Nearly 30 years ago, research showed that preschool children reared by parents with differing parenting attitudes or styles, differed in their degrees of social competence. To test this theory, a two-year study was conducted. During "Year 1," 2,250 high school seniors and 406 university freshmen from the middle South were surveyed regarding their perceptions of their parents' parenting style, their families' family type, and their own participation in a variety of problem behaviors. Significant results at "Year 1" indicated that, in regard to behavioral outcome, "authoritative" parenting was superior to "indulgent" and "neglectful" parenting, and that "balanced" and "moderately balanced" family types were superior to "mid-range" and "extreme" family types. In "Year 2" (N=261), significant differences among parenting styles and family types persisted even when "Year 2" scores were statistically adjusted for those from "Year 1." Although many participants had left the direct influence of their families, authoritative parenting continued to be superior to "neglectful," "indulgent," "authoritarian," or "middle range" parenting. Also the "balanced" family type continued to demonstrate superiority over the "extreme" type in providing resiliency against some problem behaviors. The results expand the growing literature regarding the continuing influence of home environment on older adolescent behavioral outcome. Summary tables showing covariate analyses are included. (EMK)
Parenting Style and Family Type Revisited: Longitudinal Relationship to Older Adolescent Behavioral Outcome

Abstract

During Year 1 of the current longitudinal study, 2250 high school seniors and 406 university freshmen from the middle South were surveyed regarding their perceptions of their parents on parenting style (Baumrind, 1991; Steinberg et al., 1994), their families on family type (FACES II; Olson et al., 1982), and their own participation in a variety of problem behaviors. Significant results at Year 1 indicated that, in regard to behavioral outcome, authoritative parenting was superior to indulgent and neglectful parenting (Slicker, 1996b) and that balanced and moderately balanced family types were superior to mid-range and extreme family types in these older adolescents (Slicker, 1996a). In this Year 2 study, the majority of the Year 1 students were re-contacted, and 261 participated. Significant differences among parenting styles and family types persisted even when analyses of covariance (ANCOVAs) were completed, statistically adjusting the Year 2 scores for those from Year 1. Year 2 results indicated that, although in many cases these older adolescents had left the direct influence of their families, significant differences among parenting styles remained in 4 of the 8 problem behavior areas and significant differences among family types remained in 2 of the 8 areas. Authoritative parenting continued to be superior to neglectful, indulgent, authoritarian, or middle range parenting. Also, the balanced family type continued to demonstrate superiority over the extreme type in providing resiliency against some problem behaviors. Results of this study provide unique evidence and, thereby, expand the growing body of literature regarding the continuing influence of home environment (parenting style and family type) on older adolescent behavioral outcome.
Parenting Style and Family Type Revisited:
Longitudinal Relationship to Older Adolescent Outcome

Nearly 30 years ago Baumrind (1967, 1971) noted that preschool children reared by parents with differing parenting attitudes, or styles, differed in their degrees of social competence. Her theory-derived parent classification resulted in the original parenting style prototypes: authoritative, authoritarian, and permissive. Later researchers split the permissive type into permissive-indulgent and permissive-indifferent (Baumrind, 1978; Maccoby & Martin, 1983) as a result of a two-dimensional (demandingness and responsiveness) typology of parenting patterns. The resultant fourfold scheme established the four parenting styles which are commonly employed in today's research literature (e.g., Lamborn, Mounts, Steinberg, & Dornbusch, 1991; Steinberg, Lamborn, Darling, Mounts, & Dornbusch, 1994): authoritative, authoritarian, indulgent, and neglectful.

A typology considers the additive and multiplicative effects of parenting dimensions not possible through studying these dimensions independently (Rollins & Thomas, 1979). Baumrind's typological parenting style theory (1971) implies that the manner in which parents "reconcile the joint needs of children for nurturance and limit-setting" (Baumrind, 1991a, p. 62) has a major impact on the degree of social competence achieved as well as on the behavioral outcome of these children. Others (Dornbusch, Ritter, Leiderman, Roberts, & Fraleigh, 1987; Steinberg, Elmen, & Mounts 1989) have continued to increase the age range for which significance of parenting style applies. Significant differences in behavioral outcome have been found not only in children but also in early and middle adolescents reared by parents using the four "classic" parenting styles. Those behavioral and psychosocial characteristics that have been reported in the literature as associated with parenting style include social competence (Baumrind, 1991a; Lamborn et al., 1991; Steinberg, 1990), academic achievement (Dornbusch et al., 1987; Lamborn et al., 1991; Steinberg, Mounts, Lamborn, & Dornbusch, 1991; Steinberg et al., 1989), self-reliance (Steinberg et al., 1991), psychological distress and delinquency (Lamborn et al., 1991; Steinberg et al., 1991), substance use (Baumrind, 1991a), adolescent drinking and delinquency (Barnes & Farrell, 1992), and peer group selection (Brown, Mounts, Lamborn, & Steinberg, 1993). In general, the results of these studies indicate that adolescents reared by authoritative parents experience the most favorable outcomes, while those reared by neglectful parents have outcomes that are least favorable in regard to psychological adjustment and social conduct. The "middle two"
parenting styles (authoritarian and indulgent) have resulted in mixed outcomes for the adolescent population (Steinberg & Darling, 1994).

While prior research completed in the areas of parenting style had progressed by stages through a theory applied initially to preschoolers, then to children, to young adolescents, and finally, to adolescents in high school, no literature existed that carried this theoretical model into an older adolescent population. Laurence Steinberg, one of the foremost researchers in this area, believed this would be an important line of research to pursue (personal communication, 9/30/94) and provided his most recent measure for use in the Year 1 study. Year 1 results found that, in a sample of graduating high school seniors and second semester university freshmen, parenting style was significantly related to behavioral outcome using a constellation of eight problem behaviors as dependent variables (see Table 1). Authoritative parenting was negatively associated with problem behaviors, while the converse was true for indulgent and neglectful parenting styles. Authoritarian and middle range parenting (a style added for the Year 1 study), while adequate to prevent some of the negative effects, did not provide the resiliency necessary to produce positive results in the majority of the outcome variables. The first-year study expanded the previous range of four parenting styles to five and extended the age range for which this theoretical typology applies from high school students in general to graduating high school seniors and university freshmen.

In addition to parenting style, family type was also considered in the Year 1 study. Olson et al. (1992) devised the Circumplex Model of family interaction that primarily considered two facets of family functioning: adaptability and cohesion. From the Olson et al. family inventories, the Family Adaptability and Cohesion Scale (FACES II; Olson, Portner, & Bell, 1982) was chosen as the measure of family type. With the currently recommended linear scoring of this scale, Olson and colleagues found that higher levels of flexibility and connection within a family predicted greater functionality of that family (Olson, 1993).

The bulk of prior FACES research had involved the discriminate power of the Circumplex Model in distinguishing between families experiencing some malady and those without (Olson, 1993). In these studies, the investigator considered whether a larger percentage of subjects in afflicted families fell within the expected dysfunctional family types by virtue of their low cohesion and adaptability scores and whether a greater proportion of those not afflicted gained higher scores in adaptability and cohesion, thus placing them in the more functional family types. While useful, this method did not help us to understand how parents in functional families behave, nor did it provide us with an outcome gauge to determine the result of having
lived in a “functional” or “dysfunctional” family from a generally “normal” population. Year 1 of the present longitudinal study determined that family type was significantly related to specific behavioral outcomes in older adolescents (see Table 2). The balanced and moderately balanced family types were negatively associated with problem behaviors while the mid-range and extreme family types were positively associated with those problem behaviors.

Although prevailing wisdom suggests that parental importance all but disappears by the time older adolescents reach college age, there is a growing body of research to suggest that this is not the case (Steinberg & Darling, 1994). Parenting style effects appear to continue both indirectly, through the playing out of long-established patterns in the youth’s behavior, and directly, through continuity in parenting practices over time and continued contact with parents. Therefore, we hypothesized for the Year 2 study that the influence of parenting style and family type would persist, even when statistically controlling for Year 1 behavioral outcome scores.

Procedure

Review of Year 1 Study

This longitudinal study was begun during the spring semester of 1995 via self-report surveys administered to 2250 graduating high school seniors in 14 high schools in the middle South region as well as to 406 second-semester college freshmen from a large state university in the same region. Students indicated their level of personal participation in a variety of problem behaviors (school misbehavior, drinking problems, alcohol use, drug use, theft / deceit, risky sex, aggression, and delinquency). The students also rated their perceptions of their parents on two parenting dimensions: behavioral control (parental limit-setting and monitoring) and acceptance (emotional nurturance and warmth) and on two family type dimensions: adaptability (flexibility in family roles) and cohesion (emotional bonding among family members). Based on high, moderate, and low values of the parenting dimensions (as per the typology), students were assigned to one of five groups representing the parenting style with which they were reared: authoritative, authoritarian, "middle range," indulgent, and neglectful. Based on high, moderately high, moderately low, and low values on the combined family type dimensions (as per published norms), students were assigned to one of four family types, representing the type in which they were reared: balanced, moderately balanced mid-range, and extreme.
Measures

Internal consistency reliability (coefficient alpha) is provided for Year 1 (alpha 1) as well as Year 2 (alpha 2) for each scale. In addition, test-retest reliability is given for a two-week intervening time interval (r2) and again for a 52-week intervening time interval (r52) which is the correlation between the scales at Year 1 and Year 2.

Parenting Style

Behavioral control. The 8-item behavioral control subscale assessed the degree of parental limit-setting and monitoring of the adolescent, as well as parental demands for mature behavior in the adolescent. It included such items as "In a typical week at home, what is the latest you can stay out on Friday and Saturday night?" and "How much do your parents try to know what you do with your free time?" with three possible responses ranging from "none" to "alot." (Alpha 1 = .78; alpha 2 = .77; r2 = .70; r52 = .54).

Acceptance. The 9-item acceptance subscale assessed the older adolescents’ perceptions of involvement, responsiveness, warmth, and nurturance of their parents. Items such as "My family does fun things together" and "My parents spend time just talking to me" were scored on a four-option Likert scale from "agree strongly" to "disagree strongly." (Alpha 1 = .79; alpha 2 = .79; r2 = .88; r52 = .65.)

In order to determine parenting style groups, first, scores on each of the parenting dimension subscales were divided into three groups following the procedure used by Baumrind (1991a, 1991b). The high group on each subscale was defined as all those parents with scores greater than or equal to 1/2 standard deviation above the mean for that subscale, while members of the low group were those falling at or below 1/2 standard deviation below the mean. Medium-low to medium-high scorers (those falling closer to the mean, between the high and low groups) formed the middle group. A division such as this, although sample specific, assured that marked differences would appear among groups so designated for this normal population.

Then using the classic typology, parents were categorized into the first four parenting style groups. Authoritative parents were those in the high groups on both behavioral control and acceptance. Authoritarian parents were those high on behavioral control, but in the low group on acceptance. Indulgent parents were high on acceptance, but low on behavioral control. Neglectful parents were low on both behavioral control and acceptance.

An additional parenting style was also defined for this study using the same categorical approach. The fifth parenting style, "middle range" parents, were those who fell within the
middle group on both behavioral control and acceptance (see Baumrind’s “good enough”
parents, 1991a). Although the method of using only extreme types of parenting tends to
strengthen internal validity of a study (Steinberg et al., 1994), by including a portion of those
parents who fall within the moderate ranges of the parenting dimensions (i.e., middle range
parents), external validity is also strengthened. In addition, inclusion of a more moderate
parenting style allows examination of older adolescent behavioral outcome results in other
than "extreme" parenting styles.

**Family Type**

**Adaptability.** The 14-item adaptability scale (FACES II) assessed the older adolescents’
perceptions of their families’ ability to change in regard to negotiation style, power structure,
role relationships, and response to situational and developmental stress (Olson et al., 1992).
This scale included such items as “It is hard to know what the rules are in our family” and
“Each family member has input into major family decisions” with 5 response choices, ranging
from “almost never” to “almost always.” (Alpha 1 = .73; alpha 2 = .73; $r_{52} = .66.$)

**Cohesion.** The 16-item cohesion scale (FACES II) assessed the older adolescents’
perceptions of the emotional bonding that members of their families have toward one another
in the areas of family boundaries, friends, time, space, decision-making, interests, and
recreation (Olson et al., 1992). It included items such as “Family members feel very close to
each other” and “We have difficulty thinking of things to do together as a family” with the same
5 response choices as above. (Alpha 1 = .55; alpha 2 = .41; $r_{52} = .70.$)

In order to determine family type, adolescent self-reported scores on both adaptability and
cohesion were totaled. Then, via published norms (Olson et al., Circumplex Model, 1992),
students were categorized into one of four levels on each subscale. Once placed in a
numerically ranked adaptability category (range = 1.0 - 4.0) and cohesion category (range =
1.0 - 4.0), the ranks were combined and averaged. This placed the family in one of the four
family types (theoretically, most functional to least functional): **balanced** (range = 3.5 - 4.0),
**moderately balanced** (range = 2.5 - 3.0), **mid-range** (range = 1.5 - 2.0), and **extreme** (0.5 - 1.0).

**Problem behavior**

Scales used were those found in the adolescent literature. An attempt was made to
include variables representing a wide variety of problem behaviors and those most typically
mentioned in numerous prior studies. Problem behavior was measured by eight standardized
subscales with varying numbers of items per subscale, each item containing five response
options ranging from "never" to "6 or more times." Unless otherwise noted, the students were
asked about their involvement "during the past year" in a variety of problem behaviors. Self-report of problem behavior has been used by many researchers (e.g., Hirschi, 1969; Jessor & Jessor, 1977; Kline, Canter, & Robin, 1987) and has been shown to be reasonably reliable and valid (Oetting & Beauvais, 1990; Patterson & Stouthamer-Loeber, 1984), perhaps even more so than police records which suffer from under-reporting (McCord, 1990).

The 5-item school misbehavior subscale (alpha 1 = .72; alpha 2 = .55; r^2 = .65; r^52 = .40) addressed issues from copying a classmate's assignment to skipping class or work without any real excuse (Dornbusch et al., 1985; Gold & Mann, 1972; Lamborn, Brown, Mounts, & Steinberg, 1992; Ruggiero, 1984; Windle, 1993). The 9-item drinking problems subscale (alpha 1 = .75; alpha 2 = .67; r^2 = .83; r^52 = .55) asked, for example, how often "within the past year" the student had been drunk or very high or had been in trouble with other individuals (e.g., parents, friends, teachers, police), each mentioned separately (Barnes, 1984; Jessor & Jessor, 1977). In addition, students were asked how many times "within your lifetime" they had been arrested for drunken driving or arrested for other drunken behavior (Jessor & Jessor, 1977). The 2-item alcohol use scale (alpha 1 = .87; alpha 2 = .88; r^2 = .85; r^52 = .67) was formed by combining the frequency of drinking, self-reported on a 5-point scale from "never" to "daily," with amount. Amount was also self-reported on a 5-point scale ranging from "0" to "more than 10" "beers, wine coolers, glasses of wine or mixed drinks" consumed "each time you drink (during one day or in one evening)" (Barnes, 1978, 1984; Rachal et al., 1975). The 5-item drug use scale (alpha 1 = .70; alpha 2 = .53; r^2 = .74; r^52 = .73) asked how often the student used: marijuana; an hallucinogen (acid, LSD, etc.); and cocaine, crack, stimulants, or other hard drugs (Jessor & Jessor, 1977; Ruggiero, 1984). An item asking the number of cigarettes smoked per day was included (Windle, 1993), and finally, the students were asked "Are you high on any substance right now?" which required a "yes" or "no" response. The 2-item lie scale and 3-item steal scale were combined to form a 5-item deceit/theft scale with increased reliability over the other two scales separately (alpha 1 = .65; alpha 2 = .44; r^2 = .68; r^52 = .43). The questions ranged from how often students used a phony ID to how often they took something from someone else worth over $30 (Barnes, 1984; Gold, 1970; Gold & Mann, 1972; Ruggiero, 1984; Steinberg et al., 1991; Windle, 1993). The 3-item sex risk scale (alpha 1 = .48; alpha 2 = .71; r^2 = .93; r^52 = .72) asked whether the student was sexually active (Jessor & Jessor, 1977), and, if so, how often condoms were used during sexual intercourse, on a scale from "never" to "always," and asked if the respondent had ever been pregnant (or if male: ever participated in causing a pregnancy to happen). The 5-item aggression subscale
(alpha 1=.73; alpha 2 = .60; r = .72; r = .46) queried frequency of involvement in activities
ranging from damaging or vandalizing something not belonging to them to taking part in a fight
where a group of friends were against another group (Barnes, 1984; Gold, 1970; Gold & Mann,
1972; Ruggiero, 1984; Steinberg et al., 1991; Windle, 1993). Finally, a 3-item delinquency
(alpha 1= .55; alpha 2 = .21; r = .53) scale asked the students "during your lifetime how many
times have you been stopped for..." and "how many times have you actually been arrested or
placed on probation for... something you did or they thought you did (not traffic violations)?"
The lifetime occurrence of running away from home with intentions of staying away was also
queried on this subscale (Dornbusch et al., 1985; Gold & Mann, 1972; Windle, 1993).

Year 2 Study

Older adolescents from the Year 1 study (Slicker, 1996b; 1996a) for whom addresses
were available were re-contacted and asked to complete a similar survey for Year 2, providing
261 participants. Most of these individuals continued to reside in the middle South and most
continued to be enrolled in a post-secondary institution. The proportions of respondents were
26.1% male and 73.9% female (90.8% Caucasian). These older adolescents (30.3%, age 18
years; 46.4%, age 19 years, 21.1%, age 20 years) were asked once again to report on their
current levels of involvement in various problem behaviors (school / work misbehavior, drinking
problems, alcohol use, drug use, deceit/theft, sex risk, aggression, and arrests). Parenting
style groups (authoritative, authoritarian, middle range, indulgent, and neglectful) and family
type groups (balanced, moderately balanced, mid-range, and extreme) established in Year 1
were retained as the independent variables in Year 2.

Results

Table 3 contains descriptive statistics from both years for each total sample. The
decreases in standard deviations are reflected in more restricted ranges for this sample due to
smaller sample size in Year 2.

An analysis of covariance (ANCOVA) was performed for parenting style and then for
family type on each Year 2 problem behavior scale, statistically controlling for Year 1 scores.
This allowed us to examine the continuing impact of parenting style and family type separately
on changes in the outcome variables over the 12 month period between Year 1 and Year 2.

A significant difference among parenting style means (p < .05) persisted in Year 2 for
school / work misbehavior, drug use, deceit / theft, and delinquency, and approached
significance (p < .10) in the areas of drinking problems and sex risk (see Table 4). In
considering family type for Year 2, school / work misbehavior and aggression were the areas in
which significant differences ($p < .05$) among family types persisted (see Table 5). For those variables with significant ANCOVA results, pairwise comparisons on least squares means were completed. In these pairwise comparisons, type I familywise error was controlled for parenting style and for family type. Effect sizes presented in Tables 5 and 6 were calculated for Year 2 means, using Cohen's $f$. According to convention, .10 is considered small, .25 is considered moderate, while .40 is considered a large effect size. Moderately large effect sizes were evident for 7 of the 8 dependent variables with regard to parenting style. Those for family type were not as great, suggesting a more tenuous relationship between family type and behavioral outcome than between parenting style and the outcome variables.

School/work misbehavior (such as cheating, copying others’ work, skipping classes/work) was significantly more prevalent in older adolescents who were reared by authoritarian parents that those who were authoritatively reared even after statistically controlling for Year 1 scores. In addition, there continued to be more of this kind of misbehavior among adolescents from the extreme family type (disengaged, yet rigid) than those from balanced families (emotionally close, yet flexible).

Drug, but not alcohol, use remained significantly more pronounced in older adolescents reared by indulgent parents than those reared in authoritative homes. Since alcohol consumption (and often resultant drinking problems) is highly prevalent among most older adolescents, it should not be surprising that significant differences did not appear among parenting or family type groups in this area. In fact, amount of alcohol consumption increased across all parenting style and family type groups.

Deceit/theft is a scale that considers behaviors such as using a phony ID, trying to get something by lying, and taking money or possessions from someone else. Whereas at Year 1 deceit/theft was significantly greater in offspring of all other parenting styles than in those of authoritative parents, at Year 2 offspring of middle range parents were still participating in significantly more deceit/theft than were those older adolescents reared by authoritative parents even after adjusting for Year 1 scores. Significant differences on family type did not appear.

Sex risk (such as numerous sexual partners, early age at first sex, infrequent condom use, pregnancy) increased for adolescents from all parenting styles and all family types for Year 2 resulting in no significant differences among these groups. Increase in sexual activity is a developmental expectation in older adolescents.
In regard to aggression, although continued significant differences did not remain among older adolescents reared by various parenting styles, a significant difference did persist between balanced and extreme family types. This indicates that older adolescents from highly cohesive and adaptable families continued to participate in significantly less aggressive behavior (carrying a weapon, physical fighting, hitting adults, gang activity) than did older adolescents from disengaged, rigid families.

Finally, delinquency (being stopped by and/or arrested by law authorities for illegal activities) was found to prevail for those older adolescents reared by neglectful parents over those reared by authoritative parents. Family type was not related to delinquency in the Year 2 results.

Conclusions

Parenting style and family type were shown in the Year 1 study to be significantly related to behavioral outcome in older adolescents (high school seniors and university freshmen; see Tables 1 and 2). Specifically, the study demonstrated the clear superiority of authoritative parenting (high levels of responsiveness and behavioral control) and of a balanced family type (high levels of cohesiveness and adaptability). The Year 2 study demonstrates that many of those significant relationships in regard to behavioral outcome continue even after 12 months. Although neither Year 1 nor Year 2 results can provide clear directionality for the above-mentioned relationships, the longitudinal results (adjusted for Year 1 scores) provide evidence of a persistent influence of parenting style and family type even in the early-college years.

Limitations of this study include the usual drawbacks and potential for bias (such as common source and method variance) found in any self-report research using a single informant. Poor response rate (a problem inherent in longitudinal research) afflicted this study, as well, with only 10% of the original sample responding in Year 2. Although hand-delivery of surveys, phone call reminders, and second-survey mailings were employed, there was no monetary remuneration given (although approximately 1/3 of the respondents did receive extra credit from an instructor to apply to one class in which they were enrolled). Finally, as a consequence of categorization into the parenting style typological schema, 40% of the respondents (those who did not fit a particular style) were eliminated from the analyses of parenting style. This practice, however, strengthens internal validity by using only extreme types. External validity, while limited somewhat by the categorization, was also strengthened by including at least a portion of those students whose parents fell within the moderate ranges (middle range parenting) on the parenting dimensions.
There has been considerable research concerning the effects of parenting practices on childhood, and even middle adolescent, behavioral adjustment. The present line of research extends the age range and breadth of the parenting style studies begun by Baumrind, demonstrating parental behavior necessary to promote positive outcomes in older adolescents. In addition, the family type research completed on a normal population expands and more clearly delineates Olson’s Circumplex Model (1982, 1992, 1993). Evidence is noted of a generally linear relationship among the family types on most of the outcome variables. The results of the statistical procedures used in this study appear to be more useful than the sorting procedure used in much of the previous family type research. One-year follow-up finds maintenance of differences among parenting styles and family types in older adolescents with continued evidence for the superiority of certain parenting styles and family types even after these youth have begun to establish autonomy from their parents. These findings expand the growing body of literature regarding the enduring effects of home environment. This suggests that parental importance does not automatically cease with the completion of puberty and that, indeed, parental presence continues to be influential in older adolescent psychosocial development.

I. DOCUMENT IDENTIFICATION:

Title: Parenting Style and Family Type Revisited: Longitudinal Relationship to Older Adolescent Behavioral Outcome

Author(s): Ellen K. Slicker, Ph.D. and Jwa K. Kim, Ph.D.

Corporate Source: Paper Presented at: 104th Annual Convention of the American Psychological Association, Toronto, Canada

II. REPRODUCTION RELEASE:

In order to disseminate as widely as possible timely and significant materials of interest to the educational community, documents announced in the monthly abstract journal of the ERIC system, Resources in Education (RIE), are usually made available to users in microfiche, reproduced paper copy, and electronic/optical media, and sold through the ERIC Document Reproduction Service (EDRS) or other ERIC vendors. Credit is given to the source of each document, and, if reproduction release is granted, one of the following notices is affixed to the document.

If permission is granted to reproduce and disseminate the identified document, please CHECK ONE of the following two options and sign at the bottom of the page.

Check here for Level 1 Release:

Permitting reproduction in microfiche (4" x 6" film) or other ERIC archival media (e.g., electronic or optical) and paper copy.

The sample sticker shown below will be affixed to all Level 1 documents.

PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL HAS BEEN GRANTED BY:

Sample

TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)

Check here for Level 2 Release:

Permitting reproduction in microfiche (4" x 6" film) or other ERIC archival media (e.g., electronic or optical), but not in paper copy.

The sample sticker shown below will be affixed to all Level 2 documents.

PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL IN OTHER THAN PAPER COPY HAS BEEN GRANTED BY:

Sample

TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)

Documents will be processed as indicated provided reproduction quality permits. If permission to reproduce is granted, but neither box is checked, documents will be processed at Level 1.

"I hereby grant to the Educational Resources Information Center (ERIC) nonexclusive permission to reproduce and disseminate this document as indicated above. Reproduction from the ERIC microfiche or electronic/optical media by persons other than ERIC employees and its system contractors requires permission from the copyright holder. Exception is made for non-profit reproduction by libraries and other service agencies to satisfy information needs of educators in response to discrete inquiries."
