stereotypy or repetition, interventions are required to improve the therapeutic flow and processing. Each model offers clues and guidelines to help therapists remove these resistances. The organization of patient art, along with transference and countertransference phenomena, lends itself to a particular model of treatment. This paper attempts to clarify the variety of differentiations that lead to adapting different therapeutic models and the variety of therapeutic interventions that are associated with this understanding.

The Multi-Model Approach

The multi-model approach to treatment has been extensively elaborated by Pine (1990), who provides models of treatment into drive theory, ego psychology, object relations, and self psychology. Lazarus (1976) also uses the term "multi-model," but his orientation is heavily behavioral and cognitive. The authors of this paper recognize that different models of treatment and their particular languages may speak more or less eloquently to each therapist, depending on his or her particular personality. Yet, regardless of the therapeutic orientation of the therapist, all patients may at some time during the therapeutic process demonstrate resistances to treatment. The intent of this paper is to present a broad framework for resistance work that is not embedded in one particular therapeutic school.

Four Models of Resistance

Resistance can be viewed as any psychic obstacle that interferes with the therapeutic process. The concept of resistance was originally developed in drive psychology and remains fairly central in each psychoanalytic framework, having taken on new meanings in the contexts of object relations theory, self psychology, and ego psychology.

1. Drive Psychology: Drives are energetic expressions of sexual and aggressive tensions. Patient communications are funneled toward the expression, organization, and mastery of drives and/or their equivalents. Affects of guilt, shame, and anxiety that are associated with defensive operations lead to resistances; they are lowered through therapeutic interventions. Integration of drives in one's functioning becomes the central theme of this treatment model.

   From a drive psychology perspective, the therapist works with the patient to make resistance ego-alien, and thus lessens the obstacles to the treatment process (Fenichel, 1934). Within a drive psychology framework, the focus is on the patient's integration...
of drive material into his or her everyday functioning. Resistance occurs when the patient feels overwhelmed and frightened by drives and becomes defensive. But the pioneers of treatment did not foresee that resistance work could, on occasion, be experienced by the patient as critical and unacceptable. Direct confrontative resistance work can cause even more pronounced resistance. Perhaps in reaction to the limited classical appreciation of resistance, Moustakas (1974) redefines resistance as the psychological protection developed by a patient to preserve an inner sense of ego integrity. Consequently, a respect for the adaptive importance of resistance enters the treatment process.

2. Object Relations: Therapeutic work is organized around issues of internalized relationships (objects) that are associated with fears, longings, or conflicts around attachment, loss, and the process of separation and individuation. Interventions are focused in the area of abandonment and loss. The constancy of the real relationship and the structure of art making become an important piece of the reparative process.

From an object relations perspective, resistance calls for a variety of holding environments which, it is hoped, increase the patient's ability to tolerate the vagaries of object attachment and loss (Kernberg, 1976). Personality is organized by a series of early relationships that are internalized, both unconsciously and consciously. These relationships are constantly repeated in the present, and therapeutic challenges to these embedded patterns create fears of abandonment. In an object relations framework, the therapist creates a "good enough" holding environment, within which the patient can internalize both the strength and perspective of the therapist, thus becoming more able to withstand the problems of change. Defensive patterns of resistance to treatment are resorted to when fears of abandonment become overwhelming.

3. Self Psychology: Under the psychic construct of the self that represents our interests, values, and attitudes, interventions are directed toward affirming self cohesion. Anxiety represents a threat to the self and interpretations are organized around mirroring and supporting the self.

From a self psychology perspective, appropriate mirroring or empathy reduces resistance and facilitates treatment (Kohut, 1971). By mirroring, we reflect back to the patient the dissociated parts of the patient's self. This mirroring is both cognitive and affective. It is expected that the patient may go through an idealization process, perhaps creating a transference/countertransference relationship marked by "twinship." ("Only you and I understand each other.") When treatment bogs down, the problems can often be traced to a lack of empathy on the part of the therapist. Resistance is ameliorated when the therapist responds to the patient's communications with appropriate empathy or mirroring.

4. Ego Psychology: The therapeutic focus is placed on reinforcing the adaptive abilities of the patient that are consistent with his or her developmental maturation. Interventions are directed toward enhancing the patient's ego resources that are intimately related to self-esteem issues. The ego represents a series of functions that integrate for the patient's inner and outer reality demands.

Ego psychology can encompass both behavioral therapy and cognitive therapy and offers a developmental perspective on the patient's ego adaptational conflicts with reality. Treatment centers around the management of reality and the reinforcement of more effective ego-based coping mechanisms. Included in this orientation are such techniques as offering therapeutic contracts, supporting and improving ego skills, and creating models of identification which improve social effectiveness. In working with art, the specific skills necessary to make meaningful art are reinforced and supported by the therapist.

Within the context of ego psychology, resistance occurs when the therapist demands behavior or relatedness that is inappropriate to the patient's developmental level (Hartmann, 1939). In these instances, the patient's competent functioning and self-esteem are considered pivotal in treatment. Supplying appropriate developmental tasks and emotional support becomes the therapist's goal. Resistance occurs when the patient feels overwhelmed by developmental tasks that are inappropriate to his or her skills or cognitive and emotional integrative ability.

Art Diagnosis

The challenge for the art therapist within a multi-model approach is manifold. First, an assessment of the artwork in terms of its developmental level and defensive organization is necessary. Second, the meaning of this organization within the context of the transference/countertransference relationship must be considered. Third, a series of interventions that lessen the patient's resistance and increase his or her ability to be therapeutically present in the treatment relationship must be developed.
RESISTANCE IN ART THERAPY

Psychoaesthetic organization in artwork informs a diagnostic perspective with therapeutic implications. The authors’ assessment is based on their subjective experience with the patients’ art; that is, their internal visual experience upon viewing the artwork. This appraisal is admittedly a subjective one, but is consistent with an intersubjective notion of psychotherapy, a therapeutic assumption that the subjectivity of both the patient and therapist are always present and that both are interrelated in any given therapeutic engagement. These subjective interpretations of art are based, however, on 40 years of clinical experience with patients and their art expressions.

For example, in Figure 3, the art expression lacks grounding and does not seem connected to the outside. There are problems in creating a gestalt and a tendency toward fragmentation. Such skills as judgment, planning, and the capacity for symbolic abstraction are not apparent in this artwork. The material seems obvious and, at times, stereotyped. This visual organization in fact parallels the behavior of patients who are overwhelmed by reality and present to the therapist feelings of inadequacy and low self-esteem (ego psych).

An object relations framework will prove useful when the structure of the art form shows enmeshment of two forces “fighting” one another. The viewer’s focus moves to the center and then is bound or trapped by an outside force. The usual oscillation of the eyes’ movement from inside to outside and back is inhibited. In contrast, when there is true object constancy, a fairly clear flow of in and out in the artwork is observed. From the artwork’s perspective, the flow of energy toward the center is thought to represent the self, while the horizontal and vertical axes represent the object. The flow of energy in the artwork—horizontally, vertically, and from inside to outside and back—tells the story of the patient’s internal object relations.

When a patient’s artwork pulls our eyes toward the center, or when there is no pull at all toward the center, the self psychology model is also relevant. Sometimes there is relatively little movement back and forth from the inside to the outside and no great enmeshment of self and object. Focus moves toward the inside of the artwork and remains there. Often the material is shallow and expansive, or at times small and limited. One experiences the viewing of this artwork as being enmeshed in the center, or of not being able to find the center.

When a patient has worked through the basic issues of object constancy, he or she may produce artwork featuring a relatively stabilized organization of movement from inside to outside. In this case a drive psychology framework is useful. There may be evidence of strong defenses around drive material, with the flow of energy being stopped either on the horizontal or longitudinal axis. For instance, there may be a heavy overbalance of horizontal art activity that stops the flow of energy upward, or tight obsessional forms that interfere with the movement or flow of the artwork as a whole. The viewer’s attention is then directed to where the flow stops. Does he or she see strong, emotional, affective colors being overly contained with strong lines either in a horizontal or vertical direction? Sometimes the artwork will be overly elaborated or overly structured, as a way of muffling or restricting strong emotional engagement with the viewer. The opposite may also be present with a chaotic display of emotional coloration, primitively organized. Here therapeutic interventions will be directed to create a flexible structure that facilitates patients’ affective connection with the therapist, without overwhelming or overly restricting them.

Transference and Countertransference

Although the scope of this paper precludes extensive discussion of transference and countertransference as understood within each model of treatment, it does emphasize that different models of treatment offer different means of processing the communications of patients and that different models of treatment tend to create different transference and countertransference reactions. For instance, working from an ego psychology perspective, the therapist will be very active and structuring, creating a very powerful authority transference. Within an object relations framework, the therapist adheres to firm boundaries, while the patient is constantly struggling against “falling into a dark pit” and may go through a number of provocative maneuvers. In this case art serves as a transitional object and holds the patient in spite of the transference and countertransference machinations that may go on between therapist and patient. When approaching cases from a self psychology viewpoint, however, the experience is one of being present for and with the patient. In this instance the patient enters into either an idealizing or self object transference relationship with the therapist. Building the patient’s sense of self through mirroring and empathy is the main thrust of this
treatment. Finally, the therapist working from a drive psychology perspective will attempt to maintain a fairly neutral and separate therapeutic stance with the patient. A variety of drives and fears may be projected onto the therapist which ultimately are either interpreted or confronted. As there is less use of the therapist’s personal resources as a holding or healing agent, countertransference responses are associated with the traditional notions of countertransference: past conflicts of the therapist getting in the way of treatment process.

Treatment Interventions

We have already discussed in some detail the interventions that are typically indicated by these four models of therapy. In an ego psychology model, structure, support, and reinforcement are basic underpinnings of treatment intervention. In self psychology, mirroring and empathy are the basic tools to work with resistance. In an object relations framework, the art form becomes the transitional object that deals with object loss and a need for holding. Finally, in drive psychology terms, defenses are constantly encouraged as well as interpreted and/or confronted as seen in the art form to effect greater synthesis and ego integration.

The implementation of these four models of therapy can flow from one to another. They often overlap and become central for one phase of treatment and peripheral to another. The artwork itself usually offers the diagnostic clue as to how the therapeutic material may best be understood and treated. Following are four clinical sketches that illustrate how to apply the four models of treatment to different clinical problems and manifestations of resistance. Cases 1 and 2 are by Arthur Robbins; cases 3 and 4 are by Barbara Cooper.

Case 1

Joan, a married woman of 40, without children, enters treatment with complaints of loneliness and depression. In her capacity as theatre director, she views herself as unsuccessful and frustrated, in spite of the fact that from time to time she has directed important pieces that have received good reviews. Her husband, a busy professional in the medical field, works long hours and is not always available either physically or emotionally. On the surface he is supportive, but he feels uncomfortable in any intimate dialogue. With their busy professional schedules, they rarely spend time with one another except on vacations. Joan’s parents were also busy professionals, leaving the children to surrogate caretakers. Private school beginning at age 8 afforded Joan some structure in which she felt cared for and secure. Joan describes an overly anxious and infantile mother, who, out of her own sense of insecurity (rather than concern), was both overprotective and neglectful. Now in her third year of treatment, Joan has moved from a very distant and unrelated connection to the therapist to one in which she feels far more connected and emotionally grounded. Mirroring, empathy, and reflection have been important modes of intervention. Joan brings her loneliness and sadness to the session; she can be very elusive and difficult to reach. At times her relationship to her mother is referred to as being repeated in the transference, though the focus has been basically on her self. Joan rarely refers to her father, who was largely absent and emotionally disengaged from his daughter. The treatment is basically verbal in nature though on occasion the patient works with art to clarify a particular issue.

In a recent session, Joan speaks about her dissatisfaction with her job. She feels unappreciated and unrecognized and despairingly complains about her inability to do much about her situation. She admits that her colleagues view her as competent, but she gets no gratification or pleasure from this. Joan speaks of a secret place inside of her that even she does not know very well. This juncture in our dialogue seems to be an excellent place to move into a nonverbal mode. I ask her if she can draw this place, and she says she will try. She chooses a soft pink pastel that she says represents some vague far-off place in herself. She asks me if I will accompany her in her drawing, and I agree. The closeness and intimacy are consistent with the self psychology approach. I would be far more hesitant to accompany my patient if there were issues around boundaries or regression. In the following interaction there is a mutual mirroring process. This technique seems most applicable in cases where the object attachment needs firming up. Mirroring occurs on conscious and unconscious levels, in both participants. The relationship has a symbiotic quality. Out of this rhythm of give and take, the patient develops a new perspective on the self.

Joan draws a half-circle and 1 complete the other half with sharp angular lines (Figure 1). This intervention comes fairly spontaneously, though I am subliminally aware that I want to offer her a framework in which she can feel held and yet have something to bounce up against. I am also trying to
mirror the masculine and feminine elements of the self so that she has a frame for exploration. She chooses brown and orange pastels and transforms my harsh lines into something more flowing and soft. We both recognize that she would like me to hold and recognize the soft flowing part of her. I then draw a box, as my representation of the missing object, and then she fills it with a pink color. She proceeds to draw a green outline inside the box, and I fill it in with green. I say to myself that her emptiness can be filled, even though I hear, somewhere, her green envy. Once again, I mirror her wish to be filled, and at the same time suggest perhaps that envy is something that can be accepted without judgment. Perhaps this secret place may be the envy and hunger in my patient, but I do not feel it necessary to verbally articulate these impressions. The simple nonverbal mirroring is all that seems required. I then draw a circle and she shades half of it with green pastels. I outline one part of it with red, and she softens it with a red flow. She comments on the empty spaces and wonders if that’s what’s really inside of her. I comment that perhaps the empty space feels too enclosing and she needs to express the flowing part of her without being entrapped. She smiles to herself as she observes that her flow of brown lines has its own entrapment. “I guess,” she says, “I’m a woman of the ’90s; I want softness, I want to be held, I want to feel strength, and I want freedom.” Here, in visual dialogue, the soft parts of the patient’s self encounter the firm straight line of the therapist, and the sense of flow resonates with the soft flowing part of the patient. In this mirroring dialogue, I mirror her need for closeness and intimacy, as well as her desire to make her own art structure. We both participate in, share, and observe this complicated mirroring. The paradoxical nature of the self becomes highlighted in this mirroring. The wish for freedom interposes and interfaces with the need for softness and holding. In this session the patient takes some risk in being close while at the same time expressing her need for freedom.

The therapeutic engagement is directed at the patient’s sense of self. To be sure, she wants freedom from encroachment, but most important, she wants to be seen. There are many sessions of this nature. Gradually the patient evolves into a more defined and definitive woman who addresses her needs both in work and with her husband. There are of course many regressions, particularly when the therapist takes her vacation. However, slowly the patient has become more organized and clear, as well as related to an I-thou therapeutic dialogue. The mirroring techniques of self psychology have been especially helpful to this patient.

Case 2

Mary, a married woman of 35, mother of two young children, a girl of 4 and a boy of 6 months, has been in intensive psychotherapy for approximately 6 years. During one 3-year period, Mary was seen three times a week. She is currently worked with once a week. Initially, the patient was a very lost and confused woman, but slowly she discovered herself, fell in love, married a very supportive husband, and prepared herself for the profession of medicine. A good deal of therapeutic emphasis has been placed on the self and object loss during the main part of treatment. Mother, viewed as infantile and immature, and Father, all too busy with his business, left much of the parenting to a live-in nanny. The mother was fairly warm and caring when the patient was preadolescent, but the teen years created for the patient a good deal of alienation and estrangement from the family. The mother was seen as a very poor role model and as a woman whose interest in sexual matters was minimal. Currently, Mary has little to do with her mother. Mary’s father died 2 years ago from a sudden heart attack.

During the most recent stage of treatment, Mary has grown very articulate in addressing her problems. Treatment is basically verbal in nature though the patient on occasion works with art to clarify a particular issue. She also works with collages in an art class and often shares her newest creation with the therapist. Her sexual life has improved, but now, after the birth of her latest child, she once again wants little or nothing to do with sex.
This has caused problems between her and her husband. Mary is visibly upset over her inability to deal with her sexual problems. She considers her body ugly and unappealing. She hates her round hips and hairy body. (Most people, I believe, would view her as very pretty.)

In this reported session she states that she wants to take a breather from talking about sex. She is concerned about her daughter, Donna, who hates wearing pretty clothing and prefers the torn jeans that adolescents commonly wear. Donna hates bathing and is generally oppositional toward any suggestions that Mary makes about her clothing. The mother laments that her daughter is turning out to be like herself. While Donna exhibits oppositional behavior, she is also very concerned about showing favoritism to either parent: after spending time with her father, she reassures her mother that she really cares about her, and in turn, when she spends time with her mother, she then reassures her father that she cares about him as well. The patient laughs and comments that it looks like her daughter is in the middle of the oedipal phase. "What does this have to do with you?" I ask. The patient shrugs her shoulders, and I suspect that we are ready to move to another level of expression. I ask her if she would like to draw her mother, her father, and herself. She readily agrees, but draws a small box-like figure for her mother, a long straight line for herself, and an even longer line for her father (Figure 2). I comment that she could at least add some meat and substance to her representations. I feel, however, that any more interpretation would not be useful at this point. She calls her mother "the fecal baby" and says there is nothing she can add to it. What she really wants to do is rip and tear.

I encourage her to do so and she takes the side of the paper with the fecal mother and tears it in pieces. She complains that she does not have brown paper, which would be far more appropriate to accompany her affect. I proceed to give her some brown paper and she proceeds to make a pile of pieces of paper. "What would you like to do now?" I say, and she comments that she would like to burn the pieces. "Shall we?" I say, and she breaks into tears and says, "My poor mother. She has been mean to me in many instances, but I can't hold it against her that she is so inadequate." I reflect back, "It is very hard to be furious at such an inadequate mother, for she was such a pushover and does not know how to fight back. Do you really think that your anger can be so destructive to your mother?" "Well, if this is what's holding me back, I'm going to do something about it," she says. I remind her that her most creative work in a recent art class dealt with collages. The patient decides to take the pieces home and bring back a creative work of the cut-up pieces of her mother. "Maybe," I say to myself, "the patient can find some transformational qualities in her rage that can truly lead to a separation from her mother and a more adequate notion of the female image."

Though there are issues around separation from the mother, the overwhelming thrust of the material deals with defenses against rage and guilt, and the reintegration of these impulses into a more organized picture of the female self. In this therapeutic instance the toleration of rage, as well as a creative reorganization of this drive material, becomes the focus of treatment. Subsequently, the patient entered a rather protracted period of loss and depression that seemed to be precipitated by problems with her child. However, it also became apparent that after the period of rage toward her mother, she was able to externalize the object of her mother, which set the stage for feelings of loss and abandonment. So, at this particular juncture of therapy, the therapist moves from a drive psychology framework of processing to an object relations model that is more appropriate to work through object loss.

Case 3

Rose, a 30-year-old woman, came into the Harlem-based clinic for help. She claimed to feel angry and depressed much of the time and the precipitating factor was a fight with her mother. Rose is a welfare recipient with a seventh grade education and has been employed only once in her life for 6
weeks. Rose has a 13-year-old daughter who lives with her mother. When Rose was 5 she witnessed her father stab her mother. She was assaulted as well and was hospitalized briefly for a concussion. Rose is married to Joseph, now serving a prison sentence for selling drugs. They met through a friend of Rose's while Joseph was in prison for assault. They married while Joseph was still in prison. They lived together for a year before Joseph was reincarcerated. During that year, Joseph was physically abusive with Rose. She was hospitalized for a head wound after she was thrown against the refrigerator.

When I met Rose she was both abrasive and tearful—pleading for help. She attached to me in a positive way immediately, almost too quickly. Her case history, coupled with her immediate attachment, led me to believe that Rose was a borderline personality. A few months passed and Rose continued to become more attached to our sessions. She identified with me in a profound way. During this time I asked her to do some drawings. She complied, though reluctantly. Her drawings gave a crucial indication as to the direction of treatment.

In Figure 3, her drawings are childlike, exhibiting a floating, empty, simple quality of expression. The emptiness has a more organic quality than is usually associated with the borderline personality. (The organic factor was later ruled out by psychological tests.) I tended to be confrontative, addressing any acting out and encouraging a search for the self, assuming that this self, when emerging early in life, had been treated harshly, negatively, and/or with ambivalence by the mother. I was working with Rose assuming that she was a borderline patient; however, Rose's responses to my interventions were uncharacteristic of the borderline patient. My confrontation of her acting out was not met with rage, but with appreciation, a deepening of trust, insight, and change.

I recommended vocational training for Rose, as well as a group that met at the clinic once weekly. In addition, I scheduled a brief second weekly session with me. She responded positively and came to the next session wearing glasses (that I had never seen her wear) claiming: "I'm going to be going to school soon, and I need to see!" She received much encouragement and support for this. Unfortunately, I went away for 2 weeks shortly thereafter. I hoped Rose would attend the group to keep some continuity with the clinic, but when I returned, I found that Rose had not attended the group. She missed our first session as well. When she called to say she was ill and couldn't come in, I suggested we have our session over the phone. We talked for 45 minutes. Apparently, Rose hadn't left her apartment since I had gone away and she was extremely depressed. She cried that when I went away she realized that she had nobody. She threatened not to keep her appointment with the Office of Vocational Rehabilitation that week because of her depression. I gave her a "pep" talk about getting out and being with people. I asked her to picture myself on her shoulder saying, "Go for it!" She laughed at this and promised to go.

Up until now, my countertransference reactions to Rose varied from anger at her ability to love the husband who abuses her, to compassion for her, to admiration for her strength and fearlessness in seeking treatment, having come from a street culture that views therapy in a negative light. Now, my countertransference response was overwhelming to me. I detested being needed in this way, knowing that without me she couldn't function. I understood my response and where it came from in my life, but felt paralyzed in my role as therapist for Rose. I presented this case to my weekly supervision group to gain some insight and clarity. My supervisor diagnosed Rose as an inadequate personality, which required different treatment than that recommended for a borderline personality.

I had been approaching Rose from an ego psychology viewpoint, becoming quite involved in her life, structuring her time, etc., yet I had believed this to be erroneous, nonpsychodynamic, a crossing of boundaries that ought not be crossed. Through presenting this case, I could see that my approach with her was actually on target. I also came to see that I needed to set Rose up with more structure, perhaps in a day hospital. The feelings of dread subsided as I began to feel hopeful about Rose's treatment once again.

When Rose came in for our next meeting, she
arrived uncharacteristically early. I heard her speaking in a loud rapid voice in Spanish to the receptionist and to another caseworker. (She knows that I don’t speak Spanish.) The therapist told me that she was “badmouthing” me, claiming that I expect so much from her (groups, vocational training, etc.), and that she felt like killing herself. When Rose came into my office, she wept and talked about how glad she was to see me and how much she missed me. I asked about her anger. At first she denied being angry. I told her that the other therapist had told me what she said. Coupled with her missing her first session back with me last week. I said, her behaviour amounted to this: I held up my middle finger. She laughed and poured out her anger at me for leaving her. Her “heavy” affect became brighter and more energetic. We talked about what was now going on with her and what our immediate goals were. As treatment progressed, within an ego psychology framework, Rose felt increasingly grounded and effective in handling reality demands.

Case 4

Betty, a 43-year-old woman, was admitted to the inpatient unit of a private psychiatric hospital after a very serious suicide attempt. She had sent her husband and two teenage sons off to the movies and taken an overdose behind her locked bedroom door. During the movie, the older son “had a funny feeling,” left the theatre, rushed home, and found his mother nearly dead. She recovered in a medical hospital for about a week. Reportedly, upon regaining consciousness, she spotted a plastic knife on a food tray near the bed, grabbed it, and tried to stab herself. When she was admitted to the inpatient unit, she spent a few days in her room with constant, 24-hour “suicide” watch. Her first group as a patient in the unit was in my “Visual Journal” group, in which the whole unit (15 patients) participates.

Her first drawing in the Visual Journal group was of a tree with a black hole with blood dripping out of the hole. She shared with the group her ambivalence as expressed in the tree: Is it shedding leaves for fall (to bloom again in spring), or is it dying? She admitted to feeling suicidal, although not as violently as before.

When she presented that first drawing to me, she was well aware of the effect of the black hole with the blood running out of it (Figure 4). She sought my attention outside of the group and asked for individual sessions. I declined her request because I did not conduct individual sessions at the clinic. However, I would have refused in any case, so as not to feed her need for special treatment; also, she was currently seeing a primary therapist. Betty agreed to continue with the group treatment that I felt was appropriate for her.

In the first art therapy group that she attended, I spoke about the tree she had drawn and asked her if she could crawl into the hole and experience the blackness there. She was quite willing to do this. She closed her eyes as I sat with her and talked her through the experience. I then asked her to draw what came clear as her eyes adjusted to the darkness. The second drawing is her image of the rage in the darkness (Figure 5). She then told her
RESISTANCE IN ART THERAPY

story: She had been having an affair with another counselor at her work place, and he had left her. She believed that without him there truly was no air for her to breathe in this world, so she attempted suicide. After this session, she began bringing me poetry from her journal which exhaustively described her symbiotic attachment to this man and her rage and despair at the abandonment. Her next drawing was a further exploration of the black hole, which takes more form than the first, and again describes ambivalence: the death-mask and the rage (Figure 6). This drawing also brings to light her delight in shocking the group. I think she believed she was shocking me as well.

The next drawing was another expression of her rage, also disguised as a question mark (Figure 7). Her work was quite contained even as a statement of rage. Betty was a model of control and perfection in her personal habits, appearance, poetry, and artwork.

She brought me a clay piece she had done on her own and of which she was very proud. A woman in the fetal position is unsure if she is going to stay curled up and die, or unwind and give birth to herself. Betty’s choice of pink (flesh) for the glaze was, she reported, a clue that this figure would give birth. This “psychologizing” of her own work was, I believe, part of her continuing campaign to impress me.

The next drawing (Figure 8) is one which she had done in her journal, again on her own, and exemplifies her drawing style when in control. Again, the theme of life or death is apparent. Also, there is seductiveness here—the beautiful flowers detract from the horror of their being uprooted. Are they going to be repotted and live, or starved and left for dead? Betty wouldn’t say.

The next drawing was done during group time when the assignment was to “take a picture from inside you and put it outside of you to look at.” As she finished drawing this, she gasped and jumped out of her seat. She hadn’t intended the red mass of blood that dripped from the wound to be a figure and had just noticed its shape (Figure 9). This truly frightened her and prevented her from talking about the picture in any detail. She did say that it accurately described how she felt. She responded with anger when I made a comment about “the good breast and the bad.” This was followed by the next drawing of a black door with blood running out from underneath it. She sobbed as she talked about her relationship with her father and how there was always a wall between them. The only way he would validate or notice her would be if she cut herself and let the blood run out under the door. She was enraged at him and, in response, I gave her clay, suggesting that she “wedge the hell out of it” as she shouted resentments at him. For all her drama, I felt that this was one of our genuine times, when she truly felt and her feelings were truly processed. The next drawing was produced the following morning in Visual Journal group: a peaceful, calm drawing. The last drawing came a few weeks later and represents her moods and feelings as she prepared for discharge (Figure 10). Her last artwork was a drawing of herself looking out into the future.
In this series of artworks, the outside object seems to be choking off the inside self of the patient. In her life Betty acts this out with her former lover. She cannot leave this object and is constantly hounded by its presence, yet she dances around this conflict, not really getting into the pain of loss for she cannot face feelings of abandonment. On brief occasions, however, she does move into a very authentic place and starts to deal with her problems. Betty uses art to impress others and to present a false self. This manipulative controlling behavior is commonly part of the borderline. There is obviously a good deal of splitting in her searching for the good object while at the same time subtly acting out the introject, and ultimately repeating her abandonment anxiety.

My countertransference toward Betty ran the gamut. I liked her; her artwork was quite seductive, an art therapist's dream and she knew this. The times that real growth took place, I believe, occurred when I consistently confronted her grandiose/false self for a few sessions. She would then be enraged at me and withholding. I would validate her angry stance and provide materials for the expression of this. She was then able to use the materials for authentic expression. Clay and pastels proved to be the best media for her. (They both defied control to the extent that would challenge her without over-frustrating.) At these times she allowed her clothing to become soiled with the materials; she "played" with them. She let herself cry, thus letting her makeup run off, which was uncharacteristic of her style.

Unfortunately, time wasn't available to work through a synthesis of the bad/good breast within Betty. I felt that my role with her was to stand back, and yet be firm in setting boundaries: to be the voice of truth confronting a false self; to provide the means for her to ground herself and through this, to discover herself. I believed she had a rich, creative, intelligent, very funny, wonderful self somewhere deep inside. I let her know this in many ways—most importantly in the way I confronted her phoniness.

Summary

Patients can and do resist therapeutic process. Treatment is concerned with the problems of patients being out-of-process and the variety of interventions necessary to help patients regain therapeutic process. Indeed, when patients are in charge of their process and have acquired the ability to regain
their process upon losing it, they are very close to the terminal phase of treatment.

As with any creative endeavor, problems are often intensified when therapists have only one way of seeing patients' communications. In all the above cases, it is the structure of the art form that gives diagnostic clues as to the treatment intervention. Yet art diagnosis must always be viewed within the context of the transference/countertransference relationship. In the first case, the mirroring became very complex and symbolic. Here, mirroring involved the play of hidden shadows and nuances within the patient's personality that the therapist represents and which become reflections for the patient to feel, touch, and reintegrate. Attachment issues, as well as mirroring, are illustrated in the therapeutic dialogue.

In the second case under discussion, Mary's three brief lines were not truly a representation of her inner world, but an acting out of her contempt for her parents. The resistance that was manifested in the art form did not prevent the patient from processing her therapeutic material. On a very profound level, albeit in a very simple and direct form, she informed the therapist that they were not worth much involvement. However, the direct expression of her rage became the pivotal point in the shift toward a new level of painful therapeutic engagement—that of depression and loss.

In the case of the third patient, it can be observed how knowledge of a therapeutic model of treatment helps the therapist understand what is needed in treatment. On the surface the patient acted like a borderline, yet her artwork offered a true representation of her condition. Structure and reinforcement worked with this patient. Trying to be a holding agent and reflect the self simply would not be enough to contain this patient in treatment. In short, survival and functioning were far more important at this stage in treatment than going through the various stages of mirroring.

In the fourth case, the variations in ego states that are so prevalent in the borderline condition are reflected in the artwork. In Figure 10, the sublime fused quality of her representation is apparent as she retreated from any real struggle of self object differentiation. Figures 4 and 5 represented the inner black self trapped in the surrounding object, while Figure 9 demonstrated the split of good object and bad object. In the latter, the patient's passive self was connected with a very frightening introject. The artwork seems to have contained this very difficult representation of a bad object, and perhaps gave the patient some room for a reorganization before she left the hospital. On other occasions, her artwork seemed too pretty and false. Thus, the slippery and fast-moving ego states often move in and out of the patient's artwork; yet her language was rarely connected to the symbol except in Figure 9.

Questions may be raised concerning the subjective appraisal of the patients' art representations. The authors believe that there is no such thing as one truth in art or in therapy. The mutually interacting personalities of patient and therapist will determine many subjective/objective realities. The therapist's evaluation of the resistance will set the course of the therapy. Interventions arise out of a given diagnostic appraisal and are shaped by a therapeutic model.

Verbal dialogue can be elusive, and the same can be said for representations in artwork. Both types of expression offer an important means of understanding the composition and organization of the patient's personality. From this understanding, a way of working with patient's can be derived that may be of help to therapists who are lost in the quagmire of therapeutic resistance. Obviously, therapists will be drawn to one therapeutic model or another, but in stormy times, when the resistance is high, a multimodel approach will offer an additional compass to navigate through muddy therapeutic waters. Each therapeutic model offers a mode of intervention for coping with resistance. Each can become an indispensable tool for organizing therapist/patient communications.

Countertransference: A Theoretical Review and Case Study with a Talented Client

Gussie Klorer, MA, A.T.R., Edwardsville, IL

Abstract

It is our dual identity of artist and therapist that can be particularly problematic for the art therapist. Transference and countertransference issues are complicated by these roles. In this theoretical review and case study, my role as artist, and my narcissism at seeing a talented young client blossoming under my direction, complicated the therapeutic process greatly. Fourteen-year-old Carlos was the “dream client.” He was motivated, prolific, talented, enthusiastic, and was dramatically improving behaviorally as a result of art therapy. This article points out serious complications which are attributed to problems of transference and countertransference.

Introduction

When supervising novices or students of art therapy, it is important to create an environment where they feel free to share, not only their triumphs and glories, but their failures and mistakes as well. It is from our mistakes that the most profound learning takes place. In looking back over an art therapy practice of 13 years, many of my own mistakes come to mind. I recall a case very early in my career which was important enough to influence the direction of my research during the last few years. I hope, through this paper, to stimulate discussion and thought about two very complicated issues, transference and countertransference in art therapy.

The lack of art therapy supervision is an important issue in this case study which, 10 years ago in the Midwest, was a common occurrence. Additionally, there were problems unique to the child residential treatment setting which complicated the transference and countertransference issues. Nell (1988) discussed this phenomenon as it is experienced in a residential treatment center. In traditional therapy, the client becomes completely known to the therapist, but the therapist can remain anonymous to the client, which contributes to the transference. In residential treatment, where the therapist and client share working/living space for 40 hours per week and more, the countertransference of therapist to client can be stronger than the transference of client to therapist.

Nell noted three factors that intensify and nourish the countertransference, all of which were identifiable as factors in this particular case. First, the treatment staff were at times socially involved with residents, eating meals together, sometimes planning and attending parties for them, and occasionally serving as crisis intervention staff when acting out behaviors interfered with daily interactions. Second, the amount of time and the interest shown to residents truly represented the therapists’ personal investment and created hopes and expectations for the residents’ success. Third, in a situation such as this, the therapist and supporting staff are not just a parental symbol—they are functioning in the role of parent, despite the fact that there may still be involvement with the actual parent.

Literature Review

Art therapists have studied, discussed, and debated transference and countertransference issues for many years (Allen, 1988; Agell, Levick, Bhyne, Robbins, Rubin, Ulman, Wang, and Wilson, 1981; Wolf, 1985; Robbins, 1987, 1988). Although there is a continuum of opinion ranging from a strictly tradi-
tional psychoanalytic approach to advocates of techniques that allow for the unique aspects of art making, all agree that transference and countertransference are relevant to art therapy. Rubin (1984) has stated that although remaining as anonymous as possible is useful for the therapeutic process, an art therapist cannot maintain an analyst’s total neutrality. Through interaction with the client and art materials, the art therapist may be perceived as the nurturer, the teacher, the sadder, the good or bad parent, the policeman, the helpful guardian. She further sees differences in countertransference: “As with transference, there are factors peculiar to the art therapy situation. Since the art therapist is also an artist, she [or he] must be careful not to let her [or his] enthusiasm for the quantity or quality of a person’s art products influence her [or him] unduly” (Rubin, 1984, p. 57).

Agell (Agell et al., 1981) reminds us that the art material bears the brunt of the transference, allowing the art therapist the freedom to explore the art with the client from a more detached and cooperative position. More recently, Allen (1988) questions the usefulness of transference in the art therapy arena, where providing a situation of psychological safety and creative stimulation is different from that of psychoanalysis. She urges therapists to decline the power that a therapist has in a transferential relationship, and direct the client to use the art as a container, thus promoting the art process.

Countertransference issues also will pose unique problems for the art therapist. Wilson, defending the classical psychoanalytic position of countertransference, declares it to be a potential impediment to therapy and makes a strong argument against art therapists adopting the current popular therapeutic techniques of using countertransferential feelings as a source of information and as a means of active intervention with the client (Agell et al., 1981).

However, both Robbins (1987) and Wolf (1983) do just that in their work with clients. Wolf, influenced by Kernberg, Masterson, Racker, Robbins, Roland, Searles, and Winnicott, believes that “less emphasis should be placed upon viewing this phenomenon as the analyst’s deficiency, but should be seen instead as a new and unique tool with which we can better understand the patient’s transference projections and early object, or self-object experiences” (p. 129). He suggests that rather than repressing countertransference feelings and “inductions,” the therapist use them to better understand what is happening with the client.

Robbins sees countertransference as unavoidable and suggests that both the therapist and the client are in treatment within the art therapy relationship. Robbins states, “It is hoped that the therapist will be more in charge of the process than the clients, but the therapist should not fool himself [or herself] with false notions of professionalism or objectivity” (1987, p. 150). Robbins advocates an active use of countertransference and recognizes that art and creativity can be used to mask countertransference reactions and keep the therapist at a distance.

It should be noted, as recognized by Wilson (Agell et al., 1981), that therapists such as Robbins and Wolf advocate techniques which are solidly based in their extensive and additional training as psychoanalysts. This is not the case with many art therapists. It is hoped that art therapy training programs impart to their students an understanding of the limitations of their training so they do not borrow techniques unwisely. Yet, because of the relative newness of our field, we often need to go to psychoanalytic sources when we struggle with theoretical issues in our work with clients. The difficulty arises when we attempt to adapt ideas and techniques when we do not have the training from whence these ideas emerged.

Within the psychoanalytic field, there is a continuum of opinion on countertransference which ranges from Freud, who saw it as an indicator that the analyst needs further therapy, to those who accept countertransference as inevitable, to those who actively encourage using countertransference feelings in therapy (Hedges, 1987; Little, 1981; Scharff, 1992). If one were to take the most conservative position, that is, to recognize its existence as inevitable, but not to actively respond to it, one might be missing an important communication from the patient.

Scharff (1992) describes the process of projective identification as being a communication from the projector (client), who expels part of the self onto an object (therapist). Duncan (1981) suggests that the therapist will commonly experience a thought, sensation, or feeling in response to the client’s material that is a reflection of the projective and introjective processes. At the moment of object induction, that is, when the therapist experiences the same feeling state as that of the projector, countertransference feelings which can be useful to the therapy are experienced by the therapist. It is important that the analyst not be damaged, hurt, or changed by the projection, but rather be able to contain it for the client, so
that it can become neutralized. Both Robbins and Wolf recommend the use of artwork for this containment (Robbins, 1987; Wolf, 1985).

A further complication when looking at the issue of transference and countertransference is the nature of the population. Very little is written about the application of these issues to the child population (Berlin, 1987). Marshall (1979) found only 10 references to countertransference in 25 years of The Psychoanalytic Study of the Child. Notable in this area are writings from Klein and Anna Freud, who both recognize difficulties with the child population because the transference reactions are altered with the existence of actual parents in the child’s present life. Klein felt transference was observable through play, verbalizations, and behaviors. She saw transference as the result of experiences with the early mother image, not necessarily the current real mother. Anna Freud saw the presence of parents in the child’s life as allowing for transference reactions, but not a real transference neurosis (Freud, 1946).

Bollas: “The Unthought Known”

It is useful, when searching for a theoretical framework, to find someone whose work and ideas parallel one’s thinking, despite the difference in training and technique. Bollas (1987), who works with autistic children from an object relations perspective, has thoughts which are important for art therapists. He recognizes the difficulties clients have in expressing thoughts and longings into words when they may have no cognitive memory of the infant’s longing. The search for the transformational object enacts a preverbal memory. His term the unthought known refers to reliving early memories of being and relating through language of that which is known, but not yet thought. Further, he sees the unthought known as being stimulated by the aesthetic moment, such as through a painting, a poem, or music.

Bollas believes that the aesthetic moment constitutes part of the unthought known. “The aesthetic experience is an existential recollection of the time when communicating took place primarily through this illusion of deep rapport of subject and object. Being with, as a form of dialogue, enabled the baby’s adequate processing of his [or her] existence prior to his [or her] ability to process it through thought” (Bollas, 1987, p. 22). Within the clinical situation, because the client cannot express his or her conflict in words, the full articulation of preverbal transference evolves in the therapist’s countertransference.

The transference/countertransference interaction is an expression of the unthought known, according to Bollas, and the therapist will assist in bringing the unthought known into thought through the experience of transference and countertransference. Bollas addresses the difficulty of making material available to a client when the therapist does not as yet know the unconscious meaning. Bollas states: “Were the analyst to wait until that time when he [or she] knew what the patient was communicating . . . through the transference, it might well be months before he [or she] could speak. . . . The analyst must be prepared to be subjective in selected ways in the presence of the patient in order for the patient to use his [or her] own nascent subjective states. How does one do this? To some very considerable extent it is a question of the analyst’s relation to his own feelings and thoughts” (Bollas, p. 205). Bollas defends Liddle’s position that the analyst should be asking herself/himself how she/ he is feeling and why now. Analysts in the British School see a continuous interplay between the client’s transference, analyst’s countertransference, and projective identification.

For art therapists, the ability to stimulate the aesthetic moment Bollas speaks of through the client’s use of art materials is a provocative one, although this presupposes that the therapist will understand the unconscious meaning projected in the pictures. We can only dream that interpreting pictures is so accessible to us. This is where art therapists can, as suggested by Robbins (1987), Wolf (1985), Allen (1988), and others, use the art process themselves to understand their countertransference reactions. This also underscores the need for good supervision, specifically art therapy supervision, as opposed to supervision by a supervisor who has little experience with the power of the visual image.

Case Study

Carlos was an attractive biracial 14-year-old who was a difficult child to engage in therapy. Our first sessions were noted by an initial flirtation, followed by distrust, disrespect, and belittling comments directed toward me. It was not surprising that his drawings also reflected a rage toward women. Because of his guarded behavior and propensity for aggressive outbursts, I approached Carlos tentatively and began working with him on art techniques, offering art instruction as a nonthreatening means of getting close to him. This approach, although not
COUNTERTRANSFERENCE

typical of my normal working style, worked quite well with Carlos since he fancied himself an artist and sought out the teachings of someone whose talents he appreciated, even if she was a female. Using this approach I was able to establish a relationship with Carlos which grew to be much more positive than he had with most women staff and ultimately allowed us to deal with issues surrounding his fear of closeness and abandonment. However, because of this approach, the transference and countertransference issues became particularly complicated. During the course of a therapy that lasted approximately two years, one drawing dramatically and embarrassingly revealed the countertransference to me, which necessitated a change in the direction of the therapeutic process.

Carlos had a history of abuse and neglect, not unlike many of the children at this placement. He was a twin, and his twin was the more disturbed of the two boys, exhibiting paranoid and confused thinking at an early age. Carlos exhibited more stable and controlled behavior, although he, too, had an angry and at times, violent streak.

The boys were placed into foster care at age four by the child protective agency due to abuse and neglect by the mother. The father regained custody 4 years later, despite his own history of intoxication, burglary, paranoia, and child abuse. Three years later, the boys were again taken into custody because of alleged sexual abuse by the father. After a year of residential treatment for both boys, Carlos' behavior stabilized, and he was placed back with his mother. Mother then kidnapped his twin from placement and hid him in the attic for 2 months, until Carlos finally told the police. Mother's rage and rejection toward Carlos were so great that it became impossible for him to live there any longer. Both boys were placed back in residential treatment at that time, aged 13. As is typical for children who have received mixed messages from a parental figure, the boys continually longed to be with mother and never accepted the rejection. They made her cards and pictures and waited anxiously each holiday for her to come to pick them up, only to re-experience again the anguish of rejection when she would fail to show up.

Carlos was initially suspicious of me. He tested the minimal behavioral parameters I set forth in the art room. He had leadership potential, and the success or failure of a group frequently revolved around his attitude. Carlos knew how to dissolve whatever group process I had going by sudden outbursts of malicious, explicitly sexual comments directed to-

ward me. This would, of course, send the other boys in the room into peels of laughter, and it would be all I could do to maintain control of the group. After disrupting a group art session, Carlos would linger at the art room door, not wanting to leave. He seemed intrigued by the possibilities the art room might hold for him. His disruptiveness and need for attention were such that early on I decided to see him individually for art therapy. I also saw him in a verbal therapy group of nine boys which I co-led with a female social worker.

Carlos appeared to have some talent in art. He most often drew female figures, and I felt some of his pictures related to adolescent identity issues. He seemed to be struggling with sexuality and his racial identity (Figures 1 & 2). As he continued to show a preoccupation with his portraits of women, I felt he was working through feelings for his own mother on a deep and unconscious level (Figure 3). Distortions

Figure 1.

Figure 2.
in color, proportion, and form made his portraits appear angry and grotesque (Figure 4).

Simultaneously, Carlos would make sculptures for his mother; his excitement over his gifts was touching. He always made sure that he carved his name into the clay figure prior to firing so that his mother would believe he made it. Somehow, he never acknowledged the fact that his mother never came to receive the gifts. A sculpture of a mermaid he made for her was given to me. I was willing to take on the role of the good, nurturing mother at this time. Our relationship was becoming one that Carlos could trust: the provider, teacher, nurturer. Carlos was also beginning to accept the role of artist. I loaned him books on drawing, gave him professional art materials with which to work, and we talked the language of art. He was beginning to receive campuswide recognition for his art.

Despite the good relationship we had in the art room, Carlos presented another side in his verbal group. Here, he was nasty and malicious toward the cotherapists, to the impediment of any group process. After one particularly horrendous group, where he was belligerent and disruptive during the entire session, he then waltzed into his individual art therapy session 20 minutes late, and I had had enough. I confronted him and told him how I personally was affected by his behavior since I spent so much positive time with him in art. He could not handle the confrontation and instead began talking about a painting he was doing, a sad, depressed, dark picture of a person on a horse. He talked about the aesthetics and technicalities to avoid the real issue. Again, I brought up his behavior and he said angrily, “I know what you want me to think. You want me to think that this painting is about my feelings or something dumb like that.” Gradually, he came to accept the idea. Then, when confronted again about his group behavior he said, “Well that’s the trouble with getting close to people. You see me down here in art and then you expect that everywhere I have to act like that.” This was the first time that he acknowledged his fear of closeness and his closeness to me. Subsequent sessions continued along these themes.

In art, Carlos spent hours studying proportion and movement. He wanted to understand the structure of the human figure and would ask peers or me to hold an arm or leg a particular way when he was struggling with drawing a particular pose. It was interesting that he always started with the feet and drew his way up the figure, sometimes omitting the head. According to Miehver (1949) this may suggest a difficulty in interpersonal relationships and a reluctance to undertake emotional commitments, which certainly seemed true of Carlos.

The staff saw art as the arena where Carlos could experience success and used it as a reward for appropriate behavior. He was allowed extra time in the art room for “independent study” as a reward when he was doing well in other areas of the program. This, in addition to Open Art Studio and his individual art therapy session, potentially gave him quite a bit of time in the art room, and behavioral changes were quick to follow.

Carlos’ improved behavior sparked the narcissistic gratifications and assurances I needed at that time. I was eager to prove, through Carlos, the effectiveness of art therapy to a sometimes skeptical staff. Since his artistic gains resulted in noticeable behavioral improvements, there developed a specific form of countertransference which Reich (1973) terms the “Midas touch,” wherein the therapist’s
gratification for the therapeutic success becomes intertwined with the client's needs. My role as artist, and my narcissism at seeing a talented young client blossoming under my direction, complicated the neutrality which I needed to strive for in a therapeutic sense. I was particularly invested in this child's therapy and was missing the obvious.

When Carlos drew the following picture I realized what should have been apparent earlier. Carlos had come to his individual art session late again, a testing pattern which had become more frequent. This session was followed by Open Art Studio, at which time several other children came in to work on ongoing projects. I was engaged in conversation with two other children, and Carlos began drawing my portrait. I could not see his easel. When he was finished I looked at the drawing, titled, "Gussie When She Is Tired" (Figure 5). The obvious sexualization of the portrait was a shock to me, and I realized that I had inadvertently supported this love-transference. My countertransference feelings, had I been more cognizant of how much I enjoyed his presence in the art room, could and should have been used as a measure for where our therapy was headed. Contained within this single image was such a multitude of emotions and "unthought knowns." I wondered immediately about his relationship with his mother, the mixed messages, and his unfailing devotion to her. I was also frightened of my own feelings and humiliated that I had missed something so blatant. Looking back through his drawings, I discovered that he had added my head to some of his unfinished nudes.

I made a decision then to diffuse the transference by separating the art instruction from our therapy sessions. I felt the intensity of working with the female figure had become too personal. I was able to arrange for Carlos to join a figure drawing class at Washington University for talented high school students. In this way, he was able to draw female and male live models without the stimulation of my presence (Figure 6). I also introduced him to the idea of using magazine pictures as models.

In our sessions, we talked about boundaries and I attempted to define our relationship for him more clearly. We were also able to explore other issues in art therapy, most notably, a series of losses. His brother was discharged to a more intensive treatment center due to increased pathological behaviors, and his social worker of two years was moving out of state. With each of these losses, there was a deterioration and regression in his behavior, and then an obvious retreat into art to process the feelings.

Carlos gained immeasurably from the art instruction, and his pictures became less overtly sexualized and more balanced as he and I worked through our issues. I introduced him to acrylic paint and encouraged him to put his figures into an environment. This led to an interest in landscape painting. Something that we were never able to work through was that "unthought known," that undefinable longing for a mother who in actuality could not be there for him in any healthy way.

Throughout his two years in treatment, Carlos requested to go back home numerous times. He believed that if he could be reunited with his mother, they could live happily ever after. Finally, at age 16, he and his brother ran away to live with their mother. She moved them to another state, where she abandoned them again.
Conclusion

It should be emphasized that, when the client cannot express the "conflict in words, the transference/countertransference interaction can be an expression of the "unthought known." Bollas feels that the infantile element in the client speaks to the therapist through object usage that is revealed through the therapist's countertransference, and the therapist should, in fact, allow the client to affect him or her. He states, "This inevitably means that the analyst must become disturbed by the patient. . . . Each analyst, working with, rather than against, the countertransference must be prepared on occasion to become situationally ill" (Bollas, 1987, p. 204).

Only in retrospect do I see that my feelings of humiliation and embarrassment were based upon an induction which may have specifically related to a projacive identification with Carlos' own experience of humiliation when his mother rejected him. He was able to get me to understand his humiliation on an affective level, and it made me feel ill.

According to Little (1981), the greatest danger and difficulty in countertransference is a paranoid or phobic attitude toward the therapist's own feelings. "The very real fear of being flooded with feeling of any kind, rage, anxiety, love, etc., in relation to one's patient and of being passive to it and at its mercy leads to an unconscious avoidance or denial" (p. 45). I hid the drawing this client made from myself so that I would not have to confront the issues. I wish no that I had stayed with my discomfort. felt it more deeply, and perhaps drawn something in response to it.

The other point to be underscored is the importance of continued self-exploration, processing, supervision, and study. I was driven to learn more about these issues because I suddenly found myself at such a loss and knew that I had made a mistake. Little (1981) notes that all therapists make mistakes, but because they are painful to us, we tend to avoid talking about them. I hope, through example, to encourage a process of sharing mistakes or failures so that a deeper understanding of therapeutic issues can take place and so that clients can reap the benefits of our lifelong struggles to provide what they might need when we do not know what that might be.

Brief Reports

Survey of Doctoral Work by Art Therapists

Vija B. Lusebrink, PhD, A.T.R., Louisville, KY; Marcia L. Rosal, PhD, A.T.R., Louisville, KY; Michael Campanelli, EdD, A.T.R., Perth, Western Australia

Abstract

A survey of art therapists with doctoral degrees was conducted to obtain information on the types of doctorates received by art therapists and the research topics and methodologies of the dissertations. The 78 responses received showed that there has been a rapid increase in the number of art therapists with doctoral degrees in the last several years. The dissertation topics were diverse; the predominant topics were studies of art therapy assessment tools, identification of abuse, and the use of art therapy in the treatment of serious illness/grief. Art therapists equally utilized quantitative and qualitative research methods.

A mentor and resource pool, based on the information gathered in this survey, is recommended to assist art therapists conducting research.

Introduction

The field of art therapy is growing and expanding. Every year graduates with master’s degrees in art therapy enter the mental health work force. As more art therapists are trained, seasoned registered art therapists continue their education by obtaining doctorates in disciplines related to art therapy. By investigating different aspects of the field through doctoral studies, art therapists enrich and enliven our profession. In addition, the array of dissertation topics add needed knowledge to the research base of art therapy.

This paper presents the results of a survey of art therapists with doctoral degrees and the topics of their dissertations. Vija B. Lusebrink, Chair of the American Art Therapy Association, Inc. (AATA) Research Committee for 1992, conducted the research. Michael Campanelli, who independently compiled information on dissertations with topics in art therapy or related areas, supplemented the survey with his data.

The purpose of the survey was twofold: (a) to obtain information on the types of doctorates received by art therapists, and (b) to survey the research topics and methodologies of dissertations. The research from art therapists’ doctoral dissertations is rarely published or may be published in journals outside the field of art therapy. Thus, the valuable information obtained through doctoral research is not easily accessible to other art therapists. The information garnered from the survey will provide a resource for art therapists who are thinking about doctoral studies and the research uncovered may impact the knowledge base of the field.

Method

A total of 143 questionnaires were mailed to art therapists with doctoral degrees. These art therapists were identified through three sources: (a) by the AATA membership survey (Gordon & Manning, 1991), (b) by the 1990 AATA Membership Directory, and (c) by responses to an announcement placed in the Art Therapy Newsletter soliciting information from art therapists with doctoral degrees.
Respondents were asked to provide the following information: (a) name of institution, discipline studied, degree type, and year of degree; and (b) title and abstract of dissertation. Respondents were also asked to send a brief discussion of how the research may benefit the field of art therapy. If the dissertation was published, respondents were asked to send the appropriate reference.

Seventy-two (50%) questionnaires were returned. In addition, six art therapists who did not respond to the AATA survey were identified by Campanelli, making a total of 78 responses. All but eight of the art therapists surveyed were Registered Art Therapists (A.T.R.s).

Results

The results of the survey are presented in five areas: (a) types of degrees earned, (b) the trend of art therapists earning doctorates, (c) types of institutions granting degrees, (d) dissertation topics, and (e) research methodologies used by art therapists in dissertations.

Types of Degrees Earned

The 78 art therapists who obtained doctorates received four types of degrees: (a) 60 received Doctor of Philosophy (PhD) degrees, (b) two obtained Doctor of Psychology (PsyD) degrees, (c) 15 held Doctor of Education (EdD) degrees, and (d) one earned a Doctor of Arts (DA) degree. Of the 72 respondents of the AATA survey, the largest number of doctoral degrees by discipline were in psychology including clinical psychology (22), followed by art education (9), educational and counseling psychology (8), and art therapy (8). (See Table 1.) Unfortunately, there were no data about the type of degree earned on the six doctorates from Campanelli’s survey.

The Trend of Art Therapists Earning Doctorates

There has been a rapid increase in the number of art therapists who hold doctoral degrees. Only five art therapists received doctoral degrees from 1966 to 1969; similarly, only nine art therapists obtained doctoral degrees from 1970 to 1979. However, there was a rapid increase during 1980 through 1989 when 49 art therapists obtained doctoral degrees. From 1990 through 1992, 17 art therapists received doctoral degrees, indicating an increase in the number of art therapists working on doctoral degrees in the 1990s.

Institutions Granting Degrees

Sixty-nine of the doctoral degrees received by art therapists were from universities, professional schools, and external degrees accredited by agencies recognized by the Council on Postsecondary Accreditation (COPA) as listed in the Accredited Institutions of Postsecondary Education (1991–1992). Five degrees were from professional schools in psychology. Eighteen art therapists (23%) obtained external degrees from The Union Institute, formerly The Union of Experimenting Colleges and Universities; seven of these degrees were obtained before The Union Institute was accredited. Of the 18 degrees completed by art therapists through The Union Institute, eight degrees have art therapy as part of the degree title.

Four additional degrees were from external programs: three art therapists hold doctorates from the Fielding Institute and one from Saybrook Institute. (The degree obtained from Saybrook was prior to its accreditation.) Three art therapists completed degrees from nonaccredited institutions of higher learning which are not listed in Peterson’s Guide to Graduate and Professional Programs: An Overview (1993).

Dissertation Topics

Fifty-four (69%) of the 78 dissertation topics developed by art therapists related to the field of art therapy. The survey of dissertations reveals a wide diversity of topics grouped around particular subject areas derived from terms, topics, or concepts found in the titles of the dissertations. Table 2 is alphabetically arranged by subject area and shows the number of dissertations within each subject. When a topic could not logically fit into a category, a new subject area was created. The selection of categories is arbitrary to some degree; thus, it is important to keep in mind that the choice of subject areas listed here does not preclude the possibility of arranging the references into other feasible categories.

Studies of art therapy assessment tools, art education, and art therapy as a means of treatment for serious illness/grief were the predominant areas investigated. It is interesting to note that six dissertations were about women’s/men’s studies. Only seven studies researched the efficacy of art therapy (outcome studies).

Research Methodologies Used in Dissertations

The classification of the types of research was divided into two areas: (1) basic or applied research, and (2) the methodology utilized in the dissertation. The categorization of basic or applied research was based on the definitions stated by Cates (1985): Basic research (sometimes called pure research) explores or expands our knowledge of theory, and applied research studies how theory relates to practice. The classification of research methodologies used in the dissertation survey was based on categories discussed by McLaughlin and Carolan (1992) and Rosal (1992). The types of research paradigms encompass six quantitative methods (survey, assessment, outcome, correlational, comparative, and descriptive) and four qualitative methods (naturalistic- ethnographic, phenomenological-hermeneutic, historical, and cybernetic). A category designated as “other” included the development and writing of books and journals and was considered a qualitative study. The classification of the different methodologies used in dissertations was based on the information available in the dissertation abstracts. The classification of methodologies is not to be regarded as absolute, but as indicating general trends of the approaches used. Abstracts were available for 74 dissertations.

Art therapists equally utilized quantitative research methods and qualitative research methods (37 in each classification). Table 3 indicates that a wide variety of research methodologies were used. By far, the most popular method used in dissertations by art therapists was the phenomenological-hermeneutic methodology (21 dissertations).

Discussion

The survey of doctoral work by art therapists highlights several exciting trends and may offer the field some guidelines for future thinking about research in art therapy. First, the survey found that the number of art therapists who earned doctoral degrees increased dramatically in the 1980s. It appears that this trend will continue at a more rapid rate in the 1990s. Additionally, despite the fact that there are no doctoral programs in art therapy, art therapists are obtaining degrees in fields related to art therapy such as psychology, art education, and counseling psychology.

The art therapy profession has long struggled with when and how to teach research to art therapists. Teaching research on the master’s level versus the doctoral level has been debated. Now, teaching research as a part of master’s level art therapy education is mandated by the AATA, Inc. (1993 Guidelines for Training). To help understand what programs teach on the master’s level, Linesch (1992) surveyed art therapy programs concerning the format and philosophy of approaches to research education. She found the main goals for master’s research projects were to gain mastery in an area of concentration and

</table>
LUSEBRINK ET AL.

to synthesize clinical experience. The case study was the research methodology utilized most often in the master’s projects.

Some art therapy educators hypothesized that the critical thinking skills necessary to conduct research can begin on the master’s level (Junge, 1989; Rosal, 1989). However, there is evidence that in order to become a critical thinker and builder of theoretical models of any substance one needs training beyond the master’s level (Junge, 1989). The authors of this article agree that development of new research paradigms and theories is beyond the scope of master’s level training since master’s programs in art therapy focus on the development of clinical skills. Thus, teaching and training in research methodologies commensurate with the development of clinical skills may be most appropriate on the master’s level. As Linesch (1992) found in her survey, most master’s programs have opted to teach research skills which enhance clinical practice and, thus, the majority of master’s projects or papers are based on case studies.

The use of both quantitative and qualitative research methodologies utilized by art therapists for their doctoral studies reflect the dual nature of our field as being from both behavioral sciences (quantitative focus) and fine art (qualitative focus). Both types of research are important, timely, and necessary for our nascent field. In addition, the need for art therapists to find alternative research paradigms and to develop unique methodologies is vital and has been discussed by several authors (Gantt, 1986; Junge, 1989; Junge & Linesch, 1993; McNiff, 1987). The development of new research paradigms is worthy and exciting. Again, this type of intensive work cannot be expected from master’s level students who are grappling with obtaining clinical expertise and is more appropriate for doctoral level inquiry.

It should be noted that all but eight of the surveyed art therapists with doctoral degrees are A.T.R.s. Holding an A.T.R. implies that the individual had at least one year of clinical experience beyond the master’s degree prior to beginning doctoral studies. Therefore, it is possible that clinical experience contributed to the types of research and dissertation topics art therapists chose. In fact, the use of clinical case study research was popular in doctoral work. Of the types of methodologies used in doctoral studies, the descriptive case study was utilized in 29.5% of the dissertations.

Art therapists need to be challenged and supported in their quest for conducting research. An en-
virement where peers and mentors are available for advice and consultation is a must. The following is a proposal for an Art Therapy Research Mentor and Resource Pool (MRP) based on the information gathered in this survey. The MRP would have two components:

1. The mentor pool would include art therapists who are familiar with particular research methods and topics and would be willing to consult with and mentor novice art therapy researchers.

2. The resource pool would initially include information compiled from the present doctoral degree survey of art therapists. This compilation of dissertation abstracts would be the primary resource and could be expanded as more therapists engage in research.

Also, it is evident from this survey that art therapists are multidisciplinary thinkers and have conducted doctoral studies in several areas. A continuation of multidisciplinary research may enrich and enliven our field. As McNiff (1987) stated, in the field of art therapy “interdisciplinary cooperation has been the norm rather than the exception” (p. 285)—let us hope this continues!

Conclusion

An increasing number of art therapists are obtaining doctoral degrees. The topics investigated and the approaches and methodologies used in the dissertation studies are diverse. The majority of art therapists use qualitative (specifically phenomenological-hermeneutic) types of research in doctoral work.

Three general recommendations can be drawn from the present survey. First, it may be timely to develop doctoral degree programs in art therapy. This conclusion is based on the information garnered from this survey and from a survey of art therapy educators about the development of doctoral programs (Lusebrink, 1993). Second, strong support from within the professional organization for individuals seeking doctoral degrees is recommended in view of the lack of programs offering degrees in art therapy. A rich pool of information regarding doctoral dissertation research for prospective doctoral students is now compiled and should be available for use by future art therapy doctoral students. Finally, a meta-analysis of the doctoral studies conducted may illuminate both strengths and weaknesses in art therapy research and may highlight areas for future research emphases.

Vija B. Lusebrink, Ph.D., A.T.R., is Professor of Expressive Therapies, University of Louisville; Marcia L. Rosal, Ph.D., A.T.R., is Associate Professor of Expressive Therapies, University of Louisville; Michael Campanelli, Ed.D., A.T.R., is Professor of Art Therapy, Edith Cowan University, Perth, Western Australia. The Effects of Directed Art Activities on the Behavior of Young Children with Disabilities: A Multi-Element Baseline Analysis

Susan Banks, MEd, Pat Davis, MEd, Vikki F. Howard, PhD, and T. F. McLaughlin, PhD, Gonzaga University, Spokane, WA

Abstract

The effects of directed art activities on the behavior of two preschool children and one kindergarten child with disabilities in a rural classroom were examined. A multi-element baseline design across participants was used to compare directed art activities with typical preschool art activities. The behaviors measured were aggression, eye contact, and social initiation. Each art activity directed by the teacher focused on an affective concept such as anger or happiness. The control condition used the same art materials as the directed art activity, and the children chose how they would use the materials. The results indicated that the directed art activity had a larger effect than the control condition on the social behavior of two children, while the control condition generated little effect. Neither art activity had a measurable effect on the targeted behavior of the third child. Implications for use by preschool and other teachers were suggested.

Introduction

Art, as a part of child development, has been studied in terms of creative expression, psychosocial development, and cognitive development (Silver, 1978). Art activities have traditionally been included in preschool programs for children with developmental delays as they provide the opportunity for creative expression; practice of fine and gross motor skills; and the application of language concepts relating to form, shape, color, texture, and spatial relationships (Bailey & Wolery, 1984, p. 124). These activities have also provided a "conduit for responding to experience and expressing the change that occurs at every developmental stage" (Ferrara, 1991). Through art, children are able to express feelings of aggression and anger, fear and anxiety as well as expressions of love (Salant, 1975). Preschool children have been particularly vulnerable to disruptions in family life. When these children have been unable to express feelings of anger, fear, and pain, behavior problems and learning difficulties have often resulted. Naumburg (1973) suggested that the procedures of art therapy could be used in art education for both normal and emotionally disturbed students.

Recently, Swenson (1991) illustrated the relationship between art education, art therapy, and special education. Aspects of art education have provided value as therapy. These include participation in group projects which have encouraged cooperation as well as reduced competition and feelings of isolation encountered by most children in special education. Kramer (1979) stated that when children with emotional and behavior problems have inner...
THE EFFECTS OF DIRECTED ART ACTIVITIES

conflicts, they are often inaccessible to education through normal teaching practices.

Art therapy has a long history of application for children with serious behavioral, intellectual, and emotional problems. However, there is very little empirical evidence to support such applications. Furthermore, since practices vary widely depending on the theoretical foundations of the practitioner, no single method can be viewed as “art therapy.” The present study relied primarily on Kramer’s viewpoint that art therapy does not need to involve interpretation or assumption of underlying pathology. Rather, art can be a form of communicating emotions which might then be healing. This study was developmental in nature as great care was taken to incorporate materials, activities, and discussions to facilitate emotional responses at the children’s developmental levels (Silver, 1978). Behavioral techniques used throughout the activities included modeling, contingent reinforcement, and prompting (Roth, 1987).

This study was designed to measure the direct effects of art therapy. Its purpose was to evaluate the effects of directed and nondirected art activities utilizing some strategies of art therapy within a behavioral context on high-risk, preschool and primary grade students with developmental disabilities. Directed art activity was selected to attempt to facilitate an emotional outlet which would then allow the children to be ready to experience a successful peer encounter.

Subjects

Jack was a 6-year-old child enrolled in the combination preschool/kindergarten program. Jack’s cognitive skills were not a concern as he appeared to be developing normally. Since he had not been referred for services, his IQ scores were not available. The Vineland Adaptive Scale (Sparrow, et al., 1984) showed a social skills composite standard score of 47 (3 SD below the mean) with a composite score of 70. The child frequently displayed sensory integration problems (inability to screen out stimuli, unable to complete tasks), aggression, and psychosocial coping skill loss as observed by the classroom teacher. His mother reported that he had a history of experiencing violence within the family.

Jerry was a 4-year-old boy with significant cognitive delays. His IQ composite score was 64 according to the Stanford-Binet Intelligence Scale (Terman & Merrill, 1973; Thorndike, Hagen, & Sattler, 1986). The Vineland Adaptive Behavior Scale indicated a social skills composite standard score of 70 (2 SD below the mean). He also showed significant delays in speech and language, gross and fine motor skills, and social development. Jerry was noncompliant and displayed frequent temper tantrums. His mother reported that he had been a victim of physical violence within his family.

Andy was a 4-year-old boy with an IQ score of 121 on the Stanford-Binet Intelligence Test. The Vineland Adaptive Behavior Scale showed a composite social skills standard subscale score of 85. Although his social skills subscale composite score was too high to qualify him for developmental delay in social skills, he had difficulties playing cooperatively with his peers. He qualified for the preschool special education program because of delays in gross and fine motor skills.

For the first half of the study, the children’s classroom was located in the basement of a 61-year-old school building. The remainder of the study took place in a new preschool/kindergarten through sixth grade school building in a small rural community. The entire population of the school included 110 students. Approximately 25% of the students received special education or related services. A large portion of the community was comprised of families of lower socio-economic status.

Materials

Selected art materials were appropriate to the developmental levels of the children and included watercolors and paintbrushes, play dough, chalk, crayons, fingerpaints, and paper and glue.
Behavior Definition and Measurement Procedures

Target behaviors were selected based upon the classroom teacher’s observation and consultation with various support service providers. Physical aggression, the behavior under study for the first child, was defined as hitting, kicking, choking, pushing, or grabbing toys from a peer. Prior to the study, Jerry initiated interactions primarily with adults. A determination was made to attempt to increase the frequency of self-initiated peer interaction. The third child had poor attending skills, lack of impulse control, and eye contact. Eye contact was chosen as the targeted behavior in an attempt to increase overall attending skills. Since he rarely engaged in even fleeting eye contact, frequency of eye contact was selected rather than duration.

The three target behaviors were selected with the overall goal of increasing adaptive social interaction with peers. These students had developed no sustaining peer relationships, although each verbally expressed a desire to have a friend.

For ease of classroom management, all target behaviors were measured by a frequency count. Data collection lasted for an interval of 5 minutes. Two data collection periods per day were conducted during center time: the first immediately after the treatment probe and the second 30 minutes later. Center time consisted of free exploration with toys, games, puzzles, and books and peer social contact within a small group (three to four children). Two observations were carried out to assess possible generalization of effects across time.

Experimental Design and Experimental Conditions

A multi-element baseline design (McLaughlin, 1983; Ulman & Sulzer-Azaroff, 1975) replicated across individuals was chosen to evaluate the use of various art activities. This design calls for alternating conditions so that contrasts between the two treatment probes could be examined. The condition in effect was first determined by a coin toss. An alternating pattern was followed throughout the remainder of the study (Kazdin, 1982).

Baseline: Baseline data were collected in absence of either treatment condition. Data were collected during center time which usually lasted 1 hour per day. This condition was in effect for 5 school days.

Control condition: During the control condition, art materials were provided along with the verbal statement, "Boys and girls, you have 15 minutes for this activity." During this phase the entire class participated in the activities, but data were collected on the targeted subjects only. No adult direction was given to the students except when inappropriate behaviors were observed. Teachers observed the activity. The art media were preselected to maintain consistency with the directed art activity. Each child determined how the materials would be used and what product they developed. Target students did not receive special attention during the activity. Data were collected 5 minutes after the art lesson, and again 30 minutes later.

Directed art activities: The second phase consisted of directed art activities utilizing preselected media which matched the corresponding control condition and a period of 5 minutes in which the teacher directed the children to focus on a "feeling" word or concept (mad, happy, love). The "feeling" word was written on the board and the teacher then asked, "What makes you (feeling)? A 15-minute period for execution of the art activity followed. Verbal cues to refocus on the concept were given as needed during the activity; for example, "(Child’s name), think about what (feeling) means to you" or "How do you feel when you’re (happy, sad, etc.)?" When the time period ended, each child was asked to describe how his/her artwork reflected the focus concept. The class discussion lasted 10 minutes. The following script was used:

1. "(Child’s name), tell us about your (picture)."
2. "How do you feel about your (picture)?"

Data were again collected immediately after the directed art activity and 30 minutes later during center time as the target behaviors were more likely to occur at that time.

Interobserver Agreement

A paraprofessional was trained to observe the target behaviors of each child. These data were taken twice for each child. Reliability of measurement was calculated by dividing the smaller number by the larger number and multiplying by 100. Interobserver reliability was 93% (range 83% to 100%). Reliability data were taken during initial observation (the first 5 minutes of center time).

Independent Variable

After she had been verbally informed of the methodology for the procedures to note for which type of art activity (directed or control condition) was
being conducted, an outside observer randomly vis-
ited the classroom following baseline. The para-
professional observed the class three times. Agreement
as to the implementation of the independent vari-
able was 100%.

Results

Visual analysis of the data indicated that both
experimental and control art activities resulted in
therapeutic improvement of social behaviors across
individuals. Furthermore, social behavior following
directed art activities was more improved than fol-
lowing control art activities. Of the three subjects,
Jack’s data showed the most marked improve-
ments. Overall, the mean rate of aggression per session was
7.2 for baseline (range 3–10), 5.0 after control art ac-
tivities (range 0–9), and .75 after directed art activi-
ties (range 0–2). During baseline, Jack emitted ag-
gressive behaviors an average of 7.8 times (range
7–10) at the beginning of circle time, and an average
of 6.6 times (range 3–9) 30 minutes later (see Figure
1). A comparison of aggression at 5 and 30 minutes
following treatment conditions showed means of .5
and 1.0 respectively after directed art activities
(ranges: 1–2 at 5 minutes; 0–2 at 30 minutes) and
means of 5.0 and 5.2 respectively after control art ac-
tivities (ranges: 3–9 at 5 minutes; 0–8 at 30 minutes).

In an overall comparison of social initiations,
Jerry emitted a mean of .2 responses per session
(range 0–1) during baseline; a mean of 1.6 responses
per session (range 0–4) following control art activi-
ties; and a mean of 3.4 responses per session (range
1–5) following directed art activities. The data
showed that in circle time Jerry emitted an average
of .2 responses during both the first 5 minutes and
30 minutes later (see Figure 2). Directed art activi-
ties were followed by increased social initiations
means of 3.6 (range 2–5) and 3.2 (range 2–5). By con-
trast, self-initiated responses were emitted an aver-
age of 1.7 times (range 0–3) and 1.5 times (range
0–4) respectively at 5 minutes and 30 minutes fol-
lowing control art activities.

Differences across conditions were less marked
for Andy than for either Jack or Jerry. An overall
comparison revealed a mean of .6 eye contacts
(range 0–2) per session during baseline; a mean of
1.5 eye contacts (range 0–3) per session following
control art activities; and a mean of 1.9 eye contacts
(range 0–3) per session following directed art activi-
ties. During baseline, Andy was observed establish-
ing eye contact an average of .8 and .4 times (ranges
0–2) respectively for the first 5 minutes and then 30
minutes later. Mean number of eye contacts follow-
ing directed art activities were 1.5 (range 1–3) and .8
(range 0–2) respectively at 5 and 30 minutes follow-
ting treatment. Similarly, eye contact was observed
an average of 1.5 (range 1–3) at 5 minutes and 1.0
(range 0–2) 30 minutes later following control art ac-
tivities.

Figure 1. The frequency of aggressive behaviors during each of the various experimental manipula-
tions.

Figure 2. The frequency of social initiation during each of the various experimental manipula-
tions.
The results of this study indicate that directed art activities may be effective for improving social behaviors for children. The process of pairing manipulation of selected art materials and activities with communication between children and the teacher seems to be an effective outlet of emotional expression, particularly for students who have a history of repression and violence. Although the data for Andy were not as dramatic, some change was found. Halfway through the study this pupil was also absent a large percentage of the time. Later, it was determined that due to his type of sensory motor problems, he was not capable of engaging and maintaining eye contact without physical and verbal prompts.

The changes noted in the students’ behaviors after the nondirected activity may have resulted from a whole group activity as opposed to small group art activities that were previously conducted in the class. A large group may also have stimulated students’ expressive output (Thompson, 1990). The outcomes here appear to support strategies used in the work of Malchiodi (1990) [facilitating emotional responses], Roth (1987) [behavioral techniques], and Silver (1978) [child development].

It is possible that when students are exposed to directed art activities for a period of months rather than weeks, the impact would be more enduring. Though there was an immediate impact on all children, the results were not sustained from day to day. Thus, the length of time spent in art therapy is a factor which warrants further investigation to determine the real potential of art therapy in the classroom.

Using directed art activities seemed practical, cost-effective, and manageable in an integrated setting where all children could benefit in individual ways. In further studies, it would be advantageous to collect data on the entire class using videotape. The tape could be analyzed, target behaviors selected, and permanent data records kept. Moreover, the child who made the greatest gains in the study was behaviorally involved (aggressive), and further replication with a target population of children exhibiting aggression may further validate the results or reveal some comparison data.

Although most early childhood special education teachers are not trained art therapists, their education has typically included a good background in the psychology of younger children as well as research methodology. Provided that they work closely with school psychologists and counselors to refer cases to trained specialists when necessary, knowledge of art therapy techniques could be invaluable as a preventative measure with children who are developmentally delayed and at risk for developing emotional and behavioral problems.

Though the current study revealed that art therapy could be effective, additional research is warranted to establish the generalizability of these findings to other populations. A study contrasting the combination of art and discussion with just a discussion of emotions would be advantageous in establishing the critical elements involved in the behavior changes. The maintenance and effectiveness of employing various types of art activities also warrant further study; for example, whether or not the medium employed in the art activity would produce different rates of behavior and if behavior changes could be maintained over time. Finally, the use of methodology from applied behavioral analysis allows one to evaluate and make appropriate data-based judgments as to the effectiveness of new interventions, including art-based interventions, for children with disabilities.

THE EFFECTS OF DIRECTED ART ACTIVITIES

Viewpoints

The Ear of the Physician

Shirley Low Gerstenberger, MS, Topeka, KS

Three decades ago, as a sociology student, I received an assignment to design and implement a research problem relevant to my discipline. The in-depth study I attempted with a university drawing class was qualitative, using participat-observation, interview, questionnaire, and sociogram techniques. Just what insights this vast array of collected data brought me were somewhat ambiguous, but I polished it off with descriptive statistics and felt certain that the results were more promising than tables of numbers replete with complex statistical manipulations. Part of my methodology was based on naivete, but part was grounded in a discipline that did not subscribe to the theory that quantitative is always better! I had the freedom to investigate my subjects from many perspectives, to organize, reorganize, and enhance my information in varying ways, and to recognize that to generalize my findings was overstepping boundaries, inviting bias.

Indeed, President Johnson at the nation’s helm seemed eager to hand out grant funding and encouragement for a wide range of research topics and methodologies among the social sciences. Social science research seemed a ready opportunity, and one not necessarily constrained by the rigors of experimental methodology. Behaviorism flexed its muscles but did not eliminate qualitative approaches. Accountability was to one’s academic doctrine.

Many years later, after employment in data collection and other areas of research in psychology/psychiatry and the completion of graduate training in art therapy, I find myself sorting through a morass of possibilities for teaching a one-semester graduate course in research problems and art therapy. My sociology background exerts a fundamental influence on my perception of individuals and their behavior. I find myself pulled toward a methodology that will focus on the unique aspects of the individual, and not to an approach that strains out those special characteristics of humanness. Furthermore, my propensity to view the total context of the person, a need to climb with empathy into another’s world and experience its complexity, is ever stronger. How can we hear an individual speak through art without being part of the process, participating in the dialogue, responding to the drummer who stirs both client and self?

It is natural to speak strongly for phenomenological or hermeneutic research models, any model that allows the process of treatment itself to be the mother of the research method. However, just as there is necessity to study people within their own ecosystem, it is equally necessary to conduct research within our current sociopolitical context. Today’s health care is one based on a medical model. Psychological treatment is addressed and made legitimate, albeit often in the back closet, within the confines of our health care system. With burgeoning costs of medical care and growing expectations for health care provision, we look for the discipline of art therapy through an ever more confusing maze of reimbursement issues.

Art therapy exists in a tenuous position within psychiatric treatment; its credibility generally does not reach the hallowed doors of the reimbursement agencies. Perhaps its destiny is a specialized treatment, available only to people able to finance service out-of-pocket. Even given that destiny, its healing potential must be touted, and with rigorous, professional support, its potential made apparent to the public. Better yet, why surrender to the exclusion from the insurance system and limit the population...
for whom art therapy might find a responsive chord? With either position, it seems obvious that to herald art therapy as a treatment of good choice we must promote research and we must publish our findings. To gain appropriate acknowledgment and recognition of our potential, we must know the audience to whom we first speak.

Our reimbursement system, both public and private, is based on a medical model. Our access to that system is through the door of the physician. Discourse on the pros and cons of the medical model can continue at length. Battles can be fought for wholistic treatment that springs from a psychological or spiritual framework. However, the final arbitrator in our pragmatic society is the person or institution that pays the bill. Mainstream treatments are those that public and private reimbursement agencies have deemed cost-worthy.

Consulting physicians in specialty areas are contracted for review and consultation by reimbursement agencies. Such a procedure carries with it the assumption and responsibility that the physician-consultant is a knowledgeable resource on any treatment modality. Should a query on the effectiveness of a proposed art therapy treatment reach the desk of such a physician, a decision crucial to our discipline lies in the hands of the psychiatrist. It is incumbent upon us to deliver our information, our research data, into such powerful hands. Even such a contact may not be possible if the reimbursement agent is not sufficiently cautious to check for medical opinion, but rather dismisses a request perfunctorily. And, as often is the case, such a claim may never be filed.

To successfully work the system we need to conduct research and supply findings in a professional manner, one comfortable to the psychiatrist. Recently, a psychiatrist of many years called upon me for published research that would support an art therapy program. A large insurance company had requested his opinion. Clearly, the physician was not interested in theory or anecdotal material. Case histories were not solicited. The limited research world to which the psychiatrist subscribed was couched in such concepts as control and experimental groups, pretests and posttests, and quantitative findings. His experience was based on medication studies. To him, expressive therapy referred to a verbal psycho-

therapy aimed at insight. The basic potential of imagery and its dynamic interplay with the unconscious was linked to dreams, not art therapy. I was not well-prepared to provide concise, supportive data for art therapy treatment.

While the media, both televised and in print, currently appears to be giving more attention to the use of art therapy, the scope of the discipline is not well-understood. It may be more easily acknowledged as an assessment tool, a crisis technique, or a leisure activity primarily suited to children. Unfortunately, diagnostic indicators or reports of children's art created after national disasters do not justify the effectiveness of art therapy treatment to reimbursement agencies psychiatrists.

The psychiatrist with whom I spoke wanted evidence, empirical data, for treatment success using art therapy. The message was clear. Regardless of treatment approach we must actively promote research in art therapy that incorporates measurement tools that quantify change. It would be advantageous to maintain a central file that contains reliable and valid measurement tools. Certainly a graduate course in research methodology has vast ground to cover with little or no time to explore instruments or become skilled in the administration of psychological assessment. Outcome studies based on control groups are needed. Using such control and experimental groups, the psychiatrist has no need to delve into the actual procedure of art therapy, but can give a cursory yet endorsing glance at quantitative results. Though I balk at moving from a qualitative model, and fear the loss of special data that our client art and its context yield, it appears that acceptance of the profession of art therapy lies in such a move.

Research for our own edification can be conducted in whatever method is most fruitful. Research to bring us to the awareness of reimbursement agencies must speak the language of the psychiatrist. Our health care system may be in the midst of great change as its complexity and troubles mount. Art therapy needs to purposefully locate its position in the health care arena at this time. A portfolio of data is a resource to which all art therapists need access. It is a resource all art therapists need to promote, vigorously and assertively.
Reviews

214 pp., 190 black & white illustrations. $20.00 paper. ISBN 1-56032-223-3.

Reviewed by Hannah Sherebrin, RN, A.T.R., London, Ontario, Canada

When the lights dim and the audience is asked to sit through yet another slide presentation at a conference, often one can observe people discreetly nodding off. Not so when Dr. Sandra Bertman shows her double-slide presentation “Facing Death.” I first saw the images two years ago at the International Conference on Death and Dying at King’s College, London, Ontario, Canada. Bertman’s original and provocative juxtaposition of literary, artistic, pop culture, photography, and cartoon images depicting death made the audience sit up and take note. Faced with images that challenged our own mortality, we were emotionally moved and forced to re-evaluate our previously held impressions. When familiar paintings were presented side-by-side with unexpected cartoons or a literary quotation, we were provoked to discover new meanings, new insights. Among the many thought-provoking examples, a humorous one comes to mind. Jacques Louis David’s painting The Death of Socrates, in the collection of the Metropolitan Museum of Art, is fairly well-known. It depicts the elderly philosopher, surrounded by his distressed students. As he is handed the cup of hemlock, he speaks, punctuating his words with an upheld finger. We typically ascribe to Socrates the example of willingness to die for an ideal; here death is the ultimate expression of virtue. Another interpretation was suggested by an oncology patient: It looks like Socrates is giving God the finger!

The freshness of the slide presentation is beautifully preserved in book format. Although the illustrations, unlike the slides, are not in color, the impact is extremely strong throughout the book’s four chapters. The first chapter is an introduction to terminal illness in contemporary society and a discussion of the value of using the arts to stimulate dialogue. Medical staff have been trained to be detached, scientific, and analytical in their views of illness and death; Bertman finds both patients and medical personnel can benefit from another approach. She offers this insight: “The arts uncover realities that lie outside the quantifiable or statistically measurable. They invite us into the world of dying persons in a manner different from, but not less penetrating than, scientific analysis” (p. 6).
FACING DEATH

In the second chapter we are challenged to explore critical themes through a selection of writings and images. The themes cover a wide span, from loneliness, facing the moment of death, sorrow of the survivors, the art of dying, to depictions of afterlife. The selection of images is based on three criteria: their relevance to the theme and the concerns they identify, their ability to elicit an emotional response, and their implicit humanistic bias. This non-threatening sequence of poetry, imagery, and letters is designed to aid disclosure of beliefs and fears. For example, Woody Allen’s words, “... the fear that there may be no afterlife—a depressing thought, particularly for those who have bothered to shave. Also, there is fear that there is an afterlife but no one will know where it is being held” (p. 26).

The third chapter is dedicated to validity research on this tool and presents responses from various populations with whom the images were used. Bertman, who is professor and director of the Program in Medical Humanities at the University of Massachusetts Medical Center, Worcester, tested this teaching method on her nursing and medical students. Images were also experimentally used with 54 West Virginia junior and senior high school students, Lesley College students in Cambridge, Mass., and hospice volunteers who were attending a statewide conference in Massachusetts. The Death Attitude Questionnaire and a form for discussing the “Most Memorable Image” are included as appendices. Readers can duplicate her research and collect additional data. To further validate her method for teaching and therapy, the Death Attitude Questionnaire can be administered several weeks after the presentation to detect changes in attitude.

Both similarities and differences in attitudes and choice of images are apparent when responses of the five populations are compared. Commonly held attitudes dealt with difficulty in communication about the subject, concerns about physical and emotional pain, control, and desire for a dignified death with some form of immortality. These concerns have been recognized in existing clinical literature and this study supports their validity. Most significant from a therapeutic perspective is the impact of particular images on each group. The junior/senior high school group identified more with pop culture images and literal or symbolic depictions of afterlife. College students also frequently selected symbolic images of afterlife, whereas the medical and nursing students tended to select realistic or photographic portrayals of death. Both nurses and palliative care volunteers identified with depictions of loneliness, communications, or lack of communication, at the deathbed.

The photographs of Mark and Dan Jury, titled “Gramp,” were the most emotionally charged for me. Simultaneously viewing the photograph of the grandfather, Mark, holding his grandson Dan, a baby, in his arms, and then Dan carrying his fragile, diapered grandfather, was a moving and loving experience. It brought back memories of diapering my mother before her death. The goal in all presentations was “to enable participants to relate to the images in personal terms” (p. 159). Bertman certainly achieves this goal.

The fourth chapter further explores and develops the instrument, providing us with guidelines for using the book effectively in death education and counseling. Readers are challenged to go beyond the book and create images of their own. With the use of the arts, and through the arts, we are encouraged to broaden our experience of death. Dr. Bertman’s aim is to support front line staff who continue to “be there” for the dying and their families. The book does much more. It is a sensitive document which evokes laughter and tears and provokes us to rethink our attitudes. “Art, presented in a sensitive, non-threatening format with a carefully directed focus, can evoke deeply personal understanding and can provide a sort of emotional vaccination that induces protection and a sense of empowerment, community, and humaneness” (p. 168).

As a unique teaching tool, this book merits a place of honor. It is rich with examples and provides excellent reference lists and an extensive bibliography. Because loss and bereavement are central issues in therapy, this volume could well be included in the curriculum of art therapy programs. Facing Death is a welcome addition to any art therapist’s library, for it is a true reflection of art therapy values.
Freeing the Creative Spirit: Drawing on the Power of Art to Tap the Magic and Wisdom Within

Reviewed by Vija B. Lusebrink, PhD, A.T.R., Louisville, KY

In *Freeing the Creative Spirit*, Diaz, a teacher of painting and pottery, presents a mixture of philosophical, expressive, and instructive advice for novices in art and self-exploration. This volume of "how-to-do" offers 20 art experiences and instructions in the use of art materials, five pages of reflective questions, and two meditative descriptions. Interwoven within are personal comments, references from artists, various philosophical approaches, and basic advice on obtaining and using art materials. On page margins selected quotes from artists, poets, and others enliven the text. The author's own pen sketches are interspersed throughout the book.

The introduction briefly covers the concept of *creative meditation* as "a prayerful integration of play, self-discovery, community building, and aesthetic spirituality" (p. 3). Diaz conceptualizes her approach through a diagrammatic schema of six concentric rings expanding outward from "the core of divinity, exploring the realms of the ancestral, personal, social, and universal selves through creative experiences, rituals, meditations, and reflective questions" (p. 7). These rings are surrounded by "divinity." A flow of creative energy is presumed to permeate and traverse the separate parts.

The first chapter deals with the "Ancestral Self." Diaz combines some thoughts on creativity and play with personal comments and anecdotes from observation. In the experiential section of this chapter, she briefly introduces the components of ritual: smudging or herb burning, a text for meditation, and the yoruba blessing. Simple directions are given for building an altar from a cardboard box. An exploration of paint and simple art experiences, coupled with reflective questions, conclude the chapter.

Chapter 2, "Reflections in the Inner Well," gives suggestions for using sensation and paint colors to explore emotions related to others. Additional art experiences focused on the self are discussed along with self-exploratory questions.

The third chapter, titled "The Reverential Eye," is the most integrated in the book. It includes a guided meditation and exercises in drawing from observations. Emphasis is on empathy and sensory exploration of the drawn object. An introduction to the color wheel concludes this chapter.

Chapter 4 explores the social self and briefly discusses play, autonomy, and trust. Trust is examined from five viewpoints: trust in teacher/facilitator (i.e., author), oneself, medium, process, and the divine creative force. Healing of relationships and personal healing are illustrated with brief anecdotes from the author's experience. Art experiences in this chapter incorporate the mandala, nonverbal communication, and conversation painting preceded by the "Machine," a synchronous group movement experience (pp. 139–140).

The artist as witness, prophesy, and the universal self are explored through collage exercises related to home, neighborhood, and city, in Chapter 5. The last chapter, titled "The January Time," is a period of transition between the past and the future. Diaz
suggests reviewing one's visual expressions and gives suggestions for personal and public view of the work created. She includes short descriptions of the elements of formal expression, such as style, line, texture, force, and balance. One of the exercises is rewriting the Ten Commandments in the form of "I shall" rather than "Thou shalt not."

The author's concluding thoughts speak to a "New Renaissance." "Our descendants," she writes, will "read about how we began to carry pencils and sketchbooks everywhere. They'll learn how we healed ourselves and our cities by painting murals together and sculpting monuments out of recycled materials" (p. 183).

The book includes a section on resources, including descriptions of supplies, the "Five Minute Teaching-Anybody-How-to-Draw Anything" guide, brief instructions on how to look at pictures, and working with groups. Her bibliography covers a fair list of readings in art, philosophy of art, and self-exploration. The most glaring omission is that of any art therapy references, especially Lucia Capacchione's The Creative Journal: The Art of Finding Yourself (1979), since the present work covers similar material. The only reference even somewhat related to art therapy is Margaret Frings Keyes' The Inward Journey: Art and Therapy for You (1974); this work is mentioned in the context of Jung's concept of the mandala.

After reading Freeing the Creative Spirit I could appreciate Diaz' intention to share her creative experiences and her basic structure of concepts related to self. The leaps of thought from brief glimpses on art and philosophical musings to self-exploration to detailed basic descriptions on where to obtain art materials and how to use them, however, appeared disjointed. Diaz' simplistic editorial comments throughout the book are annoying despite her assertion that the concepts shared "are not a Pollyanna philosophy. Reading ominous newspaper headlines and walking past the homeless on the streets takes me into the dark recesses of life's mysteries" (p. 181).

As an art therapist, I bristle at statements such as "working in groups . . . ensures everyone's emotional safety" (p. 115). My question is, "If it is a self-exploratory group, then who guides it?" Several times Diaz asks us to "trust me," but the above statement along with the nature of most of her art experiences makes me cautious. I hesitate to recommend this book to persons without previous training either in art or counseling, for whom this book is apparently geared. The 12 colored reproductions of visual expressions provide examples of the various art experiences; from these it is obvious that the author is talking about art experiences in art therapy and not artistic expressions. Another weakness is in the format and organization of the book. Different print sizes obstruct an easy flow from one part of the book to the next. On the positive side, however, the section related to art education is the strongest in philosophy and instructions. Specifics for supplies for each experience reflect the author's teaching experience.

Nevertheless, a few basic drawing experiences do not make one an artist or a creative individual, nor do a dozen and a half basic art experiences offer one deep and safe insight into one's personality. Art therapists with the appropriate training will benefit little from this volume. The book, however, dangerously has the power to create "creative meditation" instructors/therapists who use art therapy methods without the appropriate background training in art or counseling.

The Creative Journal for Teens: Making Friends with Yourself

Reviewed by Marcia L. Rosal, PhD, A.T.R., Louisville, KY

What do Anne Frank, Anais Nin, and a teen in your life have in common? According to Capacchione, they all have a need to express themselves privately, confidentially, and safely. Capacchione recommends the adolescent be given a journal. I couldn’t agree more! Creative journal-keeping (Capacchione’s term) can help teens discover who they are, how they feel, and what they need and want from others and the world around them.

This book about the creative journal-keeping process is written for teens. The text is simply worded in a down-to-earth style; yet, it is elegant and comprehensive, explaining why journaling can be enriching and describing the range of issues that can be addressed by regular use of a journal. Capacchione augments her recommendations for working in a journal with excellent examples from the Diary of a Young Girl by Anne Frank (1952), Linotte: The Early Diary of Anais Nin 1914–1920 (1978), and examples from teens with whom she has worked.

Capacchione begins with an example of how creative journal-keeping helped her through a serious illness. This personal story links creative journal use to her inquisitive, curious, 15-year-old self. She observes how much adolescents know instinctively without being conscious of the range and depth of their understanding of the world. The short story ends with an endearing photograph of the author energetically learning to ride a skateboard!

Next, Capacchione helps the adolescent get started by discussing the basics of creative journal-keeping. She succinctly defines and describes the uses of pictures and words as journaling expressions, dispelling the myth that drawing and writing are only for those who possess talent or are creative. Talent and creativity are not prerequisites for this work. She sets guidelines for the journaling experience and discusses when journaling can be useful. Journaling requires honesty; Capacchione carefully creates a link between honesty and the need to feel the journal is sacred and private. The teen is assisted in setting guidelines and boundaries for maintaining this privacy.

Chapters 2 through 7 are devoted to helping teens use the journal. Exercises are presented under six main topics: (1) what’s happening, (2) more about me, (3) getting it all together, (4) me and others, (5) my world, and (6) creating my future. The first three topics help the teen focus on the self and get in touch with feelings, thoughts, and ideas. Helping the adolescent to relate to others, including family, friends, heroes, significant others, and enemies at home and school, is the thrust of “me and others” and “my world.” Exercises in Chapter 7 help teens to focus on their futures (hopes, dreams, and plans). Throughout the book, teens are encouraged to create their own journaling exercises.

The developmental plan of exercises is excellent and in concert with cognitive psychologists’ view of treatment strategies for troubled teens. Capacchione confirms what I have experienced in working with preadolescent and adolescent clients—they need assistance in getting in touch with who they are before dealing with others and thinking about the future.
Particularly with troubled teens, focusing on the future can be especially useful. Often they feel stuck in time and sense that growth and change are beyond their reach. By helping them through a developmental sequence such as is outlined in Capaccchione’s book, even troubled teens can begin to sense some power and control over their destinies.

As in her previous books (1989a, 1989b), Capaccchione does not claim this book to be a comprehensive text on creative journaling. Rather, it is a workbook for “hands on” journal-keeping by teens. In this regard the book is stimulating and may energize the teen in your life to begin a life-long commitment to creative journaling and self-discovery.

Dwight Mackintosh: The Boy Who Time Forgot

Monograph, paperback, 96 pp., 50 plates, $11.00 + ship/tax, from Creative Growth, 355 24th St., Oakland, CA 94612.

Reviewed by Elizabeth (Liz) Ratcliffe, MS, MFCC, A.T.R., Book Editor

Just as John MacGregor’s 1989 Discovery of the Art of the Insane, challenged long held attitudes about the aesthetic value of art produced by mentally ill and psychotic people, so his present little volume persuades the reader that the creative work of retarded people can represent aesthetic productions of high quality. MacGregor’s monograph is focussed on a man named Dwight Mackintosh.

Dwight Mackintosh, christened here “the boy who time forgot,” is not easily forgotten by any serious reader of this generously illustrated monograph on a still-living 86-year-old California outsider artist. Today, a silent shuffling old man, withdrawn under a Greek sailor’s cap, Dwight is unaware of his surroundings unless they include paper, markers, and a familiar place to sit and lose himself in his uniquely expressive art work. Virtually unable to communicate with speech, his days are spent between a warm and caring board and care home in nearby Berkeley, and Oakland’s Creative Growth Center for severely disabled adults.

Spurred on by his long-term interest and research in art of the mentally disturbed, author John MacGregor spent some two years as consultant, advisor, and friend helping Creative Growth’s director Irene Brydon put together a 1992 symposium on Outsider Art. During those two years scholar-author-researcher MacGregor occupied many hours observing artist-client Mackintosh hunched over his table at Creative Growth obsessively producing his uniquely expressive art. Of this art MacGregor comments:

His need to draw is clearly obsessional: when interfered with he manifests very marked anxiety and distress... powered by intense fantasy, he explores his inner world in endlessly varied drawings... He is
RATCLIFFE

unmistakably compelled by forces beyond his control . . . drawing has, by chance, become his chief mode of communication, a means of establishing contact between himself and his environment, and beyond that with a world of which he is completely unaware. (p. 14)

In 1978 at age 72, Dwight Mackintosh was brought by his older brother Earl to Creative Growth, which in that era of massive mental patient evacuation from California state institutions, provided a friendly open environment for transition into community living. The Oakland center had been established with six artistically inclined clients in 1974, as a part-time community program, and was a natural choice for Dwight, who, recently discharged from Stockton State Hospital, had shown interest and talent in the Alan Short Center art classes there.

Prior to his six years at Stockton, Dwight had spent 25 years at each of two California state hospitals. His first admission had occurred in 1922 when he was 16. There are no records from that hospitalization, but later ones indicate that for 56 of his 86 years, his life experience had revolved around the loneliness and humiliation of institutional warehousing.

The fact that Dwight Mackintosh has survived into old age at all is near miraculous, let alone that his art increasingly is shown and collected in the U.S. and abroad, commanding prices from $500-$4,000 (Brydon, 1993). This financial bonanza has not affected his sense of self since he is unable to grasp the connection between his art making and its selling. At one point, when first his work began to bring in money through the Center's gift shop, the staff bought him a cornet in which he had expressed interest, thinking it might revive some past musical involvement. At first Dwight seemed entranced with his shiny new instrument and attempted for a full day to blow sounds on it; then, taking it home, apparently he forgot it, although in a few works he does include musical instruments.

Dwight's graphic style is essentially calligraphic, with rangy tendrils of undecipherable writing intimately married with the drawn scene into a distinctly personal statement. His major choice of subject matter, from the earliest known work to the present, has remained: restricted: people (usually boys), motor vehicles, and buildings. In the early years vehicles were school buses (with or without faces in the windows); buildings were large structures (with cupolas, bells, or flags); and people were groups of boys (usually naked and with gigantic erect penises, perhaps involved in masturbation). It would seem that springs for his graphic presentations were fed by past memories of adolescent institutional living and masturbatory fantasies. In keeping with starkly etched memories of teen-age male rituals involving mirror and living, and sex, black line was his chosen medium in his early pictures.

Gradually over Dwight's 14 years of productive work, changes have appeared, with colored pencils and chalk on pastel paper seriously entering his aesthetic repertoire around 1988. At that time his obsession with curvilinear writing also began to be replaced by perseverated strokes of color producing a warmly tinted emotion overlay, previously lacking in his black and white work. MacGregor sees these changes as perhaps physically set in motion by a 1986 seizure, followed by neurological damage, and a series of small strokes. However he maintains that to suggest that Mackintosh's final phase is influenced by neuropathology can all too readily be assumed to imply that his work has been damaged. . . . While the changes in his physical and mental state are not reflected in his drawings, his graphic images have paradoxically become freer, more powerful, and in purely linear terms, richer and more consistent. While he may be in decline, his art emphatically is not. Rather, an event rare in the history of art is occurring: the development of a true "late style." (p. 41)

Besides learning a great deal about the work of Dwight Mackintosh, author MacGregor was able to observe the other Creative Growth variously impaired artist-clients, making some intriguing observations to do with creativity and retardation. Staffed by 25 caring practicing artists, the Center's open happy atmosphere encourages the 120 clients' ability to concentrate for many hours without interruption, and to return to their work day after day with no loss of intensity. The author states, of the "possible effects of inhibited intellectual development on the image-making impulse. . . . It appears that even severe limitations in functioning do not interfere with creativity. . . . may even enhance it" (p. 15).

Although the overall quality of art produced by Creative Growth clients is amazingly high, MacGregor sees Dwight's work as clearly having a place of its own: inside the camp of Outsider Art. Though less disabled than many clients, Dwight is without a doubt intellectually impaired: on the Goodenough Draw-A-Man test in 1974, he scored at the 8-year-old level; a year later in 1975, his I.Q. was found to be 56, mildly retarded. Yet Dwight is less able to
function on his own than would be predicted from these results. The author attributes his low functioning, as well as the unique aesthetic quality of his art to a powerful natural artistic talent, which demanded to give expression to the endless years of institutional isolation where he experienced extreme physical and psychological deprivation and, quite likely, periodic withdrawal into psychosis. Thus marked, today his aloeness is profound.

He has no strong emotional attachment to anyone. Beneath the shadow of his cap, he has withdrawn into a world of his own. Almost all of his mental experience now seems to originate from deep within and from long ago. He lives for the most part in a subjective realm of recurring images, memories and fantasy, into which it is but rarely possible to intrude. . . . Given his profound isolation and inward focus, what impresses one most is the urgency of his need to create. (p. 19)

These are the kinds of experiences MacGregor's research has shown to be contributing factors in the production of Outsider Art, sometimes called Art Brut. MacGregor quotes French artist Jean Dubuffet, originator of the term, "Two criteria are essential in identifying Art Brut: intensity of expression and freedom from cultural influences. . . . (These) works arise from spiritual states of a truly original kind, profoundly different from those to which we are accustomed" (1989, p. 301).

Surely for creative people of any sort, especially practitioners of art therapy, MacGregor's ideas and discoveries are not entirely new. However, at times we all welcome a powerful reminder of the healing truth which we ourselves have experienced and in which we are professionally trained. We do not all work with either psychotics or retarded people, nor do we need to discover outsider artists among the clients we see daily. But to turn the pages of John MacGregor's beautifully printed, compassionate monograph on Dwight Mackintosh supplied for me the thrill of a true success story, as well as a personal aesthetic tonic and a professional inspiration.

References

I have been asked to respond to the review of my book, Essentials of Art Therapy Training and Practice. I find the process of reading reviews of my work to be both interesting and challenging. Generally, I am pleased by the supportive comments Bernier/Manning made, as well as stimulated by the constructive criticisms they offered.

Disturbing, however, are their repeated misrepresentations of what they describe as my, "attacks on the AATA degree guidelines." In the book I say, "It is of great concern to me that the guidelines generated by AATA for Master's Degree programs do not support continued engagement in studio art coursework." (p. 49). This is a fact. The Guidelines mention studio art courses only as possible electives. Many graduate students from programs throughout the United States have shared their worries that they have no time to make art while they are in art therapy educational programs. My concern is born of my love for the profession. This is not an attack. Surely this must be a matter of ethical concern for all art therapists.

The reviewers also question a passing reference made to a course, Studio Methods Seminar, that I taught at the Clinical Internship in Art Therapy at Harding Hospital. This refers to the last chapter of the book in which I share my artistic process of working through my mother's stroke and eventual death in 1991. Their comment is, "sounds like group art therapy." This comment seems to hold a mysterious edge of derision that I fail to understand. Bernier/Manning's misunderstanding of this chapter reflects other significant shortcomings of their review.

The final paragraph of their review begins, "In the practical world. . . . This seems to suggest that Essentials of Art Therapy Training and Practice may not be a pragmatically applicable text. I remind the reader that I spend 40 hours a week in a psychiatric hospital filled with real patients who have significant emotional problems. I don't know how I could possibly write from a more practical perspective.
Video Review

Creative Arts Therapies at the PACE School

Produced by Simone Alter Muri, EdD, A.T.R., LMHC

25 minutes, color. Purchase: $60; rental: $40, from Simone Alter Muri, 56 Bradford Street, Northampton, MA 01060.

Reviewed by Carmello Tabone, MA, A.T.R., Morgantown, WV

It may be necessary to view this video several times to truly appreciate what it has to offer. Hidden between the pictures, music, and rapidly moving narration is a valuable message about using the creative arts therapies, principally art and music therapy, with a predominantly autistic and mentally retarded adolescent and adult population. My first impression of the video was that it was little more than a promotional tape for the PACE School. However, upon closer scrutiny, I was able to recognize its potential value to art therapists, especially those who are contemplating work with the developmentally disabled. It not only provides the opportunity to see this population in action, but also demonstrates the effectiveness of arts therapies.

The video’s narrative focuses almost exclusively on the creative arts therapies, broken only by comments by the school’s director and various therapists employed by the school. Scenes from art and music therapy sessions demonstrate how the therapies are used and the goals they achieve. The happy faces of the clients involved in creative arts therapies should be more than enough to establish the effectiveness of this intervention.

The initial scenes explain the meaning of creative therapies and state they are used to help clients “discover new aspects of themselves or make changes in their minds.” The narrator says these nonverbal therapies “encourage both the expression and resolution of conflict” and “encourage individual skill development and social interaction.” The meaning of therapy, as it applies to this population, is defined as:

an ongoing relationship between a trained specialist and a client that fosters acceptance, ability to share, trust, ability to make choices, skill acquisition, learning, ability to symbolize, self-esteem, release of tension, independence, and expression of pent-up emotions.

At this point, focus on the creative arts therapies stops, and an introduction to the PACE School is provided by its director. He gives essential background information about the clientele who are developmentally delayed adolescents and adults, ages 12 to 22 years. Most clients are autistic or mentally retarded. Many have behavioral problems at home and school, difficulty interacting with others, and communication deficits. The director also discusses the school’s overall goals; this section seems quite unrelated to the arts therapies.

Switching back to the creative arts therapies, goals for music and art therapies are established. There are four main groups: (1) the need to develop better social or interpersonal skills, (2) the need for better developmental skills, such as improved fine muscle and gross motor skills, (3) the need for a strengthened sense of self, and (4) the need for a creative outlet which allows the expression of emotions or pent-up feelings. Later in the video, the first three goals are explored in depth. However, the one goal I consider most important to art therapists is the need for a creative outlet; unfortunately, an expansive discussion of this goal is omitted.

The next topic is on assessment of client strengths, weaknesses, and needs. Consultations with staff, evaluations of behavior, and an initial evaluation by the creative arts therapist are used to accomplish this task. At this point, the video would have been enhanced by a discussion and demonstration of specific evaluation methods used by the creative arts therapists.

The narration once again is interrupted by sev-
eral short segments. The director provides details on funding the creative arts therapies program and the "crux of the program," and speech, art, and music therapists talk about their roles at the school. The art therapist discusses her successful work with three clients, providing this section's most interesting segment. A similar presentation is made by the music therapist. Although this review is aimed at art therapists, I must admit I was impressed with the work of the music therapist. She certainly seems to be a valuable asset to this program and easily demonstrates what an important role music therapy plays with this population.

Concluding the video is a comparison between art conducted in an "education system" versus that at the PACE School. We learn that "at the PACE School both the process and product are important." This contrasts with other programs for special needs children where emphasis is on production of stereotyped artwork.

This video's strength is the vast amount of information it offers on using creative arts therapies with the developmentally disabled. Its weakness is a lack of organization and formatting. An introductory segment that would provide an overview is missing. Several segments seem to be out of sequence; for example, clients are shown in therapy long before the population is identified. This could have been corrected by careful sequencing. Viewers who are unfamiliar with autistic and mentally retarded clients then would not wonder why apparently typical looking young adults were scribbling and communicating with difficulty. Several pieces of information seem unrelated to the film's intent; these include many comments by the school's director and the speech therapist's segment.

Technical quality also needs some attention. In some segments the volume of the background music detracts from the narration; in other places the sound quality is poor. Color varies from segment to segment, and a few scenes are out of focus.

Overall, I find Creative Arts Therapies at the PACE School has accomplished its mission. At this writing it is the only video that I know of devoted entirely to art and music therapies with autistic and mentally retarded clients. Just seeing this population in action is in itself valuable, particularly for the uninitiated who have never worked with the developmentally disabled. After reviewing this video, I am convinced it contains sufficient information to establish and justify a creative arts therapies program. I feel confident the video will encourage other art therapists to work with the developmentally disabled.

Call for Papers

Art Therapy is seeking submissions for two special issues:

✓ STUDIO APPROACHES TO ART THERAPY

Art Therapy is seeking full-length articles, brief reports, and viewpoints for a special issue devoted to applications of art therapy occurring in a studio setting or where the therapy takes place primarily through in-depth art making. Submissions may focus on any population. Of particular interest are the pragmatic, logistical, and political issues involved in applying art therapy to a studio environment. Theoretical papers are welcome, provided they are grounded in direct experience.

✓ ETHICS IN ART THERAPY

Art Therapy is seeking full-length articles, brief reports, and viewpoints for a special issue devoted to ethics and art therapy. Submissions may focus on, but are not limited to, ethical issues specific to the practice of art therapy, pedagogical considerations in the incorporating ethics in art therapy, training, ethics in art therapy research, and ethical dilemmas in exhibiting client art expressions.

DEADLINE FOR SUBMISSION IS APRIL 1, 1994. Please refer to "Guidelines for Authors" in this journal for specific requirements regarding style and format. All manuscripts should be submitted to:

Cathy A. Malchiodi, MA, A.T.R., Editor

INSIGHTS, DISCOVERIES, SURPRISES
Drawing from the Model

Ghitta Caiserman-Roth and Rhoda Cohen

The authors, one a psychoanalyst-artist and the other an artist-teacher, reveal their struggles with the creative process. Combining candid dialogue, reproductions of their drawings, and practical teaching notes, the unique structure of this book allows the authors to share their creative approach to the subject-matter. The frank and personal disclosures and highly individual artistic styles of the authors will stimulate and encourage a diverse audience. Specialists in the psychological or psychoanalytical facets of creativity will be fascinated with this approach.

Guidelines for Submissions

All submissions will be acknowledged upon receipt by the AATA National Office. *Art Therapy* uses a blind peer review procedure for full-length articles and brief reports; final decisions regarding publication are made by the reviewers and the Editor. Decisions regarding submissions to other sections are made by the Editor, Associate Editor, and special section editors.

The following are guidelines for developing and submitting a manuscript. Manuscripts that do not conform to these guidelines will be returned to the author without review.

**Manuscript Categories**

1. **Full-length Articles.** Full-length articles may focus on the theory, practice and research in art therapy or related areas. Manuscripts must include an abstract of approximately 75-125 words summarizing the major point of the article.

2. **Brief Reports.** Short articles which focus on the results of research are appropriate for this section. Manuscripts should include information on the research design, methodology and results; an abstract of approximately 75-125 words should also be included.

3. **Viewpoints.** Short articles focusing on personal experiences, poetry or original art may be submitted to this section.

4. **Book Reviews.** Reviews of books of interest to art therapists may be submitted at any time. Books which authors wish to have considered for review may be sent directly to the AATA National Office at the address listed above.

5. **Film/Video Reviews.** Reviews of media (films or videotapes) may be submitted at any time. Media which producers wish to have considered for review may be sent directly to the AATA National Office at the address listed above.

6. **Comments.** Brief comments on articles published in *Art Therapy*, issues critical to the profession and practice of art therapy, or letters to the Editor may be submitted to this section and should conform to the style of all other submissions.

**Other Requirements**

1. Send five (5) clear copies of each manuscript to Cathy A. Malchiodi, A.T.R., Editor, *Art Therapy: Journal of the American Art Therapy Association*, c/o AATA, Inc., 1202 Allanson Road, Mundelein, Illinois 60060. Neither AATA nor the Editor can be responsible for submissions sent to any other address.

2. Only original articles that are not under consideration by another periodical or publisher are acceptable.

3. Manuscripts must be typewritten on 8½" x 11" white paper with margins of at least an inch. The body of the paper, references, tables and quotations must be double-spaced.

5. An abstract of 75-125 words must be included with full-length articles and brief reports.

6. Please avoid footnotes wherever possible.

7. A cover sheet should be prepared to include the full name(s) and degree(s) of the author(s), professional affiliations, and the return mailing address of the author to whom correspondence can be sent. Authors’ names, positions, titles and places of employment should not appear in the body of the paper to assure anonymity and to facilitate blind review.

8. Use tables sparingly and type them on separate pages. Refer to the APA *Publication Manual* for style of tabular presentations. All tables, charts or diagrams must be legible and able to withstand reduction: Include originals and four (4) photocopies.

9. Photographs must be at least 5" x 7" and black and white glossy prints, preferably with high contrast. Photocopies of illustrations or art expressions are not acceptable for publication. Figure numbers and captions should be noted on the back of photographs; captions must be typed and submitted on a separate sheet of paper. Please refer to figures in the text as Figure 1, Figure 2, etc. Include four (4) sets of photocopies of original photographs.

10. Lengthy quotations (300 words or more from one source) or reproduction of works of art (this does not include client art expressions, which is addressed below) require written permission from the copyright holder for reproduction. Adaptation of tables or figures from copyrighted sources also requires approval. It is the author's responsibility to secure such permissions; a copy of the copyright holder’s written permission must be provided to the Editor immediately upon acceptance of the article for publication.

11. Client/patient confidentiality must be protected in the title, abstract, text, photos, illustrations and other accompanying material. Proper releases for use of client art expressions and other client information must be obtained and kept on file by the author.

12. It is expected that any manuscript accepted for publication in *Art Therapy* will go through at least one revision before publication. If authors have prepared their manuscripts on either an IBM, IBM-compatible or Macintosh computer, upon acceptance, they can send a 3.5" diskette containing an electronic copy of the manuscript to the AATA office. This will help speed processing, editing and publication.

Note: Authors bear full responsibility for the accuracy of all references, quotations and materials accompanying their manuscripts.
RELATIONSHIP TO ART THERAPY: Faith in the Product. '94, 242 pp. (7 x 10), 16 il.

It is the author's goal to completely introduce the complex and diverse field of art therapy as it is now practiced in the United States. This text touches the major themes and issues of the profession. This should be the first book, or one of them, which students new to the field read about art therapy. There is provided clinical service to many specific patient populations; the basic tenets are applicable to all human beings. For the past twenty years the author has worked with mentally ill patients and makes reference in a readily understandable manner of experiences with patients, colleagues and students. Art therapy can be used with the very young through the very old. No one is disqualified on the basis of gender or sexual orientation. Art therapists work with persons from all races, creeds and religious traditions. Art therapy is effective with individuals, couples, families and groups. It works well with the intellectually gifted and the learning impaired. It can be used with the chronically mentally ill, the terminally ill, the vision impaired and the deaf. It is a safe assumption that patients admitted to psychiatric hospitals have already tried to alleviate their emotional distress with traditional verbal psychotherapy without significant relief. It is the creation of an objective thing that separates art therapy from the work done by psychologists, social workers, psychiatrists and counselors. Art therapy is particularly effective with posttraumatic stress disorder—from aftereffects of war, physical, sexual or emotional abuse. This book describes the essential elements of the process of facilitating therapeutic change in forming a foundation from which art therapists construct treatment plans and philosophies.

SHATTERED IMAGES
Phenomenological Language of Sexual Trauma

by DEE SPRING, Ph.D., A.T.R.

SHATTERED IMAGES:
Phenomenological Language of Sexual Trauma
Dee Spring, Ph.D., A.T.R.
Dee Spring has specialized in the treatment of Post-Traumatic Stress and Dissociative Disorders for twenty years. Her pioneering efforts in this field have gained international recognition because of her unique treatment style which includes art therapy, imagery and hypnosis. This book presents a treatment model that simultaneously helps the therapist stay on track amid the myriad crises encountered with sexual trauma victims and creatively explains the complex, multi-level treatment process.
Featured throughout are 57 drawings by adult victims of sexual trauma. These drawings are at once disturbing, dramatic and hopeful, representing an intense private testimony that unwraps individual secrets.

The 1993 Annual Conference: Rediscovering Our Common Ground

Cathy A. Malchiodi, MA, A.T.R., Editor

When the title of the 1993 Annual Conference, "Common Ground: The Arts, Therapy, and Spirituality," was announced over a year ago, art therapists expressed a variety of preconceptions about the theme. Some connected it with the transpersonal or contemplative psychologies, others saw the theme as relating to religion; some felt it might be an attempt to replicate the success of the “Common Boundary” conferences which focus on the connections between psychotherapy and spirituality; and others worried that the AATA and art therapy might be stepping too far into the "weird."

However, as it turned out, the annual conference was much more than its theme may have implied from any of these perspectives, and was much different than many could have imagined. First, it was the most well-attended conference in recent AATA history (almost 950 registrants), which lent an energy that has not been present in the past few years. Also, despite the negative trends in the economy, the talk of art therapy positions being eliminated, and the threat to the future of the profession within the changing health care system, a hopeful and positive feeling gradually emerged that has not been present for quite sometime at AATA conferences.

Beginning with the well-orchestrated opening ceremony and presentation led by Cathy Moon, Program Chair, several themes which became pervasive throughout the conference were initiated. One theme which many found particularly stimulating was the important role visual art played in the opening session of each day. The use of a formal gallery-like slide show of art therapists’ work at the beginning of two of the general sessions was both artistically impressive and inspiring, and demonstrated the importance of the central position of art in our work. There was also a great deal of sharing of personal art and art process in both the general sessions and individual presentations that followed, reinforcing the idea that personal art making can indeed be a valuable way of researching and clarifying theoretical and methodological issues in our field.

Additionally, the idea of unity was initiated during the opening session through many aspects, including a performance which encouraged audience participation. Although some people may have felt uncomfortable with group participation, it did indeed force a connection with others in the space (e.g., through the symbolic tying of pieces of string and yarn, among other aspects). The discussion groups which followed provided another forum for connection with others as well as a comfortable and humanizing environment for people to reflect on issues presented in each general session. Since the annual conference serves as a place for people to reconnect with each other each year, to get support for their often difficult and isolating work as art therapists, and to exchange ideas, this opportunity to meet and talk in such an intimate space was both congenial and collegial.

A third theme that emerged as the conference unfolded was a feeling of diversity. Although many art therapists initially saw the conference theme of arts, therapy, and spirituality as restrictive, it seemed to have no obvious effect on the diversity of presentations. There were numerous stimulating presentations, some related to the designated conference theme and others quite divergent in theoretical perspectives and philosophies. Attendees could find well-designed research studies and clinical applications as easily as heuristic explorations of the art making process and personal perspectives on the arts and spirituality. Additionally, there were a number of presentations that emphasized interdisciplinary themes (anthropology, feminism, art history, medicine, performance art, etc.) which were both refreshing and provocative.

In this 25th anniversary year of the AATA, it is important to remember that within the field of art therapy diversity has been our common ground. It is the diversity within the profession that has served as a stimulus and has given us vitality; it is also our diversity that sometimes bewails us, inflames us, and often creates chaos within our ranks. As Editor, I am often confounded by the diversity in opinions formally expressed to me concerning the journal; some think the journal is too research-oriented; others say there is not enough research and that more rigorous research papers, particularly empirically based, should be encouraged; some readers feel there is too much emphasis on art and the language of art over principles of psychotherapy, managed care, and diagnosis-related groups (DRGs), while others are left feeling the journal does not adequately represent art-based theories of practice; others would like to see more current paradigms (e.g., transpersonal, feminism, mind/body, social constructivism, etc.) presented, in contrast to those who find such thinking dangerous and controversial, and would like to see more emphasis on traditional theories and methodologies of psychotherapy.
This diversity of opinion can obviously be quite healthy; it is our collective ability to make connections between these diverse ideas that will see art therapy through the years ahead. Our ability to connect diversity within our field, allowing it to emerge as a strength rather than a disabling factor, will be necessary if we expect to survive as a profession with any life into the next century. There is plenty of room in our profession for art, quantitative research, spirituality, managed care, heuristic inquiry, psychotherapy, standards of practice, contemplation, licensure, studio work, and certification, as diverse as they sound; needless to say, there is room for all these topics and more on the pages of this journal. We must also remember that it is also our history of passion, of being for or against one or more of these diverse topics, that often has propelled us forward to new vistas and terrain, resulting in the growth of the field.

Lastly, although we may feel vehement about a certain theory or methodology and angered by another, we need not fear arguing with each other about what gives each of us the passion to continue on as art therapists. The point is that we need not be afraid of any of these ideas which make us diverse, nor do each of us have to embrace all of them simultaneously. The point is that as long as we allow for all of them and are willing to continue a dialogue with our diversity, we will have the stimulation and tools we need not only to survive as a profession, but also to keep our souls alive in the workplace and in life.

Art Therapy is seeking submissions for two special issues

Studio Approaches to Art Therapy. Art Therapy is seeking full-length articles, brief reports, and viewpoints for a special issue devoted to applications of art therapy in a studio setting or where the therapy takes place primarily through in-depth art making. Submissions may focus on any population. Of particular interest are the pragmatic, logistical, and political issues involved in applying art therapy to a studio environment. Theoretical papers are welcome, provided they are grounded in direct experience.

Ethics and Art Therapy. Art Therapy is seeking full-length articles, brief reports, and viewpoints for a special issue devoted to ethics and art therapy. Submissions may focus on, but may not be limited to, ethical issues specific to the practice of art therapy, pedagogical considerations in the incorporation of ethics in art therapy training, supervision, and practice; ethics in art therapy research; legal aspects of art therapy practice; and ethical dilemmas in exhibiting client art expressions. Potential authors are reminded to consider the topic of ethics as specifically related to the field of art therapy, not counseling, psychology, or other related mental health fields. Submissions will be reviewed for publication in part on the ability of the author to make this connection.

Art Therapy is also seeking full-length articles, brief reports, and viewpoints for a second special issue devoted to the use of art in relation to medicine. Submissions may focus on, but may not be limited to, theory and application of art therapy to medical settings; the use of art therapy with specific populations (cancer, AIDS, chronic physical conditions); the relationship of art therapy to changes in healthcare delivery and the forthcoming national healthcare plan. Submissions which explore the connections between the art process and mind/body concepts and psychoneuroimmunology are also welcomed.

Deadline for submission for Studio Approaches to Art Therapy and Ethics and Art Therapy is April 1, 1994. Deadline for submissions for Art and Medicine is June 1, 1994.

Please refer to Guidelines for Authors in each Journal issue for specific requirements in terms of style and format. Please send all manuscripts to Cathy Malchiodi, A.T.R., Editor, Art Therapy, c/o AATA, 1202 Allanson Road, Mundelein, IL 60060.
Response to Dr. Lusebrink

I wholeheartedly agree with Dr. Lusebrink that a fruitful dialogue can occur between adherents of various approaches to art therapy, and I appreciate her engaging in dialogue on these pages with me. As Suzi Gablik (1992) notes: "Contradictions in beliefs offer not only the greatest depth of field, but also project clear alternatives from which to choose" (p. 27).

However, as I have written previously (Allen, 1992), this dialogue requires consciousness in order for it to be useful. Art therapists, I suggest, need to choose how to practice based on clear intention rather than allowing ourselves to be wholly shaped by outside forces such as the health care system, insurance underwriters, or even our own beloved AATA as it evolves into an ever larger and more bureaucratic entity. While certainly many art therapists practice in a more clinical manner from both natural affinity and the conscious choice to work in clinical settings, too many believe they have no choice but to do so at the bidding of an institution.

We are co-determining factors in the making of reality. To again quote Gablik:

What we are learning is that for every situation in our lives, there is a thought pattern that both precedes and maintains it so that our consistent thinking pattern creates our experience. By changing our thinking we also change our experience. . . . The basic step is to confront what we actually believe. . . . (p. 27) (emphasis mine)

To confront what one actually believes is no small matter. It is worthwhile to examine our deeply held attitudes for we are not the sole creators but are co-creators of our own reality. We share the creation of our work-reality with doctors, mental health and insurance professionals, administrators, and not least of all, those whom we serve as art therapists. Among this host of co-creators, if we are not the clearest voice for working through the art, who will be?

Dr. Lusebrink correctly identifies my approach to knowing as heuristic. This is a method of knowing which requires the taking within one’s self of ideas, concepts, and feelings in order to discover meaning. Through the heuristic process, one discovers the fears, fantasies, and projections associated with an idea or feeling and over time thoroughly digests these in order to arrive at the essence or meaning. There is a recognition that there is no way to step outside one’s self and be, in some detached way, "objective." Rather, the element of the subjective self is used in a rigorous manner towards the end of deriving meaning. Clark Moustakas (1991) quotes Polanyi (1958, pp. vii-6) in Personal Knowledge: "Into every act of knowing there enters a passionate contribution of the person knowing what is known, and . . . this coefficient is no mere imperfection but a vital component of his knowledge."

Sincerely,

Pat B. Allen, PhD, A.T.R
River Forest, IL

Letters to the Editor

I wish to respond to your excellent editorial discussing Art Therapy and Professionalism in Art Therapy: Journal of the American Art Therapy Association, 10(3), 122–128. My view is that art therapy must build on its own interdisciplinary roots. You made the point that art therapy is not fully articulated as a separate discipline in the sense that the body of literature is lacking rigor and relying heavily on the foundation of other fields. I wish to extend this argument with the help of the metaphor of amalgamation. My goal is to articulate a position that protects and develops the interdisciplinary values of art therapy.

If we look at the very structure of the name for our professional field, we see that art therapy is interdisciplinary, reflecting the combination of two fields of process—art and therapy. Let us consider a metaphor for art therapy as an amalgam, the admixture of metals. In art therapy, similarly, two processes, art and therapy, are combined.

As the literature of art therapy has developed, it seems that another metaphor has been misapplied—the metaphor of the alloy, a process in which metals are also combined. However, in the alloy process, a metal having a lesser value is generally used to reduce the purity of the mixture. The arguments for either "art" or "therapy" in art therapy seem to me to have been similarly alloyed by implying the "other" to contain the nature of an inferior. I hope we can leave behind the metaphor for art therapy as an inferior blend of either art and therapy or therapy and art. In its place I offer the metaphor of the amalgam, the intermixture of art and therapy. I further call for this interdisciplinary endeavor to be valued as a strong foundation for art therapy to build upon.

In looking ahead, if we are committed to the idea that art therapy is an interdisciplinary field, the new literature must reflect this interdisciplinary nature. While the literature has adequately, and at times painfully, reflected the growth of art therapy to its present stature, we must remember that the field is not fully grown, and for art therapy to be recognized as a fully functioning, mature, and unique field, rigorous literature must be produced. Our growth as a field has been reflected in literature that "relies heavily on the foundation of
other fields," which has not been inappropriate. However, we
must now move ahead and develop rigorous literature that
does not neglect our interdisciplinary roots.

Your editorial made the valuable statement that we are
"utilizing models of theory and practice that have not been in-
formed by ongoing developments in other disciplines. Our in-
flexibility or unwillingness to incorporate new paradigms into
instruction severely compromises our own vitality as a profes-
sion." I agree that new paradigms are needed to give con-
tinued potency to our development. And this points toward
growth through incorporating ongoing developments in other
fields that will enhance our own interdisciplinary develop-
ment.

We must not discount the accomplishments of our pro-
fession that have brought us to the point of licensure and in-
elusion in the Older Americans Act. We are accepted as a
separate discipline. Art therapy has been hardened in the fire
of the growth process. However, for art therapy to move ahead
and to function as an articulated field we must continue
with the amalgamating process that has brought us this far.
We must continue to develop as an interdisciplinary field.

Roberta Toby Pashley, MA. A.T.R.
Marietta, CA

I am writing in response to your recent editorial in Art

My primary concern is whether art therapy can survive
as a discipline. Your editorial underscored my fear that we are
rapidly becoming a modality when you observed that "in-
creasingly large numbers of art therapists become licensed
under job titles such as counselor, marriage and family ther-
pist, or psychologist." My predicament (as an art therapist
trained at New York University) leaves me in the position of
not being able to be licensed unless I go back for another de-
gree, despite the fact that my coursework overlaps with
MFCC requirements in California.

More worrisome to me, however, is that certificate pro-
grams are popping up to prepare applicants to become
A.T.R.s in 21 credits if the applicant already possesses a Mas-
ters degree. It is my firm belief that art therapy is a discipline
and that a Masters program in art therapy should be required
because of the extent of the training involved. Certificate pro-
grams promote the idea of art therapy as a modality.

The irony is that my degree is not sufficient training in
the eyes of the Board of Behavioral Science Examiners in Cali-
ifornia to be allowed to sit for licensure as an MFCC (even if I
take 21 additional units). However, an MFCC could take 21
units and become an A.T.R. When I was accepted into a so-
cial work program, the requirement was to complete an MSW
in order to be a social worker, regardless of whether or not I
had a Masters degree. Why? It is because social work is a dis-
cipline, not a modality. The same should be said for art ther-
apy. How can we expect to be taken seriously when we allow
certificate programs? The training one would receive in a cer-
tificate program would be inferior to that which is provided in
an MA art therapy program.

Furthermore, I am opposed to combining art therapy
within MFCC programs. The discipline of art therapy seems
to get too diluted and the focus seems too broad. I feel that
instead of becoming MFCCs, we should push for state-by-
state licensure as art therapists, define our field, and not blur
the boundaries between us and other professions. We are
separate but equal, with knowledge specific to our art therapy
training.

Alison Brooks, MA. A.T.R.
Napa, CA

The Fall issue of Art Therapy: Journal of the American
Art Therapy Association included your editorial which ad-
dressed the question, "Is there a crisis in art therapy educa-
tion?" The editorial noted that during the foregoing year
three AATA-approved programs have sealed their doors to
new applicants and still other educational programs are in
possible jeopardy. The paper linked this occurrence with se-
veral factors, yet, I feel your most significant observation is the
question of whether art therapy is a discipline or a modality.
The editorial contends that if art therapy is viewed as a
modality, then it is unlikely it will survive within institutions
of higher education. As a modality, art therapy will undoubt-
edly become embraced within other fields of study, where it
will be assimilated into their scholarly pursuits.

It is reasonable to state there is a crisis in art therapy edu-
cation; unfortunately, it may be our own stiving to obtain
state licensure that has contributed to this precarious turning
point. Many training programs have adapted curricula in
order for graduate students to obtain licensure in other fields
of study. Granted this arrangement does allow students to ob-
tain licensure which has become a requirement to practice
therapy in many states; however, it may also give credence
that art therapy is a modality rather than a discipline. By
adapting art therapy curricula for the acquisition of profes-
sional licensure in other disciplines or to create indirect av-
ues of employment, we may be diluting our identity as a le-
gitimate and distinct discipline. It is understood that
licensure is a professional reality; however, obtaining li-
ensure in other fields of study is a short-term solution and may
impede our ability to secure recognition as a distinct disci-
pline.

The recent licensing of art therapists in the state of New
Mexico is monumental in the establishment of art therapy as a
distinct discipline. It should serve as a model from which we
can begin to build a strong educational foundation that will
prepare our students for licensure as art therapists! Art ther-
apy education may find it more advantageous to direct its at-
tention to strengthening and expanding curricula which per-
tains to the students' professional skills and models of theory
and practice. We must be careful not to presume that art
therapy's survival is contingent on licensure from other fields
of study as we struggle to obtain our own licensure. Let us
not lose our identity as art therapists in the quest for profes-
sional licensure, rather, let us build our selfhood which will
bring about licensure as an art therapist.

Michael J. Hanes, MAT, A.T.R.
Ada, OK

As an art therapy educator, I read your editorial, "Intro-
duction to Special Issue on Art Therapy and Professionalism:
Is There a Crisis in Art Therapy Education?", with great in-
terest. I, too, have struggled with the question of whether art
therapy is a modality—albeit a powerful, effective one—like
behavioral, family, and play therapy, or a truly separate field
for which we should offer distinct training programs. As a consultant to The Sage Graduate School, Albany, New York, I was asked to help develop a curriculum for a graduate art therapy program. The question of the value and efficacy of training art therapists was a difficult one.

As a new graduate of Pratt Institute's program in the late '70s, I was, at times, very angry at an institution which trained me for a career in which there were few jobs. Like many of my classmates, over the years, I created a variety of positions for myself and always did more than art therapy work. I provided numerous in-service training sessions and became skilled at networking. However, job mobility was always severely limited, and with the souring of our economy, the situation has worsened. I watched many of my peers return to school for social work or special education degrees. Most put art therapy on a back burner in their work with clients. Our journals continued to be authored by A.T.R.s with doctoral degrees. This left me confused and saddened.

In my work with clients and in case conferences, I was often struck by the sheer power of the medium of art and by the skills that I had acquired during my training as an art therapist. The frustration of working in such a clinically effective modality, which was so rarely understood or taken seriously by other mental health professionals, was never far from the surface. The issue of recognition among other mental health professionals will be an even more daunting one as our health care system changes.

With some reluctance, I recommended to the Sage committee that they develop a masters degree program in community counseling with a specialization in art therapy. I felt that such a degree would offer graduates greater job diversity, security, and mobility. I also made the decision to return to school in counseling psychology. I have found some of my coursework a review, and I am stunned by the absence of the creative therapies among the recommended interventions. This absence represents a real loss for the future clients whom these student therapists will encounter.

I hope that the AATA will continue to encourage the use of this modality. However, it is my opinion that in the coming years graduate art therapy program directors will be forced to take a hard look at the world of work into which they are sending their graduates. They will have to ask themselves how well their students are armed for success. While I would deplore the loss of art therapy training for mental health practitioners, I would prefer the development of training institutes similar to those for family therapists. I feel that every teacher has a responsibility to his or her students. Were I advising my own child, I would recommend a more generic, marketable degree, in concert with additional training in art therapy. I can offer no different advice to my students.

Lucille C. Larney, MPS, A.T.R.
Slingerlands, NY

The Interchange for Mental Health Professionals, a newsletter published by the Institute for Psychosocial Studies, is available to help art therapists be heard and make their profession known. This dynamic, new eclectic publication offers:

- a variety of strategies and techniques from a variety of different perspectives and disciplines for clinicians to use with clients.

- interaction among mental health professions so you have a chance to learn about different approaches to problems

- a boost in your morale:
  
  * overcome burnout
  * keep in touch with colleagues
  * survive supervision
  * tap into your creativity
  * renew a sense of faith in your profession

- advance your career
- learn to stay objective
- deal with hard-to-reach clients
- develop fresh insights

The Interchange for Mental Health Professionals is published monthly at a subscription rate of $39 for one year or $72 for two years. Please contact us at:

Images of Surviving: Art Ritual as Intervention with Sexually Abused Adolescent Females/Linda Darrah Reynolds

National Practice Study of Art Therapists/Nancy Hall, Joan Knapp

Feminine Identity/Spiritual Growth in a Father's Daughter Using Art/Sandplay Therapy/Donna M. Johnson

The Art Therapist as Expert Witness in Child Sexual Abuse Litigations/Marcia Sue Liebman

The Healing Power of Art: The Transporter Series/James Torrenzano

Art of the Soul: An Artist/Therapist Reflection on St. Hildegard’s Imagery/S. Kathleen Burke

Spiritual Life of the Child. Robert Coles and Beyond/Mimi Farrelly

Identification with the Aggressor as Seen in Children’s Drawings/Tiffany M. Groves

From Sensation to Form: The Process Observed/Mari M. Fleming

Psychology, Art History, and Education, and Anthropology Contributions: New Perspectives for Art Therapy/Janie Rhynie

Assessing Attachment Patterns with the Bird’s Nest Drawing in Family Art Evaluation/Donna Kays

Idiosyncratic Religious and Demonic Themes in Art Therapy: Implications for Treatment/Elyse Capell

Hypomania vs. Hyperactivity: Using Art as an Instrument for Differential Diagnosis/Deirdre M. Cogen, Margaret Elfe

Healing Through Art: The Native Indian Way/Nadja Ferrara

The Art of Anger: Imagery, Anger Management, and Conflict Resolution/Frances E. Kaplan

Panels

Art Exhibiting for Building Awareness of the "Human Condition" by Art Therapists/Julia Byers, Abby Calisch, Leland Peterson

Death and Wilderness in the Creative Process: The Importance of Remembering/Josie Abbenante, Debra Vetterman, Ginger Mangiello

Documentation in Art Therapy/Martha P. Haaseler, Lori Gerity, Carol Greenhal, Edith Kramer

Workshops

Mining Our Inner Wisdom: Exploring Emptiness/Space as a Spiritual Reality/Marianna Ilich

Women in the Tower: Theatre for Psychospiritual Growth/Roberta Pashley

Not Everything is Good in Genesis One/Jo Milgram

Thirsting for Wholeness/Leonie Reisberg, Linda Siegel

Spiritual Wounds and Vicarious Trauma/Molly H. Gazzino

Exploring the Relationship of Ritual to Art Therapy/Randy Vick

Art Therapy Educators’ Convocation
Follow Through: Art Therapy Style

Gwen Locke Gibson, M.A., A.T.R.
1993 Honorary Life Member, awarded at the 24th Annual Conference of the American Art Therapy Association, November 20, 1993, Atlanta, GA

Gwen Locke Gibson, MLA, A.T.R., HLM began working as an art therapist at the Baltimore City Psychiatric Day Treatment Center in 1968 in pioneer capacity. In 1972, Gwen earned the A.T.R. under the regulations at that time: she could have received the grandfather clause but chose to establish her credentials. She earned her BA in 1967 at Tucson State University, her MLA in 1975 at Johns Hopkins University. Gwen has a certificate in Family Therapy Training from the University of Maryland Medical School. (Gwen received a certificate as medical laboratory technician in 1943 from the University of Pennsylvania, worked in that field while her husband completed medical school until the birth of Robert W. Gibson, Jr. in 1950.)

Gwen assisted in the early organization of the Maryland Art Therapy Association. She is well respected for her countless hours of teaching and supervising students, also for supporting and organizing art therapy positions in her home region. Nationally, Gwen held numerous offices in AATA beginning in 1972: chairing research on initiating local chapters, Treasurer, President-Elect, Chair of 1976 Conference Program, Co-Chair of overall planning of 1976 Annual Conference, President 1979–81. As President, Gwen distinguished herself by taking on and resolving many organizational conflicts. During this time, the decision was made to obtain a management office for extended services. Gwen singlehandedly established the “art therapy registered” privilege with the United States Department of Patents and Trademarks for AATA use only! Gwen was AATA’s Chairperson with the National Coalition of Creative Arts Therapy from 1979–81: was a participant and co-planner of the June 1979 Coalition Conference sponsored by the Falk Foundation through the American Psychiatric Association. Her leadership, judgement, and character helped guide AATA through a very important period of history, achieving a unity of purpose.

Gwen has published numerous papers on art therapy practice, has spoken in a variety of forums to educate art therapists and the public on the uses of our special talents. This includes radio and T.V. interviews plus regular appearances in sociology, psychology, and art classrooms in college and graduate school settings.

Since her presidency, Gwen has served on various AATA committees. Most recently, she chaired the Committee on Ethics and Professional Practice; this is a heavy responsibility requiring careful evaluation of cases, consultations with legal counsel, setting up procedures and forms for committee use, practicing strict confidentiality. Gwen guided this committee through its first years with her usual quiet, diplomatic manner. Her wisdom, problem-solving skills, professionalism, understanding, clinical expertise, reliability, dedication to art therapy, and willingness to serve AATA many hours out of a single week make her an outstanding role model for all art therapists.

Gwen is now 70 years old. She retired from full-time employment at the Psychiatric Day Hospital, Francis Scott Key Medical Center, a Johns Hopkins Institution in Baltimore. The Day Hospital persuaded Gwen to return 2 days a week. Gwen has also consented to serve AATA this year as member of the Long Range Planning Committee. She is current chairperson of the Maryland Art Therapy Ethics Committee.

Gwen considers her greatest joy and pride to be her beloved family: Gibby, his wife Chris, and children Rob and Caroline; Christopher; Peggy, her husband Irv; and children, Molly and Evan Klein. She and Robert Gibson, MD divorced in 1982 after 37 years of marriage.

The Honorary Life Member award is the highest, tangible expression of gratitude that one can receive from peers of the American Art Therapy Association. I thank all of you who forwarded my name as a candidate. I thank the Honors Committee and AATA Directors whose first appraisal found me to be deserving of acclaim. I thank the AATA members for the ballot vote of final approbation.

With modesty, I accept this gift in the company of all the “angels which sit upon my shoulders.” These angels are AATA members past and present who have labored with me to make the practice of art therapy a viable profession. Some are in the audience today. They are the committee members, pioneers, practitioners, teachers, not the least of the angels are my three kids: Gibby, Christopher, and Peggy who shared me during times when “I owed my life to the company store.” Ex-spouse Bob Gibson encouraged and supported my involvement, as well.

Taking part in the growth and development of a profession has greatly influenced my personal strength and maturity. I used to be painfully shy. When I was a youngster, my head rested more often upon one shoulder in vain efforts to hide it under one of my arms. Parents and teachers pushed me into action, because they had more faith in my potential than I did. In elementary school days, my stomach would get queasy when I was pressed into a new undertaking. Even my successes bred more stress. For example, my beloved, longtime violin teacher decided to switch me to study with a violin “master.” I upchucked first, and then auditioned. I passed the audition; however, I did not wish to make a serious commitment to this one instrument. Why follow through on a path which was not of consuming interest to me? I learned to go with “gut reaction” (excuse the pun), and assert the space comfortable for me. I enjoyed my role as member of the or-
chestra rather than aspiring to be a solo performer. Team participant, not the star.

"Follow through" became a personal pursuit when the task was important to me. Another sample of increasing self awareness began in 1939 when I joined a group of Quakers who shared my need to make efforts for world peace. We toiled all summer with workshops for children, helping them to design anti-war posters. We met with the parents to raise their consciousness to seek alternatives to global disputes. In the process of championing the ideal of world harmony, I discovered my shy voice was changing to bold and authoritative speech. Further, in the mid-1940s, our Quaker activities involved interracial volunteers who organized weekend work crews in the Philadelphia area (sort of like Habitat): we also shared once-a-week art lessons at an interracial "Y." During the AATA Conference in Denver, I skipped out to join Friends (upper case and lower case "F") in a silent vigil in the height of non-nuke hustle around the War Memorial Square: issues of U.S.A. intrusion in Central America. My commitment to peaceable negotiations continues; the follow-through felt good.

My immediate family has always been the #1 cause for me, and will always be. In 1968, art therapy became the #2 cause worthy of my time and efforts. I loved the career I launched in 1967. I vowed to learn more ways to help patients; I wanted to become an able teacher and supervisor; serving AATA was the way.

By the year 2020, I hope many more art therapy pioneers will emerge. It is true we appreciate Naumburg, Kramer, Kwiatkowska, et al., and celebrate their contributions to revive and redirect the ancient connections between art and healing. The ideal is that pioneers should not be frozen in past times. At this moment, an art therapist pioneer is traveling the birth canal. If we do not believe in this continuity and fail to nurture "new blood," the American Art Therapy Association will stagnate. Let us not defy the founders to the exclusion of acknowledging the contributions of the young.

This 70-year-old brain has 25 years of AATA history among the incised trails of memory. May I share some personal concerns? The Presidents of AATA come and go, historically, management firms and lawyers have come and gone. (I hasten to say I have no current knowledge of change, for the relationships appear mutually agreeable.) We must keep a continually up-dated text of past and present obligations to give to incoming leaders to assist them in the performance of duties. For example, as Treasurer and member of the 1975-1977 Finance Committee, upon the advice of a bank president friend, I established a "rule of thumb" to maintain in our treasury the dollar amount equivalent to one year of the association’s operating expenses. This regulation assures a safety net for unforeseen budget demands and/or emergency funds; otherwise, AATA could go bankrupt after one year’s disaster. Follow through on this advice.

As President in 1990, I applied to the Patent and Trademark Office in Virginia to register AATA’s A.T.R. for registering art therapists. Every 10 years, this official record must be reconfirmed in writing, accompanied by a required stipend. The United States Government does not send reminders or bills, so our AATA leadership must note the due date and take responsibility to communicate the association’s goals and purposes plus assurance of the continued use of A.T.R. We need a "red letter" document or manual like a "hot line" listing when the date confirmation is due. Follow through is vital for our registry trademark; otherwise, we lose it.

It concerns me that not all AATA members realize the distinctions of business management’s functions as compared with the association’s professional leadership. Too often, I have heard art therapists say, "I called AATA Office about a great idea—or—about my complaints. They gave me names of other persons to call. I didn’t call, because I thought it was enough to give my message to the office." Some members view the Mundelein site as "Big Daddy" or "Big Momma"; some believe the staff is made up of art therapists. This inability to make a distinction must pose a headache for Stogar Associates also. The individual with the distorted perception fails to communicate with appropriate Directors or Committee Chairs. Is there a way to clarify naiveté? To increase direct communications?

AATA has made great strides: setting educational guidelines, more schools offer art therapy training, an increased number of hiring persons recognize the effective results of art therapy interventions, procedures for ethical practice are in place, etc. Setting up testing and the credentialing board activities will be costly, although valuable to assure competent clinicians. Further, I hope we can afford to create our own computer database disc to inform the public about the many uses of art therapy. Directors and managers of psychiatric, medical, educational, and penal institutions rarely have knowledge of our existence. Some who express a desire to read art therapy papers and research projects have searched information data bases with little or no success. The same dead end is met by students of art, social work, nursing, and others who want to survey our modality to discover ways in which we can work together. Could AATA’s Public Information and Publication Committees study ways to make possible this important source of exchange? I believe we were once listed in psychiatry’s data base; but there may not have been the necessary follow-through to maintain the connection. Are we testing and credentialing persons who may not find employment placements, because sufficient agencies have not discovered us? Let us not keep secret our creative abilities to make a positive difference in relieving the suffering of patients and clients. Similar to the practice of wholistic medicine, we must demonstrate wholistic attention to association development.

You might ask, "Were you cured of your shyness, Gwen?" My response is that I get "flashbacks" from time to time; however, commitment to a cause bigger than self is the "medicine." I believe in art therapy; I love my colleagues. It is exciting to stand shoulder-to-shoulder with you. When standing shoulder-to-shoulder, you can’t hide your head under your arms even if you wanted to.

More AATA members must become personally involved. Some may be waiting for a colleague to invite them into service. Don’t hesitate, please write or phone the president or president-elect to announce your willingness to carry a baton in a committee of your special interest. Follow through, and make this profession the best you could wish it to be. My greatest reward is the friendships, the support, and caring; it could be your reward, too.

Post Script: I promise not to rest on my laurels. I will serve AATA as long as destiny permits. Thank you for my H.M.
1993 Distinguished Service Award
Deborah A. Good, MA, A.T.R.
24th Annual American Art Therapy Association Conference
November 20, 1993, Atlanta, GA

Deborah Good is currently the department chairperson for the art therapy master's degree program at Southwestern College in Santa Fe, New Mexico. She has a private practice which includes contract work with Family Therapy of Albuquerque, Albuquerque Public Schools and New Vistas. She is also a doctoral student in the Counseling Department at the University of New Mexico.

Debbie has worked extensively in numerous hospital and outpatient settings. She has served on many state and national committees, including: AATA Clinical, AATA Governmental Affairs, AATA Registration and Standards, NMATA Governmental Affairs, NMATA Conference Program Committee, Co-Chairperson for the Four Corners Expressive Therapy Conference, NMATA Board of Directors, NMATA president, and the Biopsychosocial Task Force for JCAHO. Debbie also was elected to the AATA Board of Directors from 1989–1992, where she served as AATA Board liaison for the Clinical and Governmental Affairs Committees. Currently, she is Chair of the AATA Nominating Committee.

Her teaching history includes receiving the "Outstanding Teacher," University of New Mexico Student Evaluation Award while a graduate student in art therapy. More recently she received "A Friend of Music Therapy Award" from the southwestern region of NAMT, Distinguished Service Award from NMATA, "Extraordinary Support Award" from Webster University, and "The 1992 Outstanding Faculty Award" from Southwestern College. She has been a visiting instructor at Mount Mary College and the University of Utah.

Debbie has been a speaker for the AATA Regional Symposium on Sexual Abuse and PTSD. Recently, she became the head of that team. Her list of presentations are extensive, ranging from clinical issues to legislative concerns. In 1988, she wrote the first state legislation to license art therapists.

Debbie lobbyed and testified for this bill during the 1989, 1991, and the 1993 New Mexico legislative sessions. The bill was successfully passed, and officially signed into law in the state of New Mexico as of July 1, 1993.

Thank you! I am honored to have been chosen as the fifth recipient of the AATA Distinguished Service Award. I am also honored today to have two very important people in my life here. They are responsible for molding me into the person that I have become. They taught me:

... to have respect for others and their opinions, but to develop my own by trusting my intuition;
... to have passion in what I do for a living always remembering that all I do affects others, not only myself;
... to make decisions after weighing all the options;
... to admit to being wrong, as well as, being right;
... and to make a difference in the world by being myself.

I'd like to introduce to you my parents, Benny and Polly Good. Thank you for being here for me today.

As I thought about what I wanted to say to you, I remembered myself in 1973. 20 years ago, as an art educator in an alternative prison program for young adolescent males. There I realized that what I was doing was more than art education. I realized that there was a therapeutic encounter happening between these disturbed young men and their art making. I remember, like it was yesterday, the first time that I pushed paper and crayons under the door to the look-up security room. Minutes later drawings were slid back to me expressing more than this troubled teen could put into words.

I grabbed everything I could find that was written on art therapy and began to work toward my career as an art therapist. A year later, I was involved in a debilitating automobile accident that left me with a seriously injured spine and partial paralysis. After going through a cervical fusion and three years of physical therapy, I moved to New Mexico and pursued my Master's degree in art therapy at the University of New Mexico.

I have a history of starting things. I guess we all do as art therapists. I had already learned that time waits for no one and that today is what is most important in life. (A serious illness will teach that very quickly.) In keeping with our spiritual theme for this conference, I can tell you that I lived through a broken neck for some reason.

I was the first true art therapy student at the University of New Mexico and the first student from that program to receive my A.T.R. Along with the other art therapy graduates, we started art therapy programs across New Mexico, creating our own internships, job descriptions... and our future employment.

I quickly realized how volatile and precious my relationships with my clients were when I watched people prepare to die as life forms left their pictures and spirit guides appeared in the upper left-hand corner of the paper. Dead adolescents told of date rape through their artwork because they couldn't verbally communicate; an autistic child learned to focus through gross body movements while painting on a wall; homicidal prisoners created a wall mural through which they could visualize and problem solve; and severely abused clients retrieved and processed memories through sequential drawings that enabled them to become empowered in their lives.
Our training to be registered art therapists is rigorous, and rightfully so. We interact with people through the unconscious images that they create with so much trust, in our presence. We meet them on a soul level. It is our strength and our vulnerability. And with this connection comes an immense responsibility, that has too often become violated by counselors and therapists. This is the reason we need licensure—for our protection and for the clients'. I decided a long time ago that if and when I became licensed, it would be as an art therapist because that is what I am.

I saw that art therapists were lagging behind other professions in state and national regulations. We are gifted practitioners, and we had no choice but to mold into other professions in order to become licensed and recognized as legitimate. I felt that we deserved to be recognized for who we are and what we are trained to do. This was the impetus behind the creation of the first art therapy licensure practice act.

Rev. Francis Rath said once that "today depends on the vision one has for the future. Historically, without a vision, people perish. The future creates the present rather than the present creating the future." Our dreams make us who we are. Acting on those dreams gives purpose to the here and now. I believe in the power of art therapy and through the spread of state licensure, art therapy will not perish. We need to keep abreast of the times and current, if not ahead of, other helping professions.

For me the Counselor and Therapists Practice Act, regulating art therapists as Licensed Professional Art Therapists (LPAT), which officially became the first law of its kind on July 1, 1993, has been the highlight of my year and professional career. It will affect many people, not only New Mexico art therapists. This state licensing law does not require residency in New Mexico. It is possible for art therapists living in other states to become licensed in New Mexico and practice in their home state. Time will provide the answers to the impact that this will have on the art therapy profession.

I want to leave you with a quote from George Bernard Shaw's play Back to Methuselah that seems to bring summation to what I have been trying to say, and what I want you to remember. The serpent speaks in the garden of Eden and says, "You see things as they are and say why? But, I dream things that never were and say why not?"

Thank you very much.

Images as Angels

Presented at General Session, 24th Annual AATA Conference

Shaun McNiff, PhD, ATR, Cambridge, MA

The figures we know as angels have many names—daemons, spirits, jinils, faeries. They are a way of looking at things, a perspective, a poetic view, or what Jung would call a "psychological fact." Japanese rituals acknowledge the ghost of the taoist, and Native communities everywhere imagine spirits inhabiting hills, rocks, and trees.

When I view my creations as angels, imagination is welcomed. Reason is not abandoned, but it steps aside and invites other participants.

The classic scenario when a person is ready to acknowledge an image as a living thing and dialogue with it for the first time sounds something like this: (Speaking to a picture) "I don't know what you mean. You're a puzzle I can't solve. What do your symbols and colors mean?" James Hillman who will be speaking to you tomorrow says, "Do you ask the person who arrives at your door, 'What do you mean?'

In extending hospitality, we greet the person, spend time together, talk, enjoy each other's company, and afterwards feel enriched or ensouled by the visit. Isn't this a perfectly adequate way to practice art therapy?

I realize that uninvited and disturbing guests also arrive at our doors and I will speak about them shortly. For now, let's stick to the image that our artist found puzzling.

Solving a picture is not likely to open the soul. As Jung said, when I try to explain an image, the birds fly away. The "puzzle perspective" on art gets all of the energy stuck somewhere in the head, and even when it moves, the process is euphemistically called "mental gymnastics."

There was tension in the face, around the eyes and mouth, of the woman with whom I was working. I suggested welcoming her image and simply reflecting on the energies of its expression, telling it how she feels about its qualities. Whenever someone begins to talk with pictures in this more intimate way, the conversation slips down to the heart.

I imagine the images loving these engagements. They say, "Art therapy, put your heads aside for awhile, keep our mysteries, feel our vibrations, our visual qualities, our beauties and provocations. Dance with us in different ways."

We are so intimidated by the "touchy-feely" label that we have overcompensated with the analyzing mind, repressing the feeling function which is the way art heals the soul's wounds.

When images express themselves and act upon us, they are behaving in ways that correspond to figures we call angels. If art therapy can accept a correspondence between a picture of a lawn mower and castration fear, then it is not too far fetched to liken images to angels. Science could be an unlikely ally in that experiencing images as angels may be closer to the new physics of interacting energies than we realize. We need an advanced physics of art therapy which expands our reflections on the interaction between matter and energy, and not the labeling of images that assumes the guise of science. I must emphasize science's role as ally rather than director. Our discipline is the artistic imagination, and it welcomes cooperation with other fields.

Approaching images as angels suggests new ways of relating to them and implies that they carry medicine. I am not endorsing images with "powers" in the sense of idols, what we have in effect done to medical technologies. The angelic nature of an image transmits its medicine through cultivation and relationship. Everything depends upon how we engage the image and the values guiding our actions. In his Italian Renaissance Book of Life, Marsilio Ficino, one of archetypal psychology's inspirations, said cultivation warms up the image so that it "penetrates the flesh of someone touching it."

Here's how I began my reflections on artists and angels in Art as Medicine: "If we imagine paintings as a host of
guides, messengers, guardians, friends, helpers, protectors, familiars, shamans, intermediaries, visitors, agents, emanations, epiphanesies, influences, and other psychic functionaries, we have stepped outside the frame of positive science and into the archetypal mainstream of poetic and visionary contemplation.

Angels are having a Renaissance throughout popular culture in bookstores, cardshops, garden centers, theaters, and mail order catalogs. The images of angels that we see are anthropomorphic cherubs and Botticelli-like feathery figures with rosy cheeks, strawberry blonde hair, and flowing garments, all displaying idealized Northern and central European racial characteristics. I love Botticelli, but I also hear D. H. Lawrence howling from the other side about "this angel business," the pretty and vaporized spirits masking the soul's dark and sensual life. Our contemporary culture of angels is exclusively oriented to light figures. I do not negate, or even dislike, aerial spirits. I am simply reflecting on a one-sided imagination which neglects the earth angels, the spirits of matter, fire, stone, and darkness.

Art therapy has been my spirit guide and its influence grows stronger and clearer every year, as I witness the wisdom of the cliche, "Trust the process," and as I let go of my need to control and let the angels step forward. Focusing all of my energies on holding the space, the temenos of the studio, where art's unexplainable transformations occur. Upsetting images are always vital agents of this medicine. If they are not welcomed and respected, we sense, perhaps even smell, that the space is not safe for an opening of the soul. The images in art and dreams may show where we hurt, but they never come to harm us. Year after year I see how the deepest conflicts of the soul are transformed through the making of art, if we can stick to the images and let them cook in our sanctuaries, always trusting the art to provide the unexpected remedy.

Outside contemporary Western culture, in India, ancient Greece, and old Europe, the dark angels, troublesome and sinister figures, live alongside the sweet and proper ones in a healthy ecology of spirits where figures like Madonna and, yes, even Howard Stern, are essential to soul's pantheon.

In my personal experience I find that what bugs me the most usually has the most to offer. Demons dig deep into avoided depths and feelings. The disturbing image is typically my guiding angel, the one who delivers the most important messages. It wants to be seen and respected. If I deny its efforts to communicate, it either up the ante and increases the pressure in order to burst through, or it may patiently wait around for years, appearing in recurring dreams and paintings until I am ready to engage it. Typically, it furthers my compassion for the places in myself and others where the soul is wounded, suffering, or confused. I call these images "angels of the wound" like the AIDS icons Judy Weiser (1993) and Michael Franklin (1993) help us see.

Again, these images want to be felt and not fixed, as James Hillman will no doubt illustrate in his keynote lecture. This is the defining quality of art therapy practiced as a spiritual discipline. The unsettling image is an ally of the soul who helps me reframe how I am looking at life and living it. The dream dog gently biting at my neck wants me to turn around and pay attention, to look in all directions, to see immediate things, while my gaze is fixed on a distant desire. My tendency is to brush aside the biting dog, tie it up, cure its biting, make it submit to my control. So it intensifies its grip and I increase my resistance, perhaps taking a pill, and it comes again and again, becoming more monstrous and nightmarish, trying to bring through repression, this messenger I make into an adversary.

Classical philosophy maintains that every thing has an essential "substance" that constitutes its being (Aristotle). The spirit or quality of a thing is the basis of its character, something that emanates from its material nature, what Rudolf Arnheim today describes as the expression of objects. Things present themselves to us and expression, as Arnheim says, is embedded in their structures. Depth is on the surface we do not fully see. This is my sense of the angel.

The arts affirm that every object or gesture has a spiritual as well as physical nature which depends upon one another. Henry Corbin, my guide to the psychology of angelic phenomena, has described the angel as the person in every thing—"beneath the appearance the apparition becomes visible to the Imagination" (1977, p. 29). Active imagination is the faculty through which "heings and things" are transformed "into their subtle state." It is a process of interpretation which is essentially meditation or prayer.

Esoteric doctrines have a profoundly practical application to art therapy where matter, body, and consciousness are infused with spirit and transformed into new forms, stories, and experiences. As colors and forms are moved and changed, our psyches experience corresponding effects. The materials and movements are shaping us. When will we see this and access its resources rather than banish soul to the shadow world through our attempts to establish art therapy as an "exact" technology?

There is a paradox at work in Corbin's reference to the spirit of an image "beneath the appearance," because the angelic nature of an image is experienced through reflection on its physical form. The angelic perspective affirms both the immediate form and its spiritual counterpart. They appear simultaneously. This is different from believing that the "true" or "deep" meaning is hidden behind a form. Deep-down is right now. If I look for something underneath, I overlook what is here.

The angel is the uplifting feeling I get when looking at Charlotte Salomon's colors and imaginary scenes and the mysteries of Frida Kahlo's faces, spirits that fly out to the viewer. Last night a dream told me there were angels in the sweeping gestures of Franz Kline's big, black strokes. "The spirits are in the motions," the dream said. "They're in there for those with the sensitivity to see and feel them when they look at a picture and when they're making one."

Interpretation is an ongoing active imagination, and creative transformation is the energy of healing. The purpose of art therapy becomes an infusion of imagination into life with a trust that a revitalized spirit will treat disorders of the spirit.

In my studio I drum to help people paint from the lower body, from the back and shoulders, to physically enact imagery from the feet and thighs as well as the fingers, arms, and head. The angel is a spirit moving through us, never fixed, a force of transformation that is healing. My studio participants love to engage finished images, but the primary experience is always art making. Do you see why I have always felt that art therapy cannot be separate from movement, drama, perform-
ance, and the sounds of creating? The angelic perspective does not fit into tidy specializations. Spirits are forever crossing disciplines within the fields of imagination.

Since we are not painting together today, I must return to reflecting on established images. As I say in Art as Medicine, I need ways to respond to pictures which correspond to their spirits. I repeatedly learn from our emphasis on gesamtkunstwerk (total expression), how the imagination is stimulated and renewed by fresh, nonhabitual expressions, like singing or moving the feeling. The angel is the surprise, the infusion of spirit, that arrives unexpectedly. For many of us talking is the most effective avoidance, the essential mode of control. Angels are more likely to arrive when we get up out of our chairs, out of our controlling heads, shutting off talk for awhile and finding new ways of engaging pictures.

I am sure there are people on the edges of their chairs, screaming silently, "My patients are hallucinating constantly, suffering from delusions. Your methods encourage this. It's crazy making. It will make them worse."

If a person talks to a specific color, picture, or texture, empathizing with its nature, isn't he or she making contact with the immediate and physical world? Maybe it's safer to talk to a painting than to a person. And even if there is an element of poetic madness involved, why not consider the homoeopathic maxim, "The toxin is the anti-toxin." Imagination offers new versions of old stories and forms an unlikely alliance with cognitive therapies. But as in creative problem solving, the linear mind relaxes its grip and allows spontaneous expression to form itself into fresh structures.

Many people find it easier to respond viscerally with their bodies to the raw energy in a painting. There is a direct expression conveyed by the painting to the body of the viewer, a charge that stimulates an equally physical countercharge, that usually corresponds to the movement and energy that shaped the painting. People are often speechless before their image, sometimes overwhelmed and even afraid. I frequently see people who fear the energy in their pictures and sculptures. They say, "You're all over the place, too much." Or, "You have so much power, no boundaries, chaotic. I'm afraid if I take you into me, I'll lose control. I'm afraid of what I'll do. I'm afraid of your power."

Talk alone doesn't work in these situations. When the artists communicate with the energy of the images with the expressions of their bodies, the situation becomes more organic, contained within their movements and within the structures of the images, as contrasted to fears without tangible embodiments.

Another artist dreamed of a frightening figure coming at her. She talked about the dream and painted it repeatedly. But only through physically enacting the experience, getting behind the mask of the figure as contrasted to having it come at her, could she know in her body that the dream demon was coming to help her accept the forcefulness of her expression rather than have it constantly turned against herself.

Physical movement helps us take the spirits of our pictures into our bodies. As we interpret the gestures of our paintings through movement, we go through yet another phase of making them our own as contrasted to the intellectualizing, disassociation, distance, and fear that we sometimes have in looking at our own pictures.

But the most basic move we make in my art therapy stu-
trees, the imaginal city, the red cloud, the dark sky, the paint, the colors, every gesture, the movement of the trees, the wind blowing through you.

Now something personal to the picture, "I didn't put you in Art as Medicine. I wasn't comfortable with you. You seemed strange. I didn't want to show you, yet you're the one I hang in my house on the biggest wall.

"You disturbed me because you brought something new . . . so red, the bleeding door, menstruating streets and skies, those weird trees dancing. My wife liked you immediately and our daughter said, 'There's magic in the red cloud and the girl knows how to find it.'"

The human figure, the man or woman, sits with the animal. Still right now.

The crazy trees whisper, "Everything will move if you can sit still."

As I settle down, and stick with the painting it feels like a vortex of energy. I begin to lose me and spin in its world, its imagination.

I ask myself: "The painting is a magical environment, but am I safe here in the place from where I look? Can I let go in front of these people? The more I look, the more I am penetrated by your color, movements, and spaces. If I'm going to travel into you, I need to relax and feel safe, protected."

"Come," the girl says. "All you have to do is sit and you will travel. Listen to the trees. They will guide you."

I begin to identify with the seated figure and feel one of my daughters hovering above. The picture is reframed from the perspective of the girl. Annie Hall style. "I can't believe he's sitting still. I can go to him, but will he get up the minute I arrive and say that he has work to do? He may be ready for me today, and the intimacy I bring."

The animal says nothing and just feels the presence of the person and comes close, smelling, looking, and sensing.

But now the animal feels like my dog who says, "Hey dude, sit . . . sit, SIT. Isn't that what you're always telling me? You need it more than I do."

The trees speak, or do they sing?

They move and make sounds.

I hear words now. "Play for us. Watch and play. Hold the space for us. Play."

The human figure says, "Yes. I sit and play, drumming and making rhythms on a mbira for the painters and dancers."

"Play," the trees say. "It's time to stop talking."

I respond with music.

This is what we do in my studios—cultivating the spirits of the image, more imagination and less explaining. Letting go in a safe place, always returning to the images, immersing ourselves in them and soul's speech which transforms everyone involved. Today I identify with the seated figure. Next time it may be the girl, or the animal, or the red. Every day I have a new relationship with the image.

When I hold the space for an artist and the images, others sit as witnesses. They are invited to respond after the artist's dialogue, but there is an essential rule—no questions and all statements are to come from the heart. If the image disturbs someone, of course he or she can express this. But the sanctity is maintained when the upheaval comes authentically from a personal feeling; as opposed to an analysis or judgment that avoids its bias. The sacred lies in the exchange of feelings and soulful expressions within the space where the work is done—this is what distinguishes a spiritual art therapy. The witnesses expand imagination and its medicine by speaking to the image, as the image, or to the artist. Artistic responses through movement, sound, or ritual enactment are welcomed, and they always seem to give the most to soul and the most satisfaction to the artist. Perhaps the angels of art therapy feel the same way.

"More art they say, feed our souls with images."

This is what you have done here in Atlanta, transforming art therapy by showing your art, infusing our community with soul and the divine influx of imagery. The angels are always a step ahead of the reflecting mind so who knows what changes are happening through these acts. As my guiding daemon says, "Let's see where it takes us."

Before I even finish I can hear the polarizing responses, insisting that I am opposing analysis, intellect, professional standards, and the rest. Please understand that I am not asking the thinking mind to leave art therapy, but only to relax its controlling grip, to step back in order to progress.

Pat Allen, who has a gift for "naming" (1992), has celebrated your imagery shown here in Atlanta, and she has proclaimed us a tribe of artists who have come out from our tents. Art therapy is appropriately transforming itself through art and bringing art's medicine to others through example, by living the discipline of art, influencing those who look and become involved as co-creators. The stream will carry us. What a difference from being asked to draw a house, a person, or a birdbath by a tester with an interpretive agenda for whatever you do. Where is our discussion of the ethics of these covert manipulations of imagery? Do we need a Miranda ruling for images?

I am drawn to the image as angel because this "metaphor of a metaphor" (Bachelard, 1987) affirms the poetic basis of creative imagination. Why not imagine images as angels for awhile and see what happens as contrasted to calling them pieces, works, graphic indicators, pictures. It's an exercise, an interpretation, just language, where metaphors try to feel, but never grasp, the untranslatable essence of a thing, das Ding. If you don't like words such as spirit, soul, and angels (Schoenholtz, 1993), cast them aside and use your own language, your indigenous speech, what Owen Barfield calls the "speaker's meaning" (1967). Articulate your offense and your longing and these expressions will open to the soul, the mystery (Moon, 1993), or whatever you call the source of creation and feeling. Carve it out for yourself and I will try to listen to your expression. The last thing I want is someone to adopt my speech. That's a disturbing echo I hear too often within associations and professions. I hunger for art's individuation of your voice, your way, into a full spectrum of colors and forms. And today we realize that art is, and will forever be, our mainstream. It speaks many languages but we have a common method, love of images.

Soul and Spirit: The Image Instructs

Presented at General Session, 24th Annual AATA Conference

Pat B. Allen, PhD, A.T.R., River Forest, IL

This presentation was inspired by a piece of writing by James Hillman called "Soul and Spirit" which appears in A Blue Fire, a collection of his selected writings. Hillman draws a distinction between soul and spirit, partly to clarify the difference between spiritual disciplines and psychotherapy. Spirit, he says, makes clear distinctions and is about refinement and purifications. Soul, on the other hand, is confusion and richness. Spirit takes the better part and seeks to make all one, while soul accepts all diversity, is contrary to category, and is messy.

The common definitions of soul and spirit are simpler; they are actually interchangeable according to Webster. Each word is used to define the other, both having to do with the ineffable, the immaterial. This would seem to reflect the bias toward spirit, pristine and transcendent, and an ignorance of soul as Hillman is using the term. While soul in our culture is marginalized, soulful is painful, and soul food and soul music are born of the suffering of the marginalized.

I was caught by Hillman's essay because he struck a chord for me when I reflected on the title of the conference and my experience with writers. It is soul more than spirit that I encounter in my images. I guess to split hairs, I would have been more comfortable with a conference entitled "Arts, Therapy and Soul" and with a figure sitting in the mud rather than flying through the sky.

Hillman associates soul with feminine and spirit with masculine and at first that annoyed me. But there is something to that, I thought, after reading about the lives of 13th century women mystics who were soulful even in their extreme spirituality. Starving themselves on one hand, the sooner to become one with their God, yet managing, like Catherine of Sienna, to give advice to Popes and to have people constantly asking for advice on daily life and living in the most chaotic profusion yet finding the divine there.

There are points where soul and spirit converge and it seems to me that this mingling occurs in extraordinary human beings who live most fully in soul (most soulfully). Then spirit, which is part of the divine, rushes in itself and cannot resist. What I am saying is that soul is our place, our job, our lot as human beings. And there can be a wish to avoid soul and try for spirit, which is more orderly, focused, clear, and light.

Thomas Moore says that the emotional complaints of our time, complaints we therapists hear every day in our practice, include "emptiness, meaninglessness, vague depression ... all these symptoms reflect a loss of soul and let us know what the soul craves" (Moore, 1992). What does the soul crave?

Soul is a cauldron, huge and dark. It is our job to keep the fire burning underneath, to replenish the contents within, and to stir and stir, endlessly. Under some cauldrons, the fire has long since burned out. The curve of the kettle is caked with rust; the stuff inside is desiccated. The stirrer has gone off to other tasks and forgotten the sacred duty: to keep things cooking, as the jazz musician says.

What goes on in the cauldron is the transformation of human suffering, the distillation of our sorrow. If our sorrow isn't cooked, it stays alive and raw, eating us instead of us eating it, and it chases us, or so we imagine, away from our cauldron, our fire, to other places until we are so weak we die inside. We can forget that the fire and the cauldron are essential, are our source, our job.

Art making is an act of remembrance—remembering that soul is our place, remembering about starting fires, combustion, cooking, and throwing everything into the cauldron and stirring it up, transforming the raw into the sweet. "Soul sticks to the realm of experience and to reflections within experience" (Hillman, 1975). It is from everyday experiences—sorrow, annoyances, jealousy, rage—that soul cooks and spirit rises.

The path to spirit is through soul and soul takes all, the dark, the dirty, the indiscriminate, the mundane, and the marvelous. Everything feeds the fire.

The images in this presentation show the instruction of the image, a path that begins with an image of rage and betrayal and pain and carries through to a spiritual insight. "Art is a process of ensoulment" (McNiff, 1989). The image instructs us to let go of judgment, of analysis, to follow instead, to trust, to dance along the path laid out for each of us, the path of the individual soul.

Why in the world do I want to show you these images?—messy and indiscriminate about messy feelings, rage, and betrayal. I guess because these images said something to me about soul. I was angry with someone, felt betrayed, and tried to reason with myself about it, look at the dynamics, let it go. I made some nasty little sketches in my sketchbook and tried to let it go. But it wouldn't; she wouldn't go away. I found my thoughts kept turning to this woman, her treachery, and I resented her intrusion. It wasn't even me she had betrayed anyway, but her husband of 10 years whom she had announced she was divorcing. Summarily, after 10 years with no discussion, no angst. She was exciting him from her life. S. felt fine about it, she said. Something about this shocked and sickened me. I felt cold, uncearably cold. But I was mad, too. I had art I wanted to be working on, and it was being pushed out by images of her. In a fit of anger, I drew an image of her, an exorcism, and painted with old smelly tempera paints (see if I waste anything good on her). I painted in a frenzy wanting nothing more than to be rid of her cold and nasty visage. I drew a bird cage with a heart in it and scratched her a scar where her heart should have been. Why
so emotional? Why so hot about this? I painted her and her husband, I collaged her mouth and eyes from magazines, betrayer, liar, false. I sat with these images feeling scared, powerful, dangerous. These would surely kill her if she saw them. I did one more her, locked into a metal collar that prevented feeling, that allowed her to be exposed, 3-D glasses on her eyes and a Pinocchio nose. Exposed as what? As an anorexic of the soul.

That insight stopped me. An anorexic of the soul. No fire under her cauldron, no mess, no feeling. Just rational decisions. I had vented my feelings, expressed my resentment at all the trouble she was causing me, distracting me from my work, yet, all this feeling can only mean I am in here too—not just the pain of betrayal but more.

The denial of feeling, of the messiness of life is for me life-threatening. The pretense of order, the denial of pain, of suffering are life threatening. The fantasy of needing no one, of self-sufficiency, is life threatening. She embodied that for me. She had simply made an executive decision—his services were no longer required. I felt that emptiness, impoverishment of empathy, that the lust for order demands. I recognized it in myself. I had struggled with it in my rage at her. I didn’t want this messy inconvenient suffering. I had a plan, work I had planned to do. The soul doesn’t plan.

The next series came shortly after, quirky images done quickly in pencil, without a plan, then washed over in watery acrylic. A figure about to punch a child or bless it, a two-sided, empty-eyed figure. Then a figure going into the water, a submerged figure, barely visible, a fetal form. Is the figure going in to save it, to rescue this suicidal or unborn form? The denied self?

The rescue of the suffering and incomplete self, and an angel appears on cue. Angels as representatives of the work of the soul, mediators of soul and spirit. “A particular image is a necessary angel, waiting for a response,” Hillman says.

In the soul, reunion takes place, the denied is affirmed, all prodigal daughters and sons are welcome. Spirit cannot help but arrive, newly held and protected, the small being. (I won’t say child, because this is about smallness in all sorts of ways.) It is always in our smallness that we suffer.

Soul is like the dog seeking out, sniffing out the dark, small, the denied. Angels are ever in waiting, as witness, even in our sense of falling, and falling, companions are there, whether we see them or don’t. The small dark self, eyeless and incomplete, can be found and reclaimed, honored and rejoiced over, even when tempted to despair in feelings of isolation. I felt compassion for my anorexic of the soul, her and me. The angels are there, whether we see them or not. I don’t think she knows that: she thinks she has to do it all alone. But actually, spirit is all. We can’t fall out of it, though we can imagine such a falling.

Simultaneously, a series of sculptures came—wrapped silent figures, anonymous and held within spaces. There is no chronological, no linear progression here. I have had to create one and it is by necessity false. All images are simultaneous, holographic, facets of a wholeness that we are, even as we misperceive ourselves as fragmented.

The work of the soul is to take all within the dark places, to find and sift out all that is wrapped and silent, its cry muffled, to reclaim, rejoice, hold, and affirm—all the suffering, all the isolation, everything—to grow it, and cook it, and eat it. And a final quote from Hillman, “Our images are our keepers, as we are theirs.”

Mystery: The Guiding Image
Cathy Moon, MA, A.T.R., Opening Session, 24th Annual Conference of the American Art Therapy Association

The theme of the 1993 American Art Therapy Association Conference in Atlanta was “Common Ground: The Arts, Therapy and Spirituality.” The opening session of the conference was a creative integration of movement, visuals, and vocals with a more traditional, verbally presented, text. This article contains the “text” part of the opening session. The intent of the whole performance was to put forth some of the questions raised by the conference theme and to set a tone of openness to diverse ideas and viewpoints.

The basis for the opening session was provided by responses to a questionnaire sent to about 75 AATA members. The questions addressed areas of interest and concern related to the conference theme. References to the responses of those questioned are contained in this article.

guided
by grace or gusts of wind
that wind
around and around our lives
lifting us here, dropping us there
to form the furrows
and twists and knots and nicks
of who we are
of how we stand
curved into the wind as if straining to hear.

guided
by unseen unspoken understood
wordlessness—
the time my mother found
the rosary beads in the drawer
of her nightstand
curled up, a coiled snake
she did not put there
had never seen
picked up without question nonetheless.
24TH ANNUAL CONFERENCE

need me, or you, to give it life, to contain and control it or to protect it. And maybe, just maybe, the connection is the text of the story itself. Maybe we will find the common ground only through the stories we tell and the images we share, replete with all the head-scratching, "now-what-does-that-have-to-do-with-anything" kind of responses that stories and images engender.

This is not to suggest that this topic grants us the permission to be vague or muddle-headed or to abandon the searching questions stimulated by our intellect. Spirituality is not a distinct category of human experience; it is a quality that pervades all of our experiences. If we are to examine the spiritual in our work we have to bring along not only our intuition, artistic sensibilities and passionate beliefs but also the piercing, prodding questioning of intellects that seek to understand and that recognize what we do not know.

Now that I've said all that (and those of you who are not so sure this conference theme is a good idea, get ready to roll your eyes) I propose that mystery be our guiding image in this search for understanding. Mystery, from the Greek word "mystos," meaning keeping silence. And from the Latin "mysterium," having to do with ministerium service, or occupation, or ministering. Silent ministry. By proposing that mystery be our guiding image I am not suggesting that we be led by some loose, vague, inarticulate notion of the meaning of our work. Instead, I am suggesting that we plant ourselves firmly and humbly in the reality of the work we do, knowing that it is, at its most fundamental level, a silent ministry. Now, don't take me too literally here. I don't mean that art therapists do not talk. The silence refers instead to the ineffable nature of our work, the inability we have to ever completely capture in words, to point to with certainty, to know without question, why engagement in art making helps people to heal.

We all know this can cause us problems as professionals in a health care system which is increasingly demanding of proof that the dollars invested will result in beneficial outcomes. So we respond, as we should for our professional survival, with research which demonstrates the validity of our work. We struggle to find research methods which are congruent with our identities as artists and art therapist clinicians. We look to anthropology, biology, and art history as well as psychology to aid us in establishing a basis for the work we do. We write articles and books, give lectures, make videos, and present workshops in attempts to articulate what it is that we do and how and why. And still, we are taken aback, startled, awed, humbled, amazed by the power of art to participate in the creation and deepening of human life. We experience this as artists and as those who bear witness to the work done by our patients. There is something going on in art making which eludes us. We are left staring, mouths hanging agape, speechless. We are in the presence of mystery.

Kirk Varnedoe (1992), director of the department of painting and sculpture at New York's Museum of Modern Art, said it this way:

"... art's strong suit is not delivering specific messages and inciting concrete deeds. Art may instead be at its most powerful when it orchestrates perplexity, fails to confirm what you already know, and instead sends you away temporarily disoriented but newly attuned to experience in ways that are perhaps even more powerful, because they are vague, vague, and indeterminate."

Many years ago I went to a presentation by a local artist who talked about and showed slides of her work. I cannot recall with clarity the appearance of her artwork. I only have in my mind vague images of sticks . . . lined up in rows, bundled together with string, arranged in patterns, given places of honor. For many ears these vague remembrances of art pieces hovered around inside me, waiting, gestating.

Then life handed me some troubled times. In the midst of loves and losses entwined, while I became thin from what was eating away at me emotionally, and my father was slipping away, piece by piece, claimed by cancer and Alzheimer’s disease, and my marriage was stripped to the bones, in that vulnerable, shivering state of readiness to be reconstructed . . . then it was time for the sticks to be born again.

I found them laying by the side of the road, someone’s discards from a spring pruning. They were cut and broken at one end. At the other end tiny buds still appeared full, ready to bloom, as yet unaware. I cradled these sticks in my arms, took them back to my studio. I loved them, and nursed them with oil paints squeezed out in violets, blues, umbers . . . deep, nourishing colors. I swathed them in soft colored twines, wrapped around and around their wounds. I laid them in the cradle of my paintings, tucked them to sleep with the swish-swish of my brushstrokes, back and forth, back and forth. At night I sat up with them, in the darkness of my studio, played music to soothe them. When it was time for them to be born again, it was I who cried, giving sound to the pain of their breathing.

I can tell you this. I cannot explain all that it meant to me. Nor can I explain why I still have sticks clustered in the corner and laying in bundles on the floor of my studio. It certainly is not because I need something to fill up the space! All I know is that they say something to me about the way life is . . . broken, discarded, utterly ordinary, potentially special, there to be disregarded or taken in hand and created anew. Out of respect. I give these sticks a home, a place of honor in my studio. They still act as guides for me though I’m not sure how or toward what.

Willingness to be guided by something not entirely known or knowable and, in so doing, to become more attuned to the way life is. Certainly this is something we ask of our patients in therapy. There is profound mystery to human suffering. This mystery cannot be tested or theorized or medicated or explained or therapized away. We don’t promise our patients a problem-free life. Instead, we offer to wade with them, kneel deep in the way life is . . . inexplicable, undeserved suffering and all.

Jan, a patient I have worked with, has reminded me many times of the mystery of human suffering. She has had very few words to put to it in the time that I have known her, but her artworks have been stunning testimonials to the painfulness of life. On one sunny afternoon I joined Jan and a few other patients in the kitchen of the inpatient unit for our art therapy group. We all set about the task of creating self symbols. Jan used the materials at hand . . . a plastic surgical glove, red food coloring, an aluminum baking pan, water, straight pins. When it came time to share her piece, she placed the pan, now filled with water, on the kitchen counter. She then floated the surgical glove, full of red-colored liquid, in the pan. Carefully she arranged the art pieces of the other group members on the counter, forming a half circle around her piece. She placed mine on the edge of the pan, then took it off. Too close I stood with the other group members, our bodies echoing the position of the art pieces on the counter, forming a half circle around Jan. Slowly she picked up a straight pin and held it above the floating glove. She moved her hand down, the sharp point of the pin barely puncturing the surface of the glove. I winced as red droplets appeared. Then she brought the pin down, and down again, and again, not roughly but with intent. And the blood red color ran in rivulets, staining the water pink, while the rest of us gave a silent witness to her suffering. No one moved. No one spoke. For a while we just stood with her. And when it was time, we helped her put these ordinary hospital kitchen things away.

It is out of the ordinary things of life, the things at hand . . . the dreams and sticks and straight pins, paints and pans, that new life is made. And in the art rooms of the hospitals, schools, jails, geriatric centers, private practice offices, psychiatric facilities, and other places where art therapists work, there are people who are making art, and in so doing they participate in the making of themselves.

But is this an inherently spiritual act, this participation in creation?

I asked art therapists this question. Is there an inherent relationship between spirituality and making art? They said “yes” and “no” and “sometimes” and “if.” It was a more complicated question than I realized at first. It followed on the heels of a question about their personal definition of spirituality, but it became apparent that their answers also were intimately tied with their definitions of art.

To summarize, and of necessity generalize, the “no” responses were tied to a view of art that is pragmatic picture-making, arising from purely human endeavors and based on intellect and training. The “yes” responses were connected to a view of art which holds that art making is an encounter with being, a response to the threat of no being, contact with authenticity, a connection with a higher creative source, a willingness to be affected by life, a bridging relationship between inner and outer, an inexplicable urge to reach beyond the superficial, a flicker of the divine within, a surrender to that “something” that takes one to new levels of understanding, an honoring of connections with others and the world around, and an act that brings meaning.

The responses leaned heavily toward the side of acknowledging if not an inherent connection between art therapy and spirituality, then at least an interrelationship. Yet this same group of people articulated many potential dangers in the integration of a spiritual focus in art therapy practice.

This is what a dangerous spiritual art therapist would be like: This therapist would not have developed sufficient trust in his or her potency as a human being, and would desperately seek a narcissistic fusion with an omnipotent other. The dangerous spiritual art therapist might wish to function as a pseudo-god and thereby undermine the clients’ ability to find the resourcefulness, the art, within themselves. In the desire to become god, this therapist would be grandiose, guru-like, inflated and vague. Art making would be used as an opiate, a way of avoidance for therapist and client alike. The reality of the physical and psychological aspects of the client would be avoided and the practice would be vague and unformed, without a clear theoretical base. "Faith" would be substituted for sincere attempts to explore and come to new understandings.
And, perhaps most grievous of all, the practice of art therapy would be used to preach the therapist's own dogmatic spiritual or religious views.

Several months ago, at the time I was working on the writing of this opening session for the conference, I did a drawing during one of my art therapy sessions. I drew myself floating in what looked like a womb-like environment with a sort of umbilical cord running off the edge of the page. I sat back and smiled at the image I had created, feeling rather smug that I was able to just float and be ready for the birthing of this conference, congratulating myself on keeping this whole thing in perspective and not getting riddled with anxiety. One of the patients looked at it and without hesitation said, "She looks inflated." Zing! Almost immediately, though barely perceptible, a s ss ss ss ss s s s s s s sound could be heard in the room and I was again ground and in some healthy, earthy anxiety!

Spiritual concerns deal with a part of life that is hard to get a firm hold on. Questioning in this area brings us to the edges of self identity and cohesion. Our response to this precarious position can be to revert to extreme doctrine, to use doctrine as a sort of "glue" to keep ourselves intact. We might also go in the other direction and become "unglued," so to speak... regress to an undifferentiated state where we lose focus and merge with what feels good, abandoning critical thinking. We are all susceptible and vulnerable to this.

In spite of these dangers, the art therapists I questioned also were able to articulate many benefits to the integration of a spiritual focus in art therapy practice.

In contrast to the dangerous spiritual art therapist, let me now present you with a compositie image of the beneficent spiritual art therapist:

The beneficent spiritual art therapist would remain firmly grounded in the reality of the tangible world while acknowledging the intangible, ineffable aspects of life. In practice, the making of art would provide such a grounding for therapist and patient alike. Clients would be assisted in exploring, identifying, and expressing the clients' own personally meaningful belief systems, viewing spirituality as an inherent quality of being human. The therapist's approach would be flexible enough to encompass the needs of clients, whether that be to address directly pointed themes like "faith" and "God" or to explore spiritual questions via themes like "creative force" or "healing power." The spiritual basis of the therapist's practice would reinforce the ability to be genuine and authentic, congruence with a value system, and awareness of limitations as a therapist. The therapist's knowledge would be limited by the literalism of Western medical or pathological theories of illness and treatment but would also include worldwide wisdom traditions and healing methods as areas of study.

I suspect that the qualities described in this composite image of a spiritual art therapist are not troubling to the majority of people here, even those who are opposed to the theme of this conference. The basis of the controversy surrounding the conference theme does not seem to stem from a repudiation of the spiritual in life. Nor does it seem to rise primarly from a rejection of art as a point of access to the spiritual, though certainly we could not claim art to be the singular point of access. The controversy seems to arise in word "spirituality," and to the images this conjures up relative to how it would become manifest in the practice of art therapy.

I have done a great deal of thinking about, reading about, and talking to others about this theme over the past year. At times this has meant taking brief dips into the bizarre, the unusual, and the humorous. Several months ago, Randy Vick, the Conference Chair, sent me something in the mail. It was a magazine article about performance art happenings. The article was a description of an "anything goes" kind of event where people proposed to do such things as jump nude into a vat of jello and staple beef jerky to their bodies while singing the national anthem backwards! Randy's quip at the top of the Xerox read, "Perhaps something like this for our opening ceremony?"

Not long after I read this article I had a dream about the opening ceremony. I don't remember it clearly, but it was smoky, weird, and swarming with people. No one had beef jerky stapled to their body, but Randy was running around, sending wafts of incense into the room with the priestly presence of a celebrant in the Roman Catholic Church. The religious, the ridiculous, the bizarre, and the reverent all collided in this dream image. Parts of my Catholic upbringing, which are imbedded in the bones of who I am, surfaced and mingled with the unfamiliar and disturbing fringe element expressions.

"Spirituality" is a loaded word. It is loaded with ancient history and trendy New-Ageism. It is loaded with the reactions of a scientific, methodological culture and the reactions of a people hungry for something to fill the void they feel. It is loaded with the good and bad of religion. It is loaded with hope and meaning and mistrust and cynicism.

It's easy to make assumptions and to jump to conclusions about what the inclusion of a spiritual focus in art therapy practice means. The challenge will be to listen past our prejudices and misconceptions and fears without losing hold of our passionate beliefs.

It seems like this should be easy for us. As artists and art therapists we have often been on the other side of this struggle for understanding. We have been perceived as unnecessary, as one of the frills to be disregarded or discarded. We have been perceived as dangerous voodooists, and met with mistrust and suspicion. We have been perceived as artsy-craftsy people who keep clients busy between the times when they have real therapy. We have been perceived as extraordinarily gifted people whose magical abilities as artists make us people to be in awe of and intimidated by. Misconceptions of art therapists have been and continue to be abundant.

It seems that this would make it easy for us to listen past our fears, prejudices, and misconceptions as we discuss the common ground between art, therapy, and spirituality, but it's not easy. "Spirituality" is such an imprecise word, so prone to misinterpretation, so difficult to define. It's a lot like "art," so prone to misinterpretation, so difficult to define. I'll say it again... maybe we will find the common ground only through the stories we tell and the images we share.

When I was a little girl my family would make yearly trips to a place called Conneaut Lake Park, an amusement park. My parents had 10 children, with an age span of about 20 years from oldest to youngest. To make these visits to Conneaut Lake Park was a family tradition, a family ritual, a family rite of passage.
children to go off on their own while they stayed with the younger children. In that magical year when it was determined that I was "old enough," I was allowed to roam the park with my sister Liz, who was a year younger than I. Our meanderings led us to a ride called the "Blue Streak." We could see that it was a ride where a series of cars attached to one another entered into a dark tunnel. It looked like fun to us so we eagerly got in line. It was not until the car we were in turned a corner and the end of the tunnel was in view that we realized we were on the roller coaster. The BIG roller coaster. I will never forget the look on my sister's face as she grabbed my arm, face as white as a sheet, and said, "Cathy, it's the roller coaster!" Being the big sister that I was, I said "It'll be okay, Liz." It was meant as a lie. But in fact, it ended up being the truth. We were okay. In spite of being carried away on something we never intended to get on in the first place, we were okay.

I am not going to stand up here and tell you that "It'll be okay," with the intention of fooling you into believing that I am calm, cool, and collected about this whole conference theme. I have been, I am, scared. I offer you my arm but, as the sign says, "Ride at your own risk." This look at mystery as a guiding image for our profession takes us into risky territories where passion runs high, individuals feel threatened, and longstanding taboos are touched upon. Fear is called for. And yet, I do not regret being program chair, or orchestrating this opening session, any more than I regretted riding the "Blue Streak." I stepped off that ride with face flushed, fingers stiff with hanging on, and stomach rolling just like the ride. I also stepped off with the understanding that it was my willingness to be guided by something not entirely visible or known that accounted for my renewed sense of being alive.

What is it that will give this professional organization of art therapists a renewed sense of being alive?

It seems that, in recent years, we have spent much of our time, effort, and energies trying to renew our professional organization's sense of aliveness through a focus on pragmatic concerns. We have fought to protect our professional identity by obtaining exclusive national trademark rights to the initials "A.T.R." We have been actively involved in legislative issues which affect whether or not art therapy services are reimbursed by third-party payers. We are in the process of developing a national certification test with the hope that the validity of our profession will be further solidified. We have attempted to adapt our educational programs and clinical practices to the expectations of a shifting health care system which demands that we provide treatment in less and less time. We have worked hard to gain public recognition and political clout. Given the general economic conditions in the United States, and the current state of health care in our country, it is understandable why we have worked so hard on these things. Is this work necessary? Absolutely! Is this work enough to give our profession a renewed sense of being alive? Absolutely not!

I suggest that this conference theme was chosen, voted on, and approved by the membership because concern with the pragmatism of our professional identity is necessary but not enough . . . because we have a need to connect with the mystery, the awe, and the faith we have that art therapy helps people to heal, whether or not we can prove it, legislate it, certify it, or be reimbursed for it . . . because we know that it is our willingness to be guided by something not entirely visible or known that leads to a deeply renewed sense of being alive as professionals.

Lynda Sesson, author of *Ordinarilly Sacred*, talks about "the human impulse to preserve the world as we know it, to make rigid its walls, secure its borders" as a religious activity. She says:

Religions reassure, reacquaint, realign us with the known and keep us safe from the chaos of new perception. But other religious activities break down walls, rearrange the borders, celebrate chaos by writing its programs and discovering its resemblances (and hence order) to ourselves. The religion of preservation tells us who we are; the religion of disorientation force us to create ourselves. (Sesson, 1992, p. 86)

We have been working hard of late on identifying and preserving who we are. It is time to risk the disorienting experience of allowing mystery to be our guiding image, of allowing mystery to force us to create our profession anew.

Volume 11, No. 1 of *Art Therapy: Journal of the American Art Therapy Association* inaugurates the first of four special sections celebrating the history of the American Art Therapy Association in its 25th anniversary year (1969–1994). In this issue, some historic material on the First Annual Conference of the American Art Therapy Association, Inc., is presented, including a transcript of the first conference program and the personal invitation extended by then Secretary, Felice Cohen, A.T.R., HLM, to members in 1970. Special thanks go to Rawley Silver, EdD, A.T.R., HLM, for providing the journal with copies of these documents.

The second section presents a record of the winners of the AATA awards from 1970 to 1993, including Honorary Life Member, the Distinguished Service Award, and the Art Therapy Clinician Award. Following this section, four AATA award recipients have responded to a request by the journal to answer the following question: 1994 marks the 25th Anniversary of the American Art Therapy Association. How will the profession of art therapy change in the next 25 years? In other words, what is your vision of the 21st century art therapist? In the three remaining issues of this volume of *Art Therapy*, other award recipients will respond to this question: we hope that their commentaries will provoke a lively dialogue on subjects both salient and controversial to the professional field.

Lastly, a photo gallery of art therapists is presented; special thanks go to Bobbi Stoll, MFCC, A.T.R., who collected the photos reprinted in this issue.

AMERICAN ART THERAPY ASSOCIATION

Dear Member:

You are cordially invited to attend, and participate in, the first conference of the American Art Therapy Association.

It is to be held at Airlie Foundation, Warrenton, Virginia, on Friday and Saturday, September 25 and 26, 1970. This lovely hotel is providing us with rooms, 3 meals a day and conference rooms. In addition it is surrounded by beautiful grounds with recreational facilities and is close enough to Washington, D.C. for those who wish to tour our Capitol.

For your convenience we are enclosing a list of our board members who are acting as committee members for Mrs. Christine Wang, our reservation chairman. For further information and reservations contact that member nearest you graphically.

The format being planned is a morning and afternoon session on Friday, with a luncheon break. During both sessions papers will be presented and immediately prior to the afternoon session there will be a short business meeting. The focus of the papers will be on Techniques of Clinical Practice. The evening will be free for socializing.

On Saturday we plan to have only a morning session during which there will be workshops. Those who wish to tour Washington Saturday afternoon will be free to do so.

If you wish to present either a paper or conduct a workshop, fill in the enclosed form and return it immediately to Myra Levick, Hahnemann Community Mental Health Center, 314 North Broad Street, Philadelphia, PA 19102. As we wish to make this as diversified as possible we are requesting that all participants send their papers and workshop formats to her also, to be received no later than June 30. Any arriving after that will not be considered. This is to insure ample time to print programs and mail them to those registered by September 15.

The board joins me in expressing the wish that you will join us in this "FIRST."

Very sincerely yours,

(Mrs.) Felice Cohen
Secretary

FC.del

AATA EXECUTIVE OFFICERS

President: Mrs. Myra Levick
The Hahnemann Medical College
Community Mental Health Center
Hotel Philadelphia–314 N. Broad Street
Philadelphia, PA 19102

President-Elect: Mr. Robert Ault
C.F. Menninger Memorial Hospital
A.T. Department–Box 629
Topeka, KS 66601

Secretary: Mrs. Felice Cohen
Child Guidance Center of Houston
3214 Austin Street
Houston, TX 77004

Treasurer: Margaret C. Howard
Children's Medical Center
Box 7362
Tulsa, OK 74105
AMERICAN ART THERAPY ASSOCIATION
Scientific Program

Morning Session — Friday, September 25, 1970

8:30 a.m.  Welcoming of the Guests
           Michelle Flesher
           Art Therapy at a Small Psychiatric Hospital

9:00–9:30  Frances Purdy
           Encounter Principles as Applied to Art Therapy

9:30–10:00 Margaret Naumburg
           Importance of Training Art Therapists in the Adequate Use of the Psychiatric Interview

10:00–10:30 Break

10:45–11:15 Dr. Arthur Robbins
           A Psychosanalytic Prospective Toward Inter-relationship of Creative Process and Functions of an Art Therapist

11:15–12:00 General Discussion

12:00–1:00 LUNCH

Afternoon Session — September 25, 1970

1:00–2:00  Business Meeting

2:00–2:30  Miriam Dergalis
           Use of Art Therapy Test to Increase Accuracy in Determining Differential Diagnosis and Contributing to Team Approach to Treatment

2:30–3:00  John Herring, MD
           Family Art Therapy in Day Hospital Setting

3:00–3:30  Edith Zeiher

3:30–4:00  General Discussion

4:00–4:15  Break

4:15–4:45  Kay Pellock
           Creative and Free Expression Techniques. Applications for Mental Retardation

4:45–5:15  Judith Rubin
           Mother-Child Art Therapy Treatment Group

5:15–5:45  Rawley Silver
           The Transfer of Attitudes and Intellectual Abilities from Art to Other School Situations and Visa-Versa

5:45–6:15  General Discussion

Morning Session — Saturday, September 26, 1970

9:30–11:30 Workshops —
           Helen Landgarten — Art Therapy Methods Utilized in Clinical Out-patient Environment
           Sandra Kagan and Myra Levick — Techniques Used to Train Psychiatric Art Therapists
           Harriet Wadeson — Techniques for Treating Couples
           Jamie Rhyne, MA — Therapeutic Art Expression
           Marjor Howard — Current Diagnostic Evaluative Techniques Utilized with Short Term Hospitalized Children
           Don Jones — Helping Patients to Experience Feeling
           Viola Dowell and Theresa Rouch — Free Expressive Techniques
           Carol Johnson — Art as a Tool in Education of Emotionally Disturbed Children
           Bert Ramsey, Dr. William Shapiro, and Miss Judith Lombard — A Demonstration of Technique and Therapeutic Value of a Large Group Drawing

11:30–1:00  General Discussion
AATA Award Winners: 1970–1993

Recipients of Honorary Life Membership in the American Art Therapy Association:

The Honorary Life Membership (HLM) is the AATA’s most prestigious award and is conferred upon Professional members of the AATA in recognition of major contributions which have had a broad influence on the field of art therapy. The award was established in 1970 when Margaret Naumburg was presented with the first HLM; since then 18 additional HLMs have been awarded by the AATA:

1970  Margaret Naumburg
1971  Edith Kramer
1972  Elinor Ulman
1973  Hanna Yaxa Kwiatkowska
1974  Myra Levick
1975  Helen Landgarten
1976  Elsie Muller
1977  Bernard Levy
1980  Janie Rhyne
1981  Judith Rubin
1983  Rawley Silver
1986  Robert Ault
1987  Gladys Agell
1988  Don Jones
1989  Felice Cohen
1990  Frances Anderson
1991  Cay Drachnik
1992  Harriet Wadeson
1993  Gwen Gibson

Recipients of the American Art Therapy Association Distinguished Service Award:

The Distinguished Service Award (DSA) is conferred on a Professional member of the AATA in recognition of significant contributions to the field of art therapy specifically in the area of the AATA’s internal development as well as its relationship with other organizations. As of 1993, five DSAs have been awarded:

1988  Lewis Shupe
1989  Suzanne Canner Hume
1991  Cathy Malchiodi
1992  Virginia Minar
1993  Deborah Good

Recipients of the American Art Therapy Association Art Therapy Clinician Award:

The Art Therapy Clinician Award (ATCA) is conferred on a Professional member of the AATA who demonstrates outstanding achievement in clinical service. There are four categories: (1) Adult Services, (2) Adolescent Services, (3) Child Services, (4) Family Services. There have been two ATCAs given:

1990  Shirley Riley (Family Services)
       Janet Bush (Child Services)

Other Awards:

The Other Awards category was developed for long-term productive involvement in the AATA and the profession of art therapy. Outstanding art therapists who have retired or who are about to retire are considered appropriate candidates for this award; the category also includes posthumous awards. Posthumous awards have been given to Clara Jo Stember and Donald Uhlin.
1994 marks the 25th Anniversary of the American Art Therapy Association. How will the profession of art therapy change in the next 25 years? In other words, what is your vision of the 21st century art therapist? Four AATA Award Recipients Respond.

**Question: Will Art Therapy Survive Universal Health Coverage Reform?**

Harriet Wadeson, PhD, A.T.R., HLM

Harriet Wadeson, PhD, A.T.R., HLM, began her art therapy career at the National Institute of Mental Health in Bethesda, Md., in 1961 under the mentorship of Hanna Kwiatkowska; she remained on the NIH staff until 1975. While there she published numerous papers in psychiatric journals and produced several exhibits for scientific conferences. One of them, "Portraits of Suicide," won the American Psychiatric Association's Benjamin Rush Award.

Toward the completion of her tenure at NIH, Harriet received a Masters Degree in Art Therapy and Psychology from Goddard College. This was followed by a Masters in Social Work from Catholic University and a PhD from Union Graduate School in 1978.

Harriet's teaching career began at NIH at its Foundation for Advanced Education in the Sciences and continued at Montgomery Community College and Lindenhurst-4 College. In 1978 she moved to Texas to direct the Art Therapy Graduate Program at the University of Houston, and in 1980 transferred to the University of Illinois at Chicago to direct its Art Therapy Graduate Program, a position she has currently held for the past 13 years. Ten years ago she established its Annual Summer Institute which she continues to direct.

Harriet has been active in AATA since its inception, having served on its Executive Board for six years as Publications and Research Chair. She has also chaired its Funding Committee, Status of Women Committee, Ethics Committee, and edited the Newsletter. In 1979 she received AATA's Research Award. She is the editor of AATA's first book-length publication, A Guide to Conducting Art Therapy Research.

Other books she has published include Art Psychotherapy, The Dynamics of Art Psychotherapy, and Advances in Art Therapy, the latter also an edited book. To date Harriet has published 30 journal articles, 14 chapters in scholarly texts, and contributed to five other published works. She has given 76 presentations at scientific meetings, 44 invited guest lectures (many of them abroad), 68 workshops, and she has held 17 visiting professorships. She has received 10 art awards (including a First Prize from the Smithsonian) and been awarded a Resolution of Commendation from the Illinois State Legislature. Her most cherished honor, however, is the HLM from AATA. Harriet's work has been highlighted in newspaper and magazine articles as well as on radio and television, in this country and abroad.

Answer: YES, NO, MAYBE! President Clinton's health care revolution spearheads the double thrust of both humanitarian and economic reform. Most art therapists, particularly those of us who work with disadvantaged populations, would support health care for all, recognizing not only its inherent humanitarianism, but also its far-reaching impact that would ripple-effect into many other areas of society.

On the other hand, the restructuring of the health care system and its economic imperatives raise questions among many. Both health care administrators and economists argue over whether the President's "managed competition" can in fact pay for the health coverage he proposes and whether the "regional health alliances" through which care would be delivered might not add an unwieldy bureaucratic superstructure to the system.

From my perspective of an individual art therapist in private practice as well as a director of an art therapy graduate program, I puzzle over the future of my profession under the President's plan. Certainly, Clinton's current proposal will undergo heavy hammering as well as detailed refining on the anvils of Congress and its lobbyists before a final version is adopted. Nevertheless, from my limited viewpoint as an individual provider and consumer, some issues spring immediately to mind. Although my knowledge of societal economic possibilities is almost nil, I do have the benefit of colleagues' experiences in today's managed health care systems to project a view of an enlargement of that format to future health care. Unfortunately, all the reports I have received have been negative. One report is from a neurologist working in a small-
or HMO that has been bought out by Humana. The physicians there have been required to buy into the organization at $20,000 or to get out. Other reports have come from hospitals bought out by Humana from a psychologist and an art therapist. They spoke of mass lay-offs and despairing morale. Apparently, Humana's expansion is part of an ongoing trend.

According to the *New York Times*:

MEDICAL NETWORKS WITH BIG DREAMS

Big health maintenance organizations are likely winners in a new system in which capitation payments would finance most medical care, replacing fees for each service (September 19, 1993, Sec. 3, p. 6). (The article notes the Humana buy-out of the HMO mentioned above, as well as others.)

According to David Himmelstein, M.D., a professor at Harvard Medical School:

This is an incredible Rube Goldberg-type structure. Essentially what they want to do is push people into HMOs and save money on that. . . . All they will succeed in doing is putting the Aetnas and Prudentials in charge of the system, giving them ownership of health care (Chicago Tribune, September 19, 1993, section 1, p. 19).

The most impactful personal report I have heard has come from an art therapist who for 10 years directed an expressive therapies department of a private hospital operated by a managed health care organization. Recently she resigned, telling me that she could no longer abide the frustrations of trying to provide patient services in a system driven primarily by economic considerations to the exclusion of attention to patients' needs. As a 10-year veteran of this system, she was certainly no starry-eyed innocent idealist. She had been successful in her work and had developed an excellent reputation for her program. Her resignation raises significant questions for me about the place for art therapists in managed care.

The *New York Times* article quoted above is titled "Changing the Fortunes of the Medical Business." As the lead article of the Sunday Business Section, it focuses on the winners and losers under the President's proposed health plan. Among the losers are specialists: "Cost-conscious medical networks make fewer referrals to specialists and entirely exclude specialists they don't need or want" (September 19, 1993, section 3, p. 6). The article is referring to medical specialties and does not cover mental health care at all. (Its absence speaks to its insignificance in the overall plan.) Nevertheless, it is clear that mental health benefits will be limited and referral for additional treatment by an art therapist unlikely. Additional losers will be hospitals (the job source for many art therapists), but the good news is that the *Times* sees nursing homes and home care as winners as patients are moved to less expensive settings as soon as possible. Certainly the former offers art therapy possibilities.

It appears clear that individual art therapists and art therapy training programs are ill-advised to look to the traditional fee for service medical model to fund art therapy positions. Those of us who are in private practice, and the many art therapy students and beginning practitioners who would like to develop a private practice, are well advised to recognize changing realities. For example, some of my private clients now receive substantial insurance reimbursement for my fees. Many art therapists look to licensure (either of art therapists or as counselors) to enable them to qualify for third-party payment. Yet it is likely that insurance coverage of private practice art therapy will become obsolete very soon.

With such a realization in mind, I contacted the insurance system that manages the State of Illinois health insurance that provides my own coverage. The concreteness of the justifications for treatment and its constant concrete monitoring appeared antithetical to the ways in which I work and view my clients. I did not pursue the contact further. I believe that art therapy services will be difficult to justify for many clients in the kind of accountability that will drive the cost containment provisions of the future health alliances. The goals of art therapy treatment are more often directed toward life enhancement realms than toward "fixing" a particular ill.

For the many art therapists who work at hospitals, prospects, are also questionable. There have already been substantial lay-offs in both private and not-for-profit facilities. If hospitals will lose out further, as the *Times* suggests, art therapists may be considered nonessential staff and given the gate. The 10-year veteran director of expressive therapies in a managed private hospital, discussed above, upon seeing her staff dwindle from successive lay-offs, decided to leave before the ax reached her position as well.

Given the grim prospects for art therapy support under "managed competition," what creative alternatives are possible? One possibility applies to a very small segment of society. The Clinton proposal retains the option of fee-for-service treatment by a private practitioner with greater out-of-pocket expense to the consumer. Therefore, as is now the case, some clients with the financial wherewithall will continue to see art therapists on a private basis. Those art therapists (like myself) who now are covered by third-party payment will probably have to reduce their fees to accommodate the loss of insurance coverage. The days when psychotherapists can bill a session from $75 (social workers) to $150 (psychiatrists) are rapidly drawing to an end. How private art therapy fees will be influenced by the fees of other private mental health practitioners remains to be seen.

Very few art therapists derive the major portion of their income from private practice, however. Most private practice work is conducted by those who work in a facility's art therapy program as well. And for most art therapists, work at a facility is their sole source of income. Where the essential mission of such a facility is to provide medical care or education, art therapy may be perceived as nonessential and therefore may be eliminated in the service of cost-cutting. On the other hand, where the mission is rehabilitative in nature, art therapy may be an essential component in promoting positive change. Examples of such programs might include shelters for the homeless, battered women and children, ex-prostitutes, survivors of violence and abuse, and aftercare facilities. Art therapy might also be integral to programs for care of individuals who are not expected to improve, such as AIDS units, hospices, facilities for the elderly. Another nonpsychiatric area, education, offers possibilities for art therapists. In some communities, such as Dade County, Fla., art therapy has become a part of the public school system. Many other school systems, however, reject any service labeled therapy. Special schools, on the other hand, often offer therapy as a major component of their programs.

Art therapy in these kinds of facilities is usually long-term in nature. Most art therapists would probably agree that
art therapy, like other nonpharmaceutical mental health modalities, is most effective on a long-term basis, providing greater opportunity for growth and integration of change. Art therapy for short-term care, such as seen on psychiatric units, may be on the way out.

Finally, there is the great grey area of personal growth. Certainly our profession has generated more heat than light around viewing art therapy as creativity—rather than as pathology-oriented. Those of us who practice and teach art therapy have known the benefits of experiencing our own art for personal exploration, healing, growth, and joy. We have done so on our own, in art therapy classes, and in workshops directed toward that end. Some of us have even received remuneration from providing such experiences for others. Few of us, however, have made a living from it. Nevertheless, this is an arena in which many art therapists would like to work. Perhaps there are creative possibilities to explore and develop in this realm.

I have written this article in order to prompt myself to come to grips with the imminent challenges that face my profession, both to help me to formulate my own directions, as well as to prepare art therapists of the future whom I train. In doing so, it appears to me that the soil for art therapy’s growth (or maybe its survival) is likely to be most fertile in the fields of social, rather than in the more traditional psychiatric, needs. Even prior to Clinton’s proposal, I have noticed a shift in our training program. More of our practicum sites are shelters, AIDS units, programs for survivors of violence and abuse. A course in art therapy for specific populations in which each class is taught by a guest art therapy lecturer expert in a specific area, has changed in recent years. The syllabus now includes more areas of social ills, such as homelessness, sexual abuse, cross-cultural problems, and AIDS.

Although art therapy has come a long way in becoming a recognized and respected profession, in the current climate of health care cost-cutting, it is essential that we become essential if we are to survive health care reform. Some of the graduates from the program I direct furnish impressive models: One is part of a staff of three that provide a day shelter for homeless women. Art is all over their community space, and the women can make art whenever they want. Two graduates run programs at aftercare day facilities. Art in groups and individual sessions make up a significant component of these facilities’ services. Another has created an innovative art program at a day care center for the elderly. All these art therapists have directed these programs for five to 10 years. Recently a program for women surviving violence and sexual abuse has hired several of our graduates and is seeking art therapy interns. Art therapy is increasingly becoming recognized as a major modality in tapping into experiences of violence and abuse that may not be accessible by words. Three years ago an art therapy intern set up an art therapy program on a hospital AIDS unit. The program became indispensable and has been generously funded to the extent of building and bountifully equipping a special art room with adjoining solarium, headed by the intern/graduate. These are but a few examples of art therapy’s movement into realms of acute social need.

To return to my initial question on the survival of art therapy and its three-part answer: NO, I don’t believe art therapy will survive if our heads are in the sand and we proceed with business as usual as the winds of change blow us away. YES, I believe we will survive and grow if we become essential providers in the realms of great need in our unfortunately needy society. And finally, I reserve a MAYBE for those gray areas of great interest to art therapists, private practice and personal growth. Perhaps they must remain sidelines for most of us.

Art Therapy: The Future

Gladys Agell, PhD, A.T.R., HLM

Gladys Agell, PhD, A.T.R., HLM, is the director of the Graduate Art Therapy Program of Vermont College of Norwich University and the editor of the American Journal of Art Therapy. She enjoys a private practice as both an art therapist and a clinical psychologist. Since joining the American Art Therapy Association in the very early days, she has been an active member of the Education Committee, in addition to serving as Education Chair, Chair of the Nominating Committee, President-elect and President, and in the recent past as Secretary.

Gladys Agell has been an active art therapist since 1967. For most of the ensuing years, she has paired the roles of educator and clinician. Clinical work has included art therapy with children, adolescents, and adults. As an educator, Dr. Agell has designed and developed the program that has been housed at Vermont College of Norwich University for over 10 years. Believing that responsible political activity is part and parcel of participating in a developing field, Dr. Agell was a founding member of both the New York Art Therapy Association (NYATA) and the Art Therapy Association of Vermont and the founding chair of the NYATA. In addition, she has served on both the Education and Nominations committees of the American Art Therapy Association, Inc. (AATA); she has chaired both committees; is a past-president and of course was president-elect of the association. AATA awarded her the Honorary Life Membership. As editor of the American Jour-
nal of Art Therapy. Agell has made an effort to follow in the tradition of Elmin Ulman, who brought to the profession a publication that was contemporary, thought-provoking, and well-written.

Agell has been interested in greater membership power and participation in the Association. She has stated, “For too long AATA has been an organization that has operated behind closed doors. It is time that members are well-informed and have the opportunity to influence decisions made by the executives. I have been advocating this for some time and there has been a marginal response to this notion. I would certainly like to see this become a practice of our association rather than an exception. This includes but is not limited to being informed about how members of the Board vote on issues.”

I was sitting with Margaret Naumburg just before she received the first Honorary Life Membership from Myra Levick, the first president of the American Art Therapy Association. I thought Margaret would be pleased that the fruits of her labor resulted in the establishment of a national association... and that she was about to receive AATA’s highest accolade. Not so. Margaret bemoaned what she predicted would become a plebeian field rather than an elysian landscape peopled by a handful of gifted art therapists. Margaret was an intellectual and her notion of art therapy was elitist. There were, in her view, only a few people suited to becoming art therapists. I wonder what she would say if she were alive today.

The present foreshadows the future, laying the foundation for what is to come. Though originating in psychoanalytic theory, contemporary art therapy is comprised of people who hold diverse beliefs and variously define ways they work. Diversity, to my way of thinking, produces vibrancy... vitality. However, a framework must be established to prevent diversity from declining into chaos. At one time the guiding documents of AATA provided that framework.

However, past editing of Guidelines for Art Therapy Training and Education, Standards and Procedures for Registration, have mutilated what were once erudite, lucid documents. In addition, the AATA ethical code, criteria for professional membership, and criteria for clinical practice reflect our lack of linguistic precision and sophistication. Documents become mandates before those affected are fully informed of their meaning. Furthermore, the lack of consistency between documents and contradictory criteria due in some measure to careless grammar, syntax, and bewildering organization presents a profile lacking in professional polish.

Educators who neglect the art in art therapy seem unaware of the danger inherent in this kind of misguided training. Quick, crude art making has been supported and the emphasis on talking about the picture or sculpture made central to the session. In the interest of encroaching on psychiatric prestige, the artwork is disregarded. However, psychiatrists, psychologists, social workers, and mental health counselors talk better than we do. If we want to enter that assembly, we should abandon brushes, pastels, and clay tools and concentrate fully on words... talk, talk, talk... because, as it is presently, we’re up against some pretty stiff competition. Not only are we outclassed, we’re outnumbered.

The slides of members’ artwork at the Atlanta conference clearly demonstrated that we are artists. We’re good with art materials. If we can relinquish our promotion of questionable idolatry, our self-image of being healers and shamans; if we can take pride in helping people discover something about themselves by pushing pigment or pulling graphite across a surface or forming clay in an effort to elicit “Eureka,” only then do I see a viable future for art therapy that is not subordinate to mental health counselors, family therapists, or special educators. If talk can succeed the experience instead of replacing it, it we can learn more about what we’re looking at and acknowledge that it has meaning beyond a more storyline; or in other words, if we can look deeply and balance our psychiatric beliefs with our art knowledge, only then can we make a credible contribution to others.

A Time for Growth

Virginia M. Minar, A.T.R., recipient of the 1992 Distinguished Service Award

Virginia M. Minar, MS, A.T.R., is currently an associate instructor in the Graduate Art Therapy Program at Mount Mary College, Milwaukee, Wisconsin; her private practice is with cancer patients. She retired in 1986 from the West Allis-West Milwaukee School District after 15 years as an art-exceptional education teacher/therapist.

Ms. Minar has held numerous positions with the Wisconsin Art Therapy Association, including 10 years on their Executive Board. Since 1978, she has served the AATA on more than 14 different committees. On the AATA Board, she has served as Treasurer, as Director, and is presently the President-Elect.

Virginia Minar has received the following awards and honors: a Wisconsin Art Education Association Award in recognition of outstanding contributions to the arts and service to the Community; the WATA Honorary Life Member Award; Very Special Arts service awards; the 1992 AATA Distinguished Service Award; Kappa Delta Pi and Phi Kappa Phi honors. She has appeared on local television programs and
been interviewed for local newspaper articles regarding her work with special needs children and cancer patients. As an artist, her early artwork was in painting and photography; she now works primarily with oil pastels, drawing, and rubbing with cloth to achieve subtle blending of colors.

Organizations, like people, go through stages of development in which events and experiences bring about changes in personal and public relationships as well as professional goals and objectives. As we celebrate our 25th year, we are ready to enter Erikson's Stage Seven, adulthood. In this stage, concern is with establishing and guiding the next generation. . . . Productivity in work and creativity . . . are important concepts in this period. Having a sense of accomplishment . . . depends on giving loving care to others and regarding one's own contributions to society as valuable. Merely producing children does not give . . . a sense of generativity; one must see one's role in rearing them as a contribution to humankind and the larger society. Dangers are self-absorption and a sense of stagnation, a sense of going nowhere, doing nothing important. (Schell & Hall, 1979, pp. 39-40)

For this discussion, I am substituting the word "growth" for "development." As an organization, we have been steadily developing. We are now ready to grow, not only in size, but also in weight and power. Our membership has increased 35% since 1989. We have been recognized by some legislative bodies at both the federal and state levels. We have established working relationships with certain allied professions and are investigating alliances with others. We need to continue to grow in all of these areas if we want to secure our place in the ever-changing health care environment. Using each letter of GROWTH, I will expand on the meaning of the word as it relates to the next 25 years of the American Art Therapy Association (AATA).

"G" stands for GENERATIVITY: Art therapy educators are producing the next generation of art therapists. As these students graduate and enter the profession, we, the elders of this organization need to embrace the role of mentor by sharing our contributions to the field with them, and by guiding these new colleagues without expecting them to mirror our images. While we should continue to honor our history, we must be receptive to their ideas and allow that new energy to generate further growth.

"R" represents RESEARCH: While some valuable research has been done by art therapists as documented in A Guide to Conducting Art Therapy Research (Wadeson, 1982), it is imperative that we continue to encourage and support research that demonstrates what we do and how it affects those to whom we provide services. Because creativity is primary in the practice of art therapy, many of us have been reluctant to conform to the requirements of clinical research. Rubin (1984) cautions that research is rarely as flexible as any of the other roles (art therapists assume), because of the necessary control of important variables. Research allows creativity primarily in its design and analysis, but hardly ever in the actual implementation of the study. (p. 179)

AATA has established a Research Fund to which members are encouraged to contribute, but this fund needs to increase substantially before it can support the implementation of innovative art therapy research. Recently, we have been granted a new tax status "enabling the AATA to solicit and accept tax-deductible contributions" including grant monies (Goodman, 1993, p. 1). The Research, Clinical, and Government Affairs committees will be able to collaborate on researching those foundations that make grants available to qualified charitable organizations.

"O" stimulated two choices: OBJECTIVES and OBLIGATION. Although our objectives may change from year to year, they must always be selected to meet contemporary challenges. In 1994, four of the board's major objectives are: (a) to offer Continuing Education Credits at the annual conference and at regional symposiums, (b) to implement revisions to our Educational Guidelines and the Education Training Board's approval process, (c) to strengthen Ethics and Professional Practice policy and procedures, and (d) to engage a legislative consultant to help us prepare testimony for various committee hearings on Health Care Reform. While the AATA's initial obligation is to meet the professional needs of its members, the ultimate obligation is the protection of the public we serve by continuous reassessment of the growing field of art therapy.

"W" suggests WISDOM: The use of wisdom is essential for art therapists. Wisdom is to know which of the various theories and methods will work best for you in your practice. Corey, Corey, and Callanan (1993) advise that:

We do not advocate that you subscribe to one established theory, because you can find ways to draw on therapeutic techniques from many theoretical approaches. . . . Ideally, practitioners' theoretical orientation will serve as a basis for reflecting on . . . goals and techniques that are most appropriate with specific clients in resolving a variety of problems. (p. 236)

AATA's role is to use the wisdom and expertise of its members in providing educational opportunities through our symposiums and conferences that offer programs and courses about contemporary topics, for example current trends in health care provision, specific treatment groups (e.g., cancer, HIV, Alzheimer's), ethics and professionalism, private practice management, and service guidelines. Such offerings will allow participants to increase their knowledge and skills in particular areas of interest. Wisdom is recognizing what theories and techniques you are comfortable using in your private practice, or within your institution of employment.

"T" represents two seemingly oppositional concepts, TENACITY and TOLERANCE. Tenacity is the ability to firmly hold on to the belief that art therapy, as a treatment modality, is distinctly different from other human service professions. That difference is the use of art materials and the creative process to allow images to emerge that can be explored by the individual or group with the guidance of the art therapist. As discussed before, there are, within the profession, various art therapy theories and techniques, but the one thing they have in common is the 'art part.' That is the part which requires tenacity, not a particular theory or technique. Tolerance of the various art therapy procedures used by our colleagues is essential. Our organization cannot grow if we are expending our energy championing one particular method over another.
Tenacity and tolerance must work together when presenting art therapy to allied professions, governmental agencies, health care institutions, and the public.

"H" is the last, but most important letter of GROWTH since it represents the HEALTH of the organization, the public we serve, and ourselves as providers of service. In order to function effectively in our increasingly complex society, we must seek to attain and maintain health in mind, body, and spirit.

What does that mean for the AATA? The Board of Directors as representing the mind needs to, at all times, make decisions that protect and benefit the body, the membership. The body needs to take an active part in questioning those decisions, suggesting alternatives, and supporting the work of the board and the committees. Both the board and the membership need to nurture the spirit of the association by exhibiting their commitment to, and belief in the profession of art therapy. The spirit should be neither narcissistic in nature nor completely altruistic in application.

Except for our responsibility as members of the society-at-large, we are not accountable for the presenting health of the public we serve. Once we have accepted a client, treatment should deal with mind, body, and spirit as a total gestalt. While many art therapists adhere to a particular theory and methodology, others use a more eclectic approach in their practice. What works for one patient may not work for another. Flexibility should be coupled with commitment to finding the most effective methodology for meeting the needs of specific clients.

Finally, we must take care of ourselves. Before we can function effectively as art therapists, we need to strive for wholeness in mind, body, and spirit. How can we help others, if we do not first help ourselves? Helping ourselves includes being active in both local and national art therapy organizations. These groups can serve as a support system, particularly for those who feel isolated in their place of employment.

Maslow (in Good, 1974, p. 143) believed that few people attain complete self-actualization in their lifetime, but that "in practically every human being there is an active will toward health, an impulse toward growth, or toward the actualization of human potentialities." The American Art Therapy Association is made up of human beings, and I would hope that we never reach the point where we feel we have attained all of our goals and objectives. We must avoid the dangers of self-absorption and stagnation. We will only remain vital if we experience on-going GROWTH. The time will always be NOW!

My Visualization for 21st Century Art Therapy

Recipient of the 1990 Art Therapy Clinician Award/Child Services

Janet Bush, EdS, A.T.R., was the founder of clinical art therapy in the Dade County Public Schools, Miami, Fla. She began the art therapy program as a pilot undertaking, and soon demonstrated the potential that is inherent in an art therapy approach. She is presently serving as Department Chairperson in the Division of Exceptional Student Education, where she directs a program of 18 master art therapists who provide services to over 400 emotionally disturbed students.

She began her career as an art educator, having received a BA degree in art and psychology from The Ohio State University. Graduate art therapy studies at Hahnemann University, in Philadelphia, led her to work in a public school setting, and she pioneered the application of art therapy to public schools in her graduate thesis. At Dade County Public Schools, she coordinated the first full art therapy program in a public school setting in the nation.

Ms. Bush is a registered, practicing art therapist, a founding member of the Florida Art Therapy Association, a university instructor, and a nationally known speaker and lecturer on art therapy in the schools. She has written numerous articles, and has served as a consultant in many clinical and educational settings. She made a major contribution to the field of art therapy with the establishment of a model program for public schools which the American Art Therapy Association recognized. She subsequently received a distinguished clinical services award for her work with children. As a result of Ms. Bush's efforts, art therapy in the public schools has become a nationwide practice in recent years.

I was the recipient of the AATA Art Therapy Clinician Award at the 1990 NCATA Conference in Washington, D.C.
The award was in recognition of my work in implementing a school system program for severely emotionally disturbed youth, in Miami, Fla. The program, which has been operating in the Dade County Public Schools since 1979, is staffed by 18 full-time master art therapists. It has served over 400 children each school year. I am encouraged to look forward to the time, during the 21st century, when art therapy may be available in every school district in the nation.

The profession of art therapy has evolved to encompass a wide range of applications. Although the field was traditionally part of the intervention for psychiatric patients, its horizons have expanded to school settings—both for the so-called normal youngster and for the youngster experiencing problems. The introduction of art therapy in the schools represents new ideas, healthy controversy, and fresh challenges. The expectation is that the 21st century will make it possible to extend the benefits of the growing sophistication of the profession and its interface with other fields—particularly, education—to a variety of new operations.

The multiplicity of training approaches has already led to numerous models of functioning not only in the clinically oriented hospital settings, but also in the schools. There has been an endless historical debate over the philosophy and the proper role and function of the art therapist in clinical settings. It is likely that as programs and art therapy services grow within education, the philosophical debates will carry over to education.

In essence, the history of art therapy has been the history of a profession seeking an acceptable identity. Thus one of the issues needing exploration and closure is the role of the art therapist in the 21st century. I do not see the art therapist as an outside consultant who delivers services to an educational setting, but rather as a professional functioning within the educational system as part of that setting. The lag between the development of appropriate training for utilization of art therapy in the schools and the beginning of professional school art therapy programs and services remains incomprehensible. There is no doubt that public agencies, parents, children, and other consumers of school art therapy services do not have an understanding of the nature of art therapy. To meet the demands of human needs in the coming century, the time has come to organize a practical implementation model and to define the role and function of the school art therapist so that both parents and public agencies know what art therapy can do for a child.

Business communities and the public are demanding change in our entire education system, wanting our schools to become more “customer focused.” And who are our customers? Many students are emotionally distraught and unable to cope. More disturbing than ever is the fact that even those students who succeed in school and who score well on conventional tests have not been educated to cope successfully with the demands foreseen for the personal, vocational, and civic life of the near future. If the schools do not meet the needs of our general student body, the response to what is perceived as school system failure may lead to a demand for the inclusion of intensive art therapy in the schools to counter the downhill learning curve. Educators must convince community members that unless we ensure the educational achievement of all students, the overall quality of life will be affected for generations to come.

Traditional educational values and well-established programs will continue to meet intense scrutiny. Public expectations have never been higher. The push for accountability, measured by student performance outcomes, is increasing. Perhaps the greatest challenge now facing educators is the question, Can you truly marshal the elements of proof that the education system can respond to public pressure in a positive way and improve the performance of the schools and of the children served by the schools?

It is no longer fair or productive simply to point to our schools and say they are failing. It is time to join forces to bring about the changes so sorely needed throughout our educational system, changes that may involve the entire community of art therapists, for they are equipped to help meet the challenge of the 21st century. Art therapy procedures used for diagnostic and screening purposes can identify youngsters at risk. When used for treatment, art therapy procedures can help individual students to better understand themselves. Art therapy in the 21st century will be equipped to offer children opportunities to work through obstacles impeding their educational success. It will facilitate appropriate social behavior and promote healthy affective development through which these children can become more receptive to academic involvement, and it will maximize their social and academic potential.

Countless numbers of children have gone unnoticed and unheard of through the years because art therapy has not been available to assist them. I invite you to join me in building a productive educational frontier with the aid of art therapy.

To those who continue to share my conviction that children deserve our best efforts, thank you for believing as I do. Let's meet in the 21st century and compare notes.

Introduction to Special Section on Sexual Abuse and Dissociative Disorder

Cathy A. Malchiodi, MA, A.T.R., Editor

This special section of Art Therapy highlights the use of art therapy with clients who have been sexually abused or who are experiencing dissociative disorder. Included in this section is a research report on the contribution of art therapy to dissociative disorders (Murphy), observations on the clinical applications of art therapy with MPD clients (Jacobson), the use of art therapy with a victim of rape (Nykas-Hargrave), and a review of published research on the use of drawings to determine child sexual abuse (Hagood). A unique personal perspective from an artist who experienced sexual abuse as a child is described through both words and art (Orleman), and this issue's cover art is by a survivor of sexual abuse (Harris).

The investigation of the unique connections between art therapy and the assessment and treatment of sexual abuse in particular has had a long history. Naumburg (1953) devoted an entire book to her study of a woman sexually abused as a child, observing that the abuse was repressed until her art released the traumatic memories. Howard and Jacob (1989) examined the art productions of sexually abused children, noting some similarities in the graphic indicators present in their limited sample. In the late 70s, Clara Jo Stember, an art therapist who worked as part of a sexual abuse treatment team, wrote of her experiences in developing art therapy programs with abused children (1978) and her observations of graphic indicators of sexual abuse in children's drawings (1980); later, Naitove (1982) described and expanded Stember's work with sexually abused children. More recently, art therapists and others have developed research to systematically examine specific graphic indicators of sexual abuse in various drawing tasks (Cohen & Phelps, 1985; Kelley, 1984; Riordan & Verdell, 1991; Sidun & Rosenthal, 1987; Spring, 1985a, 1988; Yates, Beutler, & Crago, 1985, to name a few).

Additionally, the use of art therapy in the assessment and treatment of sexual abuse has been a cutting edge topic at many of the annual AATA conferences. At the AATA 15th Annual Conference, many art therapists may remember the well-attended presentation by Felice Cohen (1984) who discussed her comprehensive study of the graphic indicators of sexual abuse in children's drawings; this landmark study was published in the following year (Cohen & Phelps, 1985). In recent years, the annual conference has continued to provide a forum for discussion of sexual abuse in relation to adult treatment issues (Anderson, Deitz, & Ward, 1993; Anderson & Deske, 1991; Cox, Cohen, Mills, & Sobol, 1991); family art therapy (Cox, 1988); developmental issues across the lifespan (Farrelly-Hansen, Lack, Safran, & Sweig, 1991); ritual abuse (Cox, 1991; Drachnik, 1991; Sweig, 1992); sex offenders (Ovedoff, 1993; Spring, Hurd, & Churchill, 1988); and other topics and presenters too numerous to list. During these years, a study group on the symbolic language of sexually abused clients was formed and led by Dee Spring, PhD, A.T.R. and others, to more closely examine treatment issues (child, adolescent, adult, and perpetrators), to discuss clinical observations and research, and to share case material.

In the mid 80s up until the present, a topic related to sexual abuse rose to prominence at the annual conference: dissociative disorder or multiple personality disorder (MPD). In 1985, Christine Sizemore (of "The Three Faces of Eve" fame) discussed her own multiple personalities and shared her paintings at the 16th Annual AATA Conference. Since then art therapists and others have been active in presenting both clinical material and research data, contributing to the area of dissociative disorders. (Cohen & Cox, 1988; Spring, 1985b; Sweig, 1988, to name a few), and in writing comprehensive texts on the topic (Kluft, 1993; Spring, 1993). One of the most requested AATA Regional Symposia has been on the topic of multiple personality disorder, reinforcing the continuing interest of art therapists in this area of study and practice.

Art Therapy, Sexual Abuse, and Dissociative Disorder: Some Unanswered Questions

Despite all the contributions by art therapists and other professionals to the body of knowledge on art-based assessment and treatment of sexual abuse and dissociative disorders, there are still many questions that remain unanswered. One area that continues to confound art therapists is the reliability of drawings in identifying sexual abuse and dissociative disorder. Despite the best research efforts, can drawings ever be utilized with reliability in such circumstances? In this issue of the journal Hagood and Drachnik pose some questions about the reliability of graphic indicators of sexual abuse in children's drawings. Hagood's overview of the literature on the graphic indicators of sexual abuse in children's drawings concludes that a great many more studies are needed to arrive at a comprehensive list of graphic indicators with this population. She also points out that developmental level must be carefully taken into account in the examination of children's drawings. Currently, Hagood is conducting a large-scale research project in Great Britain examining the art expressions of children who have been sexually abused to determine if such art expressions can be utilized with any degree of reliability and under what circumstances.

Drachnik, in her discussion of the tongue as a possible graphic indicator of sexual abuse in children's drawings, cites the fact that there may be indicators in art expressions that researchers and clinicians have not yet recognized or formally investigated. Her brief report on her clinical observations of the drawings of sexually abused children points to the need to continue research into graphic symbols with open minds to additional possibilities in this area.

Another topic of interest to art therapists who work with
sexually abused or traumatized clients is the current debate over what has been coined "false memory syndrome" (Wylie, 1993). False memory syndrome may include inaccurate recollections of past traumatic events, including those which susceptible individuals adopt at the suggestion of someone else; for this reason, therapists who work with clients to bring forth repressed memories have come under fire. Currently, clinicians and researchers who work with adult clients who state that they were sexually abused as children are investigating the reliability of such accounts. There are also questions being raised concerning the amount of and type of abuse reported by clients; in particular, the areas of cult and ritual abuse have become controversial in the eyes of both professionals and the public.

Additionally, there have been questions raised about the benefits of uncovering traumatic memories in clients (Yapko, 1993) and that repressed memory therapies are actually harming clients, rather than helping them (Jaroff, 1993). With regard to the field of art therapy which utilizes art expression and imagery to uncover or surface traumatic memories, it is interesting to speculate as to whether the use of drawings or other visual art expressions, under certain circumstances, may be more reliable than verbal accounts. Given the scrutiny that strictly verbal accounts have received over the last few years, the use of art expression may also be viewed critically by those who doubt the accuracy of traumatic memories; therefore, additional studies of the reliability of art expression in surfacing repressed memories are undeniably needed to increase clinical confidence in its use as a therapeutic tool with traumatized clients.

Lastly, will art therapists be increasingly called upon to share their unique knowledge as expert witnesses in courts of law in cases involving sexual abuse? At the recent AATA conference, two interesting presentations were given on the subject of the use of drawings in court. Graves (1993) illustrated methods of introducing drawings as evidence and discussed the acceptability of art therapy in testimony; Liebman (1993), building on the work of Levick, Safran, and Levine (1990), established and clarified the role of the art therapist as an expert witness in child abuse litigation. Both presenters underscored the important role of the art therapist as an expert witness in cases involving sexual abuse.

The use of art expression has become an important and recognized tool in both the assessment and treatment of both children and adults who have experienced sexual trauma. However, working with sexual abuse and dissociative disorders in a clinical environment, private practice, or as an expert witness is probably some of the most difficult and challenging work for any professional. For art therapists it also may be some of the most exciting work, due to the unique modality we have available to communicate with and treat our clients, and the increasingly rich body of knowledge on the use of art expression with traumatized populations that art therapists have contributed to over the last decade.

**Editor's note:** Due to space, this reference list presents a very limited selection of presentations and papers on the topics of art therapy, sexual abuse, and dissociative disorder. Those interested in additional references are advised to consult the yearly conference proceedings of the American Art Therapy Association, Inc., and books and journals in the fields of art therapy, family violence, sexual abuse, trauma, and dissociation.
Diagnosis or Dilemma: Drawings of Sexually Abused Children

Maralynn M. Hagood, MFCC, A.T.R. Edinburgh, Scotland

Abstract

The incidence of child sexual abuse in both the United States and Great Britain has been reported in increasing numbers over the past 20 years (American Humane Association, 1984; Miles, 1999). In Cleveland, England, in 1987, a national scandal arose (The Cleveland Incident) from the reporting of a large number of alleged cases of child sexual abuse by two pedagogues (“Cleveland Inquiry,” 1988). This resulted in the traumatic and, in some cases, inappropriate removal of many children from their homes by child protection authorities. The National Society for the Prevention of Cruelty to Children (NSPCC) released figures which reflected twice as many cases reported from April 1988 to April 1989 as were reported in the preceding year (Miles, 1989). The alleged case of ritual sexual abuse in the Orkney Islands in Scotland currently is being investigated in a hearing which will continue through June 1992. The need for better diagnostic tools on behalf of sexually abused children in the United Kingdom has become increasingly apparent.

Psychotherapists and art therapists working with children identified as having been sexually abused have noticed certain graphic indicators seemingly peculiar to the artwork of these children. The use of art therapy in the treatment of sexually abused children has been well substantiated. Studies have been carried out to determine what characteristics appear more frequently in the drawings of children who have been sexually abused.

Research Into Drawings of Sexually Abused Children

Goodwin (1982) carried out 19 consecutive interviews with girls aged 5 to 16 who were suspected incest victims. The drawings were of diagnostic value in understanding the child’s fears and anxieties, her view of her family, and her self-image. Images of male phallic figures were incorporated into more “acceptable” subjects, such as phallic trees. Goodwin described an 8-year-old girl’s depiction of a dream in which she was camping inside a zipped-up tent with a phallic-appearing tree intrusively overlapping the tent. Some children with whom Goodwin worked who were known to have been sexually abused drew the perpetrator with an obvious phallus, but identified it as a “decoration” or said it was “nothing.” Goodwin developed the Draw-the-Perpetrator task where she observed that children refused to draw about the sexual abuse as frequently as they refused to talk about the event. Frequently the victim crossed out his or her repeated attempts to draw the perpetrator and finally gave up or drew a figure with an obvious phallus. Goodwin found the use of drawings helpful in evaluating sexual abuse with children under 12. She did not find as much success in using drawings with adolescents. She nevertheless concludes her article by stating:

Such drawings, by themselves, are not sufficient to make a diagnostic decision. It is the child’s increasing sense of being able to communicate and her experience of being understood that are helpful to the clinician in reconstructing what is happening in the family. The discovery of a workable avenue of communication is also helpful in reducing the anxiety of a child whose emasculation in family secrets has often blocked verbal means of asking for help. (Goodwin, 1982)

Kelley (1984) examined 120 pictures drawn by 10 sexually abused children. Analysis showed that, of the self-portrait drawn, 20% portrayed prominent genitalia, 40% placed an added emphasis on the pelvic region, 43% emphasized the upper portion of their bodies, and 30% drew themselves without hands. A major problem with this study was that only 10 subjects were used, which is too small for generalization to other groups.

Koppitz (1968) found that Human Figure Drawings of normal children ages 5 to 12 rarely included genitalia. Conclusions were based on the drawings of over 1,800 school children in this age range. In examining body parts drawn by 5 to 12-year-old "normal" school children, Koppitz reported that only two of 925 girls (one 7-year-old and one 9-year-old) and nine of 931 boys (six aged 5 and one each 6, 7, and 9 years old) included genitalia. These conclusions also were based on only one drawing from each child.

DiLeo (1973) noted after reviewing thousands of ordinary children’s figure drawings that the representation of genitalia was rare and reasoned that it was because the child had been made precociously aware of the high emotional charge invested in the sex organs due either to surgery or seduction by adults or older children.

Silvercloud (1982) unsystematically listed several features reoccurring in the artwork of children known to be sexually abused from her clinical experience. Items such as stab marks, crossed out windows, heavy lines, red houses, and so on, were discussed.

Stember (1980) used art therapy extensively with sexually abused children and found that drawings sometimes revealed the possibility of sexual abuse which was substantiated upon further assessment. Sexually abused children often created disorganized drawings and clumsy images. Horizontal scribbling frequently changed to vertical scribbling and then drawings became more organized through the process of therapy.

Editor’s note: This article was originally published in the British Journal of Projective Psychology, 37(1), June 1992. Art Therapy wishes to thank Dr. Zahid Mahmood, editor of the BJPP, and Maralynn Hagood for permission to reprint this article on this occasion. Questions about this article may be directed to Maralynn Hagood, University of Edinburgh, Psychology Department, 7 George Square, Edinburgh, Scotland EH8 9JZ.
Kelley (1984) noted that pictures drawn by sexually abused children in the early phases of therapy were often below expected developmental levels, but that during the later stages of therapy children drew more age-appropriate pictures. Burgess, McCausland, and Wollbert (1981) believed that sexual abuse should be suspected in children whose drawings markedly shift from age-appropriate figures to disorganized objects or show repeated sexual figures. However, these conclusions were not systematically validated. Hibbard, Hoekelman, and Roghmann (1990), however, found no significant differences in the developmental levels of sexually abused children compared with those of nonabused children as measured in Human Figure Drawings.

Johnston (1979) evaluated 10 sexually abused children ages 5 through 11 using the Kinetic-Family-Drawing and found that the drawings revealed dysfunctional family systems. Two of the 10 children included representations of the male sex organ. Isolation was manifested by the drawing of the family members in separate compartments on the paper and role reversal was interpreted in the drawing when the child made herself larger than the mother figure. Other possible causes of size differences, such as level of anxiety, importance, or self-esteem (Thomas & Silk, 1950) were not discussed.

Empirical studies have been carried out comparing artwork between groups of sexually abused children and those who were in psychiatric treatment for other emotional problems. Cohen and Phelps (1985) compared sets of drawings of 166 children, aged 4 to 18 years, 89 of whom were known to have been sexually abused and 77 of whom were children who were being treated for other emotional problems. Statistically significant differences were found in the frequency of rated graphic indicators between the two groups on both the House-Tree-Person Test and the Kinetic-Family-Drawing. Poor interrater reliability, however, made the results inconclusive, and developmental differences in the subjects were not taken into account. Again, the comparison group consisted of psychiatrically hospitalized children, and it was suggested that the use of a "normal" comparison group be incorporated into future studies.

In an archival study, Sidun (1986) along with Chase (1987) developed a coding manual for artwork of sexually abused children from existing literature. They rated and compared Human Figure Drawings of 30 known sexually abused adolescents with drawings of 30 adolescents being treated for emotional disturbance with no known history of sexual abuse. A wide range of intelligence was represented with subjects in one group having IQ scores of 75 to 118 and the other group having IQ scores ranging between 75 and 123. Both groups were matched for IQ but possible effects of differences in intelligence on the artwork was not accounted for. Sidun hypothesized that the abused group would draw more over-sexualized and undifferentiated figures, with more indicators of anxiety and more indicators of poor self-esteem. No statistically significant differences were found, however, in measuring these characteristics.

It was further hypothesized that drawings of the sexually abused group would contain a greater frequency of wedges, phallic-like objects, and circles than drawings of the nonabused group. In a composite analysis of the data, a greater number of such characteristics was found in artwork of the sexually abused group. When these characteristics were analyzed independently, however, the only characteristic found to be statistically significant was the use of enclosed circles, which was interpreted as indicative of "oral regression." The use of enclosed circles is also a developmental characteristic in drawings of very young children (Kellough, 1969; Lowenfeld & Brittain, 1982). Results also indicated that line pressure was heavier in drawings of sexually abused adolescents than in drawings of nonabused subjects. Another graphic indicator expected in drawings of sexually abused subjects was exaggeration of taut lines. Nonabused adolescents actually drew taut lines more often than the abused group. The investigator reasoned that adolescence is a natural time for heightened concern for sexuality and therefore not specific to abused subjects. It was concluded, however, that the strongest graphic indicators seen as possible sexual abuse in adolescence were omitted hands, omitted fingers, head only, enclosed circles, and heavy line pressure. A major problem with using these graphic indicators as clues to possible sexual abuse is that they may also reflect feelings of anxiety and helplessness (Koppitz, 1968) which would very likely exist in emotionally disturbed adolescents whether or not they had been sexually abused.

Yates, Butler, and Crago (1985) compared drawings of a group of 18 girls who were incest victims and 17 girls who were disturbed but not incest victims. The age range of the first group was 3.5 to 17 years old, and the age range of the second group was 4 to 17 years old. The list of characteristics to be rated were derived from the clinical literature and consisted of 15 dimensions. These were hypothesized (failure to attend to sexual features, hypersexuality/abstraction of sexual features), degree of immaturity, level of anxiety, control of impulsive, amount of confusion between love and anger, quality of somatization, quality of denial, quality of repression, and quality of sublimation. The only two dimensions measured which proved to be statistically significant were measures of impulse control and repression, which suggest that incest interferes with the child's ability to utilize repression and to control impulses. The issue of developmental differences between this wide age range also was not addressed, nor were any correlations with intelligence made.

Two studies have been done to date using normal children assumed not to have been sexually abused as controls.

Chase (1987) compared the Human Figure Drawings and Kinetic-Family-Drawings of 34 female subjects, ages 5 to 16, who were victims of incest with those of 26 matched emotionally disturbed subjects and 34 matched subjects with no known adjustment disorders. One drawing per subject was collected for each projective drawing instrument. Using the same scoring manual as was used in Sidun's study (Sidun, 1986), significant differences were found in drawings between sexually abused subjects and emotionally disturbed subjects, as well as sexually abused subjects and nonabused subjects. There were also differences in developmental scores using Koppitz' developmental rating method with sexually abused children having significantly lower developmental scores than either normal nonabused or emotionally disturbed children.

Hibbard, Roghmann, and Hoekelman (1987) compared the drawings of 57 children, ages 3 to 7, referred for alleged sexual abuse with the drawings of 55 nonabused children matched for age, sex, race, and socioeconomic background.
Subjects were asked to draw two Human Figure Drawings, one of each sex, and asked to complete a human figure outline. Drawings were scored for the inclusion of five body parts: eyes, navel, vulva/vagina, penis, and anus. The results were that sexually abused children were 6.8 times more likely to draw genitalia than were comparison children. They concluded that few children drew genitalia and those who did were likely to have been sexually abused. However, while a drawing may alert one to the possibility of sexual abuse, it does not prove it. Because genitalia were drawn more often in the completion drawing, it is strongly recommended that such a drawing be used in future studies.

Hibbard et al. (1990) replicated their earlier study. They compared drawings of 109 children alleged to have been sexually abused with drawings of 109 children with no known history of sexual abuse. They collected two Human Figure Drawings drawn in the same session, and one Complete-A-Man drawing per subject. Matched comparison groups consisted of children ranging from ages 3 to 8. In this second study, the developmental maturity of these children was measured by the Goodenough-Harris Draw-A-Man Test and the Peabody Picture Vocabulary Test. Correlations of scores from these two tests were high in the nonabused children's group, but low with the children who allegedly had been sexually abused. Six out of 109 children allegedly sexually abused drew genitalia on the completion drawings. Only one child in the nonabused group did so. The conclusion, on such meager evidence, that sexually abused children were six times more likely to draw genitalia in drawings than were nonabused children seems inconclusive. Hibbard et al. made similar sweeping conclusions in their earlier study.

In several of these studies, graphic indicators have been compared between groups of sexually abused children and those who were in psychiatric treatment for other emotional problems. The latter groups are likely to be contaminated with a good possibility of emotionally disturbed subjects being victims of undisclosed sexual abuse. Few comparisons with normal children judged to be nonabused have been published to date. Most studies have been based on only one drawing per subject.

Variability of children’s drawings on a day-to-day basis, discussed at length by Kellogg (1969), has not been accounted for in most studies. Kellogg found in her collection of 200,000 children’s drawings, that a child’s rendition of the human figure varied considerably when drawn on a daily basis. Rubin (1984) similarly found considerable variations in drawings created at different times, and that these variations also increased and decreased at certain age levels of the children whose drawings were studied. Interestingly, studies on drawings of sexually abused children continue to use one or very few drawings, and none has been longitudinal to date.

Measurements of mental maturity made with instruments which are known and respected for their validity and reliability, such as the WISC, Stanford-Binet, and Ravens were not used to correlate the effects of mental maturity on children’s drawings in the vast majority of the studies discussed above.

Vast differences in drawing abilities of children at each age level assessed, for example, drawings of 3-year-olds versus 8-year-olds, or even 15-year-olds, were not taken into account in most studies using matched groups. Frequencies measuring certain characteristics, such as no pupils in eyes, no mouth, transparencies, no hands, heavy lines, etc., were calculated without taking into consideration the fact that young children may include these characteristics in their drawings, not as an element of abuse, but rather as the course of normal development.

An American book recently published is full of lengthy accounts of children’s drawings without adequate discussions of developmental aspects of these children’s artwork (Wohl & Kaufman, 1985). Particular attention is focused on drawings of children from abusive homes and again sweeping analytic interpretations are made. Developmental phases of these children’s creations are only superficially discussed and interpretations commonly used for adults are used in assessing drawings of young children.

Problems with Projective Drawing Instruments

Projective drawing instruments are widely used by clinical psychologists, educational psychologists, social workers, art therapists, and other professionals who work with children. Drawing tests are used as a preliminary assessment tool and are often interpreted on an analytic basis. Frequently only one drawing is used. Drawings are often discussed with other professionals on their own merit without corroboration by the child. Problems of validity and reliability abound and are a major drawback in using children’s drawings as an accurate assessment instrument.

The fact that the Human Figure Drawing (HFD), used most often in these studies, was developed in years prior to 1968 has not been taken into consideration. The level of exposure of children to sexually explicit material in the many years following the development of the HFD, as well as other projective drawing tests, is not addressed in most of these studies. The effects of sex education, “modern” parenting methods, films, videotapes, and so on are discussed only by Hibbard et al. (1990). What is now reflected in children’s drawings as “normal” in 1992 might be considerably different than what was typical of children’s drawings at an earlier period of time when the establishment of many children’s projective drawing tests was carried out. The use of old projective drawing tests as a valid measure of children’s drawings today regarding assessment of child sexual abuse becomes highly questionable.

Analytic Theory as Related to Drawings of Sexually Abused Children

Sigmund Freud’s seduction theory and oedipal complex have influenced the thinking and training of psychotherapists including art therapists throughout the world (Masson, 1984). Problems arise in assessing phallic images in children’s artwork in view of the currently debated issue of Freud’s seduction theory and his revision of his original belief that female patients suffering from hysterical symptoms usually had been sexually abused as children. Freud presented his seduction theory in a group of three papers entitled “The Aetiology of
Hysteria” (Freud, 1896) in which he publicly challenged the notion that hysteria was hereditary and identified excitement of the genitals resulting from sexual abuse in childhood as the trauma that brought on hysteria.

One year after Freud proposed his theory, he began to doubt that actual sexual abuse in childhood was the basis for hysterical symptoms (Rosenfeld, 1967). Masson (1984) argues that Freud’s reversal of opinion and creation of the oedipal complex was due to Freud’s cowardice in dealing with a doubting medical community. This debate still reverberates among mental health professionals.

Edith Kramer, one of the early founders of art therapy, was trained extensively in Freudian psychoanalytic theory subsequently influencing the training of art therapists in the United States, Great Britain, and those involved in the early development of art therapy in many other countries in the world. Kramer (1969) worked with a child whose drawings depicted genitalia and claimed that the child had not been molested because her artwork was well organized. This case study is described on several pages of graphic detail of the repeated phallic imagery of the 9-year-old child’s work. Kramer’s book was the standard textbook in art therapy training programs across the United States in the mid-1980s. In the clinical experience of this writer, the artwork of vast numbers of children known to have been sexually abused was frequently not fragmented and chaotic, but for the most part was well-organized.

Carl Jung developed his theory of the transcendent function describing it as a process whereby the unconscious is revealed in artwork and becomes integrated with the conscious (Jung, 1935). Jung had his patients paint and draw their dreams in an effort to help them to become aware of unconscious symbols and to bring them into their conscious understanding (Jung, 1933).

Margaret Naumburg (1987), another major contributor to art therapy theory, draws from psychoanalytic theories of both Freud and Jung. She defines art therapy as a process whereby thoughts and feelings are derived from the unconscious and often reach expression in images rather than in words.

By means of pictorial projection, art therapy encourages a method of symbolic communication between patient and therapist. Its images may, as in psychoanalytic procedures, also deal with the data of dreams, fantasies, daydreams, fears, conflicts, and childhood memories. The techniques of art therapy are based on the knowledge that every individual, whether trained or untrained in art, has a latent capacity to project his [or her] inner conflicts into visual form. . . . (p. 11). Art therapy accepts as basic to its treatment methods the psychoanalytic approach to the mechanisms of repression, projection, identification, sublimation, and condensation. (Naumburg, 1987, p. 2)

Naumburg (1953) dedicated an entire book to a case study of a woman who had been a victim of sexual abuse in her childhood. Anatomically correct male genitalia appear repeatedly in the paintings and drawings of the patient whose recollections of such abuse were repressed until her imagery unlocked her memories.

A phenomenon which frequently occurs in the paintings, drawings, and sculptures of young sexually abused children is the depiction of anatomically correct male genitalia. Such artwork sometimes includes ejaculation and is created at a level of realism far beyond developmental appropriateness. These children usually name the genitalia as some other object, such as a tree, a cloud, a heart, a rainbow, etc. (Goodwin, 1982; Uhlin, 1979). However, the size, shape, and proportions of these “sublimated” genitalia leave little to the imagination (Figures 1–4). This particular characteristic in children’s artwork may be one which would arouse a high level of suspicion of sexual abuse. To depict such realism at so young an age seems highly unusual. The naming of these phallics as some other object might be due to two explanations. The first might be that the child is conscious of what he or she has drawn but attempts to disguise this knowledge. The second possibility might be that the phallus as the traumatic object is unconsciously portrayed. A considerable amount of further investigation needs to be done to understand this phenomenon and to learn whether it occurs in drawings of nonabused children as well.

Additional Problems in Assessment of Children’s Drawings

Sweeping statements are frequently made about children’s drawings without considering the following phenomena:

Effects of Immediate Prior Events

What has gone on in the child’s life immediately prior to doing the drawing? For example, does a particular flower the child draws have deep significance, or has he or she just come from an art class in nursery school where everyone was painting daisies?

Effects of Therapeutic Treatment versus Ordinary Developmental Maturing During the Process of Therapy

It is easy to assume that changes in artwork are due to therapy, but in actual fact may be due to developmental maturation which would occur without therapy. For example, a child may draw legs apart at the initial phase of therapy, but later draw them together. Is this due to resolution of the trauma of sexual abuse or to mental development?

Projection into Children’s Drawings—The Child’s Intention versus Our Own Projection

It is important to get a description from the child wherever possible. When a clinician suspects sexual abuse, it is easy to project “evidence” into children’s drawings. The problem in working with sexually abused children is that these children are often unable to verbalize such a trauma, and it is easy for an overanxious clinician to read more into the artwork than may actually be there. On the other hand, it is equally easy to overlook clues that may indeed indicate that sexual abuse has occurred.

Psychoanalytic Interpretations Appropriate for Adults Carried over to Children’s Drawings

Can psychoanalytic symbols commonly used with adult patients be similarly used in working with children? For example, are interpretations commonly made by users of the
House-Tree-Person Test (Buck, 1948) which may apply to drawings of adults appropriate for drawings of young children? Existing literature on case studies suggests that this is often the case.

Implications for Clinicians Working with Sexually Abused Children

The British Psychological Society recently expressed its concerns regarding the ability of psychologists to assess child sexual abuse lest British psychologists have their own Cleveland (Howitt, 1990). The dilemma in using children’s drawings as indicators of possible sexual abuse is apparent. Caution and common sense cannot be overemphasized as British clinicians treat children who are alleged to have been sexually abused on an ever-increasing basis.

Many variables must be taken into account. Indicators listed in the literature as characteristics of artwork of sexually abused children are frequently seen at various stages of development in the ordinary nonabused population. They also appear in drawings of children with other emotional problems, perhaps suffering from forms of abuse other than sexual. Analytic interpretations used in working with adults or older children cannot be generalized to younger children’s drawings.

Knowing events which may have occurred immediately prior to seeing a child may help clarify why the child depicted certain elements in his or her drawing. Listening to what the child has to say about a drawing is important, but one must take into account the reluctance of most children to disclose sexual abuse. The child may be trying to communicate indirectly and be unable to verbally describe what could be happening.

The development of more valid and contemporary projective instruments using children’s drawings is essential. Methodologically sound studies must be carried out to better understand differences in drawings of nonabused and sexually abused children.

The theoretical dilemma currently faced by mental health professionals as to whether phallic images in children’s artwork are normal oedipal fantasies or images reflecting actual sexual abuse is in need of resolution. Such a major theoretical question will not be easily answered. Meanwhile, we are faced with the immediate task of adequately protecting the children with whom we come into contact.

At the present time, it has been consistently demonstrated that drawings alone cannot be used as evidence that sexual abuse has occurred. Hopefully, with time, the use of children’s artwork will become increasingly valuable in detecting sexual abuse and we will become better equipped to protect children from the long-term psychologically damaging effects of such abuse.

The Contribution of Art Therapy to the Dissociative Disorders

Patricia S. Murphy, PhD, A.T.R., Moscow, Idaho

Abstract

Research has shown that childhood trauma is a critical component in dissociative disorders (Putnam, 1989). Traumatic imagery and frightening emotions are right brain functions (Brende, 1984). In order to explore concepts of brain hemispheric lateralization and distinct right brain functioning in extensive dissociation, the Dissociative Experiences Scale (DES) scores of 114 engineering students were compared to the DES scores of 92 drawing students on a university campus. The DES measures the level of dissociative experiences. The engineering curriculum was presumed to require more analytical, left brain skills while the drawing class tasks were assumed to utilize more visual, right brain skills. The data were separated into three levels of scoring. A chi-square calculation found differences in dissociative scoring levels between the groups that approached significance at the .05 level. This suggests that brain lateralization may play a role in dissociative processes. Since art therapy may employ the right hemisphere through visual imagery, it may be a useful tool in accessing dissociated states.

Introduction

The usefulness of art therapy in working with persons with dissociative disorders, especially those with multiple personality disorder (MPD), has been noted (Kluft, 1984). Many art therapists can attest from personal experience that many dissociative clients have been able to use art in their healing process in ways that they have not been able to use other modalities. As an art therapist working with clients who have dissociative disorders, one cannot help but be struck with the highly evocative and traumatic imagery that often evolves from that process. Is there something specific about dissociative clients that makes them so amenable to art therapy? One answer may be found in an examination of the literature about dissociation and brain hemispheric lateralization found in MPD.

The resurgence of interest in dissociative processes and the findings of increased numbers of people with MPD in the last decade has stirred research into dissociation and its functioning. This research has provided convincing evidence that dissociation is a naturally occurring phenomenon (Wolff, 1987), and that it is common in children and diminishes with age (Ross, Ryan, Anderson, Ross, & Hardy, 1989). Thus, in a normal developmental process, dissociation usually declines over time. When this does not happen and the individual continues to experience considerable dissociation, that person may be at risk for a dissociative disorder.

The dissociative disorders, which include MPD, have as their two principal characteristics disturbances in memory and disturbances in identity (Kluft, 1988). A third principle characteristic that has emerged from large case studies of individuals with MPD is that dissociation is invariably correlated with childhood trauma (Putnam, Guroff, Silberman, Barban, & Post, 1986; Ross, Miller, Reagor, Bjornson, Fraser, & Anderson, 1990). Additionally, the broader extent of the trauma, the more dissociation (Sanders, McRoberts, & Tollefsen, 1989). Some theorists maintain that victims parcel out the trauma in order to accommodate it. It then becomes the conflicting memories and effect that keep the system from integration.

Research in recent years, in a number of fields, has focused on exploring a better understanding of how mental processes in dissociation are presumed to operate. Efforts to develop theoretical models to explain dissociative phenomena include trance-state models, neurologic models, psychological models, learning and memory models, and split brain models (Putnam, 1984). Putnam (1984) points out that these models provide a frame of reference within which specific research questions can be asked. It should be noted that the models do not necessarily contradict each other; they simply offer a way to conceptualize a research question.

The context for this paper focuses on a model of hemispheric lateralization in dissociation. It has been well established that the right and left hemispheres of the brain differ in their influence on specific brain functions. The left hemisphere controls language and uses sequential thought while the right hemisphere governs spatial arrangements and uses visual thought (Gregory, 1987). Thus, the use of art therapy may employ the right hemisphere to a greater extent than more traditional "talk" therapies.

Because dissociation is linked to childhood trauma, and traumatic imagery is located primarily in the right brain, as is visual imagery, it is suggested that there might be associated links between visual imagery, right brain functions, and dissociation. It is known that particular emotional states are related to specific areas of the brain. For example, the right hemisphere of the brain has also been associated with emotional expression, depressive affect, in addition to traumatic imagery (Brende, 1984). Studies using electrophysiological responses (EDR) have further suggested that left hemisphere functioning appears to be linked to hypervigilance and aggressive outbursts (Brende, 1984). Evidence that different alter personalities have specific characteristics and/or emotional content such as anger or depression supports concepts of brain lateralization in MPD (Putnam, 1989). Brende (1984) found evidence of hemisphere-specific functioning in an MPD patient. Other studies describe handedness changes among alter...
personalities which further suggest brain lateralization in MDI (Putnam et al., 1986).

Thus it would appear that individuals with dissociative disorders may have either greater access to more right hemispheric areas of mental functioning. Those areas are more highly elaborated by the trauma experience and/or the usual integrative function of left and right brain has been compromised. These additional capacities are usually offset, however, by the inability of the system to operate in unity and by the memory difficulties that individuals with dissociative disorders experience.

As part of a larger study to explore the prevalence of dissociative disorders in a university setting, the dissociative experiences of two groups of students were compared. One hypothesis was that those attracted to the fields which employ visual imagery would have more dissociative experiences than those attracted to fields that utilize the more analytical and logical process of the left brain, such as engineering. In an effort to provide some elucidation, a segment of the student population for this study were drawing students. The rationale was that drawing classes utilize spatial arrangements and require more right brain skills and would appeal to individuals whose interest and skills are primarily in that arena. The comparison group was comprised of engineering students who were presumed to use more left brain skills. The engineering curriculum places heavy emphasis on mathematical and analytical skills which rely mainly on left brain functions.

Method

Subjects

The subjects were a selected sample of 415 undergraduate students at the University of Idaho. The Dissociative Experiences Scale (DES) was used to measure the extent of the participants' dissociative experiences. There were six different sources for completed DES forms used for the study. These were (a) drawing classes in the College of Art and Architecture (92 students, 4 different classes), (b) basic engineering classes in the College of Engineering (114 subjects, 4 different classes), (c) a child development class in the Home Economics school in the College of Agriculture (64 subjects), (d) a cognitive psychology class in the College of Arts and Letters (42 subjects), (e) clients using the Student Counseling Service at the University of Idaho (71 subjects), and (f) users of the Student Health Service (32 subjects). Students gave written informed consent at the time of administration of the DES and also indicated if they were willing to participate in a later, personal interview.

A total of 27 participants were later interviewed using a diagnostic instrument for dissociative disorders called the Dissociative Disorder Interview Schedule (DDIS).

Although some of the broader findings of the study will be discussed, the focus of this paper is on the comparison between the 92 drawing students and the 114 engineering students.

Measures

The two instruments which have been the most widely used in studies of dissociative phenomena are the Dissociative Experiences Scale (DES) and the Dissociative Disorders Interview Schedule (DDIS) (Bernstein & Putnam, 1986; Ross, Heber, et al., 1989). In 1986, Carlson and Putnam designed and validated a self report scale of dissociative experiences (Bernstein & Putnam, 1986). The scale was called the Dissociative Experiences Scale (DES) and was one of the first instruments that attempted to measure dissociative experiences. Reliability testing showed that the scale had good test-retest reliability (.84) and strong split-half reliability. The DES describes 28 different dissociative experiences and asks the respondent to indicate the extent to which he or she has that experience (Bernstein & Putnam, 1986). The range of possible scores, 0 to 100, is the mean of all the questions. Thus, it attempts to measure the level of dissociative experiences.

The authors of the DES were testing the hypothesis that the number and frequency of experiences and symptoms attributable to dissociation lie along a continuum where normal individuals would have fewer and less frequent dissociative experiences than those with dissociative disorders or disorders with a significant dissociative component (i.e., posttraumatic stress disorder—PTSD). It was further hypothesized that individuals with non-dissociative psychiatric disorders would fall somewhere in between the two extremes. The results of this study showed a steady progression in the median DES scores from normal subjects to multiple personality patients. The scale was able to differentiate between subjects with and without clinical diagnoses of a dissociative disorder. The authors concluded that the dissociative process does make a considerable contribution to the psychopathology of some psychiatric disorders and that the DES is a reliable and valid instrument that is able to distinguish subjects with a dissociative disorder from those without (Bernstein & Putnam, 1986).

Most of the studies to date have examined the DES scores of established clinical populations in comparison to other clinical and/or nonclinical groups. In those clinical groups, high scores on the DES are correlated with dissociative pathology. Scores over 30 on the DES have been found to be indicative of a dissociative disorder in clinical populations (Bernstein & Putnam, 1986; Coons, Bowman, Pellow, & Schneider, 1989). Ross, Norton, and Anderson (1988) maintain that scores above 30 are almost always associated with DSM-III-R diagnosis of MPD or PTSD, while scores over 50 are rarely achieved in persons without MPD. Putnam (1991) reports on a multicenter study of 1,300 patients that demonstrated a blind hit-rate of 89% correct classification of MPD versus non-MPD subjects by using a cutting score of 30 on the DES.

More recent studies have suggested that this may hold true in nonclinical populations as well (Ross, Ryan, Voight, & Seide, 1991). A two-part study by Sanders, McRoberts, and Tollefson (1989) reported that individual differences in dissociation in college students are positively related to differences in self-reported stressful or traumatic experiences in youth. The authors feel that these studies have demonstrated a clear and consistent correlation in a normal population between stressful events in youth and later tendencies toward dissociation.

The Sanders and colleagues study (1989) is only part of a larger effort to examine dissociative experiences in nonclinical
populations. A major question raised in studies of nonclinical groups is whether high scores on the DES are indicative of pathology in normal populations. Although the DES has been shown to reliably differentiate patients with dissociative disorders from patients with other disorders and nonpatient groups, it is a screening device for dissociative experiences and not a diagnostic instrument. It does appear quite likely, however, that high scorers experience severe symptoms which include amnesias and identity problems and therefore could experience considerable difficulties in negotiating in the world.

The first of the diagnostic interviews to be developed and the one most widely used to date is the Dissociative Disorders Interview Schedule (DDIS) developed by Ross, Heber, Norton, Anderson, Anderson, and Barchet (1989). The DDIS is a structured interview designed to make diagnoses of the dissociative disorders, somatization disorder, major depressive disorder, and borderline personality disorder. There are 16 sections and 131 questions. The DSM-III criteria for the disorders mentioned above are incorporated into the instrument. Questions also include information about substance abuse, childhood physical and sexual abuse, Schneiderian first rank symptoms, extrasensory experiences, and secondary features of multiple personality.

In the original study, the DDIS was administered to 80 psychiatric patients: 20 MPD, 20 schizophrenic, 20 panic disorder, and 20 eating disorder patients (Ross, Heber, et al., 1989). The results found an inter-rater reliability of .68 (Ibid.). The authors state that the DDIS has excellent validity with a specificity of 100% and sensitivity of 90% for the diagnosis of MPD. The "specificity" relates to the fact that none of the patients in the categories other than MPD met the criteria for MPD. The "sensitivity" refers to the fact that two of the 20 MPD patients did not meet the criteria for MPD.

The DDIS can be administered in 30 to 45 minutes and is designed to be used by a variety of mental health professionals. Ross and colleagues claim that used together the DDIS and DDIS provide a rich source of information on clinical subjects.

In this study the DDIS was used to determine whether the individual met the criteria for one of the dissociative disorders.

A final qualitative measure used was a debriefing interview offered to each DDIS participant. During that interview the researcher discussed concepts of dissociation and each person's individual responses to the DES and DDIS. It provided an opportunity to observe and discuss dissociative experiences and thus served as a validation of the diagnoses and as a way to see how dissociation was experienced on an individual level.

Procedure

Approval for the project was received by the University Institutional Review Board of the University of Idaho. For the drawing classes, permission to elicit participation in the project was received by the head of the Art Department and the three instructors who taught the four classes from which the forms were obtained. Since the study was interested in those students who were primarily art students (rather than those taking art as an elective), it was decided to primarily use drawing classes that were above the beginning level. This group consisted of individuals who were actually doing art work and were likely to be Art and Architecture majors. The classes represented were Drawing I, Drawing II, Drawing III, and Drawing IV.

As previously stated, the primary reason for the selection of engineering classes was that the engineering curriculum places heavy emphasis on mathematical and analytical skills and was presumed to appeal more to left brain thinkers. In the case of the engineering classes, permission was received from the Associate Dean of Engineering and the three instructors who taught the four classes from which the forms were obtained. The four classes represented all the sections of a basic engineering course which is required for all engineering majors. In all, 114 students from the engineering classes completed the DES.

Since the completion of the DES was a voluntary and confidential process, no tallies were kept on those who did not complete the DES. However, virtually everyone in every class completed the DES.

Once permission was received, the DES was explained briefly by the researcher and administered during class time along with the informed consent and agreement for a personal interview. The responses were then analyzed for differences between groups. Parametric statistics were used and significance was set at .05.

In the second phase of the project, the DDIS was administered to 18 people who scored above 30 on the DES and a stratified random sample of nine people who scored less than 30 on the DES. The interviews were conducted by four graduate students in the Counseling program at the University of Idaho. The interviewers were trained by the researcher on dissociation theory and the administration of the DDIS. They met weekly as a group to discuss the interviews and to reach consensus on the diagnoses. They were blind to the DES scores of the subjects.

Following the administration of the DDIS, participants were offered the opportunity to meet with the researcher to discuss dissociation and their individual responses to the DDIS. Only one person, a low scorer, did not participate in this process.

Results

Distribution of DES Scores

The distribution of DES scores was positively skewed with 37 people (8.9%) scoring above 30 on the DES. The mean score for the sample was 14.69 (SD 10.77). Although among the groups, the art students exhibited the highest mean score of 16.36 (SD 11.29), an analysis of variance revealed no significant differences in mean scores between the DES scores obtained from different sources. $F(3, 409) = .69, p = N.S.$ Figure 1 displays the distribution of DES scores for the entire sample, the art classes, and the engineering classes.

Differences Between Art and Engineering Students

In order to ascertain if there were significant statistical differences between art and engineering students in scoring, the data were separated into three levels of score (high, medi-
um, low) using the students from the two groups. Low scorers were those who scored below 7 on the DES. They represented 25.2% (52 people) of this group. Medium scorers were those who scored between 7.1 and 28.9 on the DES; there were 135 people (65.5%) in this category. The high scorers were those who scored 30 and above on the DES. They represented 19 people or 9.2% of this sample. A high score of 30 was chosen because this is the level, in clinical populations, that is indicative of a dissociative disorder (Bernstein & Putnam, 1986).

There were approximately the same number of students in the art and engineering groups and assumptions of homogeneity were met. Table 1 displays the result of the cross-tabulation, $x^2 (2, N = 206) = 5.73, p = .0569$. This result approaches significance at the .05 level and suggests some differences between these two groups of students. The art students had four fewer low scorers and four more very high scorers than would be expected. The engineering students had the reverse situation, four more lower scorers and four less very high scorers than would be expected.

The art classes contributed 35% of the very high scorers compared to only 22% of the entire sample. By contrast, the engineering students comprised 16% of the very high scorers and 27.5% of the entire sample.

**Dissociative Disorders in Very High Scorers**

Of the 18 very high scorers who were interviewed, 16 met the criteria for one of the dissociative disorders as determined by the DDIS (89%). The other two very high scorers both had considerable dissociative experiences and one of them later told the researcher that he had not been totally honest with the male interviewer about the extent of his sexual abuse or his symptoms.

Of those who scored above 25 on the DES, 19 of 21 met the criteria for a dissociative disorder while no one who scored below 25 (and was interviewed) met the criteria for a dissociative disorder.

**Discussion**

The main question for this paper has been whether there is evidence of brain hemispheric lateralization in individuals with dissociative disorders. Specifically, do persons with dissociative disorders have more access to, or more highly elaborated, right brain hemispheres? If the answer is yes, it provides further support for the use of art therapy with dissociative clients. Since it is assumed that drawing and visual perception are more right hemispheric activities, use of art media and the process of creating graphic images may provide a way to access the traumatic imagery associated with dissociative disorders. The release and processing of these traumatic images can have a cathartic and healing effect. Likewise, the art product may be a way to describe a traumatic event that cannot be described verbally for any number of reasons. Because of the memory difficulties experienced by those with dissociative disorders, art productions may serve as clues or as a way to begin to access those memories.

The main focus of the entire study was to examine the prevalence of dissociative disorders in a nonclinical popula-

tion. The results indicated that almost 9% (37 students) of 415 students scored above 30 on the DES and that 89% of those very high scorers met the criteria for one of the dissociative disorders, including four who were positive for MPD. These figures may be quite conservative because, in clinical samples, 15% of people with MPD score below 20 on the DES (Ross, Miller, et al., 1990). At a minimum, these results suggest that extensive dissociation is a problem for a considerable number of individuals.

One question that evolved from this process was whether art students would evidence more extensive dissociative experiences than students who are presumed to use more left brain skills, such as engineering students. In fact, there were differences that approached significance. If one can support the premise that, generally, engineering skills differ from artistic skills in the use of brain hemispheres, the findings support the idea that dissociated states are associated with activity in different parts of the brain, and/or a lack of connection between brain hemispheres.

Does this mean that those in the arts have more dissociative experiences than those in more pragmatic fields? Perhaps, because dissociation can be a positive source of creativity and focus. It should be remembered that virtually everyone has dissociative experiences, and they are a normal and important aspect of human functioning. Likewise, for most people the right and left hemisphere of the brain work in concert to create our experience of the world. For some, perhaps that balance is weighed more heavily in one direction or the other. But it is when overwhelming trauma is experienced and dissociation exacerbated that people are at risk for a dissociative disorder. This study was focused on those people who are at the extremes of the dissociation scale. The very high scorers comprised 14% of the art students and 5% of the engineering students. This in no way implies that most artists are more emotionally troubled than others. It more likely appears that people who have been traumatized seek to express their trauma in some tangible way. High-scoring art students may be the most fortunate in that they have access to a socially acceptable and potentially healing expression of the traumatic events that shaped their lives. With appropriate therapy, perhaps they can come to understand and integrate their experience.

The debriefing interviews offered an opportunity to observe some of the characteristics of the high dissociators. First, it appeared that the art students were more willing to discuss their dissociative experiences. 10 of 13 very high scorers in the drawing classes came in for interviews compared to three of six engineering students. The two very high scorers who did not meet the criteria for one of the dissociative disorders were drawing students. Some clearly felt that their dissociative experiences served their artistic expression and made them better artists.

Perhaps the engineering students did not have the vehicles for release that were available to the drawing students. Since all of the interviewed engineering students were male (compared to three males of 10 drawing students), this may account for some of the perceived differences between the groups.

This paper provides evidence that 5% to 10% of a non-clinical population may experience dissociation to the extent of meeting the criteria for one of the dissociative disorders. It further suggests that there may be a connection between the use of right brain functions and dissociative disorders. It may be that those who experience extensive dissociation seek ways in which they can express their trauma, namely in the expressive arts. Those who use artistic productions to express themselves may, in fact, be using their art to help heal their trauma. (This should come as no surprise to art therapists.) Others, who do not have access to suitable means of expressing their trauma, may be more at risk for serious pathology.

We are coming to understand that many emotional disorders are rooted in trauma. Art can be a helpful and useful way to express that trauma. Likewise, a focus on creativity can help the client find new ways to resolve intrapersonal and interpersonal difficulties. This speaks persuasively for the continued and expanded use of art therapy in treating the dissociative disorders and other emotional difficulties with a posttraumatic component.

Abreacting and Assimilating Traumatic, Dissociated Memories of MPD Patients Through Art Therapy

Mindy Jacobson, MCAT, A.T.R., Philadelphia, PA

Abstract

When used to treat patients diagnosed with multiple personality disorder (MPD), art therapy aids in translating un-speakable memories into a visual format, which may be used for psychotherapeutic exploration and mastery. As anger is sublimated, associations to artwork may be actuated to bridge affective states and memories. "Stepping in," a drawing process developed by the author, may then be used to promote "cross alter associations" to the imagery drawn by other personalities. Consequently, new feeling states may be experienced through abreaction and cognitive awareness, the comprehensive expansion of memories, and the lessening of self-destructive ideation. This process may be utilized to break down amnesic divisions, and ultimately to diffuse personality barriers originally created to survive the severely traumatised child. This paper addresses the recovery of traumatic material (metabolizing the trauma) and its subsequent resolution and integration.

Introduction

Art therapy is a nonverbal treatment modality which facilitates verbalization through the art process and lends itself to the treatment of patients who dissociate. Art serves as a visual record of the personality system or inner group created by dissociative individuals, reducing denial through permanent inscription on the page for both the patient and therapist to discover together (Jacobson, 1986, 1989). At the core of art therapy is creativity, the invitation to generate imagery for restoration and growth (Wadeson, Durkin, & Perach, 1989).

In working towards crisis resolution, art activates an alternative form of communication in contrast to verbalization, the latter typically forbidden by the perpetrators of abuse. Art productions which embody the affective memories related to trauma bridge the gap between nonverbal and verbal ideation. Cathartic expression, therefore, takes place through the externalization of previously repressed material onto an art form which is safe and diminishes the potential for acting out (Fink, Levick, & Goldman, 1973).

Multiple personality disorder (MPD) has been directly linked to severe and enduring traumatic experiences originating in childhood (Kluft, 1984). The abused child, fearing the expression of feelings related to trauma, may find alternative modes for coping with them. Dissociation and the symptomatic formation of alternate personalities are the most dramatic defensive maneuvers in response to these overwhelming and horrifying experiences (Coons, 1984; Kluft, 1984). The emergence of alternate personalities allows the individual to survive both psychologically and physically. Dissociation may preserve comfort and safety in response to stress, guilt, and rage. It also enables one to take revenge, gratify narcissistic and masochistic needs, partially repeat or reenact earlier traumas, experience secondary gain, and display the fixation or arrest from previous developmental stages (Ellenberger, 1970; Kluft, 1984).

One of the art psychotherapist's roles is to provide the dissociated patient with appropriate channels for the expression of feelings and integration of deeply repressed material (Cohen & Cox, 1990; Jacobson, 1986, 1990, 1991; Jacobson & Mills, 1992). In working with patients diagnosed with MPD, the invitation to draw or sculpt typically leads to the presentation of personal nightmares related to previous abuse. This information, dissociated from the birth personality, must be externalized and integrated in order to restore psychological health (Comstock, 1986; Kluft, 1988). Similarly, the management of anger and destructive impulses is critical to the therapeutic process and survival of the individual as the phases of treatment evolve (Jacobson, 1986, 1990; Putnam, 1989; Wadeson, 1980).

Through the promotion of visual personality, the patient learns how to access parts of the internal system of alters for expressive purposes and mastery. As the investment in art productions expands, however, affective issues may become increasingly charged due to the magnification of feelings by alters concomitantly expressing themselves. This includes the expression of rage towards the self and others, and concomitant feelings of grief. The expression of these feelings is crucial in setting the foundation for subsequent personality unification, although often it can also lead to an increase in suicidal and homicidal feelings.

Managing Abreaction

Abreaction, the process of bringing into consciousness, recalling, and affectively reliving previously unconscious material, has been consistently viewed as central in the treatment of multiple personality disorder (Braun, 1986; Comstock, 1986; Hammond, 1992; Hicks, 1985, 1987; Willbur, 1984). Kluft (1988) described a traumatic experience and the corresponding affective component as an abscess waiting to be drained. Similarly, Comstock (1986), Hicks (1988), and Spiegel (1986) report that memory is a reconstructive process, and that the abreaction of traumas is essential and painful.

During abreaction a duality may exist in that some individuals demonstrate a "co-presence" between the past and current reality (Comstock, 1986; Hicks, 1986, 1988; Kluft, 1988; Spiegel, 1986). A misrepresentation of current reality based
on former traumatic or conflictual relationships, known as transference, is similar to abreaction as the person reverts in time and loses partial connection with present reality. Minor degrees of this are not considered to be pathological (Hicks, 1988).

In more severe cases, as in MPD and Post Traumatic Stress Disorder (PTSD), there may be a total loss of contact with the here and now. The misinterpretation or misperception of interpersonal dynamics or environmental stimuli may occur, and the potential for reexperiencing the past as a current phenomenon becomes likely (Comstock, 1986; Hicks, 1988; Kluft, 1988; Spiegel, 1986).

The literature reports parallels between MPD and PTSD in that psychic trauma implicates the mind with an inordinate degree of stimuli which cannot be assimilated in normal ways, which leads to a posttraumatic stress response, and which may mobilize dissociative processes (Cooper, 1983; Kardiner, 1959; Kolb, 1983; Spiegel, 1984). The ego constriction which victims of massive trauma experience reduces the potential for adaptation and requires the active reliving of the stressful events. With sustained therapeutic support, mastery may be achieved through abreactive techniques, personality disturbances may diminish or dissolve, and internal controls may improve (Cooper, 1983; Kolb, 1983; Spiegel, 1984).

According to Comstock (1986), abreactions always serve a purpose. Although initially unclear, a variety of reasons for abreactive experiences include: (a) to inform or present information; (b) to educate, reeducate, or modulate distorted thinking patterns which occurred during a trauma; (c) to complete and release repressed affects, content, and somatic material; and (d) to add details and information surrounding recollections (Braun, 1986; Comstock, 1986; Hicks, 1988; Kluft, 1988). Abreactions may be unbridged and contain automimetic, physiologic, affectual, and intellectual representations of previously repressed material. In partial abreactions, abreactive experience does not go through to completion and only segments of the memory are reexperienced.

Signals that an abreaction is about to occur may include: (a) intense hallucinations; (b) flashbacks; (c) an increased expression of anger or self-mutilation; (d) burning, anesthetic, or new somatic sensations (body memories); (e) inexplicable emotions which are evasive, pervasive, and new; (f) behavior reenactment of a scenario; (g) startle responses or hyperalertness; (h) problematic dreams or nightmares; (i) increased fears of being alone or with others; (j) newly emerged obsessive-compulsive behaviors; and (k) passive influence experiences (Comstock, 1986; Hicks, 1988; Kluft, 1985, 1987; Putnam, 1989).

As abreactive experiences are inherently regressive, the therapist's responsibility is to provide a safe environment in which to allow abreactions to occur and to estimate the time frame needed to accomplish the necessary work (Hicks, 1988; Kluft, 1988). According to Kluft (1988), this is not always possible as many abreactive experiences are spontaneous and result in the patient's leaving the session in a compromised position (i.e., with controls but without completing or fully addressing the abreactive experience). Sometimes traumas require repetitive abreactions in order to be fully understood and to desensitize the current stimuli which precipitated a flashback.

Patients should be evaluated as to when they are able to handle full abreactions. If this is not possible, internal distancing from the actual memory may be used to allow alters to view the scene from a removed position. The use of fractionated abreactions, as defined above, may prevent the escalation of acting out behavior and emotional or physical exhaustion. Therapeutic interventions such as art therapy, movement therapy, or hypnosis may also increase one's understanding of the personality system in conjunction with traumatic events and distressing relationships (Kluft, 1987; Spiegel, 1986).

In the literature on the therapeutic use of imagery, McKinnon (1984), Grigsby (1987), and Brett and Ostroff (1985) state that the role of visual imagery in the symptomatology of PTSD requires further attention. These authors hypothesize that the use of therapeutically structured visual imagery may preclude the need for hypnosis and decrease resistance, although they warn that an overly direct approach may result in the patient viewing the therapist as sadistic.

It is this author's opinion that the process of art therapy increases the potential for abreaction in MPD patients as censorship tends to decrease when nonverbal modalities are utilized in psychiatric treatment. As the therapeutic alliance progresses and art enables the patient to connect with previously repressed material, spontaneous abreactive experiences may similarly increase. Art may be therapeutically structured, however, which may circumvent the need for hypnosis to access traumatic memories.

The art process promotes the unraveling of layers existing in complex MPD patients, which leads to the provision of visual information. Through this mode of information gathering, alters may communicate and compare histories and also modify previously learned responses to foster mastery of original trauma. Art expression bridges various components of memory including behavior, affect, sensation, and knowledge (Braun, 1988).

Abreactive sessions may be orchestrated in response to imagery in drawings, and they may also occur spontaneously (i.e., triggered by art media or content in previous drawings). Safety is a priority when doing abreactive work as the patient relinquishes distance between the present and past and may lose control unexpectedly. For this reason, pre-abreactive work should be done in the initial phases of treatment and prior to planned abreactive sessions. This includes delineating the abreactive process within sessions, formulating a safety plan in the event the abreaction becomes unmanageable, and addressing the possibility of inpatient treatment to explore material which might compromise safety. The necessity of developing a therapeutic alliance with the patient and personality system is obviously paramount with this type of therapeutic work.

Case Example

Rachel was referred for individual outpatient art psychotherapy due to increased blocking in her verbal psychotherapy sessions. After several months of art therapy treatment, she began to experience pain in her buttocks, which proved to be inconclusive upon medical examination. In a subsequent collage which she had been working on independently (Figure 1), it was determined that the bridge in the
upper right-hand corner appears to be leading to the screaming young girl. The latter is connected to an underground tunnel within which a man stands; to the left of the tunnel is a disrobed figure with buttocks bared.

In conjunction with this collage, a younger alter emerged and asked to work with fingerpaint (Figure 2). Although unable to verbalize the meaning of the images, Rachel noted six phallic shapes with darkened material on the tips, an oozing substance emanating from them. Subsequently, a drawing was completed in which a portion of the cognitive memory was depicted (Figure 3). In exploring this memory through a series of fractionated abractions, another alter named Anna drew herself and the therapist in the rafters of a barn. Her perpetrator is seen as ready to penetrate, as she lies atop several bales of hay. In the final picture (Figure 4), drawn following a complete abraction of the memory, several personalities “wail and scream” as the corresponding affect is released from the wooden plank which previously contained them. Following this series of pictures and the acknowledgment of repetitive anal rapes by father, the body memories and pain Rachel experienced were resolved.

Assimilating Traumatic Material

As the therapist investigates memories, the foundation for bridging affective states is laid and the dissociated material may emerge. Repressed material held by personalities may surface, enabling the recognition and understanding of particular incidents. This data may be used to abreact a traumatic experience and expose affective fragments, allowing alters to bring forth memories and to enhance their comprehension of varying perspectives surrounding them. This last therapeutic endeavor, a process developed by this author, explicitly utilizes artistic imagery as a vehicle for sensitizing alters to thoughts and feelings other than their own. This method, called “stepping in,” involves free association plus assimilation, which may lead to resolving issues surrounding traumatic events.

Free association to art productions offers the patient and therapist text which directly relates to personal images. Through the work of Naumburg (1966), the integration of psychoanalytic theory and free associations to spontaneous art
productions yielded one use of art expressions as a therapeutic modality. In this tradition, "stepping in" is a term coined by the author to describe a therapeutic technique incorporating free association that has developed in her clinical work with alters. It is a process in which several alters are asked to free associate to the same drawing. The alters may have participated in drawing the image; however, alters who have not drawn are also asked to "step in" to an area of the image or align with another alter who has been drawn. Through this process, alters who initially denied awareness of a traumatic event may find connections to the traumatic material presented in the image. Consequently, it can be a first step toward assimilating and integrating memories, as the personalities "stepping in" may recognize some aspect of the event being explored.

The major difference between the technique of "stepping in" and traditional free association is that visualization techniques and simple hypnotic interventions are utilized to facilitate the process. Additionally, nonintegrated aspects of the self are associating to the same image.

Case Example

In examining the original dissociative split resulting in the development of alters Sarah, Dan, and Nicole, this drawing was elicited (Figure 5). The drawing depicts Daddy and three adult friends sexually violating a child (Sarah/Nicole) on a table. A young boy with arms bound is depicted to the right of the table (Dan), and another tiny figure watches from outside the shed door.

The original personality, the one near the door, reported that she was not involved in this incident and that she enjoyed laying in the grass. After reaccessing the memory depicted by the three alters in this picture, this therapist asked the observing personality to step into the body on the table for several counted seconds—to see "if it fit." Following an affirmative nod of her head, she was asked to step out of the picture. For the next few months her grief and illusion of immunity, which distorted reality in order to preserve psychological safety, were addressed. Dan’s and Nicole’s rage offered another affective component related to this trauma, as her therapy continued to explore what the group would say to Daddy if he were alive (Figure 6).

Over time it was learned that personality Dan evolved and was mute as a result of being bound and gagged during
the abuse. In therapy he gradually accepted being taught how to speak (Figure 7), and the corresponding feelings of fear and grief were retracted. Currently, the accommodation of previously assimilated schema is being addressed in order to understand the patient’s personality system, which has led to decreased personality tension and increased personality communication within the system at large (Figure 8).

Conclusion

When repetitive traumas occur, the child often revises and reformat* reality in a new way in order to safeguard his/her psyche. As the ability to comprehend recurring traumas becomes impossible, the assimilation of such trauma may result in internal fragmentation.

The use of visual imagery to recover traumatic memories offers the MPD patient a developmentally flexible modality for resynthesizing past experiences through artistic externalization. Through abreactions, and the corresponding processing of them, maladaptive accommodating and self-correcting mechanisms may be identified and relearned. In conjunction with relearning truths through “stepping in,” dissociated material may be shared among alters within the personality system. This may reduce the need for separateness and support the development of an integrated psyche.

In conclusion, art psychotherapy may offer diagnostic information and aid in uncovering psychodynamic data in patients diagnosed with multiple personality disorder. Through abreactive techniques and others, a nonverbal, comprehensive mode for both accessing and reprocessing dissociative information is available. As illustrated in the brief case examples, this modality is effective in the recovery, resolution, and integration of the traumatic material presented by patients who dissociate.

An Application of Art Therapy to the Trauma of Rape

Karen Hargrave-Nykaza, BS, Watertown, NY

Abstract

This paper explores the personal violation of rape in terms of specific trauma usually experienced after a rape: PTSD, rape trauma syndrome, and permanent life changes. The purpose of this paper is to explore the ways in which art therapy can help a rape victim engage herself in the healing process. A study of one rape victim is reviewed along with the current literature as an example of the life-altering effects of rape and the importance of art expression in their treatment.

Rape: Definition and Overview

A formal definition of rape according to common law reads:

"A man commits rape when he engages in intercourse with a woman not his wife; by force or threat of force; against her will and without her consent." (Estrich, 1987, p. 8)

The act of rape is connected with aggression. Society associates sexuality with violence and these contextual beliefs are not easily altered (Fonow, 1992). Others observe that "men are socialized to be aggressive while women are socialized to be victims" (Chapman & Gates, 1978, p. 29). Hall (1986) found that images of male dominance and female passivity allow this culture to support rape-tolerant attitudes. Male supremacy seems to be upheld at whatever cost. For women, this cost is often rape, sexual harassment, physical abuse, emotional abuse, and living in constant fear of being attacked (Chapman & Gates, 1978).

According to Chapman and Gates (1978), sexual exploitation begins at an early age when children are exposed to fairy tales, cartoons, TV programs, and commercials. It seems that before anything can be done about rape specifically, society has to change the exploitation that has become so accepted in our social mores. Vona Evans (1992) found that these exploitive stereotypes are engrained in children's minds very early and not easily erased.

Twenty-five percent of the women who report their rapes have been raped by their husbands. According to the common law definition of rape cited above, violating one's wife sexually may not be considered rape. In a televised report a woman spoke about being raped by her husband. She had the entire attack on videotape, including her being tied to her bed. Even with this evidence, her husband was found innocent. If modern law does not yet recognize rapes by acquaintances as "real" rapes, it is not surprising that the issue is rarely raised when the rapist is the victim's husband (Estrich, 1987).

The Effects of Rape

There are emotional effects following a rape. These include grief and loss, depression, guilt and self-blame, rage, terror, mistrust, low self-esteem, fears about control, body image distortion, intimacy and sexual difficulties, and self-destructive behaviors (Quina & Carlson, 1989). Most women who have been raped experience all of these emotional effects at some point; many are experienced for several years following the rape. One victim expressed, "I have gotten over the physical trauma of what he did to me, but I live every day with the emotional trauma" (Kantrowitz, 1991, p. 32).

One of the most dangerous outcomes of rape occurs when the victim blames herself (Quina & Carlson, 1989). Reilly (1992) found that less than half of the women in a category of highly victimized women acknowledged that they had been raped. According to Remer and Witten (1988), most women do not even discuss the experience of being raped with their significant other. This type of blame can only perpetuate a negative cycle and enhance an atmosphere where rape myths are perpetuated (Ibid., 1988).

Often in cases of sexual trauma involving rape, victims are told that they are to some degree responsible for being victims (Ochberg, 1988). In many cases, the woman feels like a criminal herself as lawyers present a case against her to make it look as if she as asked to be raped (Hazelwood & Burgess, 1987). A woman's entire past is scrutinized, especially if she is claiming she got AIDS from her rapist (Salholz, 1990). It is also very difficult for a victim to try to recover from rape while a defense lawyer is presenting her sexual history to a jury (Ibid.). If a defendant knows the victim's sexual history, it could be argued that such knowledge is relevant to determining what her rapist thought at the time of intercourse (Estrich, 1987). Self-blame and projected responsibility by others seem to be a pervasive problem according to Sundberg (1991). All too often the public considers the circumstances surrounding the attack rather than the victim's feelings.

Additionally, rape is the most intimate of crimes. It is the dark terror in a woman's heart as she crosses an empty parking lot. It is also the only violent crime that tarnishes the victim and the criminal (Kantrowitz, 1991). Fear of rape is one of the strongest fears reported by women and is thought by women to be worse than murder (Quina & Carlson, 1989). A common attitude among women who fear rape is that if they were attacked, they would fight the attacker because they would rather die than live the kind of life they believe they would have after such a trauma (Ibid.).

A result of the rape is the appearance of the rape trauma syndrome (Chapman & Gates, 1978). Some of the emotions described by victims who have experienced this syndrome are extreme psychological shock, fear or terror, anger, shame, guilt, anxiety, revenge, powerlessness, and humiliation (Ibid.). "Victims of criminal harm experience a special kind of trauma cre-
ated by the intentionality of the criminal act” (Quina & Carlson, 1989, p. 26). A sexual crime has additional meaning for its victim because it is such a personal violation (Ibid.). “Rape trauma syndrome can help corroborate the victim's assertion of lack of consent and also help the jury understand the typical reaction of rape victims” (Block, 1990, p. 309).

A diagnostic category that has several symptoms in common with rape trauma syndrome is posttraumatic stress disorder (PTSD). According to the DSM-III-R (1987), symptoms of PTSD include difficulty sleeping, outbursts of anger, difficulty concentrating, hypervigilance, exaggerated startle response, and physiological reactions when exposed to events that symbolize an aspect of the traumatic event. “The DSM-III-R (1987) defines PTSD as a response to a significantly traumatic event outside the range of usual human experience, markedly distressing to almost anyone, and usually experienced with intense fear, terror and helplessness” (Howard, 1990, p. 79).

The Use of Art Therapy with Trauma

Howard (1990) noted that art therapy is a visual process that has great potential in accessing traumatic memories which may have been visually encoded. Thus, the art process may be useful as an intervention for PTSD and also provide a needed distance from this traumatic material (Ibid.). “By disassociating the self from the content of the picture, the patient's sense of personal control and integrity is protected” (Ibid., p. 81). The victim uses denial to work through the traumatic imagery to discuss a picture of a feeling rather than the feeling itself.

Art therapy is also valuable to the rape victim because victims of psychological trauma have difficulty expressing their experiences directly and effectively through words (Johnson, 1987). At times of overwhelming terror, the cognitive system is bypassed and the event is recorded in photographic form. Memory may be blocked, but the visual images of art therapy may offer a unique way for traumatic memories to come to consciousness. The control of traumatic memories through the use of art materials seems to be essential to the victim at this point (Johnson, 1987). Johnson also states that “the need to disown and deny the affect and memories of the trauma, and to remain in control of them are more effectively accomplished when these images arise on paper” (p. 11).

Another purpose of art therapy is to restore a sense of order to the sensory modalities that an emotional crisis and stress have fragmented (McNiff, 1981). McNiff explained how angry the client’s early pictures were and “how they allowed her to release her feelings in a way that would not harm anyone” (p. 164). Her artwork became a visual enactment through which she could free herself of anger and fear. This type of experience obviously could be useful in processing traumatic memories and the feelings surrounding them.

Horowitz (1971) found that repressed memories are accessible to consciousness in image representations that are inexpressible in words. Art therapy seemed helpful to the rape victim in this way because it used images to represent ideas and feelings. The images were less threatening to the victim when verbal expression became too difficult.

Art therapy is a particularly effective mode of treatment for the recovering victim. One strength found in the literature on the use of art therapy with rape victims is that it is thought to be a less threatening mode of expression (Burgess, 1979). The graphic images which haunt rape victims often require an alternative outlet to verbal therapy. Howard (1990) suggested that the images can place the victim in a life-threatening situation, yet the illustration can depict the victim seeking help or escaping rather than being victimized. The art therapy process and product seem to help victims restore some continuity between image and feeling.

Peacock (1991), in a study of postsexual abuse trauma, found that art therapy enables a client to identify, acknowledge, and express feelings. Her hypothesis also proposed that art therapy enhances the client's self-esteem, decreases anxiety, and decreases depressive symptoms.

Art therapy may be effective because it is directed at the essence of image trauma (Burgess, 1979). The rebuilding of the self as separate from the attack may take a different length of time for each victim. Some of the factors that influence how long the rebuilding process takes are the severity of the abuse, the strengths and weaknesses of the victim, and the support she receives from various sources. Art therapy keeps the focus on the image, keeping in mind that the rebuilding process is different for each victim.

An article by Yates and Pawley (1987) discusses one woman's struggle with sexual abuse. The woman's internal conflict is described as the struggle between her will to remember being sexually abused by her brother and the terror of remembering. As a child she denied this ongoing abuse, but as an adult she felt that she must resolve this conflict by allowing herself to feel what she had previously denied. She accomplished this partially through the use of her own artwork. Once she was prepared to accept the images she created, she understood the meaning behind them. "By creating art and being involved in psychotherapy, she learned about the healing process. Through this imagery, psychotherapy, and perseverance, she has worked toward resolution of difficult emotional issues” (p. 41). In experiencing her own art therapy, this woman expressed her own growth regarding her sexual trauma. "I have a new enthusiasm for creating art, and I will continue to explore the relationship between my unconscious and creative self. It is through expression in imagery that I have been healed.”

The Symbolism of Sexually Abused Women

According to Spring (1985), women who have been sexually violated often draw wedges and eye forms. Posttraumatic stress also causes an increase in the frequency and sharpness of this wedge symbol. Spring noted that these symbols can be used for several related reasons: (a) use of the wedge shape to protect the vagina from penetration; (b) use of the wedge shape to equate penetration with threat; and (c) use of the eyes to symbolize guilt, being watched, and vigilance (such as watching for the rapist's return). Some of Rhyme's research (1979) suggests that subjects attach vigilance to drawing eyes. The wedges seem to appear when the victim is expressing threatening situations (Spring, 1985).

Horovitz (1988) found that triangular shapes were used to represent the vagina in a woman who had been sexually assaulted. She concurred with Spring’s findings (1985) and also
discovered that illustrations of the perpetrator were often devoid of body and contained an overly aggressive smile.

Spring (1985) stated that as the sexual abuse victim begins to make progress, the wedge and eye forms may be incorporated in the artwork in a more positive manner. These symbols may assist in the woman’s growing ability to gain mastery over her victimization. For some, drawing provided a relief from the pain; for others, it gave a sense of control.

Spring (1985) also found that chemical dependency may arise in victims of sexual assault as a way to self-medicate against unbearable emotional pain. The author found this to be true when she interviewed a rape victim about her experience. The interviewee explained that she took drugs to escape the pain of being raped. “Drugs and alcohol can create a self-induced altered state of consciousness that provides an escape from emotional pain on a continuing basis” (p. 20).

Case Example

The rape victim interviewed by the author is an art therapist as well as an artist. She found that simply realizing the attack had occurred, working on it through art, and later writing about it were tremendous steps toward rebuilding, though she feels her issues are still somewhat unresolved. The victim observed that she experienced many symptoms of PTSD including difficulty sleeping, difficulty concentrating, and a physiological reaction when exposed to symptoms that symbolize an aspect of the traumatic event. Through this woman’s self-examination through art, like others who experience PTSD, the traumatic event was persistently reexperienced. As this victim turned to art to express her pain, she was shocked by some of the images she found in her work. In addition, she found the physical activity of painting allowed her pent-up emotions to be released. According to Bauer (1992), nonthreatening imagery is important to find and diffuse negative and aggressive feelings. Art therapy also provided this woman with an opportunity for nonthreatening and nonverbal self-expression.

This victim explained to the author that she was not violently attacked, and for this reason it was difficult for her to acknowledge the incident as a rape. She tried to ignore the incident, perhaps pretending that it didn’t happen at all. During the time this victim tried to block out the incident, she found her feelings of self-worth beginning to erode. She engaged in many self-destructive behaviors, as if to surround herself with anything that would help block out the rape.

This woman explained to the author how her own art therapy helped her work through the many changes she was experiencing. She also shared a passage from a literary work that she felt expressed her feelings regarding her own work:

Upon completion of the first draft, I found myself trying once again to leave the rape behind me. I would look for ways to avoid going back to the manuscript, fearing that other feelings and issues would resurface as I reread and reworked the manuscript. Finally one year later I developed the impetus to complete the final draft. My fears that the wounds would reopen did not hold true. As I reread the manuscript, however, I gained new insights into my own healing process. I found that I described the rape as “my” rape. Somehow I was still owning being raped, that is, taking responsibility to some degree that I had been raped. Now I find the degree of anxiety has lessened.

I also discovered that the issues related to the long-term process of healing were clearer to me when I returned to the second draft. This only points out how very long it takes to integrate the experience into one’s life. Even when I thought that I had fully integrated the rape, I relearned how deep the wounds really are. (Katz, 1984. pp. 100-101)

The rape victim shared several samples of the artwork she created during her own healing process. She did not interpret them but explained that the process of doing the work was in itself therapeutic. She did not work with a therapist throughout the process, as she did not feel ready for verbal exploration of her feelings. She still feels unable to interpret her feelings and the content of her artwork, so a description of the work by the artist and some interpretation by this author will be included.

Figure 1 is an etching and was her first artistic undertaking after the rape. It seems to reflect a tragic feeling of self-blame, common among rape victims. Shame is apparent with the woman covering her face. The eyes are masked which could suggest the victim’s unwillingness to accept or deal with what has happened to her. The victim expressed feelings of denial about the occurrence of the attack along with her refusal to cope with her feelings since the attack. She seems to be concealing her identity, afraid of the stigma attached to rape in addition to her own feelings of shame. Ironically, the victim chose to etch this image in stone, which could be a metaphor for the permanent effects of the rape.

Figure 2 is the result of the previous illustration being soaked in acid. It seems that for this victim, after she created these images, she was desperate to remove them from her memory. According to the DSM-III-R (1987), recurrent distressing dreams of the event are normal. This woman expressed that she was haunted by reliving the experience while she was both awake and asleep. This might reflect her inability to accept how vulnerable she was at the time of the attack. Again the face has been covered to conceal the woman’s identity, and the mesh seems to be used as a de-
fense to protect the body. This may be her last effort to protect herself from the emotions resulting from her rape by putting an actual physical barrier between herself and the rapist.

Figure 3 was her first painting in a series and again raises the issue of being deflowered. In fact, flowers and deflowering are recurring themes in her artwork. The ghostlike figure in this painting appears to illustrate the victim’s feelings of being continuously haunted by her attacker. The combination of the deflowering imagery, the woman’s depressed background, and the ghostlike attacker may reflect a woman’s life that has been permanently altered by rape.

Figure 4 was painted next. It contains bold purples and reds to represent the victim’s anger both at herself and the attacker. When looking at this monumental painting (8' × 8’), the viewer gets a sense of the rage that is suggested by the victim’s work. This painting appears to be the combination of the victim’s anger and depression resulting from the attack. The large size of the painting might reflect the overwhelming feelings the victim experiences through these emotions.

Figure 5 was done on top of a fiberglass screen. The victim chose this material because the transparent quality allows for reflections of the past to be seen. In this painting, the many layers of paint previously used have been lifted indicating the artist’s feelings about regrowth. The possibility for light to show through the screen may be a sign of a lifting depression. The colors used are yellows, oranges, and greens again suggesting a lifting of the victim’s depression. Flowers recur again as a possible metaphor.

As Spring (1985) suggested, Figure 6 shows how prevalent the eye forms were in the artwork of this rape victim. According to Spring’s research, the eye forms may have been used by this victim to symbolize guilt, being watched, and vigilance. The sharpness of the shapes in this painting seems to suggest the victim’s harsh feelings about the attack, feelings that remain even after beginning to work through them. She chose to use red, blue, yellow, white, and black. The colors also contribute to the contrasting feeling of the painting.
The wedge shapes used were also noted by Spring (1985) to indicate a need to protect the vagina or a connection between penetration and threat.

Conclusion

There are many ways that rape victims can be helped via verbal techniques suggested by Quina and Carlson (1989). The techniques mentioned in this paper were those that are used by art therapists, including McNiff, Howard, Spring, and Horowitz. The power of art therapy in the recovery process of a rape victim has been illustrated in this paper with a discussion of recurring symbols used by victims of rape and sexual abuse in general. These symbols seem to provide these women with a voice when they have otherwise lost their ability to verbalize their emotions.

The permanence, symbolism, and sense of control that is provided through art is of great value to the rape victim. Art seems to provide a nontwoing modal entity and a safe space for the rape victim to express the emotions that otherwise might remain unexpressed.

The Tongue as a Graphic Symbol of Sexual Abuse

Cay Drachnik, MFCC, A.T.R., HLM, Sacramento, CA

Abstract

Art therapists and other professionals have explored and identified many graphic symbols in children’s drawings indicative of sexual abuse (Cohen & Phelps, 1985; Howard & Jacob, 1989; Sidun & Rosenthal, 1987). Yet many art therapists and other professionals who work with children have identified graphic symbols which they believe are indicative of sexual abuse, but have not been verified in thorough research. One such symbol which has not been substantiated by research is the protruding tongue. This paper traces the history of this symbol from ancient times to the present in an attempt to explain the tongue’s appearance in the drawings of children who have been sexually abused. Also included is an informal study by the author of the tongue symbol in the art expressions of children who have experienced sexual molestation.

Introduction

In reviewing the literature on symbols of sexual abuse noted in the art expressions of children since 1970, no mention was found of a protruding tongue as a possible indicator of molestation. Yet in my work with children in an outpatient setting, I have clinically observed the appearance of the tongue repeatedly in the drawings of sexually abused children.

In a study of sexually molested children, Chase (1985) suggested that an emphasis on the mouth in a human figure drawing might indicate sexual abuse, but the tongue itself was not mentioned. Additionally, Howard and Jacob (1969) present 11 illustrations of art expressions by sexually abused children and in two of the drawings tongues are prominent (Figures 1 and 2); however, there is no mention of these tongues within the text. Lastly, Uhlin (1972a) makes reference to a drawing by a sexually abused boy, observing “. . . notice the exhibiting of the phallic tongue . . .” (p. 112). Because Uhlin (1972b) had observed the tongue as a “phallic symbol” in addition to my clinical observations of a tongue in a number of drawings by sexually abused children, I became interested in researching anthropological and art historical information that might support the idea of the tongue as a symbol of sexual abuse.

A Brief History of the Tongue Symbol

The tongue as a graphic symbol, as other symbols, has more than one connotation which can be positive or negative or both. It can also have several meanings simultaneously.
Salmony (1954), in his book *Antler and Tongue*, observes that the tongue has been seen in statues, masks, and paintings of many cultures throughout history.

There are numerous examples of the tongue in art from ancient times until the present. One of the earliest recorded appearances of the tongue in art was in Egypt where the god Bes was often portrayed with a protruding tongue. His many roles included that of protector against evil spirits. This same god was later found in Asiatic and Greek civilizations.

Another example of the tongue symbol appeared in southern China about 400-200 B.C. on wooden busts (Figure 3). These busts also contained stag horns, which came out of the top of the head. The tongue was extremely elongated, reaching almost to the base of the stand. Also, K'uei, a Chinese deity in the Han Period, had the characteristic of a very long tongue.

In Greek art, the protruding tongue appears to have had both a divine attribute and a fearful element. This is evident in the face of Medusa, the female demon slain by Perseus. Medusa’s face (Figure 4), with its hair of snakes and protruding tongue, turned men who looked at her to stone (until Perseus looked into his mirror-like shield and cut off her head). Walker (1988) noted that Medusa appeared in antiquity as a warning to men to keep away. Campbell (1959), discussing American Northwest totem poles, observed that the faces on the poles with their protruding tongues were similar to the Greek Medusa.

A few examples of symbolic tongues attached to animal profiles were found later in the Etruscan civilization and in Yugoslavia about the fifth century B.C. Buddhist texts also made frequent use of tongue symbols in connection with animals. For example, in Cambodia the Garuda, a bird-like figure, is shown with a pendant coming out of its mouth (Salmony, 1954). This same creature is used in southern Asian countries on the corners of homes to drive away evil spirits.

Kushan Mathura art dating from the second and third centuries A.D. depicts female demons with long undulating tongues, shown ready and eager to devour their mates. Bangda, a Balinese witch who stole children, is shown with a protruding tongue (Figure 5). Neuman (1963) also notes that Kali, an Indian goddess with her elongated tongue and bloody breasts, is shown dancing on the prostrate Shiva (Figure 6). Kali is described by Jobes (1961) as a blood thirsty avenger; she is also known as the supreme mother goddess, having a dual role of both benefactress and ogress.

Although the protruding tongue appears to have many sexual connotations, it has other meanings as well. For example, in Mexico the protruding tongue was often a symbol of wisdom (Bayley, 1951). In some parts of India, it is sometimes a symbol of great respect, and in Tibet it is still used as a favorable salutation (Walker, 1988). The Maori of New Zealand stick out their tongues to impress the spirits. However, in our Western culture the protruding tongue may be a symbol of insult (Figure 7).

Later, in medieval Europe, tongues appeared on carved heads on cathedrals in Norway, Germany, France, England, and other countries. Walker (1983) observes that "this was distinctly related to the exposure of sexual organs" (p. 1003). Exposing the genitals was thought to keep evil forces at bay. Also, in medieval times, creatures with protruding tongues indicated that the cathedral was dedicated to a pantheon of both pagan and Christian deities. By Renaissance times, however, the older deities with their protruding tongues were declared to be devils. For example, in 975 A.D., a Spanish manuscript illustrated one of the earliest images of this devil, depicting him as a naked man with an ox head and a long tongue (Figure 8). From that time on, images of Satan appeared frequently with elongated tongues.

Walker (1983) noted that at this time in history, "Pictures of lusty devils showed long phallic tongues, and sticking out
the tongue at someone became a favorite gesture of insult..." (p. 1003). She added that "it was because of the tongue's sexual connotation that medieval devils were usually depicted with protruding tongues" (1988, p. 327).

Lastly, noted scholar Desmond Morris in his book Body Watching (1985) reported that the tongue is "...an echo of the male penis" (p. 103). He observes that an invitation from a prostitute is often a protrusion of the tongue between open lips, and that South American males may invite sexual encounter with the "slow wagging of the tongue from side to side within the half opened lips" (Ibid., p. 103).

Clinical Observations

Because of the number of tongues I had seen in the drawings of sexually abused children and the numerous references to the tongue as a symbol connected with sexuality throughout art history and anthropology, I decided to review my collection of drawings that I had accumulated over the past 15 years. I examined the drawings of 263 children between the ages of 2½ and 18 years who had been seen for three or more sessions of therapy. Fifty-seven of these children had been identified as having been sexually abused. Another 12 children were identified as suspected victims of sexual abuse. Fourteen of the children identified as sexually abused were under the age of four; therefore, their drawings were mostly scribbles and had to be eliminated from this informal study.

Of the remaining 43 previously identified as sexually abused, the drawings of 14 children displayed one or more tongues (Figures 9 and 10 are two examples), which is only a little less than 25% of the sample. Of the 12 children who were suspected of sexual abuse, only three displayed tongues. However, of the other 194 clients (not known to be sexually abused) seen over this 15-year period, only two drawings displayed a protruding tongue.

Additionally, the appearance of a tongue has been informally noted by students under my clinical supervision in the drawings of sexually abused children. Although their observations are also clinically rather than empirically based, these observations do support the idea that the tongue symbol may in some way be related to the occurrence of sexual abuse in children.

Conclusion

Many art therapists are expected to make assessments of children's drawings, particularly in the area of sexual abuse; for this reason, it seems that there is a great need for more research in the area of sexual abuse symbols in general. Empirical research on the tongue symbol could prove helpful, since clinical observations seem to indicate that this symbol may be related to sexual abuse. Also, additional research on the meaning of the tongue symbol from anthropological and art historical perspectives could amplify why children who have been abused may include it in their drawings.

If the tongue is a graphic symbol of sexual abuse in children's drawings, what is its purpose? Could children be using this symbol to work through the sexual abuse? Could they be unconsciously communicating the abuse to the therapist? Or could they be using the symbol as a protective device (as some cultures relate the tongue to protection or a way to ward off danger) to prevent further sexual abuse? These are interesting questions that might be explored by art therapists who continue research in this area and with this particular symbol.

Lastly, due to the nature of this informal study, therapists are cautioned in their interpretation of this graphic sym-
bol in children’s drawings. It is obvious from this small sample that not every drawing by sexually abused children contains the tongue symbol. However, there is enough evidence that the appearance of the protruding tongue in a child’s drawing may be a possible clue worthy of further investigation.

Looking In—Looking Out: An Artist's Journey Through Childhood Sexual Abuse

Jane Orieeman, Artist, Ellensburg, WA

I have been a painter for 25 of my 52 years. In the mid-1980s, I began to paint less and less. By 1989, my production diminished from an average of 20 paintings a year to only one. It was as though all of my vital energy and interest in life was draining from me. I filled the void with endless games of solitaire and science fiction.

My mother died in 1989; this seemed to release me from my stupor. I began working with a clinical psychologist in March of 1990, with the hope of overcoming my creative block. As we discussed my early life, I came to realize that it still held a powerful grip on me. I found it very hard to talk about it out loud. I whispered a lot.

I started to do one or two paintings a month. These images were inspired by subjects discussed in therapy sessions. In November, I started a series of small paintings from the point of view of myself as a child. These child-view images have allowed me to say in paint what I have found so hard to say in words. I am now doing six to eight paintings a month. About one-third of these are in the child-view. The rest reflect my feelings, as an adult, about the past abuse and about the process of therapy.

All these paintings are oils on canvas. The earlier ones are painted with small brushes. In June 1991, in response to a dream, I started using a palette knife. In August, at my therapist’s suggestion, I began painting with a butcher’s knife, an expressive and invigorating tool. Recently, I have been using two-inch wide brushes which afford me a flowing sense of freedom.

My earliest memories are of being molested. Between the ages of 3 and 8, this happened often. From 9 to 12 years, I was subject to almost daily physical or sexual assault. Rarely did a day go by when my father did not beat one of us children or my mom. I had assumed the attitude that this had all happened in a long, dead past. Painting these images has helped me to accept the memories. They continue to have a strong impact on how I feel about myself. I am grateful that I have been supported during this process by love and encouragement from my husband and two of my brothers.

I consider my paintings a dialogue with myself and approach the canvas with thoughts brought up in therapy. The painting is my deeper self telling me what I feel, think, or sometimes, remember. Very often these are feelings and thoughts of which I am not consciously aware. The comments accompanying the paintings are my attempt to understand the images on a conscious level. Often I have included dreams which seem to connect with the paintings.

The 16 images in this portfolio are from an ongoing series of over 200 paintings. My first step in the creative process always is to decide on the size of the canvas. Sometimes it is necessary to put a half dozen canvases on the easel before I sense that I have the right one. The small child-view paintings usually deal with events; the larger ones are expressive of feelings. For this article I have paired event images with expressions of feelings relating to those events.

Figure 1A. “I Was 11 When My Brother Brought His Friends Home.” 14” x 18”

This happened. The boys were 15 to 17 years old. I remember some of their names. This image shows my soul withdrawn to the corner of the room while another part of me turns into pure rage.

The night after I started the painting, I had this dream:

I was being attacked by huge worms, and I was stabbing them with a hunting knife. It was an overhead stab—using all of my force. I felt that I hadn’t really hurt them much because they were too stupid to feel it.

Figure 1B. “Guill” 28” x 22”

This week my therapist suggested a revolutionary idea to me—to paint from my own life experience. He said, “What else do you have if not that?” The idea of painting my life was repellant and frightening to me.

However, all of the other wells were dry, so I decided to try it. We had talked about my feelings of guilt associated with being a victim and this became the first image in a narrative of my early life. The secrets that I have kept until now have bound and contained me like this bottle of poison. The skull and crossesbones marks the spot where all of the painful emotions have been stored. I think it may be common to feel that one would never have been beaten or raped unless it was deserved.

Figure 2A. “Memories of Mother.” 12” x 24”

When I was 35, my parents moved to the town which had become my home. Until then I had kept 3,000 miles be-
between us. As a child I had begged mother to stay. As an adult I begged her to leave. I don’t know which was more painful. It took 5 years to get my parents to move away.

Figure 2B. "Banished" 36" × 30"

This image is symbolic of an event that occurred at the end of this week’s therapy session. Since I had just shown these revealing paintings for the first time, I was feeling very exposed. All of my feelings of rejection came to the surface and overwhelmed me. Anger was also a big part of this experience. I seldom become angry, and it was frightening to me as I felt possessed by the anger.

One of my responses was to go to the library and read three books about therapy so as to understand what was happening. Reading about transference made me realize that this "way out of proportion" reaction was in some way useful to the growth process. It didn’t make me feel any better, but the knowledge did allow me to return the next week. It took six months to work through these intense feelings.

I had this dream the night after the therapy session. The man with the knife was Dr. W.

I was in an underground labyrinth. There was ice everywhere including underfoot. I was surrounded by thin ice. I could tell where the ice was thicker because it was more white than the thin ice. There were some pathways that had the thicker ice, and I was running along them as fast as I could. There was a man with a knife chasing me. He kept hollering at me to stop, and he would guide me to safety. I knew I was surrounded by 25,000 miles of thin ice, but he seemed the larger threat. I kept running.
Figure 3A. "Go Make Your Daddy Happy." 11" x 14"

Those were the words Mom said when she sent me into the lion's den. When I began this painting, I was thinking of doing an image relating to my mother. I always wanted her love and protection, but what I felt from her was not only neglect, but also betrayal. No one could make Daddy happy, but I was the one assigned to the job.

Figure 3B. "Unacknowledged Feelings" 50" x 54"

At this time I was experiencing a feeling of a heavy nameless weight pressing in on me. I couldn't identify what was getting me down so I decided to paint the feeling itself. In doing that I realized I couldn't identify feelings I refused to acknowledge.

The night before I painted this image I had the following dream. I think it is the dirt, bugs, and mice in the house of my soul which I have refused to acknowledge.

I found that my house had large holes in the inner walls and floors, leaving it open to the dirt and bugs and mice which are found in basements. Even on the second story this was true. The house needs a lot of work.

Figure 4A. "Monsters in the Night" 16" x 20"

I find this image very disturbing. I think that in relationship to this memory I am still hiding on top of the closet. It is reasonable that I would rather think a monster had gotten me in the night rather than my own father.

The following dream puts this image into words.

I was a young girl. I went into my bedroom to take a nap. My father was there. After I fell asleep a dog started licking my vulva. I couldn't wake up but I was sure it was a dog and was afraid it would bite me and eat me. It felt physically exciting—mentally repulsive and very frightening. After a while Dick [my husband] came in the room. I was afraid he would be repulsed by what he saw. (I knew he was there even though I couldn't wake up.) But he just lay down beside me and put his arm around my shoulders. As he held me the dog melted away.

Figure 4B. "The Bones Remember What the Mind Forgets." 52" x 58"

Shortly before I started this painting I had experienced a devastating memory involving my father. It released intense feelings which I spent the next two months trying to put a lid on. I was unable to return to the unknowing state although, to be honest, a large part of me still wants to forget. I feel like my bones have been picked clean of all pretense, and I am left with the naked truth. It is ironic that the bones have more vitality than the fully fleshed figure.

Figure 5A. "Learning to Fly" 10" x 14"

My therapist had made a remark which caused me to question myself, my process of painting, and, then, my trust in him. If he could be so wrong about something I felt was important, could I really trust him? My way of discovering how I felt about him was to trust my process first—which means that I stood before the easel and asked my inner self how she felt about Dr. W. Does she trust him?

In this image I perceive that he sees where I am now and where he would like to see me someday. This means that he is not just sitting there recording. He has a vision. I do trust him.
Figure 48.

Figure 5A. "Metamorphosis" 42" x 36"

After seeing Dr. W's winged vision in "Learning to Fly," I realized that I am not tied up in that image. I am in a cocoon. My struggles will eventually lead to a 'Metamorphosis.'

The night after painting this I dreamed about using the past to build a future.

A man was asking a fraternal organization to give him a book. It was the only one on their bookshelf. I was trying to convince them not to give away their heritage. I told the man he should borrow it, read it, and bring it back to be the first one in the library. I said he would be just the man to build the library.

Biographical Note: Jane Orleman was born in Oneonta, New York, in 1942. In 1971, she married Dick Elliott, also an artist; they reside in Ellensburg, Washington. From their studio, Dick and Jane's Spot, Ms. Orleman has produced these paintings and many others. A recognized artist, she has received grants from Art Matters, Inc., New York (1989 and 1992), and the Artist Trust GAP, Seattle (1989). Her numerous one-woman exhibits in the Pacific Northwest include, most recently, "Telling Secrets" at the Whitman College Gallery in Walla Walla, Washington, and "An Artist's Journey: Looking In & Out," at the Northlight Gallery, Everett, Washington. During the past three years she has exhibited in Seattle and Ellensburg, and this year she was invited to exhibit at the Larson Museum in Yakima, Washington. Her work has been seen in juried exhibits in Los Angeles, Wisconsin, Oregon, Chicago, and New Mexico, and she has been the recipient of many awards. Her artwork has received very positive reviews in many Northwest newspapers. In addition to her exhibits, she is an articulate spokesperson. This year she was invited to lecture to offenders in Walla Walla, Washington and for the Women's Caucus for Art, National Conference in Seattle. She has presented to the American Association of Sex Educators and many other professionals who work with victims of incest and abuse. Her numerous publications, such as in Treating Abuse Today, focus on issues of sexual abuse.

Her exhibit, "Telling Secrets: An Artist's Journey Through Childhood Sexual Abuse," will be available through the National Exhibit Touring Services. Call 1-800-356-1256 for information.
Shattered Images:
Phenomenological Language of Sexual Trauma

Reviewed by Susan Cristantiello, MCAT, A.T.R., Mt. Vernon, NY

In language both metaphorical and didactic, Dee Spring makes vivid a difficult subject while providing information of indispensable value to clinicians working with victims of sexual abuse. Her work contains three main areas of expertise: first, the phenomenological rationale for the symbolic language of victims; second, the mechanisms of victimization (such as the crisis-violence cycle and mastery issues); and third, a generous section on treatment stages of restoration and special therapeutic methods and strategies. The only addition I would have liked would have been the inclusion of an index to help locate the multiple references to original terms and procedures.

Shattered Images is unique in that it focuses on the common aspects of sexual trauma. According to Spring, the effects of such trauma are the same whether it is perpetrated through incest, rape, or ritualized abuse. The effects are also lifelong—only the degree of trauma varies. It is this common experience shared by all victims, and the lack of permission to speak of it, which creates a common symbolic language—the phenomenological language of sexual trauma.

This is a crucially important synthesis since clinicians working with victims frequently find a combination of forms of abuse in a single case and must often address a combination of relationships between victims and abusers. This overlapping of forms of abuse leads Spring to define sexual trauma as the “category of experience” (p. 32). Each traumatic experience is reproduced in the “form of symbolic images which are coded messages” (p. 31).

As a result of her research, Spring concludes that the artwork of women who were sexually abused, regardless of form, showed a significant depiction of highly stylized eyes along with wedge-type configurations. These were among the most consistent coded messages found in victims’ art. She contends that the eye symbols seem to be related to the victims’ feelings of guilt, hypervigilance, and dissociation, while the wedge symbols seem to be related to fear and pain. She devotes a chapter to these phenomena and includes many helpful examples of artwork and an especially useful glossary of terms.

Too often sexual trauma remains unidentified, kept secret through the original fear of threat and society’s attitude of blame and rejection. Victims internalize these messages and lose touch with their own histories of abuse. Consequently, victims seek treatment for a variety of spurious reasons, and receive a variety of misdiagnoses, while the real problem remains hidden, intact, and toxic. Spring’s work provides an opportunity for any perceptive clinician to recognize the hidden message of trauma in victims’ artwork and to appreciate the implications for specialized treatment.

A majority of the book is devoted to a thorough discussion of her treatment model. Her “orientation is gestalt, flavored with a transpersonal overview. The course of therapy is psychodynamic carried out in a cognitive manner through art, hypnosis, imagery, metaphor, and analogy. Techniques of reality therapy, bibliotherapy, and journalizing carry weight in this model” (p. 185). This intricate blend of the verbal with the nonverbal utilizes the creativity of both the therapist and the client and is worked on individually and in groups, including couples work and sex therapy where appropriate. Her complex, variegated approach takes place over a two-year period and addresses the whole person.

Interestingly, Spring’s approach to writing and treatment is similar. The treatment plan, she warns, must be clear and systematic and shared with victims since they need to regain control and have cognitive awareness of what is to come. Intuitively, Spring seems to sense that the reader also requires glimpses of what is to come. When you are reading about the horrors of sexual trauma, it is reassuring to know that the author will shortly be discussing clinically tested methods of treating it. She takes us gently but firmly through layers of information, weaving a blend of theory, metaphor, poetry, technique, and visual and case material to create a work of great breadth, creativity, and relevance.

She also has ideas about the qualities and attitudes needed in therapists working with victims. Her insights are a valuable guide to those considering this type of work and an important review for those already engaged in it. She provides art therapies with an astoundingly organized and plentiful number of creative activities designed for individual, group, and couples work and closely relates them to specific treatment issues. The 65-page appendix contains assessment and worksheets, directions for use, and task checklists. Although the book contains basic information on art therapy and the benefits of creativity in healing, art therapists likely will not find this boring. It is precisely her blend of the old with the new that makes the material so digestible and which validates one’s own professional struggles in this challenging work. Clinicians in other disciplines who work with victims will find familiar information too, but presented in a new way. They will have the opportunity to gain new insights and rethink the old, equipped with a visual language of sexual trauma and the most detailed, multifaceted translation of victims’ experience to date.
Casualties of Childhood is a welcome addition to the increasing literature on this subject. It offers a developmental perspective of the projective drawings (House-Tree-Person, and Kinetic Family Drawing) of latency age children and of adults who were abused during latency. Latency is defined as

... the period during which youngsters are normatively venturing out into the world, taking what they have learned about relating to others and generalizing this to the environment at large... for child-victims of incest this becomes an arduous task. (p. 100)

The purpose of this book is to discuss why "generalizing to the environment at large" becomes an arduous task and how this is seen in the artwork.

Using widely-known projective drawing research (e.g., Buck, DiLeo, Hammer, Jolles, Machover, and others), and their own clinical findings, Kaufman and Wohl discuss 96 drawings by children and 56 drawings by adults in terms of symbolic language of the sexually abused. The book is filled with valuable, well-documented inter- and intrapsychic effects of sexual abuse on the latency age child. In the Introduction trauma is defined based on analytic and self-psychology literature, with the focus on sexual abuse. Chapter 1, "Paradigms of Trauma and Sexual Abuse," differentiates between child sexual abuse and Post Traumatic Stress Disorder. A review of the literature on child sexual abuse and a description of symptom formation are clearly written. Chapter 2, "General Principles in the Analysis of Projective Drawings," is a comprehensive synopsis of the history, reliability, and validity of projective drawings. It includes the developmental aspects of drawings skills and general principles used in the analysis of drawings. Each projective test used is described in detail. This chapter also contains the authors' pilot study using projective drawings with 54 children. Chapter 3 discusses "The Projections of Ego Functions of Sexually Abused Children," focusing on alterations in ego functions, mastering of affects, sublimation of drives, utilization of play and fantasy, identification with the aggressor, altruistic surrender, inhibition of self-caring functions, cognitive dysfunctions, and case vignettes. Chapter 4, "Aberrations in the Superego of Sexually Molested Youngsters," discusses guilt, identification with delinquent values, absence of anticipatory guilt, faulty identifications, guilt displacement, rigid superego functioning, and case studies. In Chapter 5, we encounter "The Incestuous Family's Influence on the Development of Object Relations During Latency." We read about the child within the family system, specifically, the relationships to the abusive parent, the silent parent, development of object relations, the child's relationships outside the family, and case vignettes. Last, the artwork of adults is discussed in Chapter 6: "Adult Survivors: the Long-Term Effects of Childhood Sexual Abuse."

Case studies support the points discussed at the beginning of each chapter. Drawings and histories of the children and adults are clearly presented and cover a wide spectrum of types of abuse and drawing styles.

As an adjunct faculty member and clinician, I find this book a valuable and welcome addition to the field. It comprehensively, clearly, and concisely brings together the work of many distinguished authors/clinicians. I have recommended it to graduate students and colleagues.

Only two related concerns come to mind. It appears that the case examples and artworks were done by children and
adults who disclosed sexual abuse before the projective tasks were undertaken, and therefore, many of the indicators in the artwork seem obvious. My clinical experience, however, is that often, particularly with latency age children, no disclosure is made, yet many of the indices of sexual abuse are present in the artwork. This places the art therapist in a highly sensitive position.

In a paragraph near the beginning of the book the authors warn clinicians of possible misuse of the symbols seen in the artwork:

We must emphasize, however, that there is danger in using projective drawing without serious consideration of the artist's age, developmental stage, cognitive strengths, liabilities, and possible neurological impairments. Moreover, while we will shortly review the general areas used in understanding the assertion a drawing makes, we again caution the reader that a drawing or painting must always be assessed within the context of the client's history, behavior, and other evaluative data. (p. 17)

This reviewer feels that more emphasis should be placed on this point, especially for students/interns and non-art therapists. It is indeed within the treatment relationship with a client that assessments of this nature need to be made. The danger is that clinicians, particularly novices, could use this text as a "cookbook" for sexual abuse identification. This would be an unfortunate misuse of a very well-written book.

In recommending this book, I see its strength in the enlightenment of clinicians to symbols in the artwork and psychodynamics of sexually abused clients. Kaufman and Wohl have done this extremely well.

Video Review

The Box: A Guide to an Interactive Film Project for Use with the Arts Therapies

1/2" VHS, 30 minutes, color. Purchase: $300, from Manna Films, 309 5th Avenue, Box 497, Brooklyn, NY 11215.

A former supervisor who had an extremely dry sense of humor once stated, "I'm going to teach you a new form of art therapy. The therapist does the drawing and the clients watch." The organizing concept behind this film is along similar lines; its primary goal is to elicit a reaction and stimulate discussion.

After seeing this avant-garde video, my reaction was exactly that. I attempted to make sense of what I had seen, and felt the urge to contact colleagues to ascertain their impressions from symbolic, clinical, and practical perspectives. Their reactions will be presented following a discussion of the content of the film and accompanying the 97-page user's manual.

It is ambiguous who this video serves and what qualifications are necessary for group facilitators. The manual suggests using it with populations such as college students training in helping professions, corporate sensitivity training programs, developmentally delayed adults, inner city teens, victims of abuse, homeless people, the withdrawn and depressed, substance abusers, the medically ailing, and artists. Some abstract reasoning ability is necessary, but the suggested age range begins at 5 years. The intent is that through reaction and discussion people will be helped "...to realize their potentials and to develop self-confidence..." gain insight in the realm of communications, understanding, healing, and spiritual enrichment (pp. 3, 8).

The video is designed to be used in therapy. Unlike television, the film does not allow viewers to be passive. In the manual Michael Kennedy writes:

People are certainly affected by this one-sided presentation. The biggest fault of television is that it presents an overload of information and image serving only to congest the mind. . . . Through this constant conditioning to absorb, few individuals get an opportunity to participate or react to what they see. (pp. 3, 4)

The use of this narrative film without dialogue is an attempt to fill this gap.

The film opens with the central figure, a female character, inside a box, the central symbol. We see them throughout the four segments of the film: winter, spring, summer, and autumn. At the beginning of each segment, the box, usually containing the female character, is placed in four environments. Without the benefit of the usual introduction of characters and formation of plot and dialogue we watch the female character struggle with her ambivalence about leaving the box and exploring her environment. We are forced to develop our own impressions or project our own issues onto this individual and her situation. This metaphorically state provides a context for discussion and/or activities that follow the viewing. The viewer must attempt to integrate what is observed with his or her own current or past areas of difficulty.

Winter begins at evening in an alley. The girl inside the box finds herself among boxes and garbage. She explores a variety of objects around her and collects things she seems to like, bringing them into her box. The scene dissolves and we next see her walking through a spring forest. Her clothes are torn. She explores the environment, coming upon a rabbit and a small box. Placing some objects inside the box, she clutches it to her heart and leaves through a sunny opening in the trees.

On a sunny day in summer, she crosses a field and comes upon a fence and a child playing by a table spread with food. This is her only interaction with other individuals. She crawls through the fence and hungrily grabs some food, but is frightened away by an angry man. She encounters another group, where a smiling man begins to pay attention to her. But the angry man approaches and she runs back to her box. She appears to think about the events and returns to the smiling man who introduces her to the group, offering her food and drink. They embrace and go their separate ways.

In autumn, she is inside the box with the lid secure, totally withdrawn from the outside world. She dips a hole in the box, looks outside, and moves the box. It rolls downhill and the lid pops open. Beautiful leaves are outside and she brings them in only to discover they lose color inside the box. She
becomes angry, appearing to throw a tantrum. Eventually she
abandons the box, gathers leaves in her skirt, returns to the
box, touches it, and then kicks it away. At the end she smiles,
picks up leaves, and looks at them in the bright sunlight.

The user's manual is extremely comprehensive. It gives a
synopsis of each season, provides lists of feeling words that
may be evoked during group discussion, offers clues to the
symbolism, provides topics to discuss, questions that can be
asked by the group facilitator, projects to use with discussion,
and includes a section for "advanced questions and projects."

The manual clearly states how the film is used is
determined by the group facilitator. It cautions against not
doing your homework prior to presenting the video. It en-
courages the group facilitator to be an "enthusiastic" leader
and strongly recommends the audience view one season at a
time before proceeding with appropriate projects and discus-
sion. The manual is an excellent resource for the novice group
leader, containing many ideas for drawing, journal-making,
poetry, psychodrama, and suggested group activities that may
be directly or indirectly related to the film (e.g., the trust
walk). A paper titled "The Box: An Interpretive Journey" de-
scribes in more clinical terms concepts that support the film
as a therapeutic tool.

After viewing this film, I contacted colleagues and asked
them to watch it and discuss their impressions. Because the
user's manual refers to "archetypes" contained in the film,
one of my contacts was Timothy Sanderson, MD, a Jungian
anayst (personal communication, June 9, 1993). The film, he
felt, was "too contrived"; he was caught with the feeling that
he was "supposed to respond rather than just responding or
reacting." The same kind of symbolic material can be used,
he felt, in a less manipulative way, as in simply presenting a
story. Using the story and its metaphoric material, one could
explore issues and raise insight through discussion. He won-
dered, however, if his impressions were biased, given that
most of the special populations who would be viewing this
video may be less psychologically sophisticated. Perhaps they
could reap the intended benefits of this modality.

Another colleague, Jane Bushman, MS, A.T.R., director of
expressive therapies for an inpatient psychiatric unit, also
viewed the film. She reported.

The Box was presented to an inpatient psychiatric adult group
on May 26, 1993. The group consisted of nine patients (two
men, seven women), with various diagnoses, including depres-
sion (some with suicidal ideation), chemical dependency, bi-
polar, and schizophrenia. Ages ranged from 19 to 56 years. The
idea of "the box" was perceived by the group as the primary
theme, representing protection and entrapment. One client re-
ferred to the box as a "shell," a metaphor for "being trapped in
his depression," and that "internal fears are a negative force that
keep (him) boxed in." Another client suggested that audience
members should hold a box while watching the film in order to
enhance the experience.

The seasons were perceived generally to represent their
own cycles of change and growth. Winter imagery evoked a
sense that even in times of despair ("bleakness"), one could
create—that there was hope. Spring generated the feeling that
one could find beauty in simple things, that life needed to
be basic for them. The summer imagery evoked little dis-
cussion to the actual seasonal symbolism. It did, however,
genender a significant reaction to the two male characters, i.e.,
"good father/bad father." The group members generally per-
ceived the autumnal sequence as a metaphor for being able to
break out of their shells and learn (gather) new ways of deal-
ing with issues.

One group member saw the rips in the actress's shirt as
representing "past wounds." The inconsistency between the
actress' ragged appearance and her relatively well-groomed
hands, adorned with watch and ring, seemed to be a source of
disbelief or distraction for several patients. They appreciated
the lack of verbal interactions in the film, sharing that the
nonverbal expression allowed them to interject their own
issues and also forced them to make connections in their own
lives.

The technical quality of the film created negative impres-
sions. Sound effects were exaggerated and distracting and at
times comical. The acting seemed amateurish and awkward
and failed to transport the audience beyond the limits of the
medium itself.

Overall, the patients viewed the film as a positive medium in
their treatment. They perceived it as being vague enough, sym-

bolic enough, that it afforded them the opportunity to interject
their own specific issues and to identify with someone else (the
actress). One woman shared that the film "reinforced the impor-
tance of imagery in the process of healing."

Conclusions

In general I found the quality of the film production to
be very good and the packaging very professional. Although
the user's manual is impressively comprehensive, I had some
concerns. Glaringly missing is how a group facilitator can
frame an introduction to this film. How the film is pre-
sented can have a lasting impact on how it is perceived. A common
reaction was, "I don't get it . . . I feel stupid," and "If there's
something that I'm supposed to get, I don't get it." The ab-
stract quality can be confusing and intimidating, just as art
materials can have a negative and intimidating impact on
adults who have not drawn since their elementary school
years. This film could benefit from an introduction that pro-
vides a disclaimer, such as "everyone has different reactions
to this film and there are no right or wrong impressions. As
you view it, pick one or two impressions that make sense to
you and we'll discuss them following the film." This may re-
lieve viewers' anxieties and encourage them to consider a spe-
cific impression rather than attempt to understand the entire
segment or series. Each segment is rich with symbolism and
behaviors that do, in fact, provide that metaphorical slate ne-
necessary for projection.

I commend the writer and producers in their endeavor.
The project is creative and original and challenges the one-
sided passivity of television watching. Like drugs, one can
take in television, sit passively, and allow it to alter thoughts
and feelings. The film purposely frustrates viewers; they can-
not remain passive. The lack of dialogue and plot forces their
active involvement in making sense of each scene. I am cer-
tain I could conduct an insightful discussion with a group of
adults after showing them Dr. Seuss' Horton Hears A Who
(1970). But in contrast to The Box, does the completeness of
Horton . . . put the viewer too much at ease? Does the in-
completeness and abstract quality of The Box succeed in en-
couraging viewers to become active, to get up from their re-
cliners (or boxes), and find sense in this film? Rather than
stating my opinion, I purposely leave my conclusions ambiguous so you may more easily "project" your own.

Archetypal Images and Art

Written by Dean L. Frantz, BA, MDiv, Produced by The Division of Psychology and Special Education, The Teachers College, Emporia State University, KS, 1988.

VHS ½", 40 minutes: 33 seconds, color. Purchase: $43, from ART, P.O. Box 15712, Ft. Wayne, IN 46885-5712.

Reviewed by Matthew Bernier, MCAT, A.T.R., Norfolk, VA

Jungian analyst Dean Frantz delivers scholarly lectures on the relationship between archetypal images and art. He discusses these within the context of Carl Jung’s concept of archetypes, the unconscious, and Peter Birkhauser, a Swiss modern artist “whose paintings are a prime example of the way in which art can reflect the archetypal background of the psyche.” Observers report that Birkhauser’s paintings have a healing power, a “medicine for the soul.”

Frantz reviews Jungian concepts such as archetypes of transformation, transcendence, numinous experiences, and the individuation process. Archetypes are archaic remnants or primordial images. They are “mental forms whose presence cannot be explained by anything in the individual’s own life which seem to be aboriginal, innate, and inherited shapes of the human mind” (Jung, 1964, p. 67). Frantz states, “Anything rooted in the archetypes may have healing power.” He explains transformation as a “growing awareness of inner archetypal background” which “brings a growing enrichment and completion of the personality.” He defines numinous experiences as “events or experiences which can be felt but not described in words.” Jung believed that real therapy involved approaching and exploring the numinous as in dreams and art, and noted that art frequently anticipates psychological changes before they come to the surface of collective consciousness.

Frantz explains there are two kinds of art. The first serves to entertain, please, or portray realism. The second “springs from within the unconscious” of the creator who is the “translator of eternal” and an “instrument of realizing purpose.” The artist creates not only about himself but expresses collective statements or messages on behalf of everyone. As a result the artist is often misunderstood, thought of as mad, and ridiculed. Frantz states, “If the artist is able to endure the suffering which is his inevitable lot, he too may be a means of bringing healing and renewal to his society.” He explains that archetypal art leads us to transcendence by “opening gates to a world not limited by time and space,” putting “us in touch with our own depths,” providing “new depths of meaning,” and enriching “our experience of being alive.”

The archetypal nature of Birkhauser’s paintings allows them to serve not only as an expression of our collective inner stories as they “translate unconscious images in the language of the present.” They “portray dimensions of life beyond the here and now” and they are “in touch with the infinite.” Frantz explains that some observers of archetypal paintings cannot tolerate seeing them, while “others are fixed on them,” “caught in an archetypal theme.” Observers of Birkhauser’s paintings have said.

It’s “as if I had been here before . . . as if I had always known these paintings.”

“There is a mutual message here. I want to run away, but I cannot. I am compelled to confront what these paintings are saying to me.”

“These paintings gave me a new insight into life.”

According to Frantz, “The artist’s job is to create art” but he or she is “not expected to interpret it.” “The interpretation is left to us who observe it. We must let a work of art work on us to shape us.” The art “reminds us of parts of our lives neglected or forgotten.” Art is a “path toward wholeness.”

The text is scholarly and interesting while the images are compelling. Unfortunately, the style of the video is boring and distracting. Frantz stands at a podium and lectures before a single camera. Throughout the video the picture switches to static images of Birkhauser’s paintings, which are intriguing and require attention and contemplation, but are often unrelated to the text. Frantz speaks slowly and clearly, but the language of the text is lofty and poetic, forcing us to listen carefully. This makes it difficult to attend to both the text and the images. Nevertheless, the content of this video, which should be made available in written form, is important and worthwhile.

The Life and Art of Peter Birkhauser

Written by Dean L. Frantz, BA, MDiv, Produced by The Division of Psychology and Special Education, The Teachers College, Emporia State University, KS, 1988.

VHS, 30 minutes: 54 seconds, color. Purchase: $43, from ART, P.O. Box 15712, Ft. Wayne, IN 46885-5712.

Reviewed by Matthew Bernier, MCAT, A.T.R., Norfolk, VA

This video is a sequel to Archetypal Images and Art (Frantz, 1988). While it follows the same lecture format of Archetypal Images . . . , this video is a little more engaging since the focus is on Birkhauser and his paintings. The images, including art and photographs, are related to the text.

Peter Birkhauser, a Swiss modern artist, attracted the attention and appreciation of Carl Jung because his artwork provided outer representations of inner archetypal images of the psyche. Birkhauser’s early art training focused on details of the outer world. Around the age of 30 he was plagued by
depression, lost enthusiasm for painting the outer world, and began to record his dreams. He entered Jungian analysis which eventually brought him in contact with Carl Jung.

Birnhauser realized that he needed to listen to his unconscious and inner messages. He changed his orientation in art in order to fulfill his task of making the contents of his unconscious visible. He allowed his artwork to be led by his unconscious, especially through dream imagery as he began to paint only images of his inner world, his dreams, fantasies, and visions.

Typical of archetypal artists, Birnhauser's art was not accepted by critics. Today, as Frantz discusses, his images are seen as having healing powers because they express archetypal forces related to our collective consciousness. Birnhauser was called from within to express universal themes such as spiritual and creative forces, renewal, wisdom, and transformation which are connected to the individuation journey.

While we view the more than 70 slides of Birnhauser's paintings, Frantz delivers comments by the artist and Jung as well as his own interpretations of the artwork. The content and images are fascinating. However, they are weakened by the less interesting presentation format, a single camera angle of Frantz lecturing at a podium, interspersed with static slides of artwork.

For a more in-depth review of Birnhauser's artwork with interpretive commentaries by Marie-Louise von Franz, and an essay on "Analytical Psychology and the Problems of Art" by Peter Birnhauser, I recommend reading *Light from the Darkness: The Paintings of Peter Birnhauser*.

**Book Review Response**

In Bernier and Manning's review of Bruce Moon's latest opus, they rightly acknowledge Moon's gift for writing. Indeed, the hallmark of this book is the manner in which Moon's ideas are presented. Examining the contents of this text is comparable to reading poetry and literature. Moon's work must be savored, occasionally put aside, and pondered. His profundities weave a tapestry of soul-filled anecdotes and life experiences. We have much to learn from the way Moon embraces life, learning, and teaching. The reader needs to tread carefully lest his or her thinking be challenged, provoked, and perhaps transformed. Moon's ability to stir up the homeostatic cobwebs of the mind is uplifting, refreshing, and far reaching.

Yet there are some who may take umbrage with this and do not embrace the theosophy that Moon proposes. Moon is quite opinionated and strongly disputes the notion of training students "to be as-if psychologists or pseudopsychiatrists" (p. 56). His desire to delineate the profession of art therapy as one chiseled and forged with art materials is aligned with the teachings of our greatest and most diverse pioneers such as Edith Kramer, Shaun McNiff, Harriet Wadeson, and Rawley Silver. Instead of hammering and pigeon-holing Moon's approach as suggested by Bernier and Manning, it would be a welcome change if educators could embrace Moon's passion for exposing the importance of hanging on to our heritage and, most importantly, our art.

Moon's vision is not a rejection of verbiage. He suggests a "metaverbal framework," a therapy that goes "beyond words" (p. 111). He implores the art therapy educator to counsel the myriad questions and struggles about art raised by inceptive art therapists. This approach is akin to that of my greatest teacher and mentor, Edith Kramer. Always she returned me to my art. And, through this tutelage I had my greatest breakthroughs as I struggled through the maze of graduate training.

Alas, Moon's pitch for accepting our art is not the whining of an "angry school hoy," as suggested by Bernier and Manning, but our ancestral lot and birthright. His viewpoint does not contradict or attack AATA's principles or guidelines. It underscores the importance of maintaining and upholding our identity and profession. His plea for approaching clinical training from a "perspective of soul" (p. 66), indeed makes this work of ours both sacred and passionate. For the sake of our future and our profession, I hope we can take heed and, as Moon so ardently demands, listen to our senses.

**Video Review Response**

This video was originally intended to educate mental health and special education professionals about the value of art therapy with autistic and developmentally delayed populations. What also emerged after several screenings was its applicability to beginning art therapists interested in working with these clients.

I agree with Mr. Tabone that a verbal introduction to the population could be beneficial, and hope to develop a written introduction that can be included with the video. I am distressed with Tabone's comment: "Viewers who were unfamiliar with autistic and mentally retarded clients then would not wonder why apparently typical looking young adults were scribbling and communicating with difficulty." I cannot believe that any serious student of art therapy would not immediately sense from viewing the video participants that this was a special needs population.

The video was not created to be a promotion for the PACE program (which folded in 1986), but as a promotion of the value of art therapy within this setting. The goal was to encourage administrators to hire more art therapists for their programs.

Salary & benefits competitive. To teach three courses per semester in graduate Art Therapy and/or undergraduate Art Studio or Introduction to Art (lecture). Start Aug. 16, 1994.

Qualifications: MA or MFA, ATR Certification. Three years of adult clinical experience in Art Therapy with studio background preferred.

Art Therapy Search, Box 1774, Art & Design. Southern Illinois University at Edwardsville, Edwardsville, IL 62026.
Moon, Bruce L. — INTRODUCTION TO ART THERAPY: Faith in the Product. '94, 222 pp. (7 x 10), 16 il., $45.75

It is the author's goal to completely introduce the complex and diverse field of art therapy as it is now practiced in the United States. This text touches the major themes and issues of the profession. This should be the first book, or one of them, which students new to the field read about art therapy. There is provided clinical service to many specific patient populations; the basic tenets are applicable to all human beings. For the past twenty years the author has worked with mentally ill patients and makes reference in a readily understandable manner of experiences with patients, colleagues and students. Art therapy can be used with the very young through the very old. No one is disqualified on the basis of gender or sexual orientation. Art therapists work with persons from all races, creed and religious traditions. Art therapy is effective with individuals, couples, families and groups. It works well with the intellectually gifted and the learning impaired. It can be used with the chronically mentally ill, the terminally ill, the vision impaired and the deaf. It is a safe assumption that patients admitted to psychiatric hospitals have already tried to alleviate their emotional distress with traditional verbal psychotherapy without significant relief. It is the creation of an objective thing that separates art therapy from other work done by psychologists, social workers, psychiatrists and counselors. Art therapy is particularly effective with posttraumatic stress disorder—from aftereffects of war, physical, sexual or emotional abuse. This book describes the essential elements of the process of facilitating therapeutic change in forming a foundation from which art therapists construct treatment plans and philosophies.

Moon, Bruce L. — ESSENTIALS OF ART THERAPY TRAINING AND PRACTICE. '92, 188 pp. (7 x 10), 21 il., $35.75.

Type of Submission (check one):

___ Article
___ Brief Report
___ Viewpoints
___ Book Review
___ Film/Video Review

Title of Submission: ________________________________________________

_______________________________________________________________

Checklist:

___ Five copies, typewritten on 8½” × 11” paper.
___ Black and white photos of original artwork plus 4 photocopies of each.
___ Abstract of 75-125 words (for articles and brief reports only).
___ Detachable cover sheet with author(s) name(s), affiliation, degrees and credentials.
___ Appropriate release forms obtained for use of client art expressions and client information. (You do not need to send these with your submission, but you must have them on file.)

Author’s signature ___________________________ Date ________________

Please send completed form with submission to: Editor, Art Therapy: Journal of the American Art Therapy Association, c/o AATA, Inc., 1202 Allison Road, Mundelein, Illinois 60060.

___/___/___
Guidelines for Submissions

All submissions will be acknowledged upon receipt by the AATA National Office. Art Therapy uses a blind peer review procedure for full-length articles and brief reports; final decisions regarding publication are made by the reviewers and the Editor. Decisions regarding submissions to other sections are made by the Editor, Associate Editor and special section editors.

The following are guidelines for developing and submitting a manuscript. Manuscripts that do not conform to these guidelines will be returned to the author without review.

Manuscript Categories

1. Full-length Articles. Full-length articles may focus on the theory, practice and research in art therapy or related areas. Manuscripts must include an abstract of approximately 75-125 words summarizing the major point of the article.

2. Brief Reports. Short articles which focus on the results of research are appropriate for this section. Manuscripts should include information on the research design, methodology and results; an abstract of approximately 75-125 words should also be included.

3. Viewpoints. Short articles focusing on personal experiences, poetry or original art may be submitted to this section.

4. Book Reviews. Reviews of books of interest to art therapists may be submitted at any time. Books which authors wish to have considered for review may be sent directly to the AATA National Office at the address listed above.

5. Film/Video Reviews. Reviews of media (films or videotapes) may be submitted at any time. Media which producers wish to have considered for review may be sent directly to the AATA National Office at the address listed above.

6. Comments. Brief comments on articles published in Art Therapy, issues critical to the profession and practice of art therapy, or letters to the Editor may be submitted to this section and should conform to the style of all other submissions.

Other Requirements

1. Send five (5) clear copies of each manuscript to Cathy A. Malchiodi, A.T.R., Editor, Art Therapy: Journal of the American Art Therapy Association, c/o AATA, Inc., 1202 Allanson Road, Mundelein, Illinois 60060. Neither AATA nor the Editor can be responsible for submissions sent to any other address.

2. Only original articles that are not under consideration by another periodical or publisher are acceptable.

3. Manuscripts must be typewritten on 8½" × 11" white paper with margins of at least an inch. The body of the paper, references, tables and quotations must be double-spaced.

5. An abstract of 75-125 words must be included with full-length articles and brief reports.

6. Please avoid footnotes wherever possible.

7. A cover sheet should be prepared to include the full name(s) and degree(s) of the author(s), professional affiliations, and the return mailing address of the author to whom correspondence can be sent. Authors’ names, positions, titles and places of employment should not appear in the body of the paper to assure anonymity and to facilitate blind review.

8. Use tables sparingly and type them on separate pages. Refer to the APA Publication Manual for style of tabular presentations. All tables, charts or diagrams must be legible and able to withstand reduction. Include originals and four (4) photocopies.

9. Photographs must be at least 5" × 7" and black and white glossy prints, preferably with high contrast. Photocopies of illustrations or art expressions are not acceptable for publication. Figure numbers and captions should be noted on the back of photographs; captions must be typed and submitted on a separate sheet of paper. Please refer to figures in the text as Figure 1, Figure 2, etc. Include four (4) sets of photocopies of original photographs.

10. Lengthy quotations (300 words or more from one source) or reproduction of works of art (this does not include client art expressions, which are addressed below) require written permission from the copyright holder for reproduction. Adaptation of tables or figures from copyrighted sources also requires approval. It is the author’s responsibility to secure such permissions; a copy of the copyright holder’s written permission must be provided to the Editor immediately upon acceptance of the article for publication.

11. Client/patient confidentiality must be protected in the title, abstract, text, photos, illustrations and other accompanying material. Proper releases for use of client art expressions and other client information must be obtained and kept on file by the author.

12. It is expected that any manuscript accepted for publication in Art Therapy will go through at least one revision before publication. If authors have prepared their manuscripts on either an IBM, IBM-compatible or Macintosh computer, upon acceptance, they can send a 3.5" diskette containing an electronic copy of the manuscript to the AATA office. This will help speed processing, editing and publication.

Note: Authors bear full responsibility for the accuracy of all references, quotations and materials accompanying their manuscripts.
STATEMENT OF PURPOSE: Art Therapy: Journal of the American Art Therapy Association is the official journal of the AATA, Inc. The purpose of the journal is to advance the understanding of how visual art functions in the treatment, education, development, and enrichment of people. The journal provides a scholarly forum for divergent points of view on art therapy and strives to present a broad spectrum of ideas in therapy, practice, professional issues and research. An emphasis is placed on the use of the visual arts in therapy, but articles in related disciplines of interest to art therapists will be considered for publication.

ART THERAPY: JOURNAL OF THE AMERICAN ART THERAPY ASSOCIATION (ISSN 0742-1656) is published quarterly by the AATA, Inc., 1202 Allanson Road, Mundelein, Illinois, U.S.A. 60060. Telephone (708) 949-6064; FAX (708) 949-6064. Non-members may subscribe at the following annual rates: $40 (U.S.) and $64 (Foreign); institutions: $57 (U.S.) and $80 (Foreign). AATA members receive the journal as a benefit of membership.

Single Issues: For price and ordering information, call or write to AATA, Inc., 1202 Allanson Road, Mundelein, IL 60060 (708) 949-6064.

This journal is abstracted in: Psychological Abstracts, INNOVATIONS & RESEARCH, Art Bibliographies Current Titles and Art Bibliographies Modern.

Authorization to copy: No part of this publication may be reproduced, stored in a retrieval system or transmitted in any form or by any means, electronic, electrostatic, magnetic tape, photocopying, recording or otherwise, without permission in writing from the copyright holder.

Change of Address: Notices should be sent at least six weeks in advance to AATA, Inc. Subscribers should notify the post office that they will guarantee forwarding postage. Undelivered copies resulting from address changes will not be replaced, but single issues may be purchased at the single issue price.

Sorting Out Certification

Cathy A. Malchiodi, MA, A.T.R., Editor

This 25th year of the American Art Therapy Association, Inc., not only commemorates the silver anniversary of the organization, but also marks the beginning of the long-anticipated certification program for art therapists. The question of certification within the profession of art therapy and the AATA itself has had a long history, almost as old as the association itself. The underpinnings of certification began with initial attempts to define competencies in art therapy (Lusebrink, 1981; Lusebrink & McNiff, 1979; Lusebrink, Nucho, Riley, & Ault, 1989), and various committees were formed throughout the 70s and 80s to explore the idea of certification for art therapists. In 1990, an ad hoc committee was appointed to once again explore the idea of a national certification program for art therapists (AATA, 1989). Subsequently, in 1991, the membership voted by ballot to proceed with the development of a certification program (AATA, 1991) and at the general business meeting at the annual conference that year a majority of those in attendance voted to complete the process of developing a certification within three years.

Although the implementation of certification and a competency examination is an important historic milestone, few AATA members seem to be openly talking about it in the pages of our publications aside from those members on the Art Therapy Credentials Board (ATCB) or those involved with actual Certification Committee work. During my tenure as Editor I have yet to receive one commentary, letter, or viewpoint that addresses the subject. Recently, a letter to the AATA Newsletter Editor made a plea for A.T.R.s with a certain amount of experience to be "grandparented," citing that the examination process may be more appropriate for less experienced A.T.R.s new, or unregistered therapists (Buchalter, 1994). Other than this brief comment, opinion within the pages of our publications has been noticeably absent.

Meanwhile, the process is moving forward and some practical aspects of certification have already been determined by the ATCB over the last year. The first examination has been scheduled and will be held during the time of the 1994 annual conference; the price of taking the examination has been set at $20; and grandparenting will be limited to a very select group of art therapists. A recertification program is currently being developed, to be in place after the initial group of art therapists becomes certified. A practice analysis survey was sent last year to professionals in the field to identify the tasks entry-level art therapists must perform in practice and the knowledge necessary for such performance. Currently, the Certification Committee, along with guidance from Knapp & Associates, is gathering material from professionals in the field and working toward the actual development of an examination.

The development of a certification examination is one of the most complex and heady tasks of the entire process, and one that may have the most profound and lasting effects on the direction of the profession. I must admit that when I was asked to write 10 questions for possible inclusion in the certification exam, I immediately felt very respectful of what I might put to paper. Simultaneously, I also felt stymied about what I could honestly design as test questions. Some areas of knowledge such as the AATA Code of Ethics or Standards of Practice came to mind, but frankly after that I became confused about what art therapy resources could actually be utilized to develop sound questions, given the requisite multiple choice format.

My confusion stemmed from several problematic aspects of the development of the field of art therapy, particularly our literature. One major problem with utilizing our publications to design exam questions is in viewing much of what is published as "truth," particularly truth on which to design multiple choice exam questions. First, much of our literature, particularly books, has not had to pass any particularly rigorous standards in order to be published. Many publishers (many of which are well-known to art therapists) are eager to print anything about art therapy and will send a contract out to a prospective author who has what sounds like a marketable topic on paper without seeing the actual manuscript. Often no request is made of the author to submit the final manuscript to objective reviewers in the field for verification and criticism of content, a practice standard in many fields and with many publishers. There is also straight-out vanity press where a publication goes to press either self-published or published under circumstances without editing. These types of practices result in publications that often have flaws in factual areas as well as theoretical and methodological areas.

Also, although less problematic, publications in the field of art therapy have tended to be based more on clinical and philosophical observations, rather than on research and hard data. Obviously, psychology, counseling, and other clinically-based disciplines have had to contend with developing examinations, given some similarities in knowledge areas. However, these disciplines have been around longer than the field of art therapy, and thus have produced literature that has withstood time as well as undergone a much more rigorous
scrutiny. Additionally, another characteristic of art therapy to be considered is the infusion of art within its literature. Art is a discipline that is based in human creativity (at best, an elusive subject) and that has very little in the way of rules; when there are rules, they often are broken.

Art-based assessments are another area of ambiguity and controversy in both our literature and knowledge base. Fortunately, many art therapists in the field are respectful of the use of art in assessment and the use and misuse of interpretation, understanding the limitations of making strict interpretations of client art expressions. In this issue of the journal, Joan Phillips, current Chair of the Certification Committee, comments in other areas of concern, particularly on the conflicting opinions art therapists express about art-based assessments through the National Practice Analysis Survey (also published in this issue). On one hand, many feel that art-based assessments, particularly "free art assessments," are intrinsic to the practice of art therapy; on the other hand, art therapists find little or no consensus on how to go about defining exactly what free art assessments are.

Another area of concern is the oral history that has abounded concerning assessment protocols. This oral tradition has generated protocols that have often been regionally-based or connected to some specific training program, and almost always never written down in depth. Once in a while the profession gets a glimpse of these assessments at a session at the annual conference, but that limited viewing does not provide the necessary data on how to implement these assessments nor their application with specific populations. Given the status of art-based assessments in the field of art therapy in addition to the conflictual feelings about utilizing art expressions as interpretative data, it is easy to understand the Certification Committee's decision not to place a focus on them in the development of the examination.

Those who were asked by the Certification Committee and Knapp & Associates to develop test questions were also asked to reference where each proposed test question was cited. Considering the varying quality of our published literature, the lack of previous peer review, and oral traditions, this will likely pose some problems in the overall process of exam development. The Certification Committee has undertaken the enormous responsibility of selecting and developing the final questions for the examination from the material submitted; however, the accompanying responsibility of verifying facts will be difficult at best, given the inherent problems previously mentioned.

A final matter regarding the actual examination is, given the previously mentioned aspects, will what is developed really be an art therapy certification exam or basically a counselor exam disguised as an art therapy exam? In thinking about designing test questions, some authors of potential questions may have passed up the art therapy literature, going to texts outside the field for references. If the majority of questions on the examination are culled from literature outside the field (e.g., questions about group therapy from Yalom or Corey & Corey, from the DSM III-R, from standard texts on family therapy such as the Goldenbergs, psychotherapy with children from the writings of Winnicott, to name a very few possible examples), then we may have missed our mark. This trend would bring the field rapidly back to the question of whether or not art therapy is a bona fide discipline in its own right, or merely a modality that is an appendage of another profession such as counseling, psychology or the like (Malchiodi, 1993).

Lastly, some would observe that the purpose of certification at present is limited, given that only one state has achieved art therapy licensure. It is obvious that by creating a certification process we are basically preparing ourselves for possible future scenarios when other states may achieve art therapy licensure and regulations our profession must meet, given possibilities of new standards for health care. However, the verdict is not in on if certification will protect the field given a national health care program that includes managed care or other similar plans. With these unknowns and other variables, the effect of certification for art therapists will not be realized for many years.

Undoubtedly, the real impact of certification at this point in time is the articulation of an art therapy knowledge base, one that truly defines our profession and distinguishes it from others in the health care arena; whether or not certification will be successful in clarifying and refining the definition of art therapy as a field also remains to be seen. The movement to define ourselves through certification also brings to mind another question for which an answer may not be immediately evident: will certification make the field of art therapy credible? This search for authenticity has dogged this profession since day one, as both the association and its members have struggled to define themselves to hospitals, governmental agencies, health care professionals, and the public. Whether or not certification will help us achieve a sense of being "real," either psychologically or otherwise, is the real question that remains to be answered.

Letters to the Editor

I write in appreciation of your editorial, "Introduction to Special Issue on Art Therapy and Professionalism: Is There a Crisis in Art Therapy Education?" (Art Therapy: Journal of the American Art Therapy Association, Volume 10, Number 3, 1993). You presented issues relative to our various philosophies and to the pragmatics of making decisions most beneficial for the survival of our profession, seeking unity without uniformity. You also posed other questions and avoided the trap of easy answers.

Though I realize that there is a crisis in art therapy education, I do not regard any of the details to give informed answers. However, regarding "art therapy and professionalism," I do have experience, knowledge, and beliefs. So, I write here in response to the section in your editorial entitled, "Art Therapy: Modality or Field?" (Malchiodi, p. 122).

In this section you include a paragraph taken from a long interview with me recorded by Henrietta Jordan (American Journal of Art Therapy, Volume 28, Number 1, 1989). From what I said, you drew conclusions relating my thoughts to your implication that art therapy must be either a "bona fide discipline or merely a modality" (Malchiodi, p. 122). I did not, and would not, use that wording nor that kind of either/or thinking in defining art therapy. Instead, I used the words "a separate field" (Jordan, p. 12). I think we all know that in the present overcrowded milieu of therapies, no one discipline can claim to be totally distinctive. Each field incorporates positions and practices advocated in related fields. Art therapy educators and practitioners wisely include in our knowledge base tenets originating in more established disciplines. Professional philosophers, educators, scientists, and artists have always done so in an ever-interactive process of reactive and proactive development of ideas and understandings. Individuals can ignore ideas inimical to their own; cultists thrive on such denial. I am wary when someone claims a direct source to power and truths unavailable to ordinary mortals. When professional responsibilities are blurred, I grow uneasy. Further, I would never label art therapy as "merely a modality." Historically art expression has been practiced as therapeutic experience for millennia. In a cultural context art experience has been and still is central in enlivening all cultures known to anthropologists. Culturally specific rituals involve art making and experience as far back as our Neolithic ancestors up to and including our present. In the wide context of humankind, art as therapy has been and will continue to be for life's sake. No person or profession can afford to this universal urge and claim the right to delimit its potentialities.

Too often we take for granted our right to freedom and give little thought to the fundamental and necessary principle that having freedom assumes being responsible. In the interview to which you refer and in the context of AATA's concerns as an organization, I spoke unthinkingly. In retrospect, I am embarrassed by the paragraph quoted. I spoke so off-handedly. I expressed my personal opinion, and by implication those of other art therapists. I referred to a serious matter as if I did not recognize or even care about the reality and complexity of the problems. The interview was recorded almost five years ago. Since then AATA membership has approved changes affecting the professional status of our members. The actual outcome of this move has yet to be determined. I read that the Art Therapy Credentials Board, far more politically informed than I, is working toward devising standards and measures of who we are and what we do. If they can do this while respecting the diversities among us, and if this can provide art therapists with more security in status and income, I applaud their efforts and wish us well.

Janie Rhyne, PhD, A.T.R., HLM

Healthy egos are both well differentiated and well integrated. Placed in this framework, the collective "ego" of professional art therapists is rich in the former attribute and deficient in the latter. We represent a diversity of opinions, viewpoints, and approaches that we articulate with emphasis (and, sometimes, a disregard for the sensitivities of others) in the pages of this journal and elsewhere. However, we have difficulty when it comes to unifying our diversity. The controversy surrounding the theme of our most recent annual conference, "Common Ground: The Arts, Therapy, Spirituality," is a case in point.

Cathy Moon's beautifully poetic opening address for the conference was moving and persuasive. But it takes more than a good speech to unite those who embraced the theme, those who value spirituality but think it should be kept separate from professional life, and those who are nonbelievers. (So that you know where I stand, I include myself among the last.) And it also takes more than majority rule—an imposition of the will of the largest group on all the rest.

My point is that we as art therapy professionals need to find better ways to interrelate. We need to work harder at understanding our diverse viewpoints, at finding ways to benefit from what each has to offer, and at devising resolutions to the inevitable conflicts that take into account our shared interests. In regard to the conference, for example, a theme such as "The Search for Meaning," developed to include separate sections on spirituality, theory, research, etc., might have bridged our differences.

We do not want to stifle debate (small chance of success in any case!) because this is one way we clarify and develop our ideas and concepts. But when we are able to come up with creative and satisfying solutions to our major conflicts with some consistency, we will be able to say that we as a profession have reached "ego" maturity—and we will have truly found common ground.

Frances F. Kaplan, DA, A.T.R.
Morris Plains, NJ
Thank you for publishing the survey by Lusebrink, Rosal, and Campanelli; this survey is a valuable asset to the art therapy research archives. For the record, I need to point out an error in the analysis of data regarding my doctoral dissertation topic. Although my topic did not have art therapy mentioned in the title, the body of research and the context within which this research was conducted, subscribed to art therapy principles and practices. I would not be surprised if this is also true of other researchers and if more doctoral dissertations than the survey indicates are related to the field. Art therapy is totally integrated into my life and was an extremely important part of my doctoral studies.

Simone Alter Muri, EdD. A.T.R.
Northampton, MA

A belated but heartfelt congratulations to you and the American Art Therapy Association for editing and publishing the special issue of ART Therapy on art and medicine (Vol. 10, No. 2, 1993).

Your own editorial was an excellent introduction to the issue and raised some central issues, not the least of which was the outstanding Barbara Graham quote that “being healed isn’t the same as being cured. . . .”

As you know, we in the International Arts-Medicine Association (IAMA) refer to our “movement” as arts-medicine and note your term “medical art therapy.” All of us in this field must continue to discuss basic definitions and terminology, and we look forward to those discussions.

Suffice it to say, it is inspiring for many of us to note that individuals and institutions around the world are increasingly and successfully utilizing arts interventions in a wide variety of medical settings.

We noted this phenomenon in our recently signed 1993 Tokyo Declaration on Arts-Medicine, on which we would like you to comment. Also of note is a six-point Rationale for the Increased Utilization of the Arts in U.S. Health Care which I published as president of IAMA in July of 1991.

More importantly, however, is that the special issue of ART Therapy is a stunning achievement, and all of us who believe in the healing power of the arts are in your debt. We are very pleased to note that the current president of AATA, Bobbie Stoll, is on the Board of Directors of IAMA.

Again, congratulations on this wonderful achievement. We very much look forward to working with you.

Richard A. Lippin, M.D., President
International Arts-Medicine Association
Philadelphia, PA

CALL FOR PAPERS

Art Therapy is seeking submissions for the following special issues:

宼 Gender Issues in Art Therapy

Art Therapy is seeking full-length articles, brief reports, and viewpoints for a special issue devoted to gender issues in the theory and practice of art therapy. Submissions may focus on any topic or population related to this theme. Of particular interest are: the effect of gender on clinical practice, professionalism, ethics, and/or training, feminist theory and its relationship to art therapy, and gay and lesbian issues in clinical practice.

宊 Ethics and Art Therapy

Art Therapy is seeking full-length articles, brief reports, and viewpoints for a special issue devoted to this and art therapy. Submissions may focus on, but are not limited to, ethical issues specific to the practice of art therapy, pedagogical considerations in incorporating ethics with art therapy training, supervision, and practice; ethics in art therapy research, legal aspects of art therapy practice; and ethical dilemmas in exhibiting client art expressions. Potential authors are reminded to consider the topic of ethics as specifically related to the field of art therapy, not counseling, psychology or other related mental health fields. Submissions will be reviewed for publication in part on the author's ability to make this connection.

宊 Deadline for submission for "Gender issues and Art Therapy" is December 1, 1994. The deadline for "Ethics and Art Therapy", has been extended until September 1, 1994. Please see "Guidelines for Authors" in the journal for specific requirements in terms of style and format. Please send 5 copies of all submissions to:

Art Therapy, c/o AATA, 1202 Allanson Road, Mundelein, IL 60060

1711
Tribute to Suzanne Canner Hume, MEd, A.T.R.  
1952-1994

On February 16, 1994, the field of art therapy experienced a tragic loss with the death of colleague, educator, teacher, and clinician Suzanne Canner Hume. Suzanne's accomplishments and contributions to the field of art therapy were many. She was a graduate of Radcliffe College and the first student to graduate in art therapy from Lesley College, later to receive her A.T.R. in 1976. She was extremely active in governmental affairs, advocating for recognition of art therapists in her home state of Massachusetts. Her untiring work in this area resulted in the passage of the Massachusetts Mental Health Counselor Bill in 1990, which included art therapists in the legislation.

Suzanne also left her mark on art therapy education. She developed and directed an art therapy program at Dean Junior College, and later designed and directed a summer art therapy institute at Simmons College in Boston; both programs were carried out while she was still in her twenties. Suzanne also served on the AATA Education and Training Board, chairing the ETB from 1985-87. She received the Distinguished Service Award from the AATA in 1989 for her achievements on the ETB and in governmental affairs.

In honor of Suzanne, a collection of letters was gathered from Suzanne's friends and colleagues. These letters extoll not only the accomplishments of Suzanne Canner Hume, but also characterize the exceptional quality of her contributions and her extraordinary spirit. They are presented as "Letters to Erika," in honor of Suzanne's daughter and husband, and respectfully as a celebration of Suzanne's life.

Letters to Erika

Dear Erika,

I knew your mother as a friend and colleague through our work in the field of art therapy. I remember when I first moved to Massachusetts, your mother came to a lecture I gave at Lesley College for the New England Association of Art Therapists. I felt quite honored that she would come to my presentation, and after I finished my lecture, I remember how she made me feel welcome in my new home. This was many years before you were born, but I can remember talking with your mother in the months after about how much she wanted to have a child, and later, how happy she was when she gave birth to you.

Suzanne was an extraordinary human being and I hope that these letters will honor her memory in an extraordinary way. But this is not the only purpose that I had in mind in collecting these letters. I know Suzanne would want you to know the story of her life as you grow up and become a young lady, because your arrival on this planet was the most important thing in the world to your mother. So I thought that if I asked some of your mother's special friends to write their memories of her for you that this could be my gift to you as you grow and want to know more about the extraordinary person Suzanne was to many, many people.

There are many words that flood my mind when I think of your mother: kind, gentle, intelligent, thoughtful, gracious, beautiful. It is still hard for me to believe that she is gone because she was so filled with life and vitality. I know that everyone who has written a letter to you feels the same way. I also know that as you grow up, everyone who has written a letter to you would be glad to personally share their memories of your mother with you. This is a treasure that we would all be honored to give you in the years to come.

Cathy A. Malchiodi  
Salt Lake City, UT

Dear Erika:

I remember Suzanne well. We worked together between 1980 and 1988. Her contributions to the New England Association of Art Therapists, the American Art Therapy Association Education and Training Board, and her successful pioneering work for licensing for art therapists in Massachusetts have affected all of us. She changed our lives. She changed my life.

My earliest association with Suzanne was in our work on the New England Association of Art Therapists. She invited me to attend a meeting in 1980. I think in late Spring. I was intrigued by her position on the Board. While it did not seem that she held elected office, she was clearly a vital part of the organization, probably as a "member-at-large." Her efforts and energy were behind numerous conferences and membership drives. These all were done with her inevitable professional abilities, with no detail overlooked, from sign-in to meals, from flowers to greeting each speaker and conference goer. She knew everyone, and everyone knew her at these conferences, and she had kind and caring words for each. When she left NEAAT to form the Massachusetts Coalition of Creative Arts Therapists and work for licensing legislation,
the organization went into hibernation for about two years. Her energy and abilities to bring people together were impossible to duplicate.

The success of Suzanne’s work for licensing came to fruition only recently, when the Massachusetts legislature approved licensing for art therapists under the umbrella of Mental Health Counselors. Her work, along with others, allowed us to apply for licensing under a grandfather clause. We all were indebted to her for this. Along the way, she coordinated the First New England Joint Creative Arts Therapists conference, held at Lesley College on March 15, 1986. She brought together creative arts therapists from all over the region, for one of the most inspirational celebrations of our profession. Suzanne knew how to work hard and how to celebrate and play in style!

Not the earliest, but perhaps one of my most vivid memories of Suzanne dates to March 1987. Suzanne, then Chair of the AATA Education & Training Board, called to tell me that my appointment to the post of Secretary of ETB had been approved, and we had better get to work, fast. The former ETB Secretary had left the post suddenly for health reasons. Meanwhile, boxes and boxes of applications for approval had been submitted by art therapy programs, and the deadlines for responding to the materials had come and gone. The applications had been sent to my home and, when they arrived, Suzanne and I scheduled a meeting for a Sunday (the only day both she and I were free).

In her typically energetic style, she rose early and made the three-hour drive from Rockport, Massachusetts, at the eastern end of the state, to my home in Amherst, in the west. I had worked previously with Suzanne for the New England Association of Art Therapists and briefly, on the licensing project, so I knew her drive and energy level were boundless. She would work until the job was done. Sure enough, she arrived ready to dive into the mountains of paper work. She carefully and thoroughly trained me, going with meticulous attention through one program. A checklist guided us. We had something like a half dozen more programs to inventory. It would be a long day. We divided the remaining pile and got down to work. Suzanne not only reviewed her stack of materials, but often stopped to help me orient myself to this new task. She would have worked without a break, but my husband insisted we take lunch. Anyone who has worked with Suzanne knows that the work continued as we sat down to eat. And the work continued well into the evening, without a break, until it was done. Around eight o’clock, Suzanne declined dinner and an invitation to stay the night. She drove the three hours back to Rockport. To this day I wonder where her energy came from; I went to bed! Oddly enough, it actually had been a fun day such was Suzanne’s ability to make heavy work into serious play.

The next day we began to work together, by phone and mail; we wrote letters to each program. She taught me the art of the gentle, but firm, request for missing or deficient materials, and, most importantly, how to write with clarity and respect. She was most sensitive to the feelings and perception of the program director who would be receiving the letter. At the same time, she was thorough and careful. Her letters were perfectly worded; I had much to learn. She knew so much!

This style of working continued throughout our association, and we were on the phone several times a week until her term on the ETB was completed in Fall 1987. Actually, she stayed on the Board an additional year to ease the transition to a new Chair. The photograph accompanying this letter was taken after the Spring 1987 ETB meeting in Rockport. Suzanne had arranged for us to stay in a nearby house for the Friday through Sunday meeting. She arranged for meals, a walk through the marshes, and some magnificent views from the huge picture window overlooking the Atlantic. The house was set on a rock, directly above the ocean, and we ETB’ers sat among piles of papers, with one eye on the crashing waves. Suzanne somehow kept our attention on work, and deftly negotiated us through discussions of the programs.
being reviewed for approval. As secretary, I took notes and then drafted letters during our infrequent breaks. Suzanne guided us through an insurmountable amount of work, remaining fresh and open to each new problem. At the same time, she arranged lunch, and later, dinner. Before the meeting started, she and your father made several trips to Boston’s Logan airport to pick up ETB members—whose flights, of course, were at all different times. By Sunday afternoon, she had served us a sumptuous lobster dinner, and the reverse trip to the airport was underway. Fortunately, I knew my energy level was no where near that of Suzanne’s, and my husband drove me home. My admiration for Suzanne’s indefatigable energy grew with each week. Clearly, she would be hard to replace.

When you were born, Suzanne brought you to the AATA Conference. She was full of her old energy, and had begun to pursue doctoral studies at the Fielding Institute in California. I knew I was not alone in looking forward to her return to “active duty” with AATA. I sorely miss her clear thinking and ability to include everyone. Her broadmindedness, generosity, and her unending dedication to the cause of art therapy, has enriched all of us. She will be sorely missed—she will not be forgotten.

Rest well, Suzanne.

Patricia St. John
Amherst, MA

Dear Erika,

I knew your Mom for a really long time, long before you were born and even before she married your Dad. We met in Boston when we were both still students. There were half a dozen of us who were friends, all deciding on careers, all involved in one way or another in art therapy. Of the whole group, only your Mom and I decided to stick with art therapy. The rest went into counseling, social work or other fields. I mention this because it shows her determination to follow her own instincts and keep to her own path.

Those were exciting days. We worked together planning an art therapy conference, one of the first ones in Boston. I remember how thorough Suzanne was, from taking care of the smallest detail like coffee and donuts, to giving an excellent presentation herself. Everything she did was done well.

One of my favorite memories is of when I met you. You were about two years old. I came to Boston from Chicago with my daughter Adina and we drove up to Gloucester to visit your family. You and Adina played together and your Dad videotaped you both. Your Mom was very beautiful, she always dressed with lots of style and usually wore a rather serious expression. Whenever she smiled or laughed, she became even prettier. I remember thinking that day how she never stopped smiling and how her beauty lit up the room. She obviously loved you so much and was so filled with joy watching you play that she glowed.

I feel very lucky to have known Suzanne, to have been her friend and to have grown up together with her in art therapy. I just wanted to share these memories with you.

Love,

Pat Buoye Allen
River Forest, IL

Dear Erika,

Two telephone calls came that terrible day from colleagues that knew and loved your mother and who knew I would want to be informed of her passing. I thought surely there had been a mistake as the defense of disbelief worked its ways to lessen the loss and grief. It was only gradually that the news began to sink in and become a reality. My heart screamed it wasn’t possible, yet my head nodded the truth, we had lost a very special colleague and friend. My heart argued it wasn’t fair; Suzanne was young and vital; she was one of the good people who makes the world better and I searched for a logical or just explanation. There simply wasn’t any, for the world isn’t always a place of justice or logic, it just is. It is a hard reality we not only die by but more importantly live by. I continue to seek meaning out of it all, and I hope someday my words will help you to know and love your mother as those of us that worked with her did.

Some years ago I had the good fortune to be appointed to the Education and Training Board of the American Art Therapy Association for four years and became part of a very special team of colleagues that included your mother. Of all of the committees, boards, task forces, and teams that I participated in over the years, this one was the most special. Not only was it composed of very special people, but our task demanded we struggle mightily together to find fairness and order in the education of future generations of art therapists. When people struggle together with respect and a sense of caring as we did, and bring to resolution difficult problems, a great depth of connection is felt with each other. I would like to refer to it as an affection connection. I will retain it the rest of my life, and when I think of our times together, I smile and my heart is reassured of the rightness of life.

I did not know Suzanne before our work on the ETB, but let me share a few of my impressions from our years together. She was a thin, wiry young woman from the East Coast that ran every day and always brought her running clothes with her to our meetings. She was so friendly and warm and although seeming casual on the outside; when we got down to the task of understanding volumes of materials on graduate programs she was like a corporate lawyer in her quickness, sharpness, and amazing accuracy of analysis. She was dedicated to the task of making the work fair and through her example and leadership she molded the ETB into a politically free body that demanded and was given respect by the membership of our organization. I always felt so proud to be a part of the process and to be an art therapist, as well as exhausted after one of our three-day marathon meetings.

One time we met at your home overlooking the ocean there in Massachusetts. I loved the place. We could watch the lobster fishermen check their traps, observe the light house on the island, and smell the salty air that is special to those of us that grew up on a coast but live in the middle of America. I still have sea shells that I picked up on the rocks below your house. As we concluded our meeting that Sunday, your father brought each of us huge lobsters for lunch and we feasted. I still remember well the bright pink shells, the juice running down our arms, the wonderful tasting meat and the cracking of jokes as well as shells, and laughing together. It was a very special time.

The group was always very affectionate with each other and as we gathered or parted there would always be a round
of greetings and goodbyes and hugs. I wanted to tell you about one such event related to saying goodbye that was especially meaningful to me and that I believe illustrates something very important about Suzanne. I don’t remember what meeting it was, but she drove me to the airport to catch my plane home. That weekend had been difficult for me as I was struggling with some personal issue that I don’t even remember now and that I did not share with the group. To my knowledge it had been kept private. We arrived at the airport and unloaded my bag and as in the past embraced and said goodbye, but your mother hesitated an extra couple of seconds in letting go. She hugged me tightly for a moment longer than usual, and I will always remember her with a deep sense of affection for it. Standing there in the bustle of the airport, she communicated her sensitivity to my pain and let me know she knew and cared about it. It was a very healing moment for me and I will always love her for it. I tell you this story because it wasn’t just with me, it was with the world and everybody she came in contact with. She loved her family most of all and wanted to have and love you so greatly. She also loved her clients, her profession, and her colleagues.

It is hard to think about how much we will all miss our future years together. I prefer to think about how much I appreciate our time we did have as friends. She was very special and will long be remembered. Like the lighthouse there by your home she helped many of us find our way in the dark and safely manage our lives and the direction of our beloved profession. My deepest sympathy to you and Ed and the rest of your family.

Bob Ault
Topeka, KS

Dear Erika:

As I sit at my desk remembering your mother, I am aware of my sorrow and sense of loss. I am saddened by the loss of my personal relationship with Suzanne, of our annual dinners in Cambridge and our friendship. I also grieve the loss of a valued colleague, her professional support, and our frequent collaborations. Your mother and I had been planning a presentation on ethical issues related to art therapy and I was eagerly anticipating continuing our work together. However it will remain forever in the planning stage.

Suzanne and I often talked together on the phone. We discussed our profession, our work, and our teaching, but we also supported each other. Whenever I left a message, I knew she would respond as soon as she could. I last spoke to her over a year ago. We had an unspoken ritual of dining together on a day when Suzanne taught at Lesley. Although Suzanne had taken a leave of absence from the college due to her doctoral studies and internship, she called to say she would like to meet at an ethnic restaurant in Cambridge. We chose Passage to India in Porter Square. It never occurred to me that this would be the last time we would see each other. We discussed a paper she had written about ethical issues working with children, and she shared her newest picture of you, Erika, saying, “One is only a mother once; it’s a lifetime.” She told me what a great pleasure it was to see you growing up. She spoke of the importance of devoting quality time to you and your family, and described her search for a balance between mothering, family life, doctoral studies, an internship, and private practice. That evening, as at other times, I was touched by her modesty and care for others. These are my memories of that night at the Passage to India.

Suzanne was a role model for me in her commitment to excellence and caring. She was a leader in establishing the profession of art therapy. She gave visibility to art therapy in the Commonwealth of Massachusetts. Due to her perseverance, consistent lobbying, educating the public, and organizing various groups of creative arts therapists, the creative arts therapists in Massachusetts are now eligible to become Licensed Mental Health Counselors.

Suzanne always aimed for the highest quality in her work. As an adjunct faculty member at Lesley College in the Expressive Therapies Program, she influenced the training of future art therapists. Her rich knowledge and numerous resources were highly valued and appreciated by her students. Her clear and supportive teaching enabled them to approach and examine their work critically and with high standards. She was able to identify the potential strengths and abilities that each student and professional could bring to their work. Her effort, her caring, and her commitment to excellence in art therapy was always a source of inspiration. She taught me about the importance of maintaining high quality and avoiding mediocrity in our profession, while remaining caring and supportive. She was a role model and mentor for many of us in the field of art therapy, professionals as well as students.

Now when I walk by the Passage to India, I am reminded of Suzanne, of what she taught me and the importance of her legacy of excellence and commitment to the art therapy profession. I feel fortunate that I was able to know and work with Suzanne, that she touched my life. It is this—her spirit—that will stay with me. I am grateful that we were able to walk together on this life path for a while.

Mariagnese Cattaneo
Lesley College
Cambridge, MA

Dear Erika:

The last time we were together you were not yet two. Your mother and I strolled with you along the palisades in Santa Monica. It was a lovely day—no smog because a breeze was blowing in from the ocean. Sometimes you ran around and your mother had to chase after you and keep you safe; other times you were content to be in the stroller nibbling a treat. When you looked at your mother, you both laughed and gave each other “mommy/daughter” loving looks. By this age you were a “big girl” and to me, looked so much like your mother that it was “Little Suzanne” and “Big Suzanne” with whom I walked.

As always, your mother had delightful stories to tell about her travels with your Dad and the vacations they planned with you. There was no doubt that you were the best thing that ever happened and taking care of you was a joy.

I wish I had the ability to send you the colors of your mother. She wore soft silk clothes that often combined marvelous colors that contrasted with her pale skin and black hair. As with everything she did, her artistry was apparent.

I remember that same day I was so attracted to the perfume she was wearing. She told me it was Estée Lauder
"Knowing" and I rushed out and bought it. When I wear it I always feel that I am sharing the scent of Suzanne.

We didn't do much more than laugh that day. We went for coffee and a sweet and you weren't the least bit interested in our conversation. You visited lots of people in the restaurant, and many people remarked on your likeness to your mother and how lovely you both were. Your mother was very proud of you.

In the past I had visited your parents' home in Rockport when they lived on the big rock by the sea. I had come to give a class nearby, and it made the trip more fun staying with your parents. Your mother had hurt her back so we spent a good deal of time lying around and talking about therapy and life. It never was just the "usual" theory conversation. Suzanne had an inventive mind and ways of putting things together that made something new out of used ideas. She spoke a good deal about supervision, since we both do that, and how she cared about the students she taught and supervised. We also wandered off into stories of our families and children. That visit was before you were "and your mother told me how much she hoped to have a little girl. Shortly after that visit she called and told me how wonderful it was to be a grandmother.

In thinking about my time with your mother, I realize, Erika, that the time didn't count up to very many hours in relation to actual time spent, but her delightful spirit and brilliant mind impacted me more in those limited hours than longer time spent with others.

I first knew Suzanne when she was involved with education. Her efforts to bring form to a newly created committee that evaluated educational standards was a lasting contribution. She worked many extra hours to put together the basic manual and did so with the full cooperation of her committee. Suzanne was able to demonstrate her dedication to education in a manner that inspired others to emulate her vision to raise standards of training. She was honored with the Distinguished Service Award from the American Art Therapy Association for her efforts.

I hope when you read this that you do not imagine that I suggest you "be" your mother. Her greatest gift to her friends, and I imagine much more to you, was to respect and enjoy individuality and independent thinking. She would have wanted that for you, I believe. She was indeed a complete individual, a creative thinker, a person who could give and receive affection and understand laughter and tears. We miss her very much.

Fondly,
Shirley Riley
Los Angeles, CA

Dearest Erika,

Your mother was my beloved friend and I want to tell you about some of my memories of her.

First of all, she was always "Suzanne." She was never Sue or Susie or any other nickname. The completeness of her and her depth and seriousness as a person were reflected in her name. But she was not only serious. When I received my PhD, Suzanne gave me a pair of earrings as a gift. They are the most wonderful and silly earrings I own. (I would never have thought earrings could be silly, but these are.) I treasure them, because they remind me so of her. Like your mother, they have many apparently contradictory elements magically made into a work of art.

Each earring is an abstract bouncing human figure with a big head and beads for arms. Contradictory to the shape, the colors are subtle—blues and greens with a gold zig-zagged line, and they are textured with gold embossed lines. They remind me of your mother's many faceted temperament and her playfulness. Each time I wear them, someone tells me how beautiful or unusual they are (like she was). Each time I wear them, they bounce up and down on my ears and catch on my clothes or hair. So they are not easy earrings to wear—they demand and invite attention and interaction—they get me tangled up, delightfully; they make me laugh (like she did).

Suzanne's seriousness and intelligence were tempered by a highly sensitive pragmatism and informed by a commitment to action. She worked long, hard, and courageously to develop legislation in Massachusetts which included art therapists. For the American Art Therapy Association, she fought to shape documents and policies for educational programs which encouraged variety, creativity, and quality. In her years on the Education and Training Board, her honesty and fairness gave an integrity to a process which had sometimes been lacking. Her stamp will be felt in many ways on art therapy education for years to come.

She wanted always to learn more and to probe deeper in her understanding of people in order to be of more help to them—and just for the sheer pleasure of learning. Your mom learned from everything she did. (She could have learned from a rock!) This is what led her to take on studies toward a PhD in Psychology at the Fielding Institute, where I was also a student at the time. And then not long after she began Fielding, she was surprised by becoming pregnant with you.

I remember her as slim and angular in her jogging clothes, looking like a marathon runner. I remember her, after a trip to Baja California with your father, tanned and looking like a gypsy princess in an intense purple blouse, blue skirt, and huge hoop earrings. The very last time we were together, you were with us. As we ate our way through huge breakfasts at a restaurant by the Pacific Ocean, you sat in your high chair grinning and playing and occasionally banging spoons. You were a wonderful child, smiley and full of life—glowing in the California morning sun. Your mom looked at you with such delight and love. You gave her a tremendous amount of pleasure and she loved her exceptional daughter exceptionally.

I look forward to knowing you, Erika, through the years to come and telling you my stories about your lovely mother. (Come to California and we'll sit by the sea and chat endlessly.) I'll keep the earrings for when you're older—I'm saving them for you. And each time I take them out, I'll think about your mom and you and about how much she loved you. Keep in touch. (Feel free to call collect!)

Much love,
Maxine Junge
Los Angeles, CA
How Will the Profession of Art Therapy Change in the Next 25 Years? Responses by Past Award Winners

We Cannot Look into the Future, Without Considering the Past and Present

Edith Kramer, A.T.R., HLM

---

1916 Born, Vienna, Austria.
1934 Graduated from Realgymnasium, Vienna.
Attended art classes at the Kunstgewerbeschule in Vienna. Studied sculpture with Fritz Wotruba, Vienna, drawing and painting in Vienna and Prague with Friedl Dicker (Bauhaus, died 1944 at Auschwitz, attained posthumous recognition in Europe).
1938 Arrived as a refugee in the United States, citizenship 1944. Continued to pursue the practice of art in the United States.
1939-41 Art and shop teacher at the Little Red School House, New York City.
1943-44 Machinist during World War II.
1950-57 Initiated and conducted art therapy program at Wiltywick School for Boys, a residential treatment home for emotionally disturbed, culturally and economically deprived city children, ages 8-13.
1960-63 Initiated and conducted therapeutically oriented art program at the Leake and Watts Children's Home, Yonkers, NY (home for dependent children of both sexes, ages 7-17).
1965-74 Art therapist at the Albert Einstein College of Medicine, Dept. of Child Psychiatry.
1964-74 Art therapist at the Guild School of the Jewish Guild for the Blind, school for the blind and visually limited children who have learning and behavioral difficulties.
1974-78 Consultant in art therapy.
Participated in art therapy training programs from 1959 onwards.
At present, Adjunct Professor of Art Therapy at New York University and professorial lecturer of Art Therapy at George Washington University, Washington, DC.

Author of three books:
Art Therapy in a Children's Community
Charles C Thomas, 1958
Art as Therapy with Children
Schocken Books, 1971
Childhood and Art Therapy: Notes on Theory and Application
Schocken Books, 1979

One Woman Shows:
USA, Austria, Germany, Argentina, Sweden, Belgium

The pedagogic methods of the Bauhaus have been formative in the artist's development and remain an essential element of her understanding of the visual arts. However, her style has remained consistently representative. Personal expression remains subordinate to the task of interpreting the subject with respectful comprehension.

The Past

When I initiated my first art therapy program at the Wiltywick School for Boys in 1950, the profession did not exist, nor was any training available. However, Margaret Naumburg had already used the term.

As preparation for my task, I could count on experience as an art teacher, as well as the Freudian psychoanalysis I had completed. Formative for my understanding of art, children, and psychotherapy was my acquaintance with ideas burgeoning in the Vienna of my youth. Working with the blind, Victor Lowenfeld was developing theories on child development in art and on ways of fostering children's sense of self. Fredrick Itten (later at the Bauhaus) was training artists. Anna Freud, August Aichhorn, Erik Erikson and others were practicing psychoanalytically oriented childcare, education, psychotherapy, and social work. I integrated these concepts with the informal training which came to me on the job. As I attended case conferences and rounds, my comprehension of my own work and of my function within the team was broadened. I formed concepts that constituted the foundation for ideas I subsequently developed. I published my first book in 1958 and taught my first course in art therapy in 1959. In course of time, my understanding was enriched by interacting with a growing body of practitioners, who had also come to the field without formal training. All of us were ill-paid and looked upon as somewhat suspect newcomers in the field of social services.
The Present

Now, in 1994, art therapy is an established profession. Universities, institutes, and clinical settings offer training on a graduate level. It is possible to obtain a doctorate in art therapy. Income from the profession, although still low, has risen. Membership with the American Art Therapy Association (AATA) is constantly increasing. The areas in which art therapy are practiced, and the populations it serves are broadening.

It seems to me that the advent and growth of art therapy is linked to the absence of art in daily life, in our industrialized society. A sense of emptiness, a hidden hunger, makes people ready to respond to art therapy when offered in the artificial milieu which society (grudgingly) provides for its severely troubled members. However, the sterility which pervades society does not halt at the doors of such institutions. Increasingly, art therapists are forced to comply with conditions inimical to art—short-term treatment, reliance on drugs. Art therapy is often considered not as an aid to individual treatment, but as a substitute for it; this limits and diminishes our work.

The Precarious Future

It is tempting to see in the achievements of the past only prospects for a bright, expansive future. But we cannot divorce the destiny of art therapy from the fate of society as a whole. We see our world poised between the road to disaster, through environmental destruction, and depersonalization of work and life, and the concomitant disintegration of the social fabric, and hope for the reversal of those trends. We hope that the industrial juggernaut will be tamed and made to serve mankind instead of destroying it.

Even today, the practice of art therapy is stultified by the limitations of a shortsighted revolving door policy, bent on reducing symptoms rather than effecting inner change. Concomitant demands to devise day-by-day treatment goals threaten to blind art therapists to the surprises inherent in making art, to finding unforeseen strengths, talents, buried troubles, unexpected solutions. The check-off lists many practitioners are required to follow lack provision for recording the essence of psychotherapy. This entails periods of increased vulnerability, periods of rebellion, and times of chaotic turmoil heralding inner change. If the present trends continue, if art therapy which belongs to the humanities is made to conform to a narrow medical model, I foresee increasing de-vitalization and the loss of art in art therapy.

However, there are hopeful signs. Experiments with half-way houses and therapeutic communities show that society may finally be ready to realize that there are large numbers of individuals who need sheltered environments for very long periods or permanently, so that they may live a dignified and productive life even though their psychic organization remains fragile and subject to breakdown. In such environments art therapy can have an essential cohesive function.

The rise of holistic medicine gives hope that there will be doctors ready to combine the vast resources of modern medicine with individual care.

Neither art nor art therapy can be midwife to society. The fate of our profession depends on forces beyond our control. Within our narrow field, however, we must be valiant. The necessity to establish art therapy as a respected treatment modality inevitably entails adjustment, even compromises. However, we must not lose our identity. As we fight for recognition, we must uphold the laws inherent in making art. Art needs space for improvisation, openness to the unexpected, acceptance of the eccentric. Artists are more often than not somewhat odd individuals. Let's strive to become respected and employable mavericks! As we lecture, write, and discuss our work, let's avoid therapeutism. Let's speak plain English.

I greatly hope that part-time jobs will become the rule in the future so that art therapists will not have to sacrifice their own art making as they serve others.

I expect that art therapists will increasingly engage in research. I am gratified to find that the colleagues who are at present so engaged are striving to include the elusive factor of quality in their thinking.

Konrad Lorenz writes that ethologists are always gratified when they can find behavior that can be counted. But before one begins to count, he cautions, one must have studied the total life cycle, the instinctual endowment, the environment, and all behaviors available to the species under observation. In the absence of this information, one does not know what one is counting. Let's keep this in mind as we investigate that mysterious human behavior of making art.

Where Will Art Therapy Be as a Profession 25 Years from Now?

Cay Drachnik, MA, ATR, MFCC, HLM

Cay Drachnik was a past president of the American Art Therapy Association (AATA) and served on AATA’s Boards for Governmental Affairs, Standards, Ethics and Professional Practice, Long Range Planning, and Nominating Committees. As a founder and charter member, vice president, and honorary member of Northern California Art Therapy Association, she served as its legislative representative for four years.
Cay was also a founder and charter member of the California Coalition of Creative Art Therapists.

Cay obtained a BS from the University of Maryland, and graduated with honors. She holds a California Art Teaching Certificate and an MA in Art, with emphasis in Art Therapy, from California State University, Sacramento, California (CSUS). Cay assisted Don Uhl, PhD, A.T.R., in founding the art therapy program at CSUS and taught art therapy courses at CSUS and at University of Utah. Currently she is on the staff of the College of Notre Dame, Belmont, California.

Cay was appointed by Governor Reagan in 1975 to the State of California Health Facilities Advisory Board where she helped draft regulations for all the licensed health facilities in the state, while protecting regulations concerning art therapy. She worked on licensing for art therapists in California and she, Honey Rawlinson, and Bobbi Stoll (current president of AATA) were the first three art therapists to be licensed as MFCC's in California.

Cay worked as a clinician at Psych West Counseling Center for 18 years until county funding was cut and the clinic closed June 31, 1993. She supervised students, worked in private practice, and consulted with schools and agencies in the Sacramento area. She has lectured widely, written about art therapy, and her manual, "Interpreting Symbols in Children's Drawings," is to be published in 1994. Currently, she is consulting in art therapy and winning awards for her watercolor paintings. She is listed in a number of "Who's Who," among them, "Who's Who in the World" and "Who's Who Among Human Services Professionals."

I was not one of art therapy's founding mothers; however, I did enter the field early-on and have devoted a great many years to my chosen profession. As I have watched our field grow, I have been proud of our progress, but at the same time I have been concerned about its future.

I believe that 25 years from now art therapy will either have ceased to exist as a separate profession or it will be an even more vital, exciting, and dynamically functioning profession. It will depend on how progressive our leadership is and how hard we, the members of the AATA, are willing to work to keep our organization on track. It also depends on how smart we are politically and especially how we, as members of the organization, work together.

I feel we have some especially far-thinking, brilliant, and talented members and that we are doing the right things, but we are not doing them fast enough. With national health care breathing down our necks, we should by this time have our certification examinations in place. Yet there were some members of our organization who saw no reason to speed up this process. I realize that changes should not be made hastily, and our membership should be educated about new proposals, but to set no time limit for implementing important policy changes means that we may be left behind in the end. Credentials, I believe, are vital to our survival. It gives credence to our educational programs and demonstrates to other health professionals and legislators our competency to practice.

Another roadblock to survival is numbers. We have only about 4,000 members, while other health professionals have organizations with 30, 40, and 50,000 members. For about 14 years, the AATA has been associated with the National Coalition of Arts Therapists Associations (NCATA), composed of dance, drama, and poetry therapists. One problem with that group was that we had different levels of terminal education. Dance and art require a masters degree, while music requires only a BA. Poetry and drama function more or less as modalities, their members having mostly degrees in related mental health fields but additional coursework is usually done in drama or poetry. There we are, to my knowledge, no masters degrees in poetry or drama therapy. Supposedly, we were to work together on legislative issues, and for a while, we did. Together, we had 10,000 members which we thought would make an impact.

However, the Coalition began to fall apart when, in 1991, the National Association of Music Therapists mounted an independent movement of its own. When writing about the coalitions in the Fall 1993 AATA Newsletter, Bobbie Stoll (our current president) stated, "There seems to be ongoing distrust of, or at least resistance to, full cooperation and collaboration. . . ." She goes on to say, "It will be time for the AATA to very seriously evaluate our investment versus the value received. . . ."

I personally feel that the time has come to leave the NCATA and to explore going under the protective umbrella of the American Association of Alcoholics, which has approximately 60,000 members, is located in Alexandria, Virginia (the outskirts of Washington, D.C.), and has a number of divergent counseling groups, such as vocational counselors and rehabilitation counselors associated with it. It has experienced lobbyists, and with its large membership, a far more powerful voice in Congress than the 10,000-strong NCATA. Also, we already have some common ground with this group. In states where art therapy is considered an equivalent degree by licensing laws, art therapists are usually licensed as counselors. The exceptions are in New Mexico, where art therapy is listed as a degree title under a generic licensing bill, and California, where art therapists can be licensed as Marriage and Family Counselors, but only if they complete all the required courses for marriage and family counseling. The American Association of Marriage and Family Therapists made it quite clear to us during our struggles in California that they did not want art therapy listed as a degree title under their licensing law. Historically, I should point out that art therapy, along with at least a dozen other degree titles, were considered equivalent degrees and were allowed to take the California MFCC licensing exam until 1985. Then, most of the degree titles were legislatively eliminated. This could happen in all other states where art therapy currently is listed as an equivalent degree. There was no counseling or generic counseling licensing law in California at that time, so art therapists had no other option if they wanted the benefit of a license.

While I was president of the AATA, Linda Gantt, Ed Stygar, and I went to Alexandria, Virginia, and explored with the American Association of Counselors the idea of joining their association. At that time they welcomed us. But there were certain disadvantages, such as setting up our national office in Alexandria under their auspices, and, also, at the time we were already committed to NCATA. However, we felt this alliance should be looked into at a later date.

I now feel this later date has arrived. Many art therapists

1719
work as counselors, but many also work as activity therapists in hospitals or other facilities. However, many activity therapists would like to eventually be in private practice and receive reimbursement from HMOs, PPOs, or whatever the new health plan would designate. Now, in most states, only licensed therapists may receive such reimbursement. We, as art therapists, need to be included in the new health plan and we will need reimbursement, otherwise others, less knowledgeable in art therapy will be taking over our jobs. If we have a powerful organization such as the American Association of Counselors behind us and an examination to demonstrate our competency, then licensing in all states should be available to art therapists.

With such a scenario, I most certainly see art therapists and our organization thriving 25 years from now. We will be serving those that need us—especially the children of this world. We have something unique that we know works, and we must see that it continues to benefit mankind.

Art Therapy in the 21st Century

Frances E. Anderson is a founding member of both the American and Illinois Art Therapy Associations, the first AATA Regional Standards Chairperson for the Midwest, and has served on numerous AATA committees over the past 25 years. A member of the committee that founded Art Therapy: Journal of the American Art Therapy Association, she has served on its Editorial Board since its inception in 1983. In 1992, as publications chair, she oversaw the publication of AATA's first monograph: A Guide to Conducting Art Therapy Research. She has just completed six years of service on the Education and Training Board.

She received her BA degree in Art and Psychology from Agnes Scott College, Decatur, Georgia, and her Master's and Doctoral degrees in Ceramic and Art Education from Indiana University, Bloomington, Indiana. Dr. Anderson taught ceramics and craft design at the University of Tennessee, Knoxville, prior to joining the Art Department faculty at Illinois State University in 1970. She has authored 40 articles, three chapters for books, 11 monographs, and eight books. In 1991, Dr. Anderson was the 16th faculty member in the history of Illinois State University to be named Distinguished Professor.

Dr. Anderson has participated in 22 AATA national conferences and has given 12 keynote addresses at related conferences here and overseas, as well as participating in over 200 workshops, panel discussions, and presentations. An exhibiting ceramic artist and photographer, her artwork is represented in galleries and collections throughout the United States and in Australia and China. Dr. Anderson has been a Visiting professor at the University of Illinois; the University of Arizona; Boston University, College of Notre Dame; Bunting Institute of Radcliffe College (Harvard University); the University of Texas, Austin; Burwood College, Melbourne, Australia; and Florida State University. She also teaches courses for five graduate art therapy training programs around the country.

For the past 25 years, Dr. Anderson has worked with children with disabilities. In 1978, based on this clinical work with children, she published Art for All the Children, with a second edition of this seminal work published in 1992. Early this year, her eighth book, Art-Centered Education and Therapy for Children with Disabilities was published by Charles C Thomas.

Dr. Anderson also has had 35 grants funded including, most recently, five grants that have supported her work with incest survivors including a newly completed, year-long outcome study of using art therapy in the treatment of incest survivors. Two grants from the Illinois Arts Council have supported both the publication of a monograph (Courage! Together We Heal) and a videotape documenting her approach to the treatment of incest survivors. One of the outcomes of these grants has been the production of several clay murals composed of messages of terror, rage, and hope from the clients.

There are trends and issues today which will greatly impact on art therapy in the next century. I want to identify these issues and make a case for addressing them now because if we do not, the field of art therapy will be substantially diminished in the future.

Need to Affiliatethe Other Professional Mental Health Associations

The membership of AATA is about 4,000, a very small number. We need to form strong coalitions with other related professional organizations. One of the largest groups that offers such an arrangement is the American Counseling Association. This group permits affiliations with other groups while allowing each group to maintain their own identity and autonomy. This and other similar affiliations may well be one of the only ways that art therapy can acquire the political clout needed to survive in the 21st century.

Expanded Job Opportunities

Today, the two largest employers of art therapists are the Miami, Dade County Public schools, which employ 15 art
therapists, and Napa State Hospital in Sonoma, California, where 14 art therapists are employed. I predict that the trend toward greater employment of art therapists will continue (in spite of the current money crunch). The public schools will continue to be inundated with children with serious emotional disturbances. The numbers of children with fetal alcohol syndrome and with addiction to crack and other drugs will continue to increase. Already public schools are struggling to deal with students with all kinds of disabilities. A part of this struggle surrounds a growing trend in special education called inclusion (Anderson, 1994). Inclusion advocates the placement of all children, regardless of the nature or severity of their disability, into regular education classrooms. Special services for these children will be provided by special consultants. If the schools do not already have art therapists on staff, art therapists could become one of the groups of consultants needed to provide educational services.

Now is the time to demonstrate to special educators at all levels the benefits that art therapy offers not only children with emotional and behavior problems, but all children with disabilities. And how can this be done? One way is to lobby for a special classification category at the state level so that students trained as art therapists do not also have to have a state-issued teachers certificate before they can work in public schools. Occupational, physical, and speech therapists already have this special designation. It is time for art therapists to be so designated.

Documentation/Justification of Art Therapy

We need research that documents what we as art therapists know about the power of art to heal, motivate, and remediate the emotional, physical, and educational problems of children with disabilities. To generate this kind of research we need to address the issue of providing the skills so that art therapists can conduct this research. This research must include other methodologies besides the case study method. Further, art therapists need the skills to comprehend, critique, and analyze research done in related fields that can enhance our field. In 1981, Very Special Arts in Washington, D.C. invited me to conduct the first comprehensive literature review of all the published studies in all the arts for children with disabilities (Anderson, Ash, & Gamback, 1982). We examined over 400,000 articles and identified 53 studies that met the project criteria (studies that were experimental and resulted in hard data). Of this number, 19 were visual arts studies. In 1983, I analyzed these studies and noted some of the issues that art therapy needed to address (Anderson, 1983).

Art therapists believe strongly that art is a major means of treatment. The profession must document this belief in terms that laypersons and scholars from other disciplines can understand and accept. If art therapists lack the research skills and training to do this kind of investigation, then it is important that they acquire this expertise or interest scholars and researchers from other disciplines in collaboration with them to do the needed research. (Anderson, 1981)

There is also a gap in systematic research in most studies being undertaken in art therapy. This research is necessary to provide standardized information for building the knowledge base of art therapy and for replication of important studies. With this need in mind it is interesting to note that the most widely used form of research reporting, the case study, has no generally accepted, systematic format for conveying information...

Well, we are not yet there. For the past two years I have been engaged in updating this literature review to cover the period between 1981 and 1992. A perusal of over 400,000 articles in the ERIC and PsycInfo Data bases (and hand searches of journals) have identified 60 studies in the visual arts which met the criteria of empirical research resulting in hard data (Anderson, Kolano, & de la Cruz, 1993). There were only five reports which could be considered outcome studies documenting the benefits of art therapy. One of the largest groupings of studies was on projective drawing techniques. This body of research shared many of the problems identified by Neale & Rosal (1993) in their analysis of 17 studies on projective drawing techniques with children. They noted a failure of many of these studies to cite related research, the inconsistent reporting of criteria used, and too often inadequate reporting of statistical analyses of the data. Six of the 17 studies were authored or co-authored by art therapists. So, although other researchers also are remiss in their reporting, this does not exonerate our field.

What concerns me is that some research is being done in a largely naive manner without solid research training. For example, the field needs valid and reliable art-based assessments. But before art therapists go out and reinvent the wheel, we must be aware of what has already been done not only in our field but in related fields of psychology, art education, anthropology, medicine, sociology, and criminal justice. We also need to have an understanding of psychological assessments, including statistical knowledge and a thorough comprehension of how assessment instruments are constructed, field tested, and refined (i.e., made reliable and valid). To date, our field has not adequately addressed this problem partly because many of our educational programs do not place a priority on this type of training, and partly because so many other areas need to be addressed in a Master's level course of study.

Without an understanding of both qualitative and quantitative research methodologies, art therapists cannot fully understand those research studies that employ such methodologies. Therefore, the possibility exists that the research conducted in art therapy may indeed be "reinventing the wheel," instead of building on work that has already been done. I am not advocating that art therapists be research experts. I am advocating that art therapists be trained sufficiently in a range of research methodologies (including basic statistics and psychology of assessments) so that they can cogently read the literature both in art therapy and in related fields.

If we cannot justify what we do in a systematic way using a variety of research methodologies, then our future as a profession is not very bright. The way art therapy will be healthy and thriving in the 21st century will be intimately tied to this justification question. We believe in what we do—but that may not be enough because we are often funded by agencies.
and enterprises that will demand more evidence than a strong belief in the art therapy process.

References

Recognized worldwide for her contributions to the field of mental health, Helen has been invited to lecture and give paper-presentations in a large number of countries. Her biography appears in over 40 national and international "Who's Who" directories.

The following books are among her long list of publications: Family Art Psychotherapy: A Clinical Guide and Casebook (1987); Clinical Art Therapy: A Comprehensive Guide (1981); Adult Art Psychotherapy: Issues and Applications (1990), co-editor and chapter author on "Termination." These books have been translated into numerous foreign languages. Her current book, Magazine Photo Collage: A Multicultural Assessment and Treatment Technique (1993), has been applauded by therapists from the Asian, Black, Caucasian, and Hispanic cultures. According to Chester Pierce, MD from Harvard Graduate School of Education, it is "well suited for conducting research that should enhance racial amity."

Helen’s paintings, sculptures, and etchings have been exhibited in museums and galleries throughout the country. Aside from lecturing, she continues to contribute chapters on art therapy, most recently for the Handbook of Child Psychiatry and Family Play Therapy. Landgarten continues to paint and writes fictional short stories for relaxation.

My predictions for art therapy in the next century are contingent upon continued quality Master’s degree programs. However, during the 21st century, our profession will blossom because in this century we have prepared fertile ground for future growth. In many states art therapists have planted their seeds in every type of institution that is concerned with individuals’ mental health.

I predict that in the future the government will realize that the early prevention of problems is more economical than eventually working with people in clinics and hospitals to solve problems. Already, art therapy has been instituted in a number of public school systems. In the future, the federal government will mandate that art therapy be placed in all the public schools, from elementary through high schools, since, in relation to purely verbal therapy, it is less threatening and less stereotyping for the children who attend.

Art therapists have always been able to acclimate their skills to treat whatever diagnosis is currently popular. For instance, during the last 10 years a great deal of attention has been paid to the following diagnoses: post traumatic disorder, drug and alcohol abuse, anorexia nervosa and bulimia nervosa. Recently, the limelight has been on multiple personality disorder, sexual abuse, and attention deficit disorder. As time goes on people in our profession will continue to adjust their practice to "new" or "renewed" disorders as they take center stage.

Outpatient work in clinics and private practice will grow in strength. We now have a collection of worthwhile publications that educate practitioners from various related fields. At one time, clinicians from other disciplines were leery of "those art therapists," where now, we are frequently embraced.

 medically related work will thrive because the health care providers will find it economically sound. They will see that art therapy, combined with a physician's treatment, will reduce the recidivation rate. Further, the current trend toward "outpatient surgery" will undoubtedly continue leaving
some patients feeling neglected if they believe their recovery should take place inside the hospital. For such patients, a set of art therapy sessions would help to prevent them from feeling abandoned and encourage a more positive attitude toward regaining their health.

There are many innovative and current surgeries such as organ transplants and lengthening limbs of dwarfs that result in dramatic body changes. In such cases patients should receive art therapy because their mental adjustment to a new body image is essential. Although some surgeons may not want their patients treated by a therapist, they are beginning to see that without this dimension, the physical results of surgery may be a success, but the patients' postsurgery disappointments and depression may hold them back from enjoying their positive physical results. Along these medical lines, pain centers will use far more art therapists in the future. Insurance companies will recognize that helping persons cope with pain through art therapy is cost-effective because repeated doctor visits will lessen.

Alternative medicine is slowly, but continually, gaining more ground, and in the 21st century, it is possible that it will become an accepted and standardized mode of treatment. Art therapists who already are engaged in this philosophy will be at a premium.

Court evidence regarding art products is beginning to be recognized. Numerous art therapists (in different states) are testifying as "expert witnesses." The utilization of these services by lawyers will increase.

The health care providers will recognize that it is cheaper for them to pay for family art therapy (when appropriate) than to treat each family member individually. Art therapists trained in this direction will find that their private practice is vastly increased.

There will be a continuance of group therapy, since this modality is cost-effective. The popularity of thematic treatment that deals with people who suffer like-symptoms or like- circumstances will increase. In the 21st century, as the world experiences new types of illnesses, lifestyles, and traumatic events, art therapy will flourish because it can be catered to fit into any type of future caseloads.

Currently in the 1990s, a big search is on for the "inner child." In the late 1990s, undoubtedly the hunt to find the "adolescent" will be popular. During the next century, art therapists in private practice will be doing their part to help people finally grow up and gain greater satisfaction from life by climbing into adulthood." These art therapists will give their clients "hope," by encouraging them to give up past expectations and grief, not from real losses, but from what was lost in their fantasies. The slate will be wiped clean. Clients will begin therapy by drawing what is both positive and possible for their life from now on. Therapists will help clients look for, and examine, their positive role models in order to be motivated and to integrate some of these characteristics into their realm of being. As someone once said, "if you don’t have a dream, then how can it come true?" I would like to alter that to, "if you don’t have a good role model, then how do you know how to aspire to a greater life."

Art therapists who adhere only to the Freudian, Jungian, Adlerian, or any other theory will find that they will fuse these schools of thought to match the needs of the times. The hardcore clinicians who refuse to advance and stay loyal to their ancient theories will become therapeutic dinosaurs. Already changes are taking place; for instance, the therapy word "eclectic" originally had a pejorative flavor. It was believed that art therapists, who indulged in a combination of theories did not have a solid psychological frame of reference and, thus, resorted to treating their clients in a variety of ways. However, the word "eclectic" has been replaced by "integrative," and is accepted as a means of treatment.

Now, in the 1990s our profession is appearing everywhere as an accepted means of treatment. Art therapy has been recognized by the media; it is often discussed in the newspapers across the country and on television newscasts as a crisis intervention mechanism, and as a diagnostic and healing instrument. A number of movies both in the theaters and on videotapes show a protagonist in the art therapy process. I have discovered our work in novels; even the soap opera, Santa Barbara, displayed the books "Clinical Art Therapy" as a prop on a doctor’s desk.

Pessimistic art therapists are our most serious enemy because their negative attitude is a self-fulfilling prophesy. They should not be allowed to contaminate our future in the 21st century.

I am optimistic about our profession; for what we have sown in this century will be reaped in the next century. Art therapists, THE BEST IS YET TO COME.

To Be or Not To Be

Myra F. Levick, PhD, A.T.R., HLM

Myra F. Levick postponed pursuing her own art career education to work while her husband, Leonard, was in medical school. In 1959, when their third and youngest daughter was in second grade, her husband encouraged her to resume her studies. She obtained a Bachelor of Fine Arts degree from Moore College of Art in Philadelphia. While planning to continue graduate study for a Master’s degree in the History of Art, Dr. Levick became intrigued by the idea of working in the psychiatric unit at the Albert Einstein Medical Center, a
general hospital in Philadelphia. The late Dr. Morris Gold-
man was the director of this unit, the first unlocked ward in a
general hospital, and was convinced of the value of having an
artist work with mentally ill patients. While Dr. Levick em-
ployed her art skills in working with the patients, she also
studied psychiatry and psychology, obtaining a Master’s de-
gree in Educational Psychology (MEd) from Temple Univer-
sity in Philadelphia.

During 1963 and 1967, Dr. Levick, Dr. Goldman, and
Dr. Paul J. Fink, a psychanalyst on the Einstein staff, pub-
lished journal articles about their experiences in art therapy,
stimulating the interests of art students, art teachers, and
practicing artists in the area to pursue training in this grow-
ning field. In 1967 Dr. Fink, then director of education in
the Department of Psychiatry at Hahnemann Medical College
& Hospital, and Dr. Goldman, then director of the Hahnemann
Mental Health Community Center, received approval for de-
veloping a graduate art therapy program in that institution.
Dr. Levick was invited to join the staff, develop a course out-
line, and coordinate this first graduate program in art ther-
apy, actively training students in didactic and clinical work.

Attracting the interest of practicing art therapists all
over the country, a guest lecture series was sponsored by
Hahnemann in 1968. This led to the establishment of an ad-
hoc committee to form the American Art Therapy Associ-
ation. In 1969, in Louisville, Kentucky, the AATA became a fact and
Dr. Levick was elected its first president. She continued to
broaden her knowledge, studying family and group psycho-
therapy while continuing her academic position and private
clinical practice. In 1974, she became a licensed psychologist
to practice art psychotherapy in Pennsylvania.

In 1976, Dr. Levick was asked to design and coordinate a
program at Hahnemann to provide training for art, dance/
movement, and music therapists. Initially supported by a
three-year grant from the National Institutes of Mental
Health, this became the model program for training creative
arts therapists together in a graduate program within a med-
ical school. Dr. Levick was named director of the program,
the Master’s Creative Arts in Therapy Program (MCAT), and
became a professor in the Department of Mental Health Sci-
ences and in the medical college.

In 1982 Dr. Levick earned a PhD in education and child
development from Bryn Mawr College in Pennsylvania. In
1984, she resigned from her position as director of the MCAT
program to continue writing, and in 1986 retired, maintain-
ing her current position as professor and consultant to the
program. Dr. Levick published numerous articles in journals
here and abroad and wrote two books, They Could Not Talk
And So They Drew (1983) and Mommy, Daddy, Look What
I’m Saying (1986). She is editor-in-chief emeritus of Arts in
Psychotherapy, an international journal.

She now lives with her husband in Boca Raton, Florida,
where, in December 1993 they celebrated their 50th wedding
anniversary. Enjoying the freedom to paint again, she also
continues to write, lecture, maintain a small private practice
and teach psychology for the New York Institute of Tech-
nology on the Lynn University campus in Boca Raton.

Twenty-five years ago the American Art Therapy Asso-
ciation was born. And I was one of the midwives. As the associa-
tion grew, this initial role became broadened to include posi-
tions on the Executive Board, from president down, and
subsequently serving on several committees. Given this long-
standing relationship, I was naturally very pleased to receive
Cathy Malchiodi’s invitation to write a response to her ques-
tion “How Will the Profession of Art Therapy Change in the
Next 25 Years—What Is Your Vision of the 21st Century Art
Therapist?” I am still pleased to have this opportunity, but as
I began to formulate my answer, the realization dawned on
me that this is really two questions. As you will see, these two
questions evoke more questions. I consider it nearly impossi-
ble to even suggest how the profession will change over the
next quarter of a century. And the vision I have for the next
century, at this point in time, remains a wish. So faced with
these ambiguities and limited space to cogitate about them, I
focus this presentation on the training of the art therapist as I
see it now, and how that impacts on the role of the art ther-
past in the field of mental health now and in the future.

The view that we maintain “quality in training” (Levick,
1978, 1989) is by no means mine alone. There are so many
professional art therapists who are strong advocates for high
standards of training and practice. Again and again the officers
and directors of the AATA have revised our standards for
practice and approval procedures for programs. A Master’s
degree will soon be a requirement for new professional mem-
bership. We have a Credentials Board working toward na-
tional certification. But the problem arises from the inter-
pretation of those “high standards of training and practice.”
Directors of training programs may meet the criteria for ap-
proval. Their course offerings and supervised clinical hours
appear to be consistent with the requirements of the Edu-
cation and Training Board.

But there is no consistency! Before you incur umbrage at
my statement, I ask for your patience. Bear with me a little
longer as I give evidence, not criticism, of how our diversity
has fragmented our image. We meet and we do not speak the
same language. How is this possible?

Looking back, I recognize my own readiness to contrib-
ute to the current state of our profession. With other mid-
wives and subsequent caretakers, I strongly supported the
need for different orientations to make our child strong. That
child has grown and multiplied and in some ways bears no re-
similarity to the original conceptualization of the nascent art
therapist. Art therapists who, regardless of orientation, see
themselves as “professionals, regardless of license or ability to
prescribe medicine, having the same moral obligations to the
people we treat as any professional in the field of mental
health” (Levick, 1979, 1989). Above, I noted we often speak a
different language; I was confronted with this contretemps
several years ago while working on a project with Janet Bush,
Director of the Clinical Art Therapy program at Dade County
school system. In another paper, (Levick, 1989) I discuss this
project in some detail. For here, let me say briefly, Janet was
charged with developing an art therapy evaluation instrument
for the then 11 art therapists on her staff. She engaged me as
the consultant to this project, using my work on cognitive and
emotional indicators manifested in children’s drawings as a
basis for what is now known as the Levick Emotional & Cog-
itive Art Therapy Assessment (Levick et al., 1989). It was
only a few short months before we realized that to move for-
ward, we needed to retreat and teach the staff a theoretical
construct only a few were even a little familiar with. It is
important to report that in doing this we emerged as a small
cadre of highly trained art therapists, not only able to speak
the same language, but also able to communicate this knowl-
edge to colleagues from different disciplines in the school sys-
tem.

There are many examples that could be cited to describe
where, what was at first glance a difference in orientation, is
in fact a fragmentation of a singular concept. I have come to
know the many faces of art therapy in practice. But now there
are new faces that, in addition to speaking differently, bear
little resemblance to the images I know of art therapy as a
therapeutic process in mental health. Nowhere have I felt this
more acutely than at the AATA conference in Atlanta.

The theme of the conference was "Common Ground, the
Arts, Therapy, Spirituality." This immediately suggests to me
that there is a question regarding the relationship between
the arts and therapy and something else, spirituality, that
heretofore had not been identified in the process of art ther-
apy. I had naively believed that after 24 years, we recognized
that art as therapy and art in therapy were equally valid ap-
proaches insofar as the needs of our patients were met. And
this raises another question. Are we training our students to
recognize the needs of our patients? Some of what I saw and
heard in Atlanta appeared to meet and gratify the needs of
the therapist, not the patient. But now another separation ap-
pears on the horizon, with yet another dimension to incorpo-
rate. The very compellation of our field, art therapy, signifies
an irreproachable relationship between the arts and therapy.
Yet, there are those among us who would add something else,
abstract and highly personal, when we are still unable to
take together on basic theoretical constructs. In looking at
the AATA program in Atlanta, it is interesting to see that
some presenters totally ignored the theme, discussing familiar
topics in old and new ways, while others totally embraced it
in an ingenuous form, an artless form, or instinctive form.
This dichotomy continues to reinforce the division in our
ranks.

But the most revealing and disturbing experience for me
was listening to our keynote speaker, James Hillman, and
then leading a discussion group on his presentation. Hillman
is brilliant, provocative, and curiously ambivalent about his
own teachings. It is not the intent here to critically review
Dr. Hillman's words, but rather to try to convey his message
and the impact it had on many who heard him. Because of my
role as a discussion leader, I took copious notes. While what I
refer to is obviously taken out of context, I make every effort
to maintain the spirit of his speech. On the one hand he spoke eloquently of the difference between criticism of art:
versus the interpretation of art; Plato versus Freud. We all
agreed he did not approve of looking at art and translating
what's there into what is not there. His discussion of good
form in art reflecting that the artist was in good shape and
that this is the primary task of the soul was esoteric and some-
times difficult to follow. But the message was clear—inter-
pretations, vis à vis art therapy, is not acceptable. This was
not fair. Responsible art therapists do not interpret artwork.
They make connections and facilitate their patients to make
these interpretations, if that is the goal for that patient. And
in the middle of these dynamically presented maxims was the
statement that, consistent with the medical model he decri-
ated, we retain the title of therapist for ourselves and pa-
tient for the people we work with. He treats "patients" who
are suffering and have pathology. He sees the title "client" as
a power word (Hillman, 1993).

I presume James Hillman was invited because he is a
well-known, controversial figure, into soul, and suggests we
hold on to some piece of the medical model that helps us
identify ourselves, while engaging in a therapeutic process
that releases "imaginative possibilities" (Hillman, 1993). And
most of the people that heard him were awed and inspired.
When I asked how we could translate what he said into prac-
tical application, the impression was that all one needed to do
was "listen to the paintings." Psychotherapy as a basis for art
therapy was definitely out. And there were other presenta-
tions that awed and inspired the younger people that were
present. They were titillated by ideas that have little to do
with the practice of art therapy. These ideas are magical and
mystical and spiritual. They distort our identity and confuse
our colleagues from other disciplines in mental health. THEY
CAST SUSPICION ON OUR PROFESSIONAL INTEG-
RITY.

We are not alone in this search for identity. Psychiatry as
a field and psychiatrists have been struggling to redefine their
problems and reconceptualize their domain in mental health
(Michaels & Marzuk, 1993). In the conclusion of two lengthy
articles on Progress in Psychiatry, Michaels and Marzuk refer
to psychiatry as "the battered child of medicine, born in
witchcraft and demoniacal possession." They go on to say "the
battered child has been transformed by a tumultuous adoles-
cence into a vigorous and successful young adult" (Michaels
& Marzuk, 1993). In 1974, I gave the commencement speech
to the first graduating class of art therapists at Eastern Vir-
ginia Medical School. For that speech I wrote an analogy of
the training of art therapists to the first six stages of man from
the Eight Stages of Man developed by Erik Erikson (Levick,
1977). In the 6th stage, intimacy and solidarity versus a sense
of isolation, I consider the graduating art therapist in the
adult stage professionally, having survived the preceding cha-
otic period (of adolescence in training) and the search for
identity as an art therapist.

At age 25, like the psychiatrists, art therapists are young
adults. But as for all young adults, that is just the beginning.
How will the profession of art therapy change in the next 25
years? The answer is the reader's response to my question:
Are we to be or not to be art therapists? To be, we must truly
become adults. We must take professional responsibility for
reconceptualizing our role in the field of mental health. We
must redefine our training objectives, learn a common lan-
guage, and require accountability of our members. From this
sound structure, we must build unique and individual styles
of treatment. My hoped-for vision of the 21st century art
therapist is that of a respected member of the professional
force who treats those young and old individuals in society
suffering from some form of mental illness, and who respects
the creativity in each of us.

1725
Art Therapy in the 21st Century

Shirley Riley, MA, A.T.R., MFCC, Recipient of the 1990 Clinician Award for Family Services

A long time ago, as starts all the fables, I was my parents' daughter, my husband's wife, and my children's mother. That was the baseline of my life. Then life did interesting things to me. One of my sons was born disabled, and so I became an expert on disabilities and how to raise money to help their causes. When my other sons grew up, demonstrated fine abilities and, in due time, the capacity to find wonderful mates, my status shifted in our relationships. My marriage endured the many changes of a long-term relationship and gave me freedom to find a different view of myself as a woman. My art education at UCLA continued to stimulate my need to make art, but it was not enough.

So one day I took daughter, mother, wife, artist, fundraiser, and educator of the disabled into a new arena—that of student. This arena was one that seemed to make all those women happy and able to engage in a kind of art that I had always wanted to produce and which never reached my critical standards. I became an art therapist.

Clinical work became my fascination, teaching and supervising clinical art therapy students became my pleasure, and arranging internship placements satisfied my curiosity about how the world worked with people needing mental health assistance. Therapy felt like the most creative process I ever experienced.

Along the way my clients helped me make theory real, colleagues challenged my notions about therapy, and students made me think more carefully about the field of art therapy. Being involved with the American Art Therapy Association gave me the wider picture and an opportunity to make some contributions.

At this date I can say my family is proud of my clinical and published work, my clients continue to make positive changes. I am still enthusiastic about my choice of art therapy as a career, and I wonder where it will take me next. I've made great friends in our field and ruffled a few feathers, but it's been a wonderful 20 years in the field that was invented, so my fantasy says, just for me. I'm grateful that I have lived during the years that this profession became a respected vehicle for creative work in psychotherapy.

My vision of art therapy in the coming years is opaque. My lenses are obscured because the world in general, and the mental health world in particular, is in a major period of transition. With change comes uncertainty, anxiety, and often a search for a new identity. It is in this area of renewing our own concepts of ourselves as clinicians in the professional world that we must be flexible and without fear.

In this postmodern world where so many basic values and attitudes are being deconstructed, it is to be expected that our art therapy foundations will also be in flux. However, to react to this global instability in a paranoid manner that personalizes the instability as a threat solely to ourselves is unhealthy.

The fear that we entertain, as I see it, is one that is focused on our identity. Intense anxiety is aroused when it is perceived that we may be facing dissolution or absorption into another professionally named group. Many fear this would result in the disappearance of art therapy. The reality points to the fact that what we do, in its many forms and in many settings, has gained respect and is requested by a growing number of agencies and hospitals which include art therapy in their basic treatment planning.

If we are to take our place in the new mental health system we must deal with this fear of a loss of identity. We will not disappear just because we add "counselor" or "MFCC" to our major title of art therapist. Practical solutions are a necessary part of range: psychological change is a personal matter. As a group, I feel, we should not be afraid to test our new ways of naming ourselves. As individuals, I believe, we cannot not be art therapists. It is an essential part of our world view and our training which we cannot shed, even if tempted to do so. We do not lose "art therapist" if we add a license to keep us alive.

I have been so impressed with the realization that what we do as routine treatment is in the vanguard of most of the current thinking in family therapy. Countless respected theorists are discussing externalization of problems focusing on narratives, discussing families' symbolic knowing, deconstructing or dissolution of problems, and other examples that are too numerous to list here. The striking concept that runs through all of these discussions is the obvious reference to concrete imagery to aid in problem resolution.

Let me give an example. When Michael White and his cohorts help a client-family externalize and "fight the enemy problem," i.e., temper tantrums, enuresis, etc., by imagin ing the problem as a personality that controls the family, the concretizing of this "problem person" cries out for an art ther-
apy approach. How much easier it would be to fight an enemy that has become real through the art expressions of the client(s). The visualization of the problem adds greater maneuverability to the therapist's plan. The art representation is an intimate, unique look at the "problem-enemy" which invites an attack and uncommon solutions, helping the family to return to a more functional relationship.

This is only one flight of clinical fancy that I had when reading a prominent author in the family field. Everywhere in the literature one can find new exciting ways of conceptualizing treatment; in almost every case the addition of our abilities to introduce the nonspeaking knowing to the therapeutic discourse begs to be utilized. We art therapists in the family field have been illustrating the families' stories for a long time. We need now to share our abilities with other therapeutic disciplines by presenting papers at their conventions and publishing in their journals. Imagine the surprise when psychologists, social workers, counselors, and the like find that we are all doing the same thing! We, too, can appreciate the gender-defined roles, socio-economic pressures as well as the multicultural difficulties stressing our society. The profession of art therapy stands on its own feet with the added strength of the creative, visual process. We are capable of incorporating and joining with theories from other fields and still retaining the magic of turning silent knowing into visible products that invite verbal exploration. How art therapy offers a vehicle to the complex human capacity to know ourselves and our world is a skill that others admire and we proudly offer to the mental health community.

Reaching our 25th year is an entrée into maturity. A developmental milestone that marks our ability to give up attachments to old family myths and rituals and create a new stance toward our profession. Moving away from our family of origin conflicts, while still retaining their strength and pioneering spirit, is an exciting opportunity. I certainly welcome the younger generation who can meet the coming 21st century with courage and the inventiveness of youth. Re-inventing the family story of art therapy by preserving the unique qualities and strengths, giving up the conflictual patterns that have repeatedly lead to discord, and inter-marrying with new families with clear boundaries and contractual agreements will lead, I believe, to a healthy future.

My hope is that we become political activists—expansive, fearless, aggressive, and convinced that our true image will dominate any modifications that may be necessary to adopt in order to survive in the new mental health system. We who believe in creativity must be willing to be creative in every way the future presents to us.

SOUTHWESTERN COLLEGE presents a day with Thomas Moore at our Thirteenth Annual Transformation and Healing Conference in beautiful Santa Fe, New Mexico. Author of best selling titles, Care of the Soul and Soul Mates, Dr. Moore will focus on the "re-enchantment of every day life" in this keynote presentation. We invite you to join us in exploring ways to spiritualize life and bring greater meaning to our existence.

August 27th, 10:00 am to 5:00 pm $65

For reservations and further information on the and other offerings of Southwestern's Transformation and Healing Conference, please call or write:

Introduction to Special Section on Art-Based Assessments

Cathy A. Malchiodi, MA, A.T.R., Editor

This special section of Art Therapy focuses on research in the area of art-based assessments. The first part of this section highlights research and recent developments in the use and application of the Diagnostic Drawing Series (DDS), featuring an introduction to the assessment (Cohen, Mills, & Kijak); research on organic mental syndrome (Couch); indicators of trauma in tree drawings (Rankin); applications to child populations (Neale); and research with eating disorders (Kessler). The second part of this section features the research of several art therapists who are exploring the application of art in the assessment in a variety of ways, including the use of diagnostic drawings with Alzheimer's subjects (Knapp); relationships between art expression and alexithymia (Heiman, Strnad, Weiland, & Wise); and connections between imagery and anger (Kaplan).

This brief introduction cannot cover the multidimensional aspects of the development and current trends in art-based assessments in the field of art therapy. However, readers who wish to know more about this topic are referred to a comprehensive description and history of art-based assessments presented in A Guide to Conducting Art Therapy Research (Wadeson, 1992) in a chapter by Linda Gaunt (1992). Gaunt traces the historical precedents of contemporary art-based assessments, identifies areas that have been problematic in assessment in general, and suggests ways that art therapists can contribute to the future development of art-based forms of evaluation.

Two additional chapters in the AATA research guide give a partial listing of art-based assessments developed by art therapists and others (Arrington, 1992; Knapp, 1992). From a quick review of these lists, the use of the term "art-based assessment" may be a misnomer since many of the tasks listed are basically art directives which have the possibility of someday becoming what might be called an "assessment." Also, for many of these so-called assessments, no interrater reliability or extensive validity studies have been conducted, and no reliable scoring systems exist. Therefore, readers are cautioned to fully investigate these aspects when formulating an opinion or using them in clinical or research settings. Eventually, these protocols may become bona fide art-based assessments through further research on their applications and through specific attention to the concepts of standardization, reliability, validity, and bias.

Lastly, a commentary on art-based assessments written by Joan Phillips (following the special feature on the Art Therapy Analysis Practice Survey) sheds some light on the inherent problems the field faces in regard to art-based assessments and their use in clinical settings. As a result of her work with the practice survey and the Certification Committee, Phillips concludes that the need for more rigorous investigation of assessment tools in the field of art therapy continues, especially if any of these tools are to be considered part of the overall knowledge base of our discipline. She also observes the ambiguity that art therapists have expressed through the Art Therapy Practice Analysis Survey concerning art-based assessments, noting that although the majority of art therapists see assessment as important, they are not in agreement about what constitutes an art-based assessment.

When thinking about the concept of assessment in art therapy, many art therapists become queasy upon hearing words such as standardization, experimenter bias, statistical analysis, and validity. However, those who are interested in pursuing the development of reliable art-based assessments realize that these and other obstacles must be systematically addressed in order to develop respectable forms of art-based evaluation in our field. Given the inherent qualities of art coupled with the variety of clients and clinical settings, this is a daunting task at best, but also one that offers a great many research possibilities to demonstrate how art-based assessments might be effectively used in the evaluation of specific populations.

Special thanks are extended to Anne Mills, A.T.R., who provided editorial assistance on the DDS submissions and whose research expertise as well as knowledge of art-based assessments was greatly appreciated.

An Introduction to the Diagnostic Drawing Series: A Standardized Tool for Diagnostic and Clinical Use

Abstract

The Diagnostic Drawing Series (DDS) is unique among art therapy assessments in that it is a standardized evaluation supported by extensive research. The DDS combines art therapy’s attention to materials, task, and process with the research methodology of the social sciences. Not predicated on any one model of art therapy or verbal psychotherapy, the DDS has proven to be a versatile resource for clinicians in the decade since its inception. The DDS, its administration, and its usefulness in clinical practice are described in the context of a structural approach which can be taught effectively to students and enhance accountability to clients and colleagues alike.

Introduction

Issues of identity and survival are of continuing concern to art therapists, as evidenced in the published and audiotaped literature of the field (Allen, 1992; Hodnett, 1973; Jordan, 1989; Kreitler & Kreitler, 1978; Malchiodi, Cattaneo & Allen, 1991; McNiff, 1992; Mills, 1996; Mills, Dougherty, Rubin, & Schoenholtz, 1992; Ulman, 1961). Although many thoughtful suggestions have been given about what practitioners could do to help ensure the field’s future, every art therapist must choose for herself/himself those which she is willing to implement.

In responding to this call for action, it is essential to recognize and respect the philosophical differences that American art therapy encompasses. For instance, one task that we all share as art therapists, regardless of theoretical approach, is to be “able to explain exactly what it is that we do in a way that is convincing to other professionals” (Malchiodi, 1995, p. 123). A group of art therapists, working in collaboration during the last 10 years, has chosen to contribute to this goal through the development of the Diagnostic Drawing Series.

A three picture assessment tool, the Diagnostic Drawing Series supports the growth of the knowledge base of art therapy by fostering extensive cumulative research (Cohen, 1986b, 1990). For example, studies have been completed that employ large numbers of DDSs to establish norms. or graphic profiles, for different groups (Cohen, Hammer, & Singer, 1988; Couch, 1992; Gulbro-Leavitt & Schimmel, 1991; Kress, 1992; Mills, 1989; Mills & Cohen, 1993; Neale, 1991). The breadth of this work, in addition to other studies currently in progress, spans the continuum from health to illness among adolescents and adults in a variety of art therapy venues. With these findings as a foundation, a clinician can decrease reliance on intuition in the reading of pictures, and make comparisons between clients and among clinical populations with confidence. This approach can promote greater objectivity in assessing client artwork and more clarity in communicating conclusions verbally and in writing.

Use of the DDS and its structural approach can strengthen practitioners’ skill in articulating “what it is that we do.” The clinical acumen of art therapists is supported when founded on research rather than “the hunches of talented judges” (Levy & Ulman, 1974, p. 25). This systematic approach can be taught effectively to students and can aid art therapists in becoming more accountable to colleagues and clients alike.

The Diagnostic Drawing Series

The Diagnostic Drawing Series was originally developed by art therapists Barbara Lesowitz, Shira Singer, Anna Beyner, and Barry Cohen and tested in the inpatient psychiatric facilities of the Fairfax Hospital Association in Virginia in 1982. The graphic profiles of the drawings in the Series are correlated with concurring diagnoses assigned by psychiatrists and psychologists at the time of the collection of the pictures; it is from this correlation that the name Diagnostic Drawing Series is derived. The original sets of standardized pictures were solicited nationally; the pictures were collected primarily on inpatient psychiatric units within three to five days of admission. The reader is directed to the DDS Handbook for the current research protocol guidelines (Cohen, 1985).

The DDS combines art therapy’s attention to materials, process, and individuality with the research methodology of the social sciences. This approach is particularly valued within institutions that emphasize intake, triage, diagnosis, treatment, and discharge planning, charting, and medication management (Mills, 1986).

The DDS was crafted according to the assumption that a well-designed art therapy assessment tool should address the following concerns:

Process

- elicit the maximum amount of information in a single brief session, but involve more than one picture (Gaunt & Howie, 1979)
- employ materials and techniques compatible with the philosophy and practice of art therapy
- reflect the affective and behavioral changes of the client throughout the session
Organization

- be standardized in all aspects of materials, administration, and record keeping
- include a protocol that controls for medication use and time period of collection (Kramer & Lager, 1984)
- have a standardized rating system with clearly defined structural criteria (Ulman & Levy, 1967)
- be supported by the foundation of normative and other research (Mills, Cohen, & Menseses, 1993)
- have a central clearinghouse for disseminating information (MacFarlane, 1942)

Versatility

- be compatible with the variety of theoretical and research approaches espoused by art therapists
- be comprehensible to a wide variety of mental health professionals
- be useful to clinicians in a variety of ways
- be compatible with medical and psychiatric diagnostic research

Once the Series was designed, a standardized rating system was developed by a group of art therapists headed by the first author. They sought to compile objective, measurable criteria from the literature of art therapy, art therapy, and art education (Dondis, 1973; Gantt & Howie, 1979; Kreitler & Kreitler, 1972; Rhyne, 1979). Definitions of such basic terms as line, blending, shape, and abstraction had to be created in order to be used as criteria in the rating process. The reader is directed to the rating guide itself for precise definitions of the descriptive art terms used in this article (Cohen, 1986).

Materials and Procedure

The Series employs 12 colors of soft chalk pastels that are flat-sided and have no paper wrappers around the sticks. Alphacolor is a widely available brand that fits this description. A single box may be used for many administrations.

Chalk pastels were chosen because of their versatility of application. They can be used to draw lines with their tips, as well as shapes with their broad, flat sides. They can be used to produce light to heavy pressures, fade to saturated color, and can be blended to create new colors.

The Series requires 18" × 24", 70 lb. white drawing paper with a slight texture, or tooth, to the paper surface (Cohen, 1985). The large format and the good quality white paper communicate respectfulness to the client; the grey paper used in another assessment procedure has sometimes been perceived by individuals as cheap or dirty. The large size of the DDS paper allows variety in the placement of images on the page and tends to amplify unusual scale or compositional relationships between image and page. The tooth allows the art therapist to ascertain how much pressure has been applied with the pastel to the surface of the paper.

The DDS is designed for tabletop administration, since using an easel or wall is not practical in all situations. The association of the easel with art education or lessons can be either beneficial or detrimental in the art therapy context. Clients lacking such formal training seem to feel more comfortable at a desk or tabletop, as it is the typical working space at home, on the job, and for most inpatient art therapy groups.

When the session begins, the client is advised by the art therapist that:
1. s/he may orient the paper in any direction
2. s/he has as long as 15 minutes to work on each drawing
3. s/he will be asked to produce three pictures, one per page, and that the directions for each picture will be given one at a time
4. the pictures will be discussed afterwards, when all three drawings are complete

For the initial (often called the "free") drawing, the client is asked to "make a picture using these materials." When presenting the second sheet of paper, the art therapist directs, "draw a picture of a tree." The final task is to "make a picture of how you're feeling using lines, shapes, and colors." In order to sound less abrupt, some art therapists say, "the instruction for the first picture is to make a picture using these materials," and so on.

Elements of the Series

To understand how each part of the Series contributes to the assessment tool as a whole, we must first look more closely at the nature of each drawing in the Series. Bolander (1977) codifies assessments into several classes with subcategories. One class—gestalt sampling techniques—tests a moment in the life of the artist from the complex whole of his or her personality, illness, transference, mood, and cognitions. Each of the three drawings of the DDS corresponds to a particular subcategory within this class.

The First Picture: Free Picture

"Make a picture using these materials."

The first picture of the DDS is the unstructured task of the Series. It corresponds to the category Bolander lists as "subject free to choose theme; materials supplied" (p. 25). The nonspecific nature of this task can evoke a variety of responses ranging from enthusiasm and spontaneity to resentment and hostility. The resulting drawing may be viewed as particularly significant inasmuch as it functions as a first picture or dream might in therapy (Shoemaker, 1977). From it we may gauge the amount and type of information the individual is initially willing to share. The theme and style of the first picture may be regarded as a graphic representation of the client's defense system.

A simple drawing of flowers in a vase, conveyed by light outlines and the use of several colors, was created as a first picture in the DDS of a mildly depressed woman. In this case, the art therapist might wonder about the woman's use of denial in defending against her depression by using the stereotypic image of flowers. Some clients, in fact, plan a picture before the session (if they have advance knowledge of it) or use an overlearned image from childhood, like a sun, house, and tree schema (Lowenfeld & Brittain, 1975).

The graphic message that is communicated may reflect the coping mechanism that is being employed by the client in response to the stressful request to draw a picture. It also in-
icates what kind of first impression the client wishes to make. A troubled, intelligent, and highly defended 16-year-old boy drew careful arcs of the colors in a spectrum, beginning with black and ending in red, and explained, "I was just trying out the chalks."

When a client with a history of severe early trauma is overwhelmed or flooded by feelings, sensations, or memories, he or she has lost the ability to modulate internal states and sometimes also behaviors. Often the only option in response to the first picture is a blatantly direct expression of his or her inner turmoil. In her first art therapy session, a woman with a dissociative disorder who alleged she had experienced multi-perpetrator, multivictim abuse made a line drawing of a robed figure holding a knife dripping blood, surrounded by dead babies.

"Tree pictures range from concrete to abstract, from remote or impoverished to direct and boldly expressive. Content, too, varies in relation to defensive style."

The Second Picture: Tree Picture

"Draw a picture of a tree."

The second drawing is most like the category Bolander describes as "instructions are highly specific" (p. 25). The dicta fight as well as the subject of this drawing is especially welcomed by adults who insist they "cannot draw" or "cannot think of anything to draw" in response to the first picture. Defenses seem to quickly lower as a result of shifting to a directive task immediately following the free picture, and so a less guarded response may emerge.

Everyone has seen a tree and most people believe they can draw one; the tree is among the first recognizable images drawn by children (Kellogg, 1970). Not surprisingly, many adults revert to their own preadolescent tree schemas when confronted with this task.

Trees have been studied extensively in relation to projective drawings (Buck, 1948; Hammer, 1958), and it is said this subject matter provides the deepest tapping of the psyche in the realm of projective drawings (Bolander, 1977; Koch, 1952). The tree can be viewed as a symbolic self-portrait, displaying one’s vegetative and/or psychic state (Jung, 1967). The inclusion of the tree drawing in the Series constitutes a link with the drawing tests and symbol-based art analyses of the past. As such, it affords an opportunity to reexamine the work of previous investigators. The introduction of colored chalk pastels and the large-sized paper, however, enhances the potential for free, expansive self-expression.

Early DDS research suggested that people diagnosed with schizophrenia often create trees that look most like those of the nonpatient research sample—complete, connected, and recognizable. This finding was particularly surprising in light of traditional notions of the split and impoverished schizophrenic tree (Hammer, 1958; Koch, 1952). This level of integration stood in contrast to the first and third pictures in the Series drawn by these individuals (Cohen, Hammer, & Singer, 1988). Perhaps people with schizophrenia draw visually coherent second pictures because this task is both directive and concrete, suggesting the way a task can structure and organize performance. On the other hand, some non-schizophrenic clients decompensate graphically despite, or perhaps because of, the structure inherent in the directive (Mills, 1988).

It appears that the structure of the task in the second picture elicits strengths in some clients while identifying weaknesses in others. For instance, if individuals diagnosed with borderline personality disorder and post-abuse syndromes draw a tree in the first picture, they often present themselves graphically with a well-organized facade. Within the more structured format of the second picture, however, underlying pathology and disorganization may be revealed by disfigured, falling apart, and floating trees (Cohen, 1989; Mills, 1989; Mills & Cohen, 1993).

A self-mutilating patient diagnosed with borderline personality disorder, who was also artistically skilled, responded to the instruction for the second picture by saying, "Oh, good—structure!" She made a drawing that was, at first, unrecognizable as a tree. After a moment it became clear that it was a cross-section of a trunk from an aerial perspective—a view of a tree that had been lopped off. In this case, the structure of the task provided the client with an artificial sense of control that allowed an image reflecting severe disturbance to arise.

Even if a client draws a tree in the first picture, the therapist should still give the proper instruction (i.e., request a drawing of a tree) for the second picture. It is important clinically to observe the difference between two trees drawn by the same client in consecutive pictures within a single series (Creekmore, 1989). In viewing the difference between any first and second pictures, the therapist becomes aware of the interaction between task, process, and pathology.

The Third Picture: Feeling Picture

"Make a picture of how you’re feeling using lines, shapes, and colors."

The third picture belongs to Bolander’s category of gestalt sampling techniques in which the “directions are specific for theme only” (p. 25). This task allows great latitude of expression for the participant despite the specificity of its wording. Certain clients, when asked to “make a picture of how you’re feeling, using lines, shapes and colors,” will respond literally to the instructions, drawing some lines and shapes in color. Others, more capable of abstract thought, will draw geometric or biomorphic forms, creating abstractions based upon their feeling states. A third group of clients will draw a scene, still-life, or portrait, reasoning that all images are made up of lines, shapes, and colors. So it is that clients, in response to this instruction, may draw images ranging from abstract to representational, from highly personal to stereotypic or mundane.

Up to this point in the Series, the clients might be performing expressly for the therapist. In the third picture, the request for a depiction of feelings invites the clients first to reflect, then to assert themselves through graphic self-expression. Compared to other drawing assessment procedures, this task is uniquely direct. A straightforward invitation is made in search of a candid answer. Patients are rarely fooled by the artifice of projective tests, which are now part of our popular culture. If we want to know about the patients’ experience or self concept, why not simply ask?
The conceptual complexity of this task seems to encourage thoughtfulness and control by some clients on a more conscious level than the second picture. However, the position of the feeling picture as the final drawing of the Series (after a two-picture warmup) also offers the opportunity for emotional release. Clients whose therapeutic issues cluster around intense feeling states, such as individuals diagnosed with affective disorders or personality disorders, seem to welcome this opportunity. These clients lavish what appears to be intense effort on the third picture. A wide range of colors is employed and a high percentage of page space is often used by individuals from both the affectively and characterologically disordered groups (Cohen, Hammer, & Singer, 1988; Mills, 1989).

In addition to providing valuable clues regarding the patient's capacity and willingness for expression on an affective level, this final drawing may show a change in energy level or mood from the initial picture. For example, a recently retired 64-year-old man was admitted for the first time to a psychiatric hospital with a diagnosis of major depression. His first two pictures were monochrome and used little space. His third drawing filled the page with a landscape featuring tiny houses and a huge storm cloud overhead. The progression of formal elements across the pictures in this Series is telling; increase in color and space usage in the feeling picture of depressed patients, while not typical, is clinically noted. The instruction for the feeling picture is purposefully phrased to encourage abstraction and can, therefore, function like a measure of cognitive capacity. Low IQ clients and those with organic brain syndrome may therefore have difficulty with this task, but generally complete the picture nonetheless. Concrete responses or stereotypic images are frequently noted in the third picture by these groups. For example, a moderately mentally retarded 36-year-old woman drew a picture of the hospital bounded by a rain cloud on the left and sun above her on the right, and stated, "I hope the sun will shine on me!"

A related response is seen in the third pictures of psychotic patients and those diagnosed with schizophrenia. In these drawings, words are often used in combination with concrete elements or highly idiosyncratic symbols. Such responses can be attributed to the inability of these clients to identify or express feelings (as noted in individuals with alexithymia), compounded by an inability to translate feelings into abstract images.

This final picture in the Series can also provide patients with an opportunity for closure on the experience of completing the Diagnostic Drawing Series and the material it stimulates. In this case, a picture of how they are feeling might communicate a specific response to drawing the DDS itself.

**Special Considerations in Administering the DDS**

Although unusual, a client's refusal or inability to complete any picture in the Series represents important information and is a valuable part of that patient's total response. If this does occur, the clinician should simply retain a blank page at the appropriate place in the Series once it has been assembled for storage.

Refusal to complete the first picture is uncommon, and rarely have clients left the session at this point after declining to draw. Even if the first picture is refused, advancing to the second picture is usually possible—probably because it is structured and therefore less threatening—and the remainder of the Series is then completed. It should be noted that refusal of the first picture may signal passive-aggressive or acting-out tendencies in the client, in the observation of these authors.

It has never been reported, to date, that a client balked at the second picture. Floridly psychotic, organic impaired, and moderately retarded individuals all executed tree pictures. These same clients—for whom feelings are difficult to conceptualize or abstract—are, however, more likely to have difficulty executing the third picture. On the other hand, clients with disorders in which affect plays a strong role are unlikely to have any difficulty completing the third picture.

Some clients may not be able to respond at all to the directions for the third picture. In this situation, ending the art-making part of the session and turning to discussion of the first two pictures is appropriate. In all cases, it is important that the art therapist normalize the experience and provide closure for the client in the session.

In certain clinical situations the art therapist may need to encourage a resistant or recalcitrant client to start or continue to draw the DDS. Such an intervention should be governed by the personal style of the clinician and be as nonspecific as possible. One popular intervention to getting started is asking the client to look over the selection of colors, and to then pick up the color that is most appealing and begin to make a mark with it.

Some clinicians feel awkward discouraging clients from dialogue until the Series is complete. This guideline was created to control for the possibility that discussion would contaminate ensuing drawings. It is true that clients are often eager to discuss their products as they work. The authors, however, have found that clients readily accept the request to delay talking; some clients even seem to gain from the experience by devoting more attention to their art making. Discussions at the end of the session typically yield more honest and thoughtful explorations of the images.

**Clinical Use of the Series**

The DDS is especially useful to keep in mind when planning a first outpatient art therapy session for which one has little information about the client. It allows the art therapist to access the client's issues, defenses, and strengths, while the client can explore media typical of an art therapy experience. Clinicians using the tool for the first time frequently express surprise at the amount of information elicited in a brief session. Clients frequently report enjoying the tasks and materials.

Inpatient uses of the DDS include assessment, group therapy, treatment and discharge planning, as well as multidisciplinary education. Although it is designed for single subject administration, the DDS has also been administered as a task in inpatient art therapy groups. The Diagnostic Drawing Series became part of the initial evaluation on one psychiatric unit, and one of the art therapy groups became a weekly DDS session. This helped to triage new patients into high-
and low-functioning teams. Intersubject contamination was examined through close observation of process and product; however, influence of picture content among group members did not seem to occur (Creekmore, personal communication, 1989).

The DDS can serve as an effective aid in educating multidisciplinary staff in case conferences, in-service presentations, and treatment planning meetings. By familiarizing colleagues with this standardized format, recognition of variations among the Series of different clients is facilitated. In fact, clinicians employing the DDS have reported increased interest in, respect for, and sophistication about client art therapy productions from their co-workers after introducing this tool. Findings from DDS research are available to substantiate clinical or diagnostic observations, which enhance the art therapist's value as a member of the treatment team.

The DDS has also been used as a discharge assessment tool and is well-suited for outcome studies. A DDS review session can also be a very potent format, as there is no denying the changes that manifest in a number of Series drawn over the course of treatment or across several hospitalizations by the same client.

Using the DDS regularly for inpatient evaluation makes it possible to compile a library of DDSs. It also allows the therapist to compare DDSs of recidivist clients across time. Changes such as the intensification, amelioration, or diversification of symptoms may be evidenced in the art.

When very specific thematic material must be elicited, other tasks may be used in conjunction with the DDS. For instance, in cases that involve family dynamics, the DDS can be completed, discussed, then followed by a Kinetic Family Drawing (Burns & Kaufman, 1970) modified by the use of DDS art materials. In such cases, neither tool alone could supply the full range of information necessary, and each tool enriches the other.

Creativity may be the culprit that causes art therapists to modify assessment techniques infinitely to suit the client, the therapist, or the setting. The authors, having found benefit in keeping the tool as constant as possible to best recognize the differences in patterns of response between clients, strongly encourage consistency. For instance, we recommend maintaining the 15-minute research limit per picture in clinical work as well. Experience shows that many patients do not require the full 45 minutes to complete a Series, so that a client who uses the full allotment of time is clearly communicating a special need.

Changing paper size, re-ordering tasks, or inserting an additional picture somewhere within the Series would result in something that is not a DDS and cannot legitimately be compared with the DDS research findings. This point cannot be overemphasized.

Research by Clinicians? The Benefits of Collaboration

Collaboration between clinicians and researchers has been very important in the development of the DDS. When a Series is collected according to the research protocol, it can be submitted to the DDS Archive in Washington, DC. There it can be used by interested student and professional investigators. Inquiries from those interested in conducting research are welcomed. All may contribute to and use the archive which now contains more than 1000 Series. In fact, without art therapists' contributions of correctly collected Series to the archive, there would be no research.

Busy art therapists or those working in isolation often find it difficult to launch solo research projects. The collaborative nature of the DDS research offers clinicians the special opportunity to pool ideas, resources, and energies. For instance, the authors have established a communication network among researchers and clinicians through the DDS Newsletter (Cohen, 1985b) that links those with similar investigative interests.

Conclusion

Selecting an appropriate assessment technique for clinical use is a complex judgment which should involve consideration of factors such as: professional acceptance, evidenced by reputation, conference presentations, and journal articles; tests of reliability and validity; the support of research; and the legal/ethical right to employ that tool. These matters are of particular importance when there is the possibility of litigation related to a case.

Sadly, the primary factor influencing most clinicians' choice of assessment techniques is their familiarity with a tool. Any assessment that is used routinely will become the one with which the clinician feels most skilled, and will become the tool on which s/he will tend to rely, regardless of the aforementioned factors.

The authors have presented the rationale for the design and use of the only assessment tool in art therapy that is supported by extensive diagnostic and procedural research. Although systematic investigations of the Diagnostic Drawing Series have been the focus of DDS presentations and publications since its inception 10 years ago, the advantages of using the DDS in clinical practice are many. They can be summarized as follows:

- simple design allows quick set up, administration, and completion
- pastels and large paper invite an experientially richer encounter than pencil-and-paper projective drawing tests
- varied task structure facilitates a wide range of responses
- format can be used effectively at any point during clinical treatment and,
- multi-center research builds clinical knowledge base.

In addition, the DDS is the only published art therapy assessment tool linked to the standards of the DSM III-R (APA, 1980). As it is not predicated on any one particular model of art therapy or verbal psychotherapy, it can be used by all art therapists as a sort of lingua franca. It is hoped that this examination of its rationale and components will contribute to a fuller understanding of the DDS as an assessment tool, as well as its utility in clinical practice. Clinicians accustomed to intuitive work with art may take note that the DDS can be an affirming supplement to their approach.

By standardizing the complex process of diagnostic assessment in such a way that all aspects of it can be articulated, recorded, studied, and taught, we advance the theory, practice, and integrity of art therapy. Building upon each
others' work, we help to ensure our survival within the increasingly embattled and competitive health care environment.

Editor's note: The authors wish to express their appreciation to Barbara Lesowitz, MA, A. T. R., Anna Reyner Blausen, MFCC, A.T.R., and Shira Singer, MA, A.T.R., without whose efforts this paper would not have been possible. Much of this paper is based on discussions with students and colleagues about their experiences with the DDS. We are grateful for their considered thoughts.

Diagnostic Drawing Series: Research with Older People Diagnosed with Organic Mental Syndromes and Disorders

Janet Beaujon Couch, MA, A.T.R., Alexandria, VA

Abstract

This paper describes the use of a standardized three-picture art interview, the Diagnostic Drawing Series, with older people. Artwork was collected from 24 patients diagnosed with Organic Mental Syndromes and Disorders as defined by the DSM III-R criteria. The formal aspects of the art were rated using the Drawing Analysis Form (Cohen, 1985), the Content Checklist (Cohen & Cohen, 1990), and the Tree Scale (Creekmore, 1989). Results were analyzed statistically and compared to the ratings of art done by a control group of older people with no apparent neurological dysfunction. The results of an intrarater reliability study are examined.

Introduction

Art therapy has proven to be a viable modality with older people, providing an avenue of creative expression, increased self-esteem, socialization, and the possibility of personal growth. The field of geriatric practice in art therapy is an emerging one and at present there is a relatively small body of written work about this population. Much of the literature describes art programs designed as an activity for older people. Media choices, suggested artistic projects, the use of art: as a life-review process, and case studies have presented the possibilities that art therapy and art education can offer in both community and institutional settings (Comger, 1979; Dewdney, 1975; Jungles, 1979; Rugh, 1985; Wald, 1983; Zieger, 1976; to name a few). However, with few exceptions (Andrews, Brocklehurst, Richards, & Laveock, 1980; Fischer & Fischer, 1977; Silver, 1976, 1981; Wechsler, Schafer, & Berghorn, 1977), the literature has lacked systematic analysis of graphic qualities seen in the art of cognitively impaired older adults. Research can be difficult due to the variations within the population and the training of those working with them. This lack of valid and reliable research can have a significant impact on how art therapy is seen as a treatment modality. Art therapists working with cognitively impaired older people often have to combat the impression that art therapy is merely a pleasant recreational activity.

The art of older people diagnosed with Organic Mental Syndromes and Disorders (OMS/D) appears to have similar characteristics. These characteristics can be difficult to research since art-based assessments often need to be adapted due to visual, physical, and cognitive impairments. The Visual-Motor Gestalt Test, developed by Bender in 1938, shows how a person uses his or her perceptual system to organize configurational wholes. Organicity is apparent in test results from brain-damaged patients; however, this test does not score for art productions (Berg, Franzen, & Wedding, 1987, pp. 89–97).

Early signs of organicity have been observed and documented by art therapists working with older adults. Wald (1983, 1986) describes characteristics of art done by patients diagnosed with Alzheimer’s disease as: perceptual distortion, tendency for simplification, perseveration (repetition of lines, shapes, or forms on the same drawing or from drawing to drawing), rotation of paper, and short, sketchy lines. Cronin and Werblowsky (1979) observed the additional features of disconnections, static affect, and difficulties in comprehension. A chart of observable characteristics seen in the art of patients diagnosed with OMS/D (all age groups) was compiled by Guntl and Howie (1984). Color was found to be unconventional (due to brain damage), limited, and used for outlining. Two-dimensional form characteristics were found to include the following: flat rendering of forms, relative size distortion, line quality sketchy or broken, one side blank (in stroke patients), bizarre rendering, incomplete forms, rotation of paper, and perseveration. Disorganization and figure/ground merging appeared, and content was idiosyncratic due to short-term memory impairment.

Cheyne-King (1990) has found that art products of young patients with brain injury show evidence of neglect of one side of the page. Images are often unrecognizable and may appear fragmented and unorganized. These characteristics are also seen in the art of older stroke patients. Andrews, et al. (1980) tested older adults with an art-based assessment (copy a picture of a house and draw a man and a clock from memory) to determine whether drawings by stroke patients had prognostic value. They found that left-brain damaged patients demonstrated more perseveration, and right-brain damaged patients had more structural abnormalities in their artwork. Some form of sensory integration abnormality was found in all tested. Art done by brain damaged older adults tends to be more expressive in higher functioning patients. Those with severe damage continue to make art that is more stereotypical and less expressive (Fischer & Fischer, 1977).

Method

A total of 24 older people, aged 67 through 93, diagnosed with OMS/D participated in this study. There were 16 females and 8 males. Each subject was diagnosed by physi-
Dentists on the basis of separate interviews. Half of the subjects live in a continuing-care retirement facility, the other half attend a day treatment center and live in the community. The sample was mixed racially and socioeconomically.

The control group consisted of 10 older people with no history of apparent neurological dysfunction. There were nine females and one male, aged 77 through 100. All live independently. This sample was not mixed racially or socioeconomically and is thus heavily skewed.

The Diagnostic Drawing Series (DDS) (Cohen, Hammer, & Singer, 1988) was administered to all participants in the study. The DDS was chosen because no adaptation was necessary, it is easily administered, and it is a "systematic research design that investigates the relationship between the various DSM III-R psychiatric diagnoses and graphic style." (pp. 11-12). The DDS is especially useful as the "clinical data ... can be communicated to other mental health professionals. The most recently analyzed interrater reliability of the DDS shows an overall percentage of agreement of 95.75% ... which exceeds many comparable studies in the field" (Mills, Cohen, Meneses, 1992, pp. 83-88).

Participants were given 18" × 24" white drawing paper, a box of 12 chalk pastels, and then asked to draw three pictures: "Make a picture using these materials; Draw a picture of a tree; Make a picture of how you're feeling, using lines, shapes, and colors" (Cohen et al., 1988, pp. 12-13). The client's way of responding to the task was noted, as well as the progression or regression in the pictures across the series.

Organic Mental Syndromes and Disorders are medical diagnoses and, as such, this study is different from previous DDS research. Most participants had been placed in their respective facilities before the study began; therefore, it was not possible to assess patients within the first five days of admission, as requested in the DDS protocol. Also, it was not possible to control for medications and the influence they may have on the art produced, the course of treatment in relation to the disease process is not addressed.

Half of the DDS in the OMS/D sample were administered in a group setting while the other half were done individually. Artwork produced in a group did not appear to be influenced by the presence of others. This conclusion is based on participant's comments and the observation of those who administered the assessment. Due to the nature of the disease process, i.e., decline in cognitive functioning and verbal skills, the patient becomes, and often remains, isolated even in the presence of others.

The drawings were rated by the two art therapists trained to administer the DDS. The DDS Rating Guide (Cohen, 1985) was used to rate all three pictures.

The first and third pictures were rated according to the DDS Content Checklist (Cohen & Cohen, 1990). This Checklist is a 111-item list which includes: figure elements, body elements, structural elements, symbols and signs, things, animals (real or fantasy), substance use, celestial, and landscape elements. Several items were added in order to rate the content of the OMS/D sample. To the category "structural elements," line fragments, background fill-in, unrecognizable shapes, radial designs, perseveration, and floating image were added. To the category "things," "other" was added.

The first pictures containing trees and the second pictures (the tree picture) were rated according to the Tree Scale (Creekmore, 1989). This is a 61-item list of structural and content elements to which were added: "other deciduous trees," to the "kind of tree category," and "floating." An "other" category was added to this scale, containing: writing, floating images, perseveration, and unrecognizable objects.

Results

The purpose of this study was to investigate the graphic qualities of art produced by people diagnosed with the various DSM III-R categories of Organic Mental Syndromes and Disorders.

Hypothesis 1 stated that images would be representational and floating; perseveration, limited use of space, and unusual placement would be found. Perceptual distortion, simplification, perseveration, short, sketchy lines, rotation of paper, fused images, boundary confusion, and disconnections would also exist. (Characteristics noted by Wald (1983, 1989) and Cronin & Werblisky (1979).

Hypothesis 2 stated that there would be little or no blending and an inability to abstract; the art would become less organized in the progression from Picture One to Picture Three; the directives would cause anxiety; and the images would be classified as impoverished according to the DDS Rating Guide.

Tabulation of the percentage of occurrence/nonoccurrence of the criteria was done using the Drawing Analysis Form (DAF). All categories in the OMS/D scores do not add up to 100% because of the blank pictures occurring in Picture One and Picture Three in this sample. In the OMS/D sample, lines tended to be longer than expected, although short, sketchy lines do appear. Idiosyncratic use of color was not found to be common, and space usage was fuller than expected (34% to 66%). Findings were as follows:

1. Monochromatic use of color
2. Use of blending rare
3. Use of line predominates
4. Impoverished pictures
5. Representational images
6. Single images
7. Lack of enclosures
8. Lack of groundlines
9. Minimal inclusion of animals
10. Minimal inclusion of people
11. Light line pressure
12. Most trees unrecognizable
13. Unusual placement

Content and quality of the images done by those diagnosed with OMS/D became more unorganized from the first picture through the third. Otherwise there was little change across the series throughout the DDSs produced for this study. Floating images were common and trees in the third picture are indicative of perseveration (see Figures 1–3).

The Content Checklist (Cohen & Cohen, 1990), designed for use in conjunction with the rating guide, was employed to rate the number of items in each picture. When any item is repeated more than once on a single picture, only one tally mark is recorded on the Checklist. Therefore, it was not possible to rate perseveration; an "other" category was added.
containing line fragments, perseveration, unrecognizable shapes, and floating images.

Seventeen (70.8%) patients produced representational images on Picture One, with 12 (50%) on Picture Three. Fifteen (62.5%) pictures contain floating images, which can be added to the "commonality" list (see Figures 4, 5, & 6). Due to the disintegration of images, the "structural elements" section of the Checklist contains the largest number of items scored in the OMS/D sample. Recognizable images tended to be concrete. In the Control sample, most responses were in the categories named "things," "celestial," and "landscape elements."

The Tree Scale (Creekmore, 1989) was designed to rate trees in the first and second pictures of the DDS. In the OMS/D sample, paper orientation tended to be horizontal (91.7%), whereas the Control sample tended to orient the paper vertically (65%). When the OMS/D sample was given a choice as to orientation of paper, usually no choice was made. Rotation of paper was noted, perhaps due to the large paper size. Writing appears in many pictures from this sample, possibly a way of reducing anxiety. Flowers and animals are absent in tree pictures from both samples.

All trees in the Control sample fulfilled the criteria for "recognizable." Of the OMS/D sample trees, 30% were rated as unrecognizable, 83% had "chaotic branch structure," and 16.7% were rated as 'falling apart' (see Figure 7).

Discussion

Limitations of this research must be noted. Although the Control sample was small, the demographics (predominantly women) seems to represent the general population of older people at this time. The Controls are all from one socio-economic, cultural, and racial group which may skew the results. The raters were not blind to the diagnoses, so results may be biased.

Of the rating tools used in this study, the DDS Rating Guide was the easiest to use and score. The Content Checklist and the Tree Scale did not have categories to rate all the elements found in the OMS/D art. The challenge of abstracting seemed too difficult for those in the OMS/D sample and the number of blank pictures (25%) on Picture Three seems to confirm this.

Perseveration of lines, shapes, or forms on the same picture (see Figure 8), as well as from picture to picture (e.g., trees in Picture Three), was seen but was not as prevalent as hypothesized. The Content Checklist and the Tree Scale had to be adapted to include this category.

Floating images, limited use of space, and unusual placement were found in the OMS/D sample, but not in the Controls. Structural qualities identified by other writers, i.e., simplification, perceptual distortion, fused images, boundary confusion (Wald, 1983), and disconnections (Cronin and Werblosky, 1979), could possibly be measured in the DDS categories "impoverished" and "disintegrated." Although the above qualities of simplification, etc., are commonly observed in the art of this population, standardized rating criteria are needed for measurement.

Concern about the paper size (18" × 24") was observed in both samples. The first directive caused anxiety in both
samples; however, all directives seemed generally difficult for those diagnosed with OMS/D. This could be described as “static affect and difficulty in comprehension” (Cronin & Werblosky, 1979), both qualities observed with these clients.

Attempting to mask deficiencies in cognition by continual verbalization is often seen when working with OMS/D clients. Most of the OMS/D sample tried to talk around the task, repeating the instructions several times before attempting to make a mark on the paper. Those unable to draw (blank pictures) spoke throughout the task.

There was little blending noted in the pictures produced in the OMS/D sample: 0% in Picture One, 8.3% in Picture Two and Picture Three, whereas the Controls had blending in 50% of their pictures. There were no blank pictures in the Control sample; the OMS/D sample had 8.3% blank for Picture One, and 25% for Picture Three, indicating difficulty both in abstraction and comprehension of the directives.

Individuals in both samples did more representational pictures than abstractions, and people, animals, and enclosures were not common. Long or continuous lines were also found in the art of both samples (30% in the OMS/D sample) which is an interesting contrast to Wald, Cronin, and Werblosky’s observations.
Pictures done by the Control sample (Figures 9–11) were integrated (100%) and the OMS/D pictures tended to be impoverished or disintegrated. Everyone in the study attempted to draw the second picture, the tree. All trees were rated as integrated and recognizable in the Control sample and 50% of the trees in the OMS/D sample were rated as unrecognizable. Groundlines were found in the pictures from the Control sample, but there were few in the OMS/D sample.

**Conclusion**

Structural qualities found in art done by clients diagnosed with Organic Mental Syndromes and Disorders have been identified using the Diagnostic Drawing Series. Observation of these qualities may aid in the early diagnosis of OMS/D and help educate medical and mental health professionals working with this population. A study of the DDSs of younger people (under age 65) diagnosed with OMS/D is recommended. Development of additional scales is needed to rate qualities seen in the art of older people with OMS/D such as perseveration, boundary confusion, and floating images.

A Study of the Diagnostic Drawing Series with Eating Disordered Patients

Kathie Kessler, MA, E.D.S., C.H.t., Peoria, AZ

Abstract

This study is based on the etiology, phenomenology, diagnosis, and treatment of eating disorders. There has become an increasing awareness and prevalence of eating disorders in our culture today. Literally, "eating disorders" implies "disordered eating." The most common eating disorders are Anorexia Nervosa/self-starvation, Bulimia Nervosa/binge eating, and Eating Disorders Not Otherwise Specified (NOS)/symptoms of both (Emmett, 1985). The combined sample for this study included women from all three diagnostic categories.

The purpose of this study was to examine the possible existence of structural and content elements in the Diagnostic Drawing Series (DDS) significant to an Eating Disorder population and to discover if there were recognizable or identifiable differences between the profiles of Anorexic, Bulimic, and Eating Disorder NOS individuals. Previous studies of the DDS have been conducted with other mental disorders in the areas of schizophrenia, depression, dysthymia (Cohen, Hammer, & Singer, 1988), borderline personality disorder (Mills, 1989), organic mental syndrome (Couch, 1992), and Multiple Personality Disorder (Mills & Cohen, 1991; Kress, 1992; Heijtmajer & Cohen, 1993). This additional study with eating disorders provides a broader application of the use of the Diagnostic Drawing Series instrument along with increased reliability and validity.

Method

This investigation uses a descriptive research method which draws attention to the degree of two events, an eating disorder and the artist's renderings of the DDS, and how they are related. This methodology produces data that is accurate and representative, describing "what is, and allowing for the study of relationships or events as they happen in human life" (Cohen, Hammer, & Singer, 1988).

The sample subjects were obtained from one source, an inpatient eating disorder program for women in the Wickenburg, Arizona area. Subjects ranged in age from 15 years to 54 years. The sample included 55 women diagnosed with Bulimia Nervosa, 17 women diagnosed with Anorexia Nervosa, and nine women diagnosed with an Eating Disorder NOS. The source of these diagnoses was the Axis I and II diagnosis made by one psychiatrist and one psychologist in accordance with the DSM-III IR categories recorded in the charts of each individual patient as a part of his or her legal record.

The instrument used for measurement in this research work was the Diagnostic Drawing Series (DDS) (Cohen 1988). Clients are given three 18" x 24" pieces of white drawing paper and a box of 12 chalk pastels. They are then asked to "make a picture using these materials" on the first piece. When this is complete they are then asked to "draw a tree" on the second one and once completed, to "make a picture of how you're feeling using lines, shapes and colors" on the third one (Cohen, Hammer, & Singer, 1988).

The collection of the drawings by each patient in this study was obtained within the first five days following psychiatric admission to the treatment facility. The drawings were obtained during the first group art therapy contact. Upon admission to the facility, patients were advised that they would be scheduled for an initial group art therapy session with the art therapist.

The characteristics of the drawings, that is, 36 elements in 23 categories, were reported on the Drawing Analysis Form (DAF) by this researcher, the resident art therapist at this treatment facility. There are 183 choices for the three drawing series, and it is important to note that although there is a blank category for all three pictures, in this study there were no blank occurrences, therefore, all the categories on the DAF add up to 100%. The data were then separated according to eating disorder diagnosis, Anorexia, Bulimia, and Eating Disorder NOS.

Results

Tabulation of the percentage of occurrence/nonoccurrence of the descriptive criteria on the Drawing Analysis Form (DAF) was completed. When the tabulations of the Combined Eating Disordered sample were studied, and a greater than 50% occurrence of elements was determined, a profile of elements for each picture emerged (see Table 1).

The profiles of this research were compared with control group data initially obtained by Cohen, Hammer, & Singer in 1988. The profiles of eating disorders did not vary from the control group profiles (Cohen, 1993b) except for two elements: groundline and falling apart trees. The Combined Eat-

Discussion

While these elements ("no groundline," "falling apart trees," and "knot holes") are not in themselves indicative of the presence of a Eating Disorder, they may add to the accumulation of data in support of a tentative Eating Disorder diagnosis.

Although the Combined Eating Disorder sample was relatively large, the individual Bulimia Nervosa sample was nearly three times that of the Anorexia Nervosa sample and six times that of the Eating Disorder NOS sample. Additional studies with larger sample sizes in these specific diagnosis groups may yield additional diagnostic data.

With the high correlation of knot holes in the Combined Eating Disorder sample, in the individual Bulimia Nervosa sample and the Dissociative samples, a specific study of dual diagnosed individuals with Bulimia Nervosa and Dissociative Disorders may yield further data which could correlate with these individual studies.

The Children's Diagnostic Drawing Series

Elizabeth Leigh Neale, MA, A.T.R., Louisville, KY

Abstract

This study investigated the Children's Diagnostic Drawing Series (CDDS). The first hypothesis was that the variables of the DDS Rating Guide applied to the CDDS would significantly discriminate between children in the treatment group (with a DSM-III-R psychological disorder) and children in a control group. The second hypothesis was that a cluster of variables of the DDS Rating Guide applied to the CDDS would emerge as criteria for diagnosing children with adjustment disorders. There were 90 subjects total, ages 5-17, who had various SES backgrounds. Twenty-eight of the children in the treatment group were diagnosed with Adjustment Disorder (DSM-III-R). Seven out of 23 objective variables of the DDS Rating Method significantly discriminated between children currently being seen in therapy and children not in therapy. Six of those seven variables had an interrater reliability of Kappa >0.50. Of the 23 variables of the DDS Rating Guide, 20 had categorical clusters for children in the treatment group diagnosed with adjustment disorder.

Method

Hypothesis

There are two hypotheses investigated by this study. The first hypothesis is that the variables of the DDS Rating Guide, applied to the CDDS will significantly discriminate between children in the treatment group (with a DSM-III-R psychological disorder) and children in a control group without a diagnosis. Thus, children with a diagnosis will be distinguished from children without a diagnosis by their performance on the CDDS. The second hypothesis is that a cluster of variables of the DDS Rating Guide applied to CDDS will emerge as criteria for diagnosing children with a DSM-III-R diagnosis of an adjustment disorder.

Subjects

Subjects in the control group attended local private schools in a large Midwestern metropolitan area and came from varying socioeconomic backgrounds. The treatment group subjects were referred by a state-funded, outpatient, mental health treatment facility in the same city. All subjects included in the treatment group were currently being seen in psychotherapy by one of the therapists at the mental health facility. None of the subjects terminated therapy while this study was being conducted. For a subject to be included in the control group, she or he must have not been in therapy at the time of the study, and did not enter therapy while the study was being conducted.

There were 160 children in the subject pool, ranging in age from 5 to 17. Of the 113 subjects in the control group, 50 were randomly chosen to participate in the study. Forty of the 47 subjects in the treatment group were randomly chosen for the study. Of this 40, 28 carried a diagnosis of Adjustment Disorder. There were 11 black children and 39 white children in the control group. In the treatment group there were 19 black children, 20 white children, and one Hawaiian child. There were 26 females and 24 males in the control group and 18 females and 22 males in the treatment group (see Table 2).

Adapting the DDS for Children

The DDS has been modified for children in two ways: (a) there was a change in the medium used, and (b) there was a change in the DDS verbal instructions (Sobol & Cox, 1991).

The original medium, a soft, square chalk pastel, was changed due to the messy nature of the pastels. Harder pastels used in the CDDS created less chalk dust and less mess while providing a similar range of expressiveness.

For this study, the data collection was conducted both individually and in groups. Due to the group format a change in the administration of the DDS was initiated; administration was simplified and instructions were made more concrete. Children need simple instructions which often must be repeated. For example, instead of "make a picture using these materials" the children were told "make a picture using the pastels and the paper." Otherwise, the instructions for the pictures did not change.

Administration Procedure for the CDDS

The procedure for data collection for the control group and the treatment group was the same. For the treatment subjects, the data were collected both in groups and individually. Data from the control group were collected only in groups. The author was the test administrator for all subjects.

Measuring Device

The CDDS consists of three drawings: (a) the free picture, (b) the tree picture, and (c) the feeling picture. Instructions for the administration of the CDDS are the same as the DDS instructions with the above-mentioned exceptions. (See the reference list for obtaining these instructions, Cohen, 1985.)

The Rating Format

The drawings are rated on 23 variables that are precisely defined in a manual which guides the rater when rating the drawings (Cohen, 1985). The Rating Guide examines many objective factors of drawings such as color type, blending colors, representational or abstract, and the inclusion of groundlines, animals, people, symbols, and words (see Table 4).

This same manual was used to rate the CDDS drawings. Exact requirements are given for variables such as line length, tilt, unusual placement, and space usage. The factors eliciting subjective responses are integration, movement, line pressure, and line or shape content. However, even these variables have clear operational definitions for rating.

Interrater Reliability

Interrater reliability was established between the author and two trained DDS raters who were blind to the nature of this study. The statistic used to define the interrater reliability was a Kappa measure of reliability. The Kappa statistic is the appropriate interrater reliability measure for the rating of categorical data. The boundaries of Kappa are −1.0 to 1.0. A value greater than +.05 or −.05 can be interpreted as a strong measure of reliability.

A statistical program was created to calculate the interrater reliability for this study (Vogel & Joshua, 1991). Interrater reliability was established by the three raters for each variable. There were 12 variables for which significant interrater reliability was established.

Statistical Procedures for Analysis of Data

The statistical procedure chosen for analyzing the data for hypothesis one (discriminating between the control and the treatment group) was the logistic regression model. The rationale for choosing this statistic was that: (a) the data are categorical, (b) the distribution of the errors for categorical data is binomial and not based on a normal distribution, and (c) because of the categorical nature of the data, the constraint of the regression equation is that the equation must be formulated to be bounded between zero and one. The logistic regression equation for this study was: \[ E \left[ y = \frac{1}{1 + e^{-x}} \right] \].

The statistical procedure chosen for analyzing the data for hypothesis two (identifying the cluster variables for children diagnosed with adjustment disorder) was the Chi-Square statistic for each variable. For each variable that was significant a percentage of responses per category was calculated to determine the trend for that variable.

Results

Interrater Reliability of Significant Variables

Six of the seven variables which significantly discriminated between the treatment and control groups were variables which had an interrater reliability (kappa value) greater than 0.5: color type (1.00), line/shape (0.58), integration (0.68), groundline (0.68), inanimate objects (0.61), and space usage (0.77). This further validates using these six CDDS variables to discriminate between the treatment and the control group. The variable, "abstract symbols" was difficult to rate as noted by the low interrater reliability.

Hypothesis One

The first hypothesis investigated in this study was that there would be variables of the CDDS which would significantly discriminate between children in the treatment group and children in the control group. This hypothesis was supported by the data. There were seven (out of 23) variables that discriminated between the treatment and the control group: color type, line/shape, integration, groundline, inanimate objects, abstract symbols, and space usage (see Table 5).

</table>

However, when each category was compared with the other two categories only "mixed line and shape" when compared to "line only" significantly discriminated between the treatment and control groups. Children in the control group were more likely to use "mixed line and shape" than children in the treatment group when "line only" was the alternative.

Integration

The variable "integration" significantly discriminated between the treatment and control groups across its three categories (disintegrated, integrated, and impoverished). When the two categories, "disintegrated" and "integrated," were analyzed, children in the control group were significantly more likely to have an integrated CDDS than a disintegrated CDDS. In addition, when the comparison was made between "integration" and "impoverished," the control group was significantly more likely to have an integrated CDDS than an impoverished CDDS. Finally, when the two categories, "disintegrated" and "impoverished," were combined, and compared to "integrated," children in the control group were significantly more likely to have an integrated CDDS than either a disintegrated or an impoverished CDDS.

Groundline

The variable "groundline" significantly discriminated between the treatment and the control group. For developmental reasons, only children age seven and above were included in the statistical analysis of this variable. The control group was significantly more likely to include a groundline in the CDDS than the treatment group.

Since the treatment group was less likely to include a groundline, the objects in the CDDS would be either paper based or free floating.
Inanimate Objects

The variable "inanimate objects" significantly discriminated between the treatment group and the control group. The control group was significantly more likely to include inanimate objects in the CDDS than the treatment group.

Abstract Symbols

The variable "abstract symbols" may significantly discriminate between the treatment and control groups. Significance cannot be certain due to the low interrater reliability. Children in the control group were more likely to include abstract symbols in the CDDS than the treatment group.

Space Usage

The variable "space usage" significantly discriminated between the treatment group and the control group across its categories: 0–33%, 34–66%, 67–99%, and 100%. However, only the 0–33% category when compared to the 100% category was significant in discriminating between groups. The control group was more likely to utilize the entire page when the alternative was the use of 0–33% of the page.

Summary of Hypothesis One

Of the 23 variables in the CDDS rating form, seven variables were found to significantly discriminate between the treatment group and the control group.

Inanimate objects were more likely to be found in the drawings of the control group. The variable, "inanimate objects," was defined in part as "concrete, immobile objects including food items, plant items, nature images . . . ." (Cohen, 1985, p. 4). Cohen also stated that "mundane signs are included: stop signs, dollar signs, flags, peace signs, smiley faces, question marks, exclamation points, arrows" (1985, p. 4).

Children in the control group were more likely to include abstract symbols in their drawings. This variable was difficult to rate as it was evident by the low interrater reliability. Therefore, the discriminatory value of this variable is weak. The definitions given in the rating guide for abstract symbols and "inanimate objects" are similar and the several examples are interchangeable. More often than not, when a child's drawing was categorized as having an abstract symbol, the drawing was also categorized as having an inanimate object.

Hypothesis Two

The second hypothesis investigated whether a cluster of variables in the CDDS would emerge as criteria for diagnosing children with adjustment disorders. When the statistical program was implemented, the data available for each diagnostic category within the entire group of adjustment disorders was insufficient, and therefore, could not be analyzed specifically (see Table 3). However, when all children diagnosed with particular types of adjustment disorders were collapsed into one set and analyzed as one group, there was sufficient data.

The data support the hypothesis. A cluster of 20 variables (out of 23 possible variables on the CDDS) was found to significantly (p < .02) describe the drawings of the 28 children with the DSM-III-R diagnosis of adjustment disorder. The statistical information on each of the 20 cluster variables is presented. The variables not in the cluster, "enclosure" and "tree" are not discussed (see Table 6). Only six of the 20 cluster variables significantly discriminate between groups and have significant interrater reliability.

Some drawing patterns emerged for several of the 20 variables that clustered for subjects diagnosed with an adjustment disorder. While not every picture drawn by a child with adjustment disorder will meet all the characteristics, this profile gives a general idea of what to expect (see Table 7). Characteristics of pictures drawn by children diagnosed with adjustment disorder seemed to parallel characteristics of both the treatment group and the control group. Of the DSM-III-R diagnoses for children, adjustment disorder is the mildest and least chronic. Thus, these children's drawings were most like the drawings by children with no diagnosis. As stated under hypothesis one, children in the treatment group were less likely to use four or more colors in their drawings. However, of the children in the treatment group who did use four or more colors, the majority were diagnosed as having an adjustment disorder (see Figure 1).

Children diagnosed with adjustment disorder used either line only or a mixture of line and shape in their drawings (see Figure 2).

As stated under hypothesis one, children in the treatment group were less likely to have integrated drawings. However, the majority of the children in the treatment group who had integrated drawings were diagnosed with an adjustment disorder (see Figure 3).

As stated under hypothesis one, the variable "groundline" significantly discriminated between the treatment and control groups. The children with a diagnosed adjustment disorder followed the pattern of not using a groundline (see Figures 4 and 5).

"Space usage" was a significantly discriminating variable and had a high interrater reliability. Children diagnosed with adjustment disorder were most likely to use 67–99% of the space (see Figure 6).

For 20 of the 23 variables on the CDDS rating form, there was a significant difference in the distribution of responses across categories. Drawings of children diagnosed with adjustment disorder have the following characteristics: use of four or more colors, use of either line only or line and shape mixed, integrated, representational mixed (angular and curvilinear), multiple images, land only (if depicting a landscape), medium pressure, long lines, and use of 67–99% of the space.

The variables which are most important in characterizing the drawings of children with adjustment disorder are: (a) variables with high interrater reliability, and (b) variables which also discriminate between the treatment and control groups. For example, the variable "groundline" seems to be a vital characteristic to look for in the drawings of children with adjustment disorders. Children with adjustment disorders do not tend to use a groundline.

*Variables which significantly discriminated between the treatment and control groups
**Variables with interrater reliability with Kappa ≥ .50

Discussion

Both hypotheses were supported by the data. First, there were six variables of the CDDS which significantly discriminate between children in therapy and children not in therapy. Secondly, there were 20 variables that characterize the drawings of children with adjustment disorders. The results must be carefully interpreted. Furthermore, the inclusion of all factors affecting the outcome must be taken into account.

In the discussion of the results, an attempt will be made to explore the interactions between the three parts of the CDDS study: (a) interrater reliability, (b) the use of the

Figure 1. Free picture, subject diagnosed with adjustment disorder. (Characteristics include: four or more colors, no blending, no idiosyncratic color, mixture of line and shape, integrated, representational mixed, multiple images, no groundline, no people, no abstract symbols, no words, land only, medium pressure, long line length 67-99% space use, and no tilt)

Figure 2. Free picture, subject diagnosed with adjustment disorder. (Characteristics include: four or more colors, no blending, no idiosyncratic color, line only, integrated, representational mixed, multiple images, no groundline, no people, no animals, no inanimate objects, no abstract symbols, medium pressure, long line length, no movement, 67-99% space use, and no tilt)

Figure 3. Free picture, subject diagnosed with adjustment disorder. (Characteristics include: four or more colors, no blending, no idiosyncratic color, mixture of line and shape, representational mixed, multiple images, no groundline, no people, no animals, no abstract symbols, no words, medium pressure, long line length, no movement, 67-99% space use, and no tilt)
CDDS to discriminate between the treatment and control groups, and (c) the characteristics of the CDDS of children with adjustment disorders.

There were six variables of the DDS Rating Guide which had high interrater reliability and significantly discriminated between the treatment and control groups: “color type,” “line/shape,” “integrated,” “groundline,” “inanimate objects,” and “space usage.” All six variables were also important in the discrimination of children with adjustment disorders from their CDDS.

The analysis of “color type” suggests that there may be a relationship between the number of colors used and whether or not a child is in treatment for psychological reasons. One possible relationship that could be explored is the one between restriction of affect and number of colors utilized with the assumption being that the more restricted the affect the fewer colors used.

Children in the control group have a tendency to utilize a combination of line/shape possibilities. In comparison, children in treatment seem to use one style of expression. Children in the control group draw with greater integration and embellishment than do children in the treatment group.

The use of the groundline in the control group CDDS is congruent with what is normally expected for graphic representation according to Lowenfeld and Brittain (1987).

While not a calculated statistic, it was noted that children in the control group used symbols and objects of various sorts in most of their pictures. Children in therapy were more likely to have impoverished drawings, and it is possible that it is difficult for a rater to recognize distinct objects.

In a comparison of the drawings of children with adjustment disorders to the control group and to the treatment group, the drawing characteristics of two variables are similar to the control group and the drawing characteristics of four variables are similar to the treatment group (see Table 8). A diagnosis of adjustment disorder is temporary (problems began six months ago or less) and is attributed to a known stressor. Based on these criteria, the problems of adjustment disorder children are less severe and more temporary, if treated, than other children with DSM-III-R diagnoses. Therefore, if children’s drawings are a reflection of their current mental health, then the drawings of children with adjustment disorders should be similar to drawings of both the control group and the treatment group. The results of the CDDS study support this assumption.

Limitations of the Study

The results of hypothesis one (the CDDS can be used to discriminate between children in therapy and children not in

therapy) can be generalized to a similar population for the following reasons: (a) a large subject pool was used, (b) from the population pools of both the treatment and the control group, a random sample of subjects was chosen, (c) a control group was used, and (d) consistent data collection and administration procedures were used.

The results of hypothesis two (a cluster of variables of the DDS Rating Guide applied to the CDDS can be used to identify children with adjustment disorders) may not be strong enough to generalize outside of the sample population for the following reasons: (a) a small number of subjects was used, (b) a comparison to other diagnostic categories was not possible, and (c) 14 of the 20 variables that clustered for children with adjustment disorders did not significantly discriminate between the treatment and control group and did not have strong interrater reliability.

In addition to the problems mentioned above, four other limitations of the study were noted. First, the data were collected both individually and in groups. It was not possible to uncover differences which may be attributed to the two methods of data collection, adding a new dimension to the test results.

Second, previous reported use of the DDS was with adults. Because the DDS was developed for adults, the variables in the DDS Rating Guide were developed for adult drawings and some of the variables may not be appropriate for children’s drawings (Cohen, 1985). The questionable appropriateness of some of these variables for children’s drawings may contribute to the low number of variables which discriminated between the treatment and control groups. Third, one aspect of the study was to include a racial balance. Due to time limitations it was not possible to collect an adequate number of CDDS profiles from both black and white children. Therefore, in the control group there was not an equal number of black and white children. Finally, there was potential experimenter bias since the primary investigator also collected and rated the data.

Recommendations for Future Research

There are four recommendations for future research. First, additional replication studies on both the DDS and the CDDS are needed. Second, the Drawing Analysis Form and the Rating Guide may need revision. Because of the categorical nature of the rating format, statistical analysis of the data is extremely complicated. For a less complicated analysis, the rating format should be comprised of variables rated on a continuous data scale. By using a continuous data scale, the distribution of errors would be normal and use of a statistical analysis with more power would be possible.

Third, the total number of subjects and the number of subjects in each diagnostic category should be increased. The total number of subjects in the control group should be equal to the total number of subjects in the combined diagnostic category groups.

Finally, it would decrease potential experimenter bias if the administrator of the drawings, rater of the drawings, and the author of the research were not the same person.

Conclusion

This CDDS study was designed and conducted with standard research principles in mind. Two hypotheses concerning the CDDS were proposed and the data supported both hypotheses. Through the implementation of the CDDS study, important research questions were uncovered. The study of the CDDS presented here is a starting point for continued investigation into the use of drawing assessments for children.

Tree Drawings and Trauma Indicators: A Comparison of Past Research with Current Findings from the Diagnostic Drawing Series

Anita Rankin, MA, Washington, DC

Abstract

An enduring hypothesis is that knotholes, broken branches, damaged trunks, and leafless trees are indicative of traumatic episodes in an individual’s life. This paper reviews selected past research which does not definitively confirm or deny the basic hypothesis and reports a current study based on tree drawings from the Diagnostic Drawing Series Archive. Suggestions for possible further areas of research on this topic utilizing the Diagnostic Drawing Series are presented.

Introduction

In 1945, C. G. Jung wrote that the most common symbolic meanings of the tree image are “growth, life, unfolding of form in a physical and spiritual sense, development, growth from below upwards and from above downwards, old age, personality, and finally death and rebirth” (Jung, 1967, p. 272). In short, Jung believed the tree image to be a “projection of the individuation process” (p. 341). Several other authors have agreed with Jung’s statement, presenting hypotheses that would support the assumption that tree drawings may represent the life history of an individual, including developmental processes, past experiences, and hopes for the future (Buck, 1948; Bolander, 1977), as well as characterological aspects (Koch, 1952; Hammer, 1958). Tree drawings may allow for a greater possibility of unconscious projection of repressed or avoided material as compared to the human figure (Hammer, 1958).

An impatient on a dissociative disorders unit wrote a powerful statement about her personal perspective of tree symbols and trauma:

I look out the window and the trees are speaking to me—losing their limbs, leaves, branches, contorted, barren—so vulnerable against the clear blue sky, so lost amongst the crown of cars and buildings—the glut of city. Some will blow again in spring, some now cry the beauty of orange, red, and yellow sleep, but others will bear their scars forever. The missing limbs will not return in spring; the leaves that come on near their branches may disguise or hide, but cannot deny the loss. How do you tend to such a tree?

The idea that a tree image can indicate presence or absence of psychic trauma has generated both interest and controversy among art therapists, psychologists, and other mental health professionals over the past 40 years. Several research studies have evaluated the basic relationship between trauma markings on trees and traumatic life episodes; associated hypotheses have also been developed from this initial concept. This article will first review some of the important research studies, followed by observations of tree drawings from the archive of the Diagnostic Drawing Series (DDS).

Published Hypotheses

Three years after the publication of Jung’s essay, John Buck published his initial description of the House-Tree-Person (H-T-P) projective drawing technique. In this article, Buck wrote, “Scars, broken branches, and the like, seem to symbolize traumatic episodes which the subject feels were scarring” (Buck, 1948, p. 390). Buck stated that the time of the trauma may be estimated by the location of the scar on the trunk, where the base of the trunk represents the birth of the person and the top of the tree the current age. He also wrote that well-adjusted people will rarely state that the tree they have drawn is dead. Buck suggested that a dormant tree is not the same as a dead tree, and that a totally dead tree may indicate a greater degree of maladjustment than one that is only partially dead. Buck and Hammer (1969) stated that a leafless tree represents “inner barrenness” and also a “lack of ego organization” (p. 186), preventing a person from being able to formulate a sense of the future.

Bolander (1977) echoed Buck’s initial hypothesis when she wrote, “Some of the scarring marks may represent objectively traumatic occurrences, such as the death of loved ones, serious accidents or illnesses, rape, or dramatic changes in life circumstances” (p. 285). Bolander suggested that scarring marks could refer to subjectively traumatizing events or to unconscious preoccupations. Her conclusions suggested that specific marks have specific meanings. Bolander’s interpretation of dead trees was somewhat different than Buck’s: “People who draw dead trees often feel that they are completely victimized by external forces. Their defenses have deserted them, for one reason or another” (p. 117).

Research Studies

Several research studies have tested these hypotheses related to tree imagery, including the work of Levine and Galanter (1953); Lyons (1955); Bolin, Schneps, and Thorne (1956); MacCasland and Judson (1960); Moll (1962); Devore
and Fryrear (1976); and Torem, Gilbertson, and Light (1990). A brief description of the methods and relevant findings of these studies follows.

Levine and Galanter (1953) collected tree drawings from 27 persons who had experienced the amputation of an arm or a leg. In this study, it was assumed that substantial body trauma would produce associated psychic trauma. Only seven of the subjects drew a scar on the tree image; the majority of the participants in this research study did not indicate their traumatic experience through the drawing of an injured tree. Observations of the placement of the seven scars on the tree images indicated there was no correlation between scar placement and the established date of the amputation.

In a subsequent study (Lyons, 1955), 50 individuals were asked to draw a tree; assume the tree had been hit by lightning, and mark an “X” on the tree where the lightning would have struck. They were then interviewed to determine the worst thing that had happened to them in their lives and when that event had occurred. No significant correlation was found in this study to indicate that placement of a tree scar is related to the date of the trauma.

Another important study to question the tree/trauma hypothesis was conducted by Bolin, Schnepps, and Thorne (1956). A total of seven spontaneous scars or broken branches were observed in the tree drawings of 51 mental patients and 31 nurses/psychiatric aides-in-training. Four of the scars were drawn by the patients, and three by the staff. These results indicated no significant differences in the number of occurrences of injured tree drawings between known mental patients (who are suspected of having experienced a higher degree of trauma) and a more generalized population. These authors also studied the relationship of the placement of tree injury to the date of reported trauma. Thirty-nine mental patients were instructed to draw an “X” on an image of a standardized tree provided by the researchers. Several days later the patients were asked to ascertain the date of the worst event of their lives. These dates were compared with the placement of the “X” on the tree image. No relationship between the date of the worst event and the placement of the “X” was found.

Two research studies (Judson & MacCasland, 1960; Moll, 1962) addressed the relationship of the weather and seasonal influences on the drawing of a tree. In the first study, 20 House-Tree-Person (H-T-P) sets for each month of the year were collected and observed to determine the presence or absence of leaves. The 240 tree drawings were created by patients (120 men, 120 women) with a range of psychiatric diagnoses. The drawings of the women patients showed a seasonal influence, with a significantly higher percentage of bare trees drawn in winter months. However, this was not true for the male population. Judson and MacCasland concluded, “Less significance should be attached to the drawing of a bare tree in winter than in summer” (p. 173). The follow-up study (Moll, 1962) considered the lack of significance in the male tree drawings. H-T-P drawings were collected from 269 male students. This author concluded that the time of the year was in fact significantly related to whether male subjects drew more or less leaves on tree drawings.

Devore and Fryrear (1976) studied a total of 1,844 H-T-P sets drawn by “juvenile delinquents.” They found 228 tree drawings (12.35%) which contained tree holes or scars, in a population that they expected to have a high level of abuse history and subsequent trauma. The researchers randomly selected 76 samples from drawings that included a tree hole and 76 samples that did not include a tree hole. The individuals who drew these trees were compared on the basis of 22 variables. Devore and Fryrear concluded that there may be certain personality variables (increased intelligence and hyperactivity) that cause a person to express psychic trauma through tree drawings which are not found in other individuals who do not draw scarred trees. No follow-up studies have been conducted to verify these results.

In a more recent study (Torem, Gilbertson, & Light, 1990) the researchers instructed 215 individuals not identified as mental health patients and 56 mental health patients to draw a tree and complete a questionnaire surveying their physical, verbal, and sexual abuse histories. Sixty-four percent of 138 subjects reporting past abuse drew trees with scars, knotholes, or broken branches. Twenty-seven percent of 133 individuals not reporting abuse also drew knotholes, scars, or broken branches. This would indicate that anyone drawing a tree with the above mentioned indicators would be suspect for having experienced previous psychic trauma, but not all knotholes, scars, or broken branches are necessarily indicative of trauma. Although there was a slightly higher percentage of trauma indicators present in the drawings of the mental health patients reporting past abuse as compared to the other group of subjects reporting past abuse, the difference was not shown to be significant. The study did not find any significance for the correlation of the placement of the traumatic indicator to the date of the trauma. These researchers also reported an association between duration of physical abuse and instances of injury markings on the tree drawings, in that the individuals abused over longer periods of time drew more numerous scars and broken branches on their tree drawings.

**Study Methods**

Most of the tree drawings which have been previously studied and reported in the research literature were obtained through either the administration of an established projective drawing technique or a simple directive to draw a tree. Included in the projective drawing techniques which incorporate the drawing of a tree are the Koch Tree Test (Koch, 1952). The House-Tree-Person Test (H-T-P) (Hammer, 1958), and the Diagnostic Drawing Series (DDS) (Cohen, Hammer, & Singer, 1988). The Koch Tree Test is not widely known or used in the United States, since revised editions of the original publication have not been translated into English. Published tree drawing research in English has primarily used either the “draw a tree” directive or the H-T-P to provide the tree images used in the studies; the H-T-P has probably been the most frequently used of the two.

The tree drawings accumulated in the DDS archive in Washington, D.C., provide an additional resource to aid in the study of tree images as diagnostic indicators of trauma (Mills & Cohen, 1993); there are currently over 1000 samples of tree drawings in the collection, including tree images collected from various diagnostic populations located in different parts of this country and other regions of the world. The
DDS is a standardized art interview (Cohen, Hammer, Singer, 1988) in which the individual is instructed to draw three pictures, the second of which is a tree.

For this study a total of 60 tree drawings were selected from the DDS archive. Thirty drawings were created by adults consecutively admitted to a post-traumatic dissociative disorders unit in a psychiatric hospital. Tree drawings of this patient population were selected because this is a population in which there is a high frequency of reported childhood trauma; the majority of therapists working with this population believe in the existence of a causal relationship between dissociative disorders and trauma (Putnam, 1989). As a control, the remaining 30 drawings were randomly selected from a collection of 50 drawings created by staff members at another psychiatric facility.

Tree drawings were observed for the presence of knotholes, broken branches, damaged trunks, and the absence of leaves. (Sears were found to be indistinguishable from tree bark texture or shading.) An independent rater reviewed the tree drawings. There was 96% agreement between the primary observer and the independent rater as to the occurrences of knotholes, broken branches, damaged trunks, and bare trees. Criteria for the identification of knotholes, broken branches, and leafless trees were obtained from the Diagnostic Drawing Series Tree Rating Scale Definitions (Creekmore, 1989).

**Findings from the DDS**

Sixty percent of the tree drawings created by individuals diagnosed with dissociative disorders contained at least one instance of either a knothole, a broken branch, a damaged trunk, or were leafless. Twenty-seven percent of the tree drawings of the control group showed one of the above indicators. These percentages seem on the surface to reflect differences in these populations; however, on closer study of each category of tree injury, the significance diminishes in some categories.

In a comparison of the occurrence of knotholes observed in the tree drawings of the two populations, almost an equal amount of trees with knotholes were observed in each, as shown in Table 1. This suggests that the presence of knotholes is not indicative of trauma. One tree drawing created by an individual from the psychiatric population was notable as it contained a total of 12 knotholes. This may suggest that large numbers of knotholes on a single tree may indeed reflect historical trauma.

Five (17%) of the tree drawings created by the dissociative population contained more than one instance of a broken branch, damaged trunk, or lacked foliage. (Knotholes were not included in the calculation of multiple indicators because they are more likely to be indicative of stereotypic schemas.) None of the tree drawings created by the control group showed more than one trauma indicator. This would imply that the presence of multiple indicators may be more suggestive of a trauma history than are single indicators.

Overall differences in the comparison between a group of tree drawings created by the psychiatric population with those created by the control group are very apparent; the dissociative group’s tree drawings include images of severely damaged trees, whereas the degree of overall tree injury in the latter group is quite minimal. However, when comparing individual tree drawings there is not always an obvious difference. Fifty-seven percent of trees drawn in the inpatient setting did not show any broken limbs, damaged trunks, or bareness. This implies that more than half of the tree drawings in a dissociative population may not indicate a history of trauma as evidenced by the above indicators, and, therefore, may not reflect a self-image which reflects historical material; the trauma experience is not projected onto the tree drawing.

The results of this small study have limited generalizability. The findings are based on a small sample, and many additional tree drawings by both groups of subjects would need to be examined to validate the findings. Obtaining accurate trauma histories for subjects in each group would aid in the overall validity of the results, although this may not be possible as some trauma instances may be repressed or dissociated. Also, the sample of participants was skewed as to gender (inpatients and staff were primarily female) and ethnicity (Caucasian).
