This proceedings contains the papers presented at SITE 98, the ninth annual international conference of the Society for Information Technology & Teacher Education. Papers are listed under the following headings: "Concepts and Procedures" (18 papers); "Distance Education" (23 papers); "Diversity" (8 papers); "Educational Computing Course" (7 papers); "Educational Leadership" (21 papers); "Faculty Development" (12 papers); "Graduate and In-Service Education" (15 papers); "Instructional Design" (14 papers); "International" (17 papers); "Mathematics" (14 papers); "New Media" (13 papers); "Preservice Teacher Education" (23 papers); "Reading and Language Arts" (11 papers); "Research" (25 papers); "Science" (12 papers); "Simulation" (6 papers); "Social Studies" (5 papers); "Special Needs" (3 papers); "Technology Diffusion" (10 papers); "Telecommunications: Graduate, In-service, and Faculty Use" (9 papers); "Telecommunications: Preservice Applications" (12 papers); "Telecommunications: Systems and Services" (27 papers); "Theory" (12 papers); "Young Child" (9 papers); and the keynote address. The preface and dedication of the proceedings are also included. (AEF)
Proceedings of SITE 98—Washington, DC
March 10-14, 1998

1998 Section Editors:

Gertrude (Trudy) Abramson, Nova Southeastern University
Deborah Bauder, SUNY Institute of Technology at Utica/Rome
Maryanne R. Bednar, La Salle University
Ray Braswell, Auburn University Montgomery
Sharon S. Brown, Nova Southeastern University
Wren Bump, Texas Southern University
Lucretia Carter, Iowa State University
Inés Márquez Chisholm, Arizona State University - West
Michael L. Connell, University of Houston
Glenn DeVogd, University of Houston
Sue Espinoza, Texas A&M University-Commerce
Carine M. Feyten, University of South Florida
Ruth Gannon Cook, University of Houston
Darrell DeMartino, University of Houston
Sara Hall, Iowa State University
Sean Jackson, University of Houston
Elissa Keeler, Grace School
Jeffrey M. Kenton, Iowa State University
Siva Kumari, University of Houston
Debra Kurth, Iowa State University
Stacey Long, Iowa State University
Kathryn I. Matthew, Louisiana Tech University
Robert Miller, University of Houston
Rosemary Mullick, SUNY Institute of Technology at Utica/Rome
Polly Mumma, Iowa State University
Dale S. Niederhauser, University of Utah
Francis J. Ryan, La Salle University
Will Sadera, Iowa State University
Ronald Sarner, SUNY Institute of Technology at Utica/Rome
Stephanie Sasser, Iowa State University
Denise Schmidt, Iowa State University
Neal Strudler, University of Nevada, Las Vegas
John J. Sweeder, La Salle University
Gregory Taylor, University of South Florida
Rhea Walker, Iowa State University
Cameron White, University of Houston
James A. White, University of South Florida
Susan E. Williams, University of Houston
Nancy Williams, University of Houston
Dee Anna Willis, Iowa State University
Increase your students reading speed and comprehension with Kurzweil 3000 software. Kurzweil 3000's multisensory approach to reading provides both visual and auditory feedback.

The Kurzweil 3000 reads aloud any printed textbook, magazine, or printed material. It gives students the advantage of highlighting and taking notes right on the computer. A dictionary, thesaurus, syllabification, and dual highlighting of printed text are additional tools for your students.

Students can now read the web. With the click of a button, Kurzweil 3000 will read aloud web pages opening a whole new world of research and learning for your students.

Your Students will:

Read with ease
Read with confidence
Read independently

... because everyone should have the opportunity to read.

For a free demo or more information call our toll free number or visit us on the web.
411 Waverley Oaks Road
Waltham, MA 02154
(800) 894-5374

CourseInfo
www.courseinfo.com

CourseInfo introduces the Interactive Learning Network v 1.5, which brings the power of the Internet easily into educational environments. The Interactive Learning Network supports delivery of courseware via the Internet to hundreds of students simultaneously. ILN utilizes intuitive interfaces which create logical navigation among educational information and learning resources without having to know any HTML. Online quizzes and tests are easily created and automatically graded for easy student tracking. The Interactive Learning Network provides a complete courseware management solution.

ComputerPREP
www.computerprep.com

The market for Online Professional Development services is exploding with International Data Corporation and other forecasters predicting unprecedented growth rates. The convergence of Internet, Video Conferencing via the Internet, and the increasing capability for the Internet to handle media types, coupled with HTML is/making the lure of Online Professional Development a reality.

The World Bank's Development Education Program (DEP)
www.worldbank.org/depweb

DEP will present its web site (www.worldbank.org/depweb) targeted for teachers and students around the world who want to study social, economic and environmental issues of sustainable development. On-line material, developed from extensive World Bank data and resources, includes comprehensive learning modules, teachers' resources and a student "newspaper".

CrossTec
www.4ctc.com

Create and interactive classroom environment by turning a Windows based PC network into a powerful learning center. Demonstrate your screen to all students, show individual student screens, monitor, help troubled students, chat room, transfer files, conferencing, and much more. Free evaluation copies available.

LCSI
www.lcsi.ca

LCSI offers institutional site licenses of its award-winning, logo-based, constructivist software for $50 per title/platform. The presentation will show the software and explain the College of Education Software Offer.

Proxima Corporation
www.proxima.com

Proxima Corporation is a global leader in the multimedia projection market, providing world class presentation solutions to corporate enterprises, workgroups, mobile professionals, trainers, and professional public speakers. Proxima markets and distributes ultra-portable, easy-to-use projectors; high-resolution, lightweight projectors; and LCD projection display panels that increase the efficiency and productivity of business meetings, presentations, and workgroup sessions.

Do We Still Need a Paper Annual?

This is the ninth Technology and Teacher Education Annual, and as I think about it a conversation I had in 1989 floats up from one of those mental storage bins that are never thrown out but rarely opened and examined. The conversation was over whether it made any sense to have an annual conference on the topic of information technology and teacher education (ITTE). My colleague had strong views. He felt that there were enough projects to support one conference. Thus, one conference was a good idea, but planning others made little sense. Once those few projects that were being undertaken had been presented there would be no content for future conferences. He felt the same way about creating a journal; there were simply not enough papers to support a journal!

There was plenty of evidence that my colleague's opinions were accurate. No one else had ever tried to arrange an annual conference on the topic - if there was a need it would already have been done. There was no journal on the topic. There were only a few papers on ITTE, and they were scattered all over the computers and education literature.

But, now, looking back over 9 years of SITE conferences and Annuals, it is clear that my colleague was wrong. Early conferences were small but they have grown each year. The 1998 Annual is over 7, SEVEN!, times the size of the first Annual. Attendance at the conference has grown each year and the number of presentations has grown. The weight of the paper version of the 98 Annual will attest to that. There is now an established discipline of both scholarship and professional practice - information technology and teacher education (ITTE) - that supports three journals and one Annual. The three journals, Journal of Technology and Teacher Education, Journal of Information Technology for Teacher Education, and Journal of Computers and Teacher Education, publish a total of less than 100 papers a year, and the Annual takes another 400-500.

The journals, the Annual, and the existence of organizations like SITE, are all indications of a thriving and maturing field. Browsing through the Chronicle of Higher Education job ads is another way of judging the viability of our field. About five years ago the University of Utah advertised a tenure track assistant professor position in "Technology and Teacher Education." That, to my knowledge, was the first position advertised that specifically identified the field as ITTE. Today many of the job ads related to technology will include at least a mention of the need for experience and expertise in ITTE. That was not the case fifteen years ago.

If I had any doubts about the viability of our field, ITTE, they were put to rest a few weeks ago when I had occasion to look through the applications for a faculty position in instructional technology. Over 60% of the applicants had published in one of the three journals or presented at SITE. Many members of the new generation of instructional technology doctorates have experience in and long term interests in ITTE. That suggests the Annual and the conference will continue to grow and that we will, for the foreseeable future, be working with a significant number of new people who are just beginning their careers as ITTE practitioners and scholars. The Annual is both a valuable publication outlet for them and a source of knowledge.

That, however, brings me to another point. Do we still need a paper version of the Annual? It has been too heavy to carry around the conference for several years and it has become a nightmare to produce in the short time between December 1 and the conference in March. The CD-ROM version of the Annual is full-text searchable, and papers can be printed out as needed. In addition, the Annuals are available over the Internet so that anyone with a connection to the World Wide Web can find them. Do we need a paper version as well? I won't give you my opinion on this issue, but I do believe it is time for us to think seriously about the question. I hope, as we celebrate and enjoy another SITE conference, that you will think about this question. If you feel strongly one way or another why not send me an e-mail message explaining how you feel and why. Send it to jerryw@iastate.edu.

Jerry Willis
Founder, SITE

PREFACE: Do We Still Need a Paper Annual? — 19
DEDICATION

Gary Marks, a scholarly communications pioneer

About 16 years ago a young doctoral student at the University of Texas in Austin became interested in the emerging field of educational computing. There were a few publications like T.H.E. Journal and The Computing Teacher that dealt with the use of computers in education, but for the most part all of us were still reading general publications like Byte Magazine. Gary Marks, while a doctoral student, saw the need for more specialized publications. He began a modest little publication titled, Journal of Computers in Math and Science Education. It actually began as a newsletter but rapidly progressed to the status of a journal. It is still in print, and it was one of the first, if not the first, publications that appealed to scholars and thoughtful practitioners in a specialized area of educational computing.

The 1998 Annual is dedicated to Gary Marks because he saw a need and instead of waiting for someone else to meet that need, he acted. The "need" was a way for people interested in the use of computers in math and science teaching to communicate with each other.

The 98 Annual is also dedicated to Gary Marks because he not only saw a need, he did a good job of meeting that need. In 1981 there were a number of publications on education and computing that can best be described as "chatty." They lacked the depth a growing number of enthusiasts wanted in a publication. Gary's first journal balanced practical issues with coverage of conceptual and theoretical topics that were important to both researchers and practitioners.

The 98 Annual is not dedicated to Gary Marks because he sought out the honor. In fact, when told about the decision, he tried to discourage us and suggested several others he thought were more deserving. If you are a Wizard of Oz fan, Gary prefers the role of the man behind the curtain. He is comfortable working behind the scenes, and bringing him out from behind the curtain required some effort. But that characteristic, his willingness to work hard to meet a need without seeking or needing high visibility, is probably one reason he has been so successful.

Gary's first journal was published by the Association for Computers in Math and Science Teaching. That was really another name for Gary Marks. In true Madison Avenue style he invented an organization to publish his journal because that gave it more credibility. It reminds me of how one of the computer accessory companies got its name. The fellows who founded the company on a shoestring lived on Curtis Street and they named the company Curtis because it would give the impression that they were doing more than working out of their garage. Gary's, or ACMST's, journal prospered, however, because it met a need and was provided at a reasonable cost.

Before Gary left Texas he realized there was a need for other journals and he changed the name of the association to the Association for the Advancement of Computing in Education. AACE is alive and well today because of Gary Marks and his vision of what was needed as well as his ability to meet those needs. AACE is still a small organization as organizations go, but it plays a very important, even critical, part in the dissemination of scholarship about technology and education. AACE still publishes the original journal on science and math teaching and six others on everything from distance education, early childhood, multimedia, and interactive learning to teacher education.

AACE also supports and organizes six conferences, including SITE, and it has active organizations or divisions associated with most of the journals. AACE also has several "chapters" - there is one in central Europe, another in the Asia Pacific region, and a third in Latin America. All of this, the journals, the conferences, and the chapters, were created because Gary had a vision and the ability to meet that need.

So, we dedicate this Annual to someone who has made a difference in the field. Many important channels of scholarly communication exist today because of the effort and vision of Gary Marks. He is someone who has truly made a difference. The organization he created is the home of SITE, the Journal of Technology and Teacher Education, the SITE conference, and the Technology and Teacher Education Annual. Without AACE, SITE might have faded from the scene after a few years because of burnout. It is difficult for volunteers who have other responsibilities to do all the things that are required to keep an organization healthy. With AACE, SITE is a thriving, healthy organization.

Jerry Willis
Most of the selections in this section reflect on some facet of the question: what information processing skills do students and teachers need to possess and how do educators insure that they, both teachers and students, are well prepared? The wide variety of projects and differing approaches clearly suggests that these are still open questions.

The first group of three papers deal largely with the skill set that is required in the information age. The first selection by Edward Caffarella of the University of Northern Colorado reviews a draft of new information literacy standards under development by the Association for Educational Communications and Technology and the American Association of School Librarians. This group has developed nine standards in three broad categories: information literacy, independent learning, and social responsibility. In the second paper, David Kumar and Valerie Bristor of Florida Atlantic University call attention to the integration of knowledge and subject matter focusing upon projects that combine both the physical sciences and language arts. Another demand often made of American education is to produce graduates whose skill set meets the needs of business. The third paper, by Ronald Abate of Cleveland State University describes a collaborative venture, based on the Ohio Goals 2000 Program, among Cleveland State's College of Education, its Advanced Manufacturing Center, and local schools.

The second group of selections focuses upon how to prepare teachers to teach adequately with technology; some in the group focus on a logically prior question - how to train the trainers, the university teacher education faculty. Two such projects at Michigan State University are examined. The first, by Andrew Topper, describes the use of "technology guides" who assist both faculty and graduate students in the teacher education program. The second, by Christina Dokter, Kaijun Hou, and Larry Heimann describes a project to support a faculty member and his graduate statistics students through the development of world-wide-web based materials.

Several selections focus upon pre-service and in-service training. David Breihaupt and Karen Smith-Gratto of North Carolina A&T State University present a model for teacher training that pairs pre-service students with professional teachers to develop computer-based instruction and materials collaboratively. Madeline Justice of Texas A&M University-Commerce and Ida Gunstanson of the Terrell Middle School describe a collaboration between Texas A&M and its surrounding public schools, "...using a combination of technology and both new and traditional teaching methods to improve the skills and abilities of preservice teachers."

Five researchers from Eastern Kentucky University, Mary Ann Koloff, JoAnna Dickey, Shirley Long, Sue Reehm, and Joyce Harris Thomas, describe how EKU plans to use technology-based portfolios to document the achievements of its pre-service students. Tina Marshall-Bradley and George Bradley of South Carolina State University describe the pre-service program at their institution, contrasting technology usage with national data. In the next paper, Nancy Luke, Joi Moore, and Sally Sawyer, all from the University of Georgia present a literature review stressing the need to integrate theory and practice. They note that authentic usage of technology, where the technology is used in a "real life" setting, helps teachers more easily integrate the technology into their work.

Elizabeth Willis of Northern Arizona University reflects upon a series of pre-service courses that she was teaching during the 1996-97 academic year. Unlike previous methods courses, during this year Willis integrated the social studies and language arts courses into a single class in which technology played an integral part. In addition to the author's own comments, the paper draws extensively upon the personal narratives of her students.

Next, Marianne Handler of National Louis University and seven other Illinois educators at four other colleges and the National Center for Supercomputing Applications
(NCSA) present a description of PIE-21, Preparing Educators for the 21st Century. This program combined pre-service and in-service training for teachers, administrators, and teacher education faculty. This descriptive paper catalogs the varied approaches that were tried at the constituent institutions.

Two of the selections in this group focus upon the collegiate technology environment. Patricia Shopland and Joan Kannegieser of Eastern Nazarene College chronicle the difficulties encountered in establishing a computer lab at their institution and remind us of the challenges that are faced in departments and colleges that are steeped in tradition. At the other extreme, James Laffey, Dale Musser, and John Wedman of the University of Missouri-Columbia describe the challenges presented by a very exciting project to infuse technology into pre-service education. In a four-part program, Missouri-Columbia first identified a series of technical competencies or "milestones" that they expected of their graduates. To assist in meeting these competencies, all incoming freshmen (and all thirty education faculty) were provided with Apple Powerbook laptop computers. This infusion of equipment required the development of a support system, called the "Reflector". In addition, an internet-based tool was developed to enable students to create and maintain journals, and finally a partnership was forged with nineteen school districts around the state.

The three remaining papers present projects that are not directly related to teacher preparation. William Stockebrand and Christine Althoff of the University of Texas at El Paso describe their department's involvement with Phi Delta Kappa's National Values Project. In this endeavor, UTEP graduate students act as catalysts and facilitators for research projects. In the second selection, Catherine Alfieri of the Jefferson Road School in Pittsford, NY describes the development of website in conjunction with a fourth grade social studies curriculum. In the final paper, Carlos Solis of Rice University traces the development of the "Electronic Studio", a series of intranet-based projects using a web-browser as a common interface.

**Ronald Sarner** is Distinguished Service Professor of Computer Science and Director of Information Services at the State University of New York Institute of Technology at Utica/Rome. His specialties include policy analysis and methodology, which of late have been directed toward educational technology innovations. His address is SUNY Institute of Technology at Utica/Rome, P.O. Box 3050, Utica, NY 13504-3050. Voice: 315/792-7440, fax: 315/792-7222, e-mail: ron@sunyit.edu

**Deborah Y. Bauder** is Director of the Learning Center at the State University of New York Institute of Technology at Utica/Rome. Her research interests include professional development and dissemination of educational technology innovations. Her address is SUNY Institute of Technology at Utica/Rome, P.O. Box 3050, Utica, NY 13504-3050. Voice: 315/792-7310, fax: 315/792-7806, e-mail: debbie@sunyit.edu.

**Rosemary Mullick** is Associate Professor of Computer Science at SUNY Institute of Technology at Utica/Rome and Acting Dean of Information Systems and Engineering Technology. Her major areas of interest include the development of social cognition including social perception, research methods, artificial intelligence, and parallels between human cognition and machine "intelligence". Her address is SUNY Institute of Technology at Utica/Rome, P.O. Box 3050, Utica, NY 13504-3050. Voice: 315/792-7234, fax: 315/792-7800, e-mail: rosemary@sunyit.edu
The New Information Literacy Standards for Student Learning: Where Do They Fit with Other Content Standards?

Edward P. Caffarella
University of Northern Colorado

There are two major factors driving the information literacy skills needed by students as we move into the 21st Century. The two factors are the growth in the quantity of information sources and the ease of access to that information. The amount of information available is growing at exponential rates with the quantity doubling every few years. Along with this rapid growth in the sheer quantity of information, the means for accessing this information has become easier. Electronic databases have placed much of the information within the reach of a few computer keystrokes.

These parallel developments present an interesting challenge for the current K-12 students who will live their adult lives in the 21st century. There will be enormous warehouses of information that is readily and directly available to the end users. Some of this information will be good while some will be bogus. The end user will need to locate the appropriate information and then separate the proverbial wheat from the chaff.

Information Literacy Standards for Student Learning

To meet this challenge the Association for Educational Communications and Technology and the American Association of School Librarians formed a committee to write a new edition of Information Power (American Association of School Librarians and Association for Educational Communications and Technology [AASL/AECT], 1988) and investigate the information literacy needs of K-12 students over the next twenty years. The author of this paper is a member of that committee. This committee has developed a set of nine information literacy standards for student learning. These standards will be published in their final form in June of 1998 (AASL/AECT, 1998). The preliminary drafts of the standards and related materials are available at http://www.ala.org/aasl/infopwrmenu.html.

The purpose of this paper is to investigate the standards and the interface of these standards with other subjects typically taught in schools. The nine standards are divided into three broad categories. The standards in the second and third categories are dependent upon the standards in the first category. The standards are:

**Category I: Information Literacy**
The student who is information literate:

**Standard 1:** Accesses information efficiently and effectively
**Standard 2:** Evaluates information critically and competently
**Standard 3:** Uses information effectively and creatively

**Category II: Independent Learning**
The student who is an independent learner is information literate and:

**Standard 4:** Pursues information related to personal interests
**Standard 5:** Appreciates and enjoys literature and other creative expressions of information
**Standard 6:** Strives for excellence in information seeking and knowledge generation

**Category III: Social Responsibility**
The student who contributes positively to the learning community and to society is information literate and:

**Standard 7:** Recognizes the importance of information to a democratic society
**Standard 8:** Practices ethical behavior in regard to information and information technology
**Standard 9:** Participates effectively in groups to pursue and generate information

In the complete documentation of the standards (AASL/AECT, 1998) there is a set of indicators under each standard. These indicators provide further definition of the standards. Each standard is written as a lifelong skill and is therefore not grade specific.

In the following sections each standard will be discussed separately. Some of the links to other subject area standards will also be identified. The publication entitled

Concepts and Procedures — 23
Content Knowledge: A Compendium of Standards and Benchmarks for K-12 Education (Kendall & Marzano, 1997) has been used for standards in other subject areas. The links to other subject areas are not meant to be exhaustive but rather to suggest how the information literacy standards can be taught within the context of other subject areas. The committee has made the assumption that the information literacy standards will not be taught separately but will be integrated with other subject areas.

Category I: Information Literacy

Standard 1:
The student who is information literate accesses information efficiently and effectively. The student who has achieved this standard recognizes the need for information, realizes that accurate and comprehensive information is the basis for intelligent decision making, formulates appropriate research questions, identifies potential information sources, and uses successful strategies to locate information. A student might look to an almanac for climatic information on a specific country but look at a thermometer when deciding to wear a coat on a fall day. In both cases the information is weather related but the purpose of the search determines possible sources of information.

Since most classes have at least some part dealing with where to find information on the discipline, this standard can be taught in a wide variety of classes such as those in the following list.

Civics: Knows how shared ideas and values of American political culture are reflected in various sources and documents (Kendall & Marzano, 1997, p. 434).

Geography: Knows the basic elements of maps and globes (e.g., title, legend, cardinal and intermediate directions, scale, grid, principal parallels, meridians, projection) (Kendall & Marzano, 1997, p. 510).

Health: Knows local, state, federal, and private agencies that protect and/or inform the consumer (Kendall & Marzano, 1997, p. 546).

Mathematics: Formulates a problem, determines information required to solve the problem, chooses methods for obtaining this information, and sets limits for acceptable solutions (Kendall & Marzano, 1997, p. 47).

By combining the teaching of the information literacy standard with the appropriate subject matter the student will see the importance of gathering information to all disciplines.

Standard 2:
The student who is information literate evaluates information critically and competently. To master this standard the student must complete tasks such as determining the accuracy, distinguishing among facts and opinions, identifying inaccurate information, and selecting information appropriate to the problem. When evaluating information the student might be making a decision that information in the supermarket tabloids is highly sensationalized and may not reflect reality. Conversely the information found in a refereed scholarly journal is probably highly accurate.

This information literacy standard can be taught in concert with the other content standards. Some of the possible content area standards are listed below.

English language arts: Determines the validity and reliability of primary and secondary source information and uses information accordingly in reporting on a research topic (Kendall & Marzano, 1997, p. 333).

Health: Knows how to determine whether various resources from home, school, and the community present valid health information, products, and services (Kendall & Marzano, 1997, p. 546).

Mathematics: Knows the difference between pertinent and irrelevant information when solving problems (Kendall & Marzano, 1997, p. 46).

Science: Understands how scientific knowledge changes and accumulates over time (Kendall & Marzano, 1997, p. 99).

Any one of these standards could be used as an opportunity to teach the second Information Literacy standard.

Standard 3:
The student who is information literate uses information effectively and creatively. The student uses the information by organizing it, integrating the new information into one's own knowledge, and communicates information. The use of the information may take the form of a traditional term paper or a page for the World Wide Web. The use may also take a different form such as replacing the brake pads on an automobile.

As with the first two information literacy standards this standard could be taught in most disciplines and classes.

Art connections: Understands how elements, materials, technologies, artistic processes (e.g., imagination, craftsmanship), and organizational principles (e.g., unity and variety, repetition and contrast) are used in similar and distinctive ways in the various art forms (Kendall & Marzano, 1997, p. 381).

Foreign language: Uses verbal and written exchanges to gather and share personal data, information, and opinions (Kendall & Marzano, 1997, p. 498).

History understanding: Knows how to construct time lines of significant historical developments that mark at evenly spaced intervals the years, decades or centuries (Kendall & Marzano, 1997, p. 111).

The first three standards describe the student who is information literate. The next six standards describe how the information literate student uses those skills.
Category II: Independent Learning

Standard 4:

The student who is an independent learner is information literate and pursues information related to personal interests. The student seeks information related to various dimensions of personal well being and evaluates information products related to personal interests. An example of this standard is a student planning a backpacking trip to Europe by collecting information on various sites to see along the way.

Theater: Identifies and researches cultural, historical, and symbolic clues in dramatic texts (Kendall & Marzano, 1997, p. 402).

Behavioral studies: Understands how language, literature, the arts, architecture, other artifacts, traditions, beliefs, values, and behaviors contribute to the development and transmission of culture (Kendall & Marzano, 1997, p. 595).

Foreign language: Understands the main idea and themes, as well as some details, from diverse, authentic, ability-appropriate spoken media (e.g., radio, television, live presentation) on topics of personal interest or interest to peers in the target culture (Kendall & Marzano, 1997, p. 500).

This standard deals largely with factual and nonfiction information that is obtained by the students for their own personal interests.

Standard 5:

The student who is an independent learner is information literate and appreciates literature and other creative expressions of information. The student is a self-motivated reader who derives meaning from information and develops creative products in a variety of formats. The student might read, for pure enjoyment, an Anne Rice novel or a play by Shakespeare.

Behavioral studies: Knows that language, stories, folktales, music, and artistic creations are expressions of culture (Kendall & Marzano, 1997, p. 594).

Foreign language: Knows some basic expressive forms of the target culture (e.g., children's songs, simple selections from authentic children's literature, types of artwork or graphic representations enjoyed or produced by the peer group in the culture studied) (Kendall & Marzano, 1997, p. 503).

History: Understands how stories, legends, songs, ballads, games, and tall tales describe the environment, lifestyles, beliefs, and struggles of people in various regions of the country (Kendall & Marzano, 1997, p. 125).

In addition to regular classroom activities this standard might be achieved through activities such as a school-wide reading program or including a large collection of pleasure reading materials in the school media center.

Standard 6:

The student who is an independent learner is information literate and strives for excellence in information seeking and knowledge generation. The student is self-reflective by assessing the quality of the process of one's own information seeking and devises strategies for improving self-generated knowledge. An example of this is the student who transfers to a new college after the first year because the original school did not offer a particular major.

This standard is only covered indirectly by all traditional subject areas that are taught in K-12 schools.

English language arts: Identifies and defends research questions and topics that may be important in the future (Kendall & Marzano, 1997, p. 333).

Mathematics: Uses a variety of strategies to understand problem-solving situations and processes (e.g., considers different strategies and approaches to a problem, restates problem from various perspectives) (Kendall & Marzano, 1997, p. 47).

Science: Knows that scientific explanations must meet certain criteria to be considered valid (e.g., they must be consistent with experimental and observational evidence about nature, make accurate predictions about systems being studied, be logical, respect the rules of evidence, be open to criticism, report methods and procedures, make a commitment to making knowledge public) (Kendall & Marzano, 1997, p. 98-99).

Since this standard is not covered in other subject areas this is an open opportunity for the school media and technology specialists to teach this concept.

Category III: Social Responsibility

Standard 7:

The student who contributes positively to the learning community and to society is information literate and recognizes the importance of information to a democratic society. The student seeks information from diverse sources and respects the principle of equitable access to information. An example of this standard is a student defending the right of someone else to speak even though that student does not support the position.

Behavioral studies: Understands how the diverse elements that contribute to the development and transmission of culture (e.g., language, literature, the arts, traditions, beliefs, values, behavior patterns) function as an integrated whole (Kendall & Marzano, 1997, p. 595).

Civics: Knows some common forms of diversity in the United States (e.g., ethnic, racial, religious, class, linguistic, gender, national origin) (Kendall & Marzano, 1997, p. 432).

Civics: Knows some of the benefits of diversity (e.g., it fosters a variety of viewpoints, new ideas, and fresh ways of looking at and solving problems; it provides people with choices in the arts, music, literature, and sports; it helps...
people appreciate cultural traditions and practices other than their own) (Kendall & Marzano, 1997, p.432).

History: Understands how individuals have worked to achieve the liberties and equality promised in the principles of American democracy and to improve the lives of people from many groups (e.g., Rosa Parks, Martin Luther King, Jr.; Sojourner Truth; Cesar Chavez) (Kendall & Marzano, 1997, p.121).

This is perhaps the most difficult standard to achieve in a K-12 setting but there are still many things that educators can do to help students understand the benefits diversity in a democratic society.

Standard 8:
The student who contributes positively to the learning community and to society is information literate and practices ethical behavior in regard to information and information technology. The student uses information technology responsibly respecting the principles of intellectual freedom and intellectual property rights. The student who has achieved this standard does not purposefully distort data to support a particular position and provides citations where appropriate.

Civics: Understands the sources, purposes, and functions of law and the importance of the rule of law for the protection of individual rights and the common good (Kendall & Marzano, 1997, p.417).

Science: Understands the ethical traditions associated with the scientific enterprise (e.g., commitment to peer review, truthful reporting about methods and outcomes if investigations, publication of the result of work) and that scientists who violate these traditions are censored by their peers (Kendall & Marzano, 1997, p.103).

This standard has major implications for the effective use of technology in schools.

Standard 9:
The student who contributes positively to the learning community and to society is information literate and participates effectively in groups to pursue and generate information. The student shares information with others, respects others' ideas acknowledging their contributions, collaborates with others, identifies information problems, and develops information products. An example of this standard is students working together in groups to solve a common problem.

Theater: Knows how varying collaborative efforts and artistic choices can affect the performance of informal and formal productions (Kendall & Marzano, 1997, p.402).

Behavioral studies: Understands that a variety of factors (e.g., belief systems, learned behavior patterns) contribute to the ways in which groups respond differently to their physical and social environments and to the wants and needs of their members (Kendall & Marzano, 1997, p.594).

English language arts: Evaluates own and others' effectiveness in group discussions and in formal presentations (Kendall & Marzano, 1997, p.345).

Geography: Knows the ways in which culture influences the perception of places and regions (Kendall & Marzano, 1997, p.518).

This standard can be taught in conjunction with programs such as drama, music, and athletics. Many activities in these subjects are built around groups that can be used as examples for other subject areas.

Conclusion
As the students of today face the enormous growth in information coupled with easier access to that information, schools must provide a new set of skills. These skills, as reflected in the nine Information Literacy Standards, will enable these students to effectively use this information for the greater good.

26 — Technology and Teacher Education Annual — 1998
This paper describes technology as a tool for creating macrocontexts for teaching integrated science and language arts. Since both science and language arts involve interrelated cognitive functions, integrating the two subjects would be an interesting way of teaching in elementary education (Krogh, 1995; Koballa, Jr., 1991; Caine & Caine, 1991). From a synthesis of literature Koballa, Jr. (1991) summarized that teaching science improves reading skills, reading readiness, written and oral communication skills, and also the development of language in students with disabilities. However, a study by Eldridge, Jr. (1988) found that the emphasis on reading skills in science lessons remains very limited.

According to Yates and Chandler (1991) learning involves making conceptual changes in cognitive structure by placing new information in a mental network of prior information in a meaningful way. In order to achieve greater cognitive gain, learning must be meaningful. According to Ausubel’s explanation of verbal learning (cited in Anderson & Pearson, 1984), learning becomes meaningful only when new ideas make relevant connections to known ideas already established in the cognitive structure of individuals. From this perspective the context of learning is critical, because knowledge is located (or situated) as a part of the context from which it is acquired (Brown, Collins, & Duguid, 1989).

**Macrocontexts and Technology**

Studies of contextualization by Brown, Palinscar, and Ambruster as well as Tharp (cited in Baker, & Brown, 1984) emphasized the importance of “essential strategies in the context of actually reading or studying with the goal of arriving at a coherent interpretation of the text” (p. 383). For example, integrating language arts with science provides those “essential strategies” in addition to augmenting the context of each content area. See Kumar and Voldrich (1994) for a report of literature-based macrocontexts for teaching science at the elementary grade level. Educational technology makes it possible to enrich contexts for the integration of science and language arts. Both science and language arts are areas which help students engage in learning cognitively. As discussed earlier in this paper, new information should be able to find a niche in the knowledge structure of the learner in order to be connected meaningfully to existing knowledge.

It should be pointed out that the kind of technology needed for the integration of science and language arts is not limited to specialized educational technology applications such as custom developed multimedia systems. In the age of information technology there are various resources such as videos and the World Wide Web (WWW) that can be used to create macrocontexts for teaching integrated science and language arts. Teachers can use several criteria for deciding what kind of technology-based resources to use for creating macrocontexts in teaching integrated science and language arts. It should be emphasized that the classroom teacher’s level of confidence in science and language arts content and knowledge of technology-based resources are vital to making such innovative curriculum decisions. The following suggestions are a few steps that should guide teachers in this task:

1. The context chosen for integration must be available on videodisc, videotape, CD or World Wide Web (WWW).
2. The context must be appropriate for student viewing at the elementary levels.
3. The context must be rich in information needed to gain the attention and interest of students.
4. The context must contain explicit information in a language of communication familiar to students.
5. The science and language arts represented in the context must fall within a topic of inquiry in the school science and language curricula.
6. The teacher should be able to clearly identify the science concepts and language skills to be taught embedded in the context.
7. The topic must be appropriate to the level of the students.

**Applications**

- **Videotapes.** Reading Rainbow series is an excellent program on videotape that can be used to create macrocontexts for teaching integrated science and language arts.
arts. The episode “Hill of Fire” (Liggett, 1985) was used in a fourth-grade Drop Out Prevention research project (Bristor, 1994; Bristor & Drake, 1994). After reading the text concerning volcanoes in their science books, the fourth graders watched the Reading Rainbow “Hill of Fire” segment. The following discussion included comparing the Kilaeua Volcano in Hawaii to the Mexico volcano in “Hill of Fire” and comparing the science text with the graphic model in Reading Rainbow. Other activities could include the following (Schweiger, 1988): Ask students how can we learn more about the Paricutin Volcano, Kilaeua Volcano, and other volcanoes; Ask students to identify what new information was in the program (Fumaroles, kinds of lava—aa and pahoehoe); Have students explore careers involving scientists who study volcanoes (Volcanologist) and instruments used to measure the intensity of volcanic eruption (Seismograph). Also, the fourth graders pretended to be on-the-scene reporters recounting the pertinent facts about the eruption. The students were delighted to hear that they would have the opportunity to read their news reports before a video camera. Even the children who were usually reluctant to write were excited about the assignment. One student combined his prior knowledge (facts concerning the event) as well as vocabulary words (such as “village,” “abandoned,” and “destroyed”) learned from the video and book along with science concepts (how volcanoes are formed) from the science textbook to write the following “draft” of his news report.

On February 20th 1943 a farmer was plowing in Mexico. Then the plow got stuck in the earth [sic] crust and the earth began to shake. Then smoke came from the ground. A hill came up from the ground and shooting [sic] rocks from the ground. And the heat and the pressure formed a volcano. The volcano erupted and the volcano covered the village [sic] was destroyed. The people abanded [sic] their homes. No people were hurt but their homes were destroyed. Now 50 years later you can go see the volcano and the covered village [sic]” (Bristor, 1994, p. 35).

Other integrated science and language arts activities can include (Butzow & Butzow, 1989; Schweiger, 1988): Using the World Almanac find the list of active volcanoes in the world. Assign cooperative groups of students to investigate and research the different types of volcanoes from around the world, including information about how the volcanoes affect the people living nearby. Use pushpins or sticky dots to indicate the volcanoes’ locations on a world map. Why is this arrangement of these volcanoes often called the “Ring of Fire”? In what area of the world are most of these volcanoes located? Have children create their own exploding volcano by using plaster and water according to package directions. Baking soda in the “crater” with a few drops of vinegar produces an “eruption”; Have children collect rocks and stones that can be used to create a stone sculpture; and Have children read fiction and nonfiction trade books related to the topic of volcanoes.

Videodiscs and CDs. Videodiscs and CD’s serve as anchors for providing macrocontexts in which the learner can further explore learning across subject boundaries (Cognition and Technology Group at Vanderbilt, 1991; 1993). Take for example instruction using the Raiders of the Lost Ark videodisc described in the Cognition and Technology Group at Vanderbilt (1993). According to CTGV, students who participated in learning activities using this videodisc were successful in making spontaneous connections between classroom lessons and events or activities outside the classroom. That is, the videodisc anchor enabled students to “use standards (e.g., the height of Indiana Jones) to measure other objects (e.g., the width of the pit in the cave; the length of the airplane). They spontaneously attempted to use similar techniques to estimate the height of objects on the campus such as height of buildings, flagpoles and trees” (CTGV, 1993, p. 61). Such a popular movie should also lend itself to a variety of language activities including the comparison of spoken English among various cultures represented in the movie.

Another example of using videos for integrated instruction is found in the CTGV’s (1993) report of the Young Sherlock project. In this project, the story of Sherlock Holmes was used to create a macrocontext for integrating language arts, scientific reasoning and history skills. According to CTGV (1993), “students discuss general principles for writing effective and coherent stories rather than focus only on the concrete story represented in the Young Sherlock video” (p. 56). Students were able to develop pattern recognition skills by noticing the wounds to the throat of the murder victims. In addition, they were able to transfer knowledge by applying vocabulary learned in the classroom to situations beyond the classroom and spontaneously create “coherent plot structures across multiple story writing activities” (p. 61).

The “Adventures of Jasper Woodbury” Series is another example of video-based integration. The Jasper Series (professionally made videodiscs of approximately 15 minutes in length) involves a series of adventures of a character named Jasper Woodbury. Each episode is embedded with data. The challenge to students is to understand the episodes and solve problems. For example, in a challenge involving a boat journey in the episode “Journey to Cedar Creek” students were to determine the speed of the boat. According to CTGV (1993), some teachers who used this episode in their classrooms “helped students construct and use charts that allowed them to determine how speeds defined as ‘minutes to go one mile’ translate into speed defined as ‘miles per hour’” (p. 55). This episode also provides visual clues for students to engage in writing activities describing a variety of characters, objects and places in the episode.

Additionally, students can explore related topics such as endangered species or principles of flight. Students can
write their own adventure story using the information in the embedded teaching episodes. For example, one embedded teaching episode contains information on how to use a compass and bearing guide, how to read a topographical map, and how to use the properties of an isosceles right triangle to estimate heights and widths. Students could incorporate this information into their stories. A discussion of the similarities and differences between the two adventures on a major topic will help students focus on general characteristics rather than specific details. After the solution is shown, students could compare their solutions with the ones on the video and evaluate the strengths and weaknesses of each approach. To assist community members in understanding what it is like to solve the kinds of complex problems that the students are working on, community leaders and parents could be invited to watch a Jasper adventure and accompany students on a field trip related to that topic within the community.

World Wide Web. Since the advent of the World Wide Web (WWW) the availability of curricular materials in science has exponentially increased. The WWW is perhaps the most reforming factor to happen to science education since the curriculum reform efforts of the late fifties and early sixties. There are a number of science education web sites suitable for integrating science and language arts. An example of a web site suitable for integrating science and language arts is the Science Power 2000 (SP2000). The SP2000 web site provides a series of interesting science lesson plans on topics such as birds, blue sky, clouds, energy flow, solid waste, etc. This web site is not only a source for hands-on instructional activities but also a platform for teaching whole language approaches to reading. Other WWW resources that are suitable for textual as well as science curricular materials include the Cable News Network's (CNN) Sci-Tech Main Page which provides macrocontexts for engaging students in Science-Technology-Society approaches to learning and problem solving in science around real world issues and also provides opportunities for developing skills in reading and oral communication. There are other WWW science resources on the Internet. Using a “Search Engine” locating WWW resources suitable for teaching science that are also suitable for language arts should not be a difficult task for teachers. However, it is strongly recommend that teachers adhere to some guidelines similar to the “Resource Selection Guidelines for Integration” listed earlier in this paper.

Assessment and Conclusion

Assessment of integrated science and language arts learning situated in technology-based macrocontexts is an important task. Teachers should not rely solely on traditional memory recall and short-answer tests insensitive to contexts (McColskey & O'Sullivan, 1993; Wiggins, 1993). In context specific situations “what is wanted is a more robust and authentic construct of understanding” (Wiggins, 1993, p. 209). Students loose their “natural enthusiasm” for learning once they notice that the ultimate purpose of the macrocontext based integrated activity is to prepare them for another paper and pencil test to earn a grade. According to Krogh (1995) and Kumar and Voldrich (1994), teachers should plan for a variety of alternative ways to assess students' performance in integrated instructional situations. The alternative assessment may include formal and informal observations, anecdotal records, portfolios, and follow-up activities. Students should not be assessed for their mastery of technology use.

Technology offers great hope for integrated science and language arts instruction. As in any technology-based instructional situation, technological applications for creating macrocontexts must be justifiable based on the foundational theories and principles of education or they will not stand the test of time in education. It is hoped that teacher education programs will incorporate technology-based approaches to creating macrocontexts for teaching integrated science and language arts in their preservice and inservice programs.

The Math, Science, & Manufacturing Collaborative

Ronald J. Abate
Cleveland State University

The concept of a collaborative math and science project grew out of the needs expressed by university engineering faculty and junior and senior high school teachers. Cleveland State University (CSU) engineering faculty have faced declining enrollments in recent years and local teachers have expressed a concern that secondary students do not perceive math or science to be relevant to their career opportunities. As such, these groups sought to provide students with connections to “real world” situations that the students will face as they transition into the workplace of the future.

The driving force behind the math and science collaborative was the Advanced Manufacturing Center (AMC) located on the campus of Cleveland State University. AMC is an affiliate of the Cleveland Advanced Manufacturing Program (CAMP), an organization that addresses difficult engineering and manufacturing problems encountered by Northeast Ohio industries. From 1995 through 1997, the AMC conducted projects with over 70 regional manufacturing companies to improve manufacturing competitiveness. These projects provided hands-on learning experiences to over 90 undergraduate and graduate students. When compared with traditional students, the AMC engineers contend that students with hands-on experience gain a better understanding of engineering concepts. The underlying assumptions of the collaborative are that secondary teachers’ understanding of engineering concepts will be enhanced by engaging in engineering problem solving and that the teachers will then incorporate lessons learned from the engineering experiences into their classroom teaching.

Other partners in the collaborative included the Colleges of Education and Engineering at Cleveland State University. The AMC and the CSU College of Education (COE) have collaborated on a variety of projects related to hands-on manufacturing education with Cleveland area high schools for several years.

The goals for the collaborative project were (a) to improve the quality of instruction provided to students, (b) to better prepare in-service teachers, (c) to increase understanding of educational barriers to curricular change, (d) to facilitate the exchange of information, and (e) to foster mutual respect among secondary school teachers and college/university faculty.

Project activities included awareness sessions, a model curriculum workshop, a summer industry experience for teachers with faculty in which curriculum materials were developed, a follow-up team teaching experience for teacher/faculty teams, and development of a monograph describing the project. Three areas of particular interest revolve around the inception of the project, the awareness sessions, the instructional support workshops, and the industry work experiences.

Awareness Sessions

Project staff spent March to June 1996 conducting awareness sessions with groups of teachers in the Westlake City School District, and representatives of other local school districts. The awareness sessions served as the first step in recruiting participants for the project. A schedule of one-hour awareness sessions were conducted and facilitated at a variety of sites by representatives of the collaborative partners. An overview of the project and the goals were presented to prospective participants. A reaction questionnaire distributed to teacher participants was used to evaluate the outcomes of the awareness sessions. Open ended questions such as; “From a teacher’s point of view, if I were organizing a program like this one, I would: (be creative)” were included as well as multiple choice questions related to the utility of the collaborative for developing curricular materials. The questionnaires provided the project staff with information to determine reasons for teacher interest in the program and barriers to attending the program so that this information might be incorporated in planning for future efforts.

Participants identified five major reasons for program interest:

1. The project is connected to “Real Life”;
2. Students will “turn on” when provided with unique experiences;
3. Teachers will be able to give students marketable skills;
4. Teachers will be able to show students the relevance of math and science to the real world and careers;
5. Projects and “hands-on” activities are important in preparing students with marketable skills.

In order to define the concerns, goals and activities that met the common educational concerns of the different
partners, five focus group meetings convened among the AMC, COE, Greater Cleveland Educational Development Center, Westlake City and Elyria School districts (teachers and administrators). The focus group participants identified several common educational concerns:

- fewer students interested in pursuing math, science, and engineering careers,
- the need to address multiple intelligence and various learning styles,
- the need to adopt methods that teach the conceptual requirements of the Ohio model curriculum,
- the need to increase the tools available to teachers that enhance teaching in an applied method,
- the need to supplement teacher’s expertise of technology skills required in a modern workplace, and
- the need to develop new curriculum and methods to prepare pre-service and in-service teachers.

The awareness groups also defined several needs of the teachers. Primary among these needs was experience working in business and industry. This leads to difficulty in redesigning curriculum to appropriately reflect “real world” applications. Some also reported a lack of awareness of the broad scope of career opportunities that are available to students who wish to pursue science, mathematics, and engineering degrees. Another need identified by some teachers was a better understanding of how to incorporate teaching methods that address diverse learning styles and multiple intelligence. Most teacher participants understand these concepts but indicated that they were uncomfortable developing appropriate classroom activities to address them. University faculty indicated that they are frequently critical of the elementary and secondary educational systems because students increasingly come to higher education unprepared for college level work. However, the same faculty admitted that they knew little about the problems that teachers encounter especially in the areas of secondary math and science instruction. The different participants agreed that an ongoing forum to foster mutual understanding among faculty and teachers was needed.

**Instructional Workshops**

One component of the project was planned to provide participant teachers with a series of instructional workshops prior to a “Summer Industry Experience”. Workshops addressed the following topics: secondary science and mathematics standards, cooperative learning, simulations, problem-centered learning, and inquiry-based learning. Participating teachers completed a questionnaire at the end of a three-day workshop. The information collected from the questionnaires was used to help the project staff evaluate the workshop effectiveness and to incorporate modifications to the project.

Seventy-two percent (23 out of 32) of the teachers completed the post workshop questionnaires. The questionnaires provided opportunities for the teachers to respond to issues regarding the usefulness of the instruction, the quality of the instructional materials presented, familiarity with the methods employed and the quality of the instructors. In general, the teachers responded favorably to the instructional workshops. The information collected from the questionnaires indicates that most of the teachers were responsive to the materials covered in the workshops. However, answers to the open ended questions suggested that the teachers were confused about project direction early on in the process. Statements such as, “lack of direction about individual projects—no idea how to select a project”, “I still feel lost. I don’t think enough time was spent discussing our individual projects”, and “the product is still not clear to me, hopefully this will be clarified as time goes on”, indicate that the teachers, though enthused about the project were not clear about the direction. One possibility for the lack of comfort may have been related to the order of activities in the instructional workshops. The workshop curriculum activities were conducted prior to teacher discussion of possible projects with the engineering faculty. As such, the teachers were unclear as to what their responsibilities would be once they began the third phase, the summer engineering experience. Most activities in the instructional workshops were highly structured to cover the different curricular topics. The result was that few opportunities were provided for teachers to discuss the actual summer engineering activities with the faculty. Additionally, faculty attendance became increasingly erratic as the workshops progressed, reducing further the opportunity for interaction between the teachers and the engineering faculty. The result was that decisions regarding the selection of a summer engineering internship were postponed until the last minute. In general, a teacher’s decision to work on one project versus another was not well informed.

In summary, some teachers indicated the workshops provided a good review and they were open to finding out more about the curriculum that they had committed to produce for the project. However by the close of the instructional workshops the teachers appeared somewhat confused about the next step - the summer industry work experience.

**Summer Industry Work Experience**

The teacher and faculty participants collaborated on 15 different engineering projects during the summer. Typical group size consisted of 1 engineer paired with 2-3 teachers. The purpose of the work experience was to provide the teachers with a context for understanding how engineers solve problems so that the teachers could then use this experience to develop curricular materials reflecting similar types of problem solving. Problem solving issues embedded in the projects revolved around Computer Science (hardware and software), Industrial Engineering, Mechanical Engineering, Chemical Engineering, and Civil Engineering.
All of the projects required working with a variety of software and hardware engineering tools. Most of the teacher participants were unfamiliar with the engineering tools at the outset of the summer work experience. The teachers were required to commit 120 hours on the industry work experience.

Teachers and faculty were asked to give the project staff feedback on their “Summer Industry Work Experience.” A questionnaire was mailed to participants in August of 1996. Participants were asked a series of questions related to their work project.

Three major themes surfaced from the teacher surveys of the industry work experience: Project Planning and Preparation, Highlights of the Learning Experience, and New Ideas for the Project’s Future.

Project Planning and Preparation
Teachers and faculty alike seemed uncomfortable with the perceived lack of information about the project at the onset and throughout the summer. Several possible issues may have contributed to this lack of comfort.

First, although the engineers had collaborated on industrial projects with manufacturing personnel this was the first opportunity for them to work with secondary teachers. Despite considerable project planning, meetings and revisions not all variables were foreseen. In particular, neither group was clear on how to achieve the goal of integrating the engineering experiences into instruction. In addition, it took time to learn what aspects of the project worked and what aspects did not. A formative report on the summer phase of project was completed after the work experience. Thus, by the time potential revisions were identified, it was too late to implement them into the summer experience.

Second, many of the teacher candidates who had expressed interest during the awareness sessions had already committed to other projects during the summer before notification of funding for the project occurred. Time was passing and the need to recruit teachers was immediate. As such, many of the newly recruited teachers had not attended the awareness sessions and did not fully understand the scope and purpose of the collaboration. Additional time was needed to clarify the purpose of the summer experience to both the engineering faculty and the participant teachers.

Third, the project was unable to hire a coordinator until after funding was secured. As such, much of the initial process of recruitment, interviewing and selecting a coordinator were occurring at a time when information critical to understanding the purpose of the project needed to be disseminated to potential participants. Engineering faculty were recruited by the Project Administrator. Most of the communication between the administrator and the faculty was oral and some of the engineers were not clear about the scope of the project or their role in it. The project brochures provided to teachers outlined the basics aspects of the program but additional detail on specifics was required.

In summary, further explanation and preparation of faculty and teachers was required in the planning phase of the project. Once the summer industry work experience were underway participants were able to work out most of the problems that confronted them but it would have been better if all parties knew what to expect from the other at the outset.

Highlights of the Learning Experience
The three basic components of the learning experience were to provide the teachers with (a) fifteen flexible days to work on complex projects developed by the engineering faculty and AMC staff at the AMC or an industrial site, (b) five flexible days for developing curriculum relevant to the teacher’s curricular goals, and (c) five days for advanced training in an area of interest. All three components were implemented and comments by the teachers help explain what worked well and what might be improved.

The “loose structure” of the summer experiences made the program expectations somewhat vague but also provided freedom for the participants to explore and develop areas of personal interest. Many of the participants noted that engineering involves a great deal of problem solving and that these problems are solved cooperatively and that it takes considerable time and creativity to solve problems. Other participants learned that communication plays an important role in engineering. Knowledge of an idea is insufficient if you cannot communicate the idea to others.

One comment by a participant “I learned that teachers can bring industry/manufacturing into the classroom and train students to have skills for the ‘real world.’” provided support to the original goal of encouraging teacher participants to create curricular materials that reflect the problem solving approach used by engineers.

Ideas for the Project’s Future
The teachers, in their questionnaire comments, offered many ideas. Many of these comments revolved around the practical constraints of applying the ideas embedded in the summer work experience in the classroom. Primary among the suggestions was the need to consider how the engineering and manufacturing experiences might be applied to the computers available in the local schools. Computer classes and equipment are required to accomplish specific tasks and both the classes and the equipment should be offered to the teachers prior to the industry work experience, so that the teachers are more adept with the technology before they become involved in a project.

Time or lack of it appeared as an important issue to the teacher participants. Several indicated that providing informal time for teachers to discuss issues such as curriculum development was critical for meaningful integration of activities in the classroom. The teachers also suggested that
the engineering faculty might benefit from opportunities to learn basic principles of teaching and learning.

Conclusion

This report was an informal assessment of the math, science and manufacturing collaborative. It was an attempt to reflect on the experiences of the participants based on their responses to a series of simple questionnaires. Although the preliminary findings are generally favorable it is too early to generalize this experience to other projects.

What is interesting about the questionnaire feedback is that this feedback does not merely state the problem but frequently includes suggestions for how the project might remedy the problem in the future. Based on the questionnaire responses it was clear that many of the teachers had developed a commitment to the project from their summer work experience. Information is currently being collected from the teachers, faculty and project administrators via in depth interviews. The interviews should provide additional information regarding the efficacy of the project.

*Ronald J. Abate is an Associate Professor in the Department of Specialized Instructional Programs, Cleveland State University College of Education, Cleveland OH, 44115 E-Mail: r.abate@csuohio.edu*
MSU has been working for several years to incorporate technology into the teacher preparation program. The state of Michigan requires that all student teachers be competent with technology, so MSU has an obligation to ensure that its students meet these legal requirements. The college of education has taken steps to infuse technology into the teacher education program by helping faculty and students use the technology, establishing the Technology Exploration Center for faculty and students in Erickson Hall, hiring technology coaches (previously known as technology mentors) to support faculty and students’ use of technology, and hiring faculty with extensive technology experience.

A variety of methods have been used to help educate staff and support innovative uses of technology within the college. In 1997, a new approach is being tested to support technology integration within the MSU teacher education program. Instead of directly supporting students in the TE program, a group of technology guides are supporting instructors who are teaching common courses in the teacher preparation program. These include TE301, TE401, TE402, TE801, and TE813, and represent the largest portion of subject matter specific classes in the TE program. This change in focus, from supporting the TE undergraduate students to supporting TE instructors, represents an important change in our philosophy with regard to our plans to prepare future teachers for adaptive and pedagogical uses of technology.

Toward this end, technology guides provide a variety of services including technology workshops, one-on-one instructor consulting, establishing Web-based resources, setting up and moderating discussion lists, publishing newsletters, and showcasing exemplary uses of technology within the college. An effort has been made to encourage and support innovative uses of technology in teaching within the TE program so that prospective teachers can observe, examine, and discuss models of teaching with technology as they move through their undergraduate program.

Goals for the technology guides are to:
- Foster and facilitate TE instructors’ use of technology within the teacher preparation program
- Support faculty uses of technology in teaching
- Showcase exemplary uses of teaching with technology
- Develop and support virtual communities within and around the teacher education program based on domains of interest
- Conduct research on technology adoption within the MSU teacher education program
- Support and monitor TE students progress towards technology requirements

History of technology adoption at the MSU College of Education

In the 1992 the MSU Department of Teacher Education formed a working committee to explore possible solutions to the challenge of exposing preservice teachers to technology. The committee was composed of faculty who had interests in teacher education and technology and who taught in the teacher preparation programs. Faculty in the MSU teacher education program decided that technology would only have an impact on education when teachers saw and used it in the same way they used libraries, textbooks, blackboards, pencils, and paper.

From a pragmatic perspective, MSU teacher education faculty members ran into several constraints on their efforts to implement a technology component in the teacher preparation program. First and foremost, were issues of autonomy and control each of the preparation teams had over the program. Initially, technology education was to occur within two hours of class time each week and was to be provided by faculty or staff from each team. This made the goal of embedding technology in curricular contexts very difficult and resulted in a focus on of a small set of generic tools which could be used in a variety of educational settings instead of a contextual technology use approach.

As a result of these constraints, little attention was paid to curricular-specific technology. A change in focus also occurred when necessary funding for faculty training and support was not forthcoming in the second year of the program. This led to a perception within the teacher preparation program, both on the part of faculty and students, of technology as an additional task and not an integral part of learning to teach.
Later, technology coaches (also called mentors) were hired by the college to support students learning to use technology and to assess their technological proficiency in five areas: e-mail, Internet, word processing and presentations, database and spreadsheet, and subject-area software.

**Technology projects at MSU**

Within the college there are a variety of ongoing research projects, that have used technology in teaching and learning. Examples include the MathLab project, the Learning Exchange for Teachers and Students through the InterNet (LETSNet), the Center for Advanced Learning Systems, the Technology Challenge Grant, the Institute for Research on Teaching & Learning Across the Life Span, the Technology Enhanced Learning Environment, and the Reading Classroom Explorer. [Note: All of these projects are described on the College of Education website.]

While these projects have focused on specific aspects of teaching and learning with technology and on research, they have not been used extensively within the college as resources for teacher preparation. The college is still trying to determine how the outcomes from these various technology research projects can be incorporated into the teacher preparation program.

For example, technology guides work with TE instructors to determine how the technology projects might be helpful for prospective teachers. In the case of some projects, such as the MathLab and LETSNet, there are valuable examples or models of teaching with technology now available to TE instructors and their students. Making TE instructors and students aware of these resources is an important part of what technology guides and TE instructors accomplish together.

**Teacher Education Course Instructors**

Within the Teacher Education (TE) program in the MSU college of education, graduate students in the TE Ph.D. program teach many of the core teacher preparation courses. While many of these students have extensive experience in K-12 classrooms, most of them have not taught classes at the college level or used technology in support of their teaching.

Some faculty members in the college of education also teach undergraduate teacher preparation classes. Most of these faculty members have little background or experience incorporating technology into their own teaching practices. While prior attempts to integrate technology into the TE program have focused on undergraduate students, we felt that providing support for TE instructors would represent a better long-term strategy for the college.

We believe that until TE instructors regularly use technology in their teaching, TE students will not understand or appreciate how technology can be integrated into teaching subject matter. Seeing their instructors use technology will provide TE students with real-world examples of teaching with technology and will hopefully stimulate ongoing discussions about the role of technology in educational at all levels. We realize that this process of technology adoption at the college level may take some time, but we strongly believe it is essential to preparing future K-12 teachers for their own technology use.

Technology guides, working with TE instructors, have developed a Web-based technology proficiency resource that includes a self-assessment that teacher education students can use to measure their progress towards technology proficiency. See http://rorschach.educ.msu.edu/TechReq/techrequirements.html. The on-line resource also includes a description of the technology requirements, a rationale for these requirements, and examples of how these requirements can be met. Currently, the MSU standards for teacher proficiency with technology call for simple or functional use of the four of the five areas suggested above, as well as one case of pedagogical or adaptive technology use.

Working with TE instructors, technology guides can help ensure that graduates of the MSU teacher education program have satisfied the state requirements for technology proficiency and support instructor use of technology in their regular teaching practices.

**Role of the technology guides**

Ongoing work for technology guides includes (a) creating and moderating a discussion list for the participants so they can have their questions answered throughout the year; and (b) creating a web page for the TE technology program with photographs of all technology guides and links to their home pages, to exemplary courses on the Web, to TE instructor web pages, and to supportive resources.

Duties for technology guides throughout the term include teaching 90-minute workshops, identifying tips of the day, identifying and showcasing exemplary uses of technology, working collaboratively with TE instructors, and monitoring student completion of technology requirements. Several technology guides are also responsible for supporting specific technology projects by incorporating the use of laptop computers into the TE internship program.

The principal role for technology guides is to support TE instructors as they work to incorporate technology into their TE classes. For those TE instructors who are not yet ready or willing to integrate technology into their teaching, technology guides also provide support to their TE students in accordance with the state mandate for technology competency.

There are a variety of benefits to using this approach including:
- More contact between TE instructors and the technology guides
- A jointly created body of knowledge about how to teach these courses
• Instructors develop their own practices and ways to teach the courses using technology
• Establishment of relationships between technology guides and Teacher Education teams
• Supporting virtual communities across physical boundaries
• Storing and passing on TE course materials among TAs
• Opportunities for TE instructors to engage in research practicum projects by studying their own teaching (practicum requirement)

Research component

As part of this effort, we are also building an infrastructure to support instruction with technology within the MSU Teacher Education program. We will do this by encouraging creation of a social support network for thinking about technology and opportunities to discuss the impact of technology on teaching. Key to this approach is the view of technology as a culture, not a subject, and a focus on content - teaching subject matter with technology, rather than a team-focused approach.

There are opportunities to collect data including interviews with people in the TE program, including students, faculty members, and instructors. For example, observing the instructors in the classroom as a basis for follow-up - using a guided practice approach; archive conversations: how do you teach with technology; multiple perspectives, etc.

In addition, some student teachers (student teachers or interns) in Detroit, Flint, and other outlying areas will be given PowerBooks to use in the field. These PowerBooks are meant to facilitate communication within the triads - interns, collaborating teachers, and field instructors - given the difficulty of meeting regularly face-to-face throughout the term.

Technology guides also work with the field instructors, interns, and collaborative teachers (triads) on fostering these communications over e-mail and supporting these people in the field. In addition, some of the participating interns and collaborating teachers were invited to take part in TE301/401/801 class discussions and assignments.

Supporting TE instructors

Each technology guide has been assigned to contact and offer support to a set of TE instructors. Some of these instructors welcome the help and support offered by the technology guides, while others are ambivalent or unready to consider how they might incorporate technology into their teaching. This is a similar problem faced by many technology advocates in K-12 schools.

When TE instructors do agree to work collaboratively with technology guides to bring technology into their courses, the results can be very impressive and lead to learning on the part of both the instructor and the technology guide. The examples described below are a few of the kinds of experiences technology guides have had working collaboratively with TE instructors.

Secondary Science TE401: Using e-mail and a spreadsheet

Deb Smith teaches a section of TE401 for secondary science majors and used two of her class sessions to demonstrate how her students could use technology: e-mail, with attachments, sent to her; and a spreadsheet, to collect and analyze data and generate a graph. Deb Smith wrote about her experiences in the computer lab:

There were the usual server crashes, disk problems, etc. — mostly because when we made the Eudora disks originally, Yong came in and used his account, remember? So, many of their disks apparently had Yong’s email address on them, and when they tried to sign on, of course the machine wanted his password. But we got that straightened out, with Deepak’s and Tim Smith’s help, and several other TEC guides who came over for short periods of time to help us.

I think the seniors were intrigued by the possibilities that Clarisworks showed them for spreadsheet representations, and played around a lot of different graphs and charts. And my in box is full of email and attachments from them today, so I’d say that they all accomplished getting that checked off! ;)

Thanks for your continuing support and help, both in helping me learn new things and in making it possible for my students to do the same.

These comments show that Deb is now feeling more comfortable with technology herself, is especially grateful for the support she gets from the technology guides, feels she has learned a lot, and is also confident she is helping her students learn and meet the technology requirements.

Elementary Social Studies TE401: Collecting Primary Sources for Social Studies

[URL=http://rorschach.educ.msu.edu/TechReq/TE401_9/]

Lynn Brace and Tim Smith developed a database assignment for Lynn’s TE401 class (Section 9, Fall 1997) where their students helped construct a database to organize their annotated bibliographies of useful social studies references.

These references were collected from a variety of sources, including books and the World Wide Web (WWW), and gathered into a single database for distribution to all students in class. The students met in the Mac lab (EH132) and learned about databases, designed the database for the annotated references, and used the Web to locate potential references.

Tim created a document describing databases and how to create them in ClarisWorks 4.0. Lynn used this assignment to help her students satisfy the database technology requirement (simple or fundamental use) as well as optionally to satisfy the e-mail and Web requirement (simple or fundamental use). Students could e-mail their Web book-
marks or database entries to Lynn or Tim, satisfying the e-mail requirement as well as the Web requirement.

Conclusion

While the MSU College of Education has taken small steps towards integrating technology into the teacher education program, we believe we have made great strides this year and our approach will eventually prove successful in the long term. We fully expect to modify our approach, especially the way we implement various aspects of the support we provide for TE instructors and faculty, as we gather more information and evaluate the success of these activities.

We also realize that this process of technology adoption may ultimately result in fundamental changes in the way we prepare future teachers within the college of education and as such may represent a 10-year program of change. This represents a challenge to all of us in the college, students and faculty included. We are hiring new technology-savvy faculty members who we believe will help us in these efforts and we expect to continue to lead the country in the use of technology in teacher education. It is through these efforts that we believe we will see our graduating teachers themselves begin to use technology in innovative and transformative ways.

Andrew Topper is at the MSU College of Education, 130 Erickson Hall, East Lansing, MI 48823 Voice: (517) 432-3531, E-mail: topperangpilot.msu.edu, http://www.educ.msu.edu/homepages/topper
The Problem

When social science students try to solve statistics problems, there are two major problems that they often face. The first is “how do I get the machine to give me results that I want.” The “machine” is often the computer, but for many it is even their scientific calculators. Many social science students do not like math (as a student once put it: “I went into political science so I could avoid equations”). As a result, they tend to shy away from the subject whenever possible. They have a basic competency in the subject because of high school math requirements, but it often ends there. As a result, they are also not familiar with computational technology. For example, in Political Science 801 at Michigan State University, when presented with an explanation of factorials and told that this can more easily be found using the n! (or x!) button on their calculators, the students’ eyes light up because now they finally know what that little button does. Another example would be students’ recent revelation of how to find the value $e^x$ (read “e raised to the x power”) on their calculators. When this was demonstrated in class, the room was literally abuzz.

Even if they are familiar with computers and calculators, there is another, often more difficult problem for students to overcome as they learn statistics. That difficulty is one of problem identification, although it comes in several forms. Since there are so many different techniques available to use in statistics, students often don’t know which to use. This is particularly confusing when the teacher demonstrates that there are often multiple ways of solving a problem - all of which lead to the same answer. Precisely because statistics is as much an art as it is a science, students need practice in recognizing which methods and approaches are most applicable to a particular problem. They also need training in converting a story problem into something they can handle as statisticians.

To do this, they must (a) be able to classify the problem and place it in one of the major categories of statistics problems. After that, they need to (b) be able to decompose the problem so that they can extract all of the relevant information from it. Following that, they would then (c) execute the appropriate method(s) to find the solution. This last stage is often the easiest; it is the first two that cause students the most problems.

Textbooks are often less than helpful in dealing with steps (a) and (b) because exercises are often placed at the end (or within) the chapters which cover the relevant material. The result is the student doing just the textbook problems rarely gets much insight on (a) since it doesn’t take a genius to figure out that problems at the end of the binomial distribution chapter probably can be classified as binomial distribution problems. In addition, textbook type problems often give the students exactly the information they need to solve the problem in an easily digestible format, hence hurting their practice on step (b). In contrast, some of the exam problems are more reflective of the real world because there is either irrelevant information included or subtlety in the way the information is presented. What textbook problems are really good at is helping a student with the mechanics (c). Not surprisingly, students often state that once they work a problem past the (a) and (b) point, they can figure it out from there.

Because the issue of problem identification is harder to address using traditional methods and affects a larger percentage of students, it is this problem that needs to be addressed first. The problem of students’ unfamiliarity with “machine” usage will naturally be mitigated with time as they use more computer-based learning.

Ideal Solutions to the problem:

1. The ideal would be to have a data bank of 100 plus questions from which the computer randomly draws to create a 10-question test for the student. This primarily...
works on improving and diagnosing deficiencies in step (a). Taking this little test would identify a student who is weak in the ability to recognize and classify (and thus solve) certain types of problems and then send that student off to a review section which may be helpful. This wouldn’t cover every area in every test, but it would give the student an opportunity to retake the test many times as they try to learn this material. Also, if students were able to see and comment on other student’s work on the Internet, they could help each other learn through the process of social constructivist learning.

2. A chat room for group studies would be ideal. Students working together in study groups can learn effectively, but some of our students (particularly MPA students) live quite a distance from Lansing and commute for classes. Commuting for study group time is harder and as a result, these long-distance students either try to get in a group which meets directly after class or skip study groups altogether. Study groups have always been ad hoc, but with a chat room, it could be more structured in terms of time and participation and give more students the opportunity to participate. The professor and the TA have committed to being available in the chat room at certain times, to answer any questions students have.

3. Get old midterm and final exam questions on the web. This is useful, but old copies of exams (and their solutions) have been floating around graduate student circles for quite some time. This information is already available for many students now through unofficial channels. However, not all students, particularly those who have less contact with campus peers, have access to these old exams. The web site would make this access more legitimate and increase the circulation.

4. Place some tutorial information related to the course on the web site. It would be helpful to have expanded information on some of the more difficult statistics concepts taught in class.

5. Post class documents on the site. This site serves mainly as an information center for office hours and course requirements, which the students already have, but may misplace later in the term.

Technology and Limitations

As developers, we found some limitations with using Internet technology, first because the technology itself is in its infancy, and second, because many school computer labs are not yet fully equipped to accommodate what net-based technology can offer. Below are examples that illustrate this point:

1) Ideally, we would like a program that asks a statistics question, then provides a wide, blank space for the students to write out the solutions. Such a program would allow the students to enter the statistical solutions into the answer bank so that others can see their process of solving the problems. However, due to the limitations of html compatibility with math symbols such as pi and lambda, this is not a practical route.

Entering statistics symbols into a website is a function that is still in its infancy in html-based environments. Thus, the best way to enter math symbols such as pi and lambda is by typing it in a word processing program, copying and pasting it into a graphics program and then saving it as a gif or jpeg file. The final step then would be to paste it into the correct designated answer slot into the webpage. This means that all students in Political Science 801 would need to know how to type math symbols, load this text into a graphics program, save it as a file compatible with html, and then load it onto a webpage.

Presently the questions are entered manually in multiple choice form and eWeb provides ready feedback. We are able to type in the feedback to the student by typing symbols out in alpha numeric form, for example, “Your answer is incorrect, the correct answer is c, 2pi X .004; please study Normal Distribution in the teaching center or the text.”

2) When Professor Heimann requested a section to show students how to operate certain functions of SPSS, a program his students are using for assignments, the developers wanted to create a video of the professor explaining how to use SPSS and load it onto the website for all students to access. The problem is that even if we use video streaming, and our computers could accommodate a large file, the students use machines that are not compatible with this type of technology, and the students may not know how to download plugins for sound and video.

Actual Solution Outcomes

According to the proposed solutions above, the developers set up the following sites:

- **Document center**: This webpage contains a syllabus with class office hours, course requirements and meeting times.
- **Virtual Study Center**: This center is composed of eWeb, a virtual learning center. Multiple-choice textbook exercises are entered into the Testing/Exercises function of eWeb. Students can use the Forum and the Chat Room in this site to conduct on-line discussion about questions and problems that occurred in class or in the textbook exercises. The purpose of this site is to foster social constructivist learning by using communication technologies over the Internet. Our theory is that as students use the social interactive components of eWeb, such as the Forum and the Chat Room, their prior knowledge will change through the process of challenge and negotiation.
• **Testing Center:** This center stores old exams, class-assigned problem sets, and solutions to textbook exercises posted in the eWeb. The main purpose of this center is to equalize the distribution of old exams that are usually passed from friend to friend in inner circles. Students who are not a part of such a circulation can now access the old exams through this site.

• **Surfing Center:** contains WWW information and links related to statistics so students can expand their understanding from various cyber resources.

• **Teaching Center:** contains demonstrations and explanations about statistics concepts and related topics with color and explicit graphics and diagrams.

**Process of Setting up the Project**

First, the developers explained the Internet's utilities and developer's capabilities. The developers stated that their ability included setting up interactive web technologies. It was stressed that this website should not be set up for the sake of show and tell, but had to serve a specific need, a need that only the Internet could fulfill.

There were numerous conversations between the client and the developers during the development of the website. Most of these conversations took place over e-mail. The developers asked the professor (client) what the existing problems were for the course; and what the client expected to achieve through applying technology in his class.

Dr. Heimann clearly stated that he wanted to use this technology as a supplementary tool to his class, and not the main teaching tool. With all the information that the developers collected from the client, they informed the professor what educational technology could do to help him improve his teaching, while constantly assessing the methods that should be used to meet his needs. Fortunately, Dr. Heimann was familiar with Internet technology, making the planning stage very accommodating.

**Reflections of the Developers**

Working as a team of developers, we noticed that good communication is a necessary dimension of working with computer based technology. Technology tends to change the way we work. We cannot work on projects by ourselves; we have to depend on other's expertise and reliability. Thus, one's success does not merely depend on making a machine work, but also on how one engineers human inter-relationships while doing so. During our project, the latter component was more unpredictable than the former.

Working with our client was easier than expected, but still a long process. The death of a member of Dr. Heimann's family was an unpredictable occurrence that discontinued the newly established communication rapport. As Dr. Heimann stopped answering our e-mail, we began to assume the scheduling of our project: Should the Problem Sets go in now, or at the end? We assumed at the end since each Problem Set was dated. We were wrong.

In fact, what we found was that communication between the client and the developer was such an integral part of this project that our every question had to be posed to and answered by Dr. Heimann. Coordinating the times that tests were to be entered was critical in helping students use the Website. Had we assumed that students would know the answers to the textbook questions before the last month of the term, the textbook questions would have been entered much earlier.

Moreover, when we set up a page and told Dr. Heimann, he did not respond right away by telling his students. It was as though we had to prove our work and ourselves before he would announce it to the class. Dr. Heimann's enthusiasm did not peak until we showed the product, in person, and explained the various webpages' functions.

At other times, Dr. Heimann would tell his students, but the students would not respond right away by going to the Website. This slow acculturation to new technology was perhaps due to three reasons: 1) They were unfamiliar with how the Website worked—although we offered to set up a tutorial session—and did not want to try to figure it out because they were already dealing with something new: statistics. Perhaps the researchers were right (Marchionini & Liebscher, 1991) when they found that people “have a tendency to try to lighten their cognitive load as much as possible.” Not until the finals neared, and Dr. Heimann encouraged them to take the textbook exercises, did the students begin to do so. 2) A few students did try the site and got confused by going into the Testing page and finding a link to a Purdue testing package (this was an error caused by miscommunication between the members of the team of developers). Once betrayed by technology, people are reluctant try it again. It was interesting to observe that at times even we, as developers tended to put something off if it did not work for us right away. Similarly, Dr. Heimann would not tell us something was not working, unless we asked him how things were going. Perhaps he did this not to embarrass us, or perhaps he, too, put things off if they were not working. 3) The nature of the Internet allows for unaccountability. The students are not required to go to the website and there's very little the professor can do to enforce this. The website is not like a piece of paper that has to be handed in. A prime example of this is the survey we put on the website. We decided that if we passed out the survey on paper during class time, students would be made to do it on the spot. In contrast, the survey on the website may remain untouched, since it is an anonymous survey.

**Research component**

As a part of this research, we will evaluate the effectiveness, acceptability and affordability of the website as a study aid for Political Science 801 and 802. In evaluating the effectiveness, we will compare the data of student performance from the last five years—in which no such study aid existed, to this year's data—in which students used the...
website for two terms. To assess acceptability, we will survey the students as to how much they used the website and how much the website helped them. We will also ask for student's opinion of what can be changed or added to facilitate their needs better. We will determine whether their comfort levels with "machines" have risen as a result. To evaluate affordability, we will compare this study aid with another similar type of study aid, the CD-ROM.

**What we expect to find**

Thus far the professor feels very confident that the student’s performance will improve as a result of using the website. He notes the following:

“I have my teaching assistant and myself log on to the chat room at designated times four times a week. This is great for students who live far away and can't come to office hours. Also, if another student asks me a similar or the same question as was discussed on the eWeb, I can tell them to go back and check out the transcript dialogue files in the chat room.”

This is an example of technology adaptation that is purely utilitarian in nature. The class passes through three stages. Both the students and the professor first try to figure out the mechanics of using the website. Then they begin to adapt to the technology to suit their needs. Lastly, they begin looking for other ways to utilize this given technology. We expect Dr. Heimann to adapt other functions of the website to better suit his teaching needs as he realizes more of its potential. For example, the testing and exercises site will eventually coincide with actual class lectures. Presently, there is little coordination in this area.

We also expect the students to become more comfortable using this type of technology and thus the computer. The result will be circular. The more they use the site, the more they will become familiar with how the site can help them, and thus the more they will use the Website. We expect student motivation to rise as they become more familiar with the site.

The difficulty students have in identifying and distinguishing various types of statistics problems should be mitigated as students began to use the testing site more. We expect the final data to show that student performance this year has improved in comparison to the past five years.

**Conclusions**

Social science students are often bewildered in the area of statistics; they are exploring an unfamiliar realm when it comes to technology and math. We hope to mitigate their fears of both areas by setting up a study aid on the Internet. The main result we hope to achieve is twofold: 1) to fulfill the missing component of what the classroom text does not provide—the generation of problems in mixed order, so that students can learn to distinguish from the various types of problems and 2) provide a communication tool for social constructivist learning over long distances. The study will be ongoing for the duration of Political Science 801, and 802, 1997-98.

**Acknowledgments**

The initial ideas for this paper came from a team of students working together on a class project for Counseling and Educational Psychology 813 at Michigan State University. We would like to thank our instructors Dr. Yong Zhao, Andy Topper, and others for their help with the proposal to SITE 98. Although the paper has changed tremendously since its original inception, we would especially like to acknowledge the efforts of Sejin Chung, a doctoral student in Educational Technology at Michigan State, for her previous association in the project and for her involvement in finalizing the proposal abstract.

AN INTEGRATED APPROACH TO COMPUTER EDUCATION FOR K-12 TEACHERS

David L. Breithaupt
North Carolina A & T State University

Karen Smith-Gratto
North Carolina A & T State University

Increasing numbers of computers have become available to teachers and students in classrooms and computer labs through recent efforts at the national, state, and school district levels. Although most schools now have computers available, the use of computers as an instructional aid is limited (U.S. Congress, Office of Technology Assessment, 1995). Berry (1994) reports that teachers often do not see the value of computer use as a teaching and learning tool, and that 67% of Chicago Public School teachers said that computers wasted students’ time. Bosch (1993) also reports that “some teachers suggest that the computer is a separate and specific learning experience apart from the general classroom (p. 8).” This paper reports on a project to combine two models for teaching computer-based instruction to student and professional teachers into a single integrated method. The models used in this project are the Instructional Technology Integration Model (Breithaupt, 1997) and the ABCD Model (Smith-Gratto & Blackburn, 1997).

The Instructional Technology Integration Model

A major component of the Instructional Technology Integration Model is focused on preservice education for student teachers and includes university classroom and field-based instruction and experiences. This model is part of the Collaborative Curriculum Development effort at a large private university, and takes advantage of the structure of school-university partnerships to facilitate and enhance student and professional teachers’ efforts to use computer technology to support their curriculum.

Student teachers are required to complete an introductory core computer course in which they are introduced to computer operations and use, software evaluation and selection, and authoring systems. They are then required, as part of their teaching methods course, to complete an instructional computer program which supports a lesson plan from their proposed curriculum. Finally, for their student teaching practicum, they are paired with interested professional teachers and collaboratively develop computer-based instruction to support their curriculum in the professional teacher’s classroom. A resource network made up of university teacher educators, arts and sciences faculty, instructional designers, and technology specialists supports the effort of the student and professional teachers.

The pilot test of the Instructional Technology Integration Model shows that it can be effective for teaching student and professional teachers to use computers to support their curriculum and that the collaborative curriculum development effort is mutually beneficial to the student and professional teachers.

The ABCD Model

The ABCD Model provides guidance in the selection and development of computer-based instruction for professional teachers in their curriculum. The ABCD Model provides a framework in which the teacher will (a) Analyze the software and their curriculum, (b) Brainstorm connections between the software and the content areas, (c) Connect the curriculum, the information obtained during brainstorming, and non-computer classroom activities, and (d) Define curriculum objectives which may be incorporated into the computer-based instruction and both the computer-based and the non-computer-based activities which will be used to address those objectives. The ABCD Model supports the decision-making process and guides teachers in the selection, implementation, and integration of computer-based instruction in their curriculum.

An Integrated Approach

Student teachers who have received their computer education with the Instructional Technology Integration Model enter their student teaching practicum prepared to select, prepare, and use computer software as a teaching tool. During the pilot test of the model, the student teachers often became the professional teacher’s best resource for information on the use and operation of computer technology. However, the student teachers did not have the
experience necessary to effectively select appropriate software for their curriculum.

Using the ABCD Model to structure the student teacher's computer education and experience and the professional teacher's curricular knowledge and experience should simultaneously (a) increase the amount of computer use in the K-12 curriculum and (b) increase the quality of computer-based instruction by all teachers participating in the project.

The restructuring of university preparation programs in professional development schools have centered on expanding the university students’ experiences in the k-12 classroom. The Holmes Group (1986, p. 56) advocated that a design for improvement in tomorrow's schools is found in the structure of the professional school, as a collaboration between universities and public schools. Practicing teachers and administrators together with university faculty in a partnership (practitioners) think, analyze, make knowledge-based decisions and implement them effectively (Levine, 1997). These practitioners are exemplars and supporters of good practice. The professional development school, a teaching hospital, emphasizes teaching and learning in clinical settings, linked with research and practice. Levine (1997, p. 66) points out three critical attributes which define the standards of quality of the professional development schools. They are: (1) the nurturing of a true learning community capable of providing support for adult and children learning; (2) the characteristic of a true collaboration both within and across partnering institutions; and (3) accountability for quality teaching and learning. These attributes are reflected in the longer time period instituted for the preservice teacher internship. Many experience both the first and last day of school, events for which there can be no training other than authentic exposure. The preservice teacher actively participates in classroom and district activities such as professional development, staffing, assessment approaches, and research much sooner. Research shows that at the end of the internship, the preservice teacher’s exit scores and the percentage pass rate of students in the field-based experience have exceeded that of the past traditional programs, indicating a trend in favor of professional development centers (NETCPDT, 1995).

One component of this successful restructuring has come through the infusion of technology in the k-12 and the university student’s learning experience. Classroom teachers reported that, with technology, their students were more motivated and productive. The reason for this success was linked to two factors: the placement of technology into the classrooms rather than in labs, and the related on-going staff development and support (NETCPDT, 1995). Because teachers integrated technology into their instructional goals, they found it instrumental in creating student-centered, project-based activities. Also this spurred many educators to use the technology for their own personal use. These teachers were using more technology than teachers from schools who previously had acquired computers for computer labs. Their efforts have led to compressed video and other distance learning technologies placed in remote areas to access more educational resources.

This paper will highlight how one university and its surrounding public schools have joined together to use a combination of technology and both new and traditional teaching methods to improve the skills and abilities of preservice teachers. What beginning teachers learned in the university technology classes, and how they have actually integrated technology into their classroom instruction is the focus. Suggestions on what technology instructors can use when training preservice teachers will also be discussed.

University Coursework: What was taught

Preservice teachers take two technology courses that prepare them for the public school classroom. They take this knowledge into the classroom and practice under the supervision of the public school mentor teacher. Students start with discovering why they should learn to use the computer and what it has to offer. Later, they move through assignments that include traditional word processing database and spreadsheet educational applications and extended applications such as sending messages by e-mail, doing research on the internet, and making slide presentations for their classes. The preservice teacher learns to use operating systems and user interfaces to run programs; to access, generate and manipulate data and to publish results. As they advance in the course, they use technology to enhance their professional growth and productivity by using technology to communicate, collaborate, conduct research and solve problems. In addition, they plan and participate in activities that encourage lifelong learning and promote equitable, ethical, and legal use of computer/technology resources.
As students continue through the second course, they apply computers and related technologies to support teaching and learning in their grade level and subject area. They plan and deliver instructional units that integrate a variety of software, applications, and learning tools. Lessons developed reflect effective grouping and assessment strategies for diverse populations. By the end of the year many are amazed at what they have accomplished and how valuable the knowledge and skills they have gained will be when used in their classrooms.

The Teachers' Story

An interview of several novice and preservice service teachers revealed what skills these teachers actually felt they were able to apply in their classrooms. They filled out a technology survey sheet that contained the following information: the type of computer used; the word processing, database, spreadsheet, and slide program used; the use of the Internet (general use), places of access, applications they used, frequency of usage to locate information, the frequency of their recommendations of resources to others, the frequency of downloading the information, and the authenticity of the information; sending e-mail; and whether or not they have been tele mentored via e-mail.

Many of the teachers and preservice teachers interviewed felt that much of the information learned during the courses or staff development was beneficial during their first year of teaching. All of the teachers said they used spreadsheets to create a gradebook, a class roll, seating charts, certificates, letters, memoranda, and overheads. The first course taught one word-processing program and its components, which they found problematic. The teachers said that they liked having access to the Web to ascertain lesson plans in various subjects, to use test data banks for support of instructions, to communicate with colleagues and participate in professional development by means of telecommunications. They used power point and other slide show programs to teacher lessons. Some of the beginning teachers reported using technology in their instructions in the following ways:

1. One preservice teacher used a math program to help students measure certain objects in weight problems.
2. With the help of the mentor teacher, the preservice teacher designed a program that helped them teach government via the computer.
3. Another teacher and preservice teacher created a persuasive paper that led to a student created slide show presentation.
4. Another preservice teacher used an art program to teach lessons through having access to different museums, and then using museum art to draw designs and create their own pieces of art. For example, with the help of his mentor teacher, the preservice teacher downloaded artwork that refined a lesson on using certain drawing lines to develop a picture. Students watched as the mentor teacher and the preservice teacher team-taught the lesson from the monitor. Students in both of these instances enjoyed and learned the latest information from the Web.
5. One preservice teacher developed a database to keep student records, and actually chart and graph student progress. The teacher charted the progress of her students in a weightlifting program. The students, for the first time, could see that they were making progress, and continued in the program instead of becoming discouraged and transferring out.
6. Another preservice teacher used the web to find information that enhanced his science lessons. The preservice teacher shared how he had asked his students about fish and their sleeping habits. He did not know the answer to his questions himself, but because he had learned how to get on-line to get up-to-date information about questions in science, he was able to retrieve his information and start his class the next day with the answer and photos he found on-line.

Preservice service teachers are encouraged to produce their own activities that can be added to some of the sites or share what they have done by sending responses to my home page (http://www.tamu-commerce.edu/coe/shed/justice) and other educational home pages. These activities give preservice teachers a chance to think about and evaluate what they see others do and what they actually do in their classrooms.

Preservice teachers also communicated with other professionals who teach in their subject area. This helped them understand the process of what other professionals go through when they were planning lessons. These professional teachers gave them tips to assist them in organizing their classroom and in the how-to-skill of applying instructional strategies and management techniques. This on-line contact has richly added to the improvement of their lessons, especially when they are also able to get tips on student motivation, learning styles, multicultural materials, government documents, biographies of scientist or authors, and news magazine articles. Preservice teachers have included some of this information in the presentations that they have made in their classes. These preservice teachers have discovered that the Web has actually added personal- ity, depth, and breadth to their original information.

These anecdotes show how some of the teachers and preservice teachers began to use technology in their classroom because of the collaboration of the public school and university faculty. These teachers are continuing to create different activities that enhance learning in their classroom.

The Collaboration: Changes

As the collaboration process continues, we have all found that the coursework and activities are always under
construction. Through surveys preservice teachers were able to communicate their needs. For example, we found that teaching one kind of program was not helpful in the transfer of that knowledge to other programs. Because preservice teachers were in a number of school districts, all schools did not use the program. Therefore, we looked into several possible alternatives. We began training students on more programs and showing them critical attributes of these programs that would apply to any other program. Because of this knowledge, did not have to stay at the university or at the school campus to complete work. This training has also increased the chances of student teachers being hired in school districts where they have spent their internship.

The preservice teachers and the mentor teachers expressed an interest in taking more technology courses. As a result the university and public school teachers designed a masters degree program. The program focuses on technology and new and innovative ways of teaching. Three different school districts have started in the program and other districts are wanting to become a part of this design.

Preservice teachers have contributed to the way the classes have been taught. As they progress through the courses, they participate in formative and summative evaluations. These evaluations are used to tell us about the needs of the teachers in the classroom. Also they suggested that instructors use larger screens to present and practice skills on the computer. They are eager to learn the latest information; therefore, they want periodic updates to what they have learned. In these courses, changes are continually made, new goals are set, and the vision is continually refined.

Summary

We have looked at our successes and obstacles. We have overcome the barriers and continue to plan a program that will continue to meet the needs of our students. We are flexible enough to take advantage of new technologies and new funding opportunities. Increased funding will help us update the equipment, software and hardware and provide support services. The professional development center has provided us with a vehicle that helps use to invest more time and money in assisting schools in their technological efforts so both can learn from the experiences. Continuous staff development has fostered exploration of advanced technologies. All of the partners feel involved in shaping the technology agenda. All of these efforts are supporting what the professional schools are all about: providing intellectual and technological leadership in the restructuring of the schools for the future.

Integrated Technologies and Teacher Portfolios

Mary Ann Kolloff
Eastern Kentucky University

JoAnna Dickey
Eastern Kentucky University

Shirley Long
Eastern Kentucky University

Sue P. Reehm
Eastern Kentucky University

Joyce Harris Thomas
Eastern Kentucky University

The Kentucky Department of Education and the National Council for Accreditation in Teacher Education guidelines direct institutions of higher education to plan a continuous assessment component in their pre-service and in-service teacher education programs. To meet these guidelines, Eastern Kentucky University (EKU) has created a portfolio requirement to be used in its undergraduate and graduate teacher education programs. The portfolio requirement incorporates a system that students use to document the achievement of meeting the New Teacher Standards for Preparation and Certification (NTS) and the Experienced Teacher Standards for Preparation and Certification (ETS) from the Kentucky Department of Education (1994a & 1994b) and the guidelines from learned societies. The New Teacher Standards measure the performance of pre-service and intern teachers. The Experienced Teacher Standards measure the performance of teachers who are participating in an in-service development program. The use of integrated technologies will play a major role in the development of a program candidate’s portfolio. The purpose of this paper is to explain how integrated technologies will be incorporated into the portfolio process.

New and Experienced Teacher Standards
The New Teacher Standards for Preparation and Certification describe what beginning teachers should know and be able to do in authentic teaching situations. Each of the eight general standard statements describes the category of teaching tasks that beginning teachers should be able to perform. Each standard is followed by a set of performance criteria to be used in assessing the actual quality of performance of first-year teaching candidates. Within the portfolio, each pre-service teacher is expected to document and record his/her performance on specific authentic teaching tasks. Thus, the portfolio is expected to contain examples of quality performance within the categories of designing and planning instruction, implementing and managing instruction, creating and maintaining learning climates, assessing and communicating learning results, reflecting on teaching and learning, collaborating with colleagues and parents, engaging in professional development, and demonstrating knowledge of content. The standards and the performance criteria are not designed as checklists, but rather are to be considered holistically in assessing the performance of pre-service and beginning teachers.

The Experienced Teacher Standards include and exceed the New Teacher Standards with additional criteria and a standard that characterizes what effective, experienced teachers should be able to know and do. The Experienced Teacher Standards stress instructional processes that demonstrate an understanding of the academic, social, emotional, and physical needs of each learner. Experienced teachers are also expected to demonstrate professional leadership within the school, community, and educational profession. The portfolio for experienced teachers contains examples of demonstrated quality performance using authentic teaching situations and a combination of continuing education, professional development and leadership.

Undergraduate Portfolios and Professional Development Plans
At the undergraduate level, teacher education majors at EKU will initiate a portfolio in their first education course, Introduction to Education, EDF 103, (or Transition to Education, EDF 310, for transfer students). They will be given a packet of information containing portfolio guidelines including definitions of terminology, description of format, and expectations of content for the portfolio. They will be required to purchase a binder and divider tabs for organizing
Education classes will require the use of word processing for the required packet in the College of Education computer lab. For example, in the first class, students can access and print the packet, and the process will include a variety of approaches. For professional development, students' reflections will provide portfolios in connection with Standard 7, engaging in student teaching experience, the service learning project, and professional development activities will include course work, the student teaching experience, the service learning project, and evidence of attendance and participation at professional meetings and workshops.

The use of technology in the development of undergraduate portfolios will be encouraged from the beginning of the process and will include a variety of approaches. For example, in the first class, students can access and print the required packet in the College of Education computer lab. Education classes will require the use of word processing for performance tasks, and other productivity software will be used for specific products (e.g. writing and illustrating a patterned language book).

**Graduate Portfolios and Professional Improvement Plans**

Beginning in the spring semester 1998, a Professional Improvement Plan (PIP) and Graduate Professional Portfolio (GPP) will become part of the Master of Arts in Education (M.A. Ed.) degree and the Rank II non-degree programs. For example, the M.A. Ed. in primary through fifth grade program consists of 15 hours of Professional Education Core, 12 hours of Subject Matter, and 3 hours of Elective course work. The Rank II non-degree program is a coordinated program of study that guides the student through 32 credit hours that meet Kentucky Department of Education guidelines. This program consists of 12 hours of Professional Education Core, 12 hours of Subject Matter, and 8 hours of Selected Elective course work.

Within the first six credit hours of either program, students are to enroll in the required curriculum course. In this course, the students will be introduced to the Graduate Professional Portfolio and will write a personal Professional Improvement Plan. The students will provide information about how they plan to improve their professional performance in each of the nine Experienced Teacher Standards. The student will use the portfolio to display artifacts providing information about performances that meet the improvement plan. Entries in the portfolio and the PIP must reflect growth in each ETS.

Each course taken throughout the program should provide students with opportunities to move toward fulfillment of the PIP. A performance or product from each course in the student's graduate program could also provide appropriate portfolio entry materials. The students will decide what materials from the activities experienced during their programs will be placed into their portfolio and how those experiences fulfill their PIP.

At the end of the Master of Arts in Education degree program a comprehensive assessment will provide the student and his/her graduate committee an opportunity to assess the fulfillment of the PIP and completion of the GPP. The portfolio should contain artifacts that provide evidence that the performance criteria for each of the nine Experienced Teacher Standards were met. Students in the non-degree Rank II program will meet with their advisor for an exit interview. Using a planned format, the advisor will conduct an assessment exit interview focusing upon the completion of the PIP and the GPP.

The first experience in providing graduate students with information about the PIP and GPP will occur in Spring 1998. Each professor who teaches a graduate curriculum course will incorporate information during course time that concerns the PIP and GPP. Information will be provided to help

**Concepts and Procedures — 49**
students begin their portfolios and write their PIPs. The elementary curriculum course will be offered as a distance learning opportunity that utilizes interactive television (viz., Kentucky Telelinking Network, KTLN). Students at distant sites will have the opportunity to learn about curriculum and the new PIP and GPP program requirements. It is believed that more students can obtain information about new program requirements through this medium.

**Learned Societies Guidelines**

Competencies identified by the professional organizations or learned societies of the disciplines of the graduate and undergraduate programs must be a part of students’ portfolios. Performance events or assignments that result in a product other than a paper and that reflect mastery of a competency will be a required entry. One way that this will be achieved is through the use of integrated technologies.

**Integrated Technologies**

Seels and Richey (1994) in their book, *Instructional technology: the definition and domain of the field,* define integrated technologies as “...ways to produce and deliver materials which encompass several forms of media under the control of the computer” (p.40). The “media” within this definition includes several forms of integrated hardware and software. To illustrate, digitized information from photographs, video segments from tapes or disks, hypermedia authoring tools, web-based development, networking software, audiographics, and interactive television are all examples of media being controlled by the computer.

Extending the definition of instructional technologies, Seels & Richey (1994) also define the domains of utilization and development of media. Utilization refers to “...using processes and resources for learning” (p. 46). Examples of integrated media utilization include use of specific software within content areas and audiovisual materials such as videotapes, film, transparencies, and CD-ROMs. The important ingredients of utilization are the introduction and follow up activities. On the other hand, development of media is “...the process of translating the design specifications into physical forms” (p. 35). These physical forms may include manuals, books, photography, line drawing, mathematical graphs, video and sound recordings, transparencies, slides, computer-based instruction (e.g., tutorials, drill and practice, games and simulations, databases), authoring tools for hypermedia, and authoring tools for developing web pages. Two current trends in development of integrated technologies are a greater integration of: (a) print technologies and audiovisual technologies with authoring tools for hypermedia and web pages, and (b) technologies for distance learning environments.

Seels & Richey’s definitions provide a useful structure when considering portfolio development for graduate and undergraduate students. While the Kentucky New and Experienced Teacher Standards combined with the learned societies competencies serve as a framework for the organization and management of the portfolios, the utilization and development of integrated media forms provide for infusion of instructional technologies into the portfolio process. As graduate and undergraduate students prepare portfolio entries, the use of integrated technologies includes four aspects: a) systematic matching of learners with instructional resources, materials, or both; b) developing lesson plans that demonstrate learners’ interaction with the resources, materials, or both; c) guiding learners while they are engaged with the resources, materials, or both; and d) assessing results achieved by the learners after they are engaged (Seels & Richey, 1994). What is most important to consider for each portfolio entry, constructed by the graduate or undergraduate student is the “interface” between the learner and the resources, materials, or both.

Sample portfolio entries that demonstrate utilization of integrated technologies into a portfolio are varied. One example would be when graduate students, undergraduate students, or both are given the task of preparing a learning environment with an interdisciplinary approach to content. P-12 students in this learning environment might be required to collaborate, research, present, and develop a product for a particular concept (e.g., the effects of war on children). The first step for the graduate or undergraduate student may be designing and implementing lesson plans for helping the P-12 students develop or refine search strategies, develop or refine research skills, and evaluate resources. This process might be introduced by discussing search structures for the various integrated technologies including print, CD-ROM, and web-based reference resources and materials. Results of the search may include locating credible videotapes. At this time, the graduate or undergraduate student may choose to model selecting and implementing videoclips in a presentation for the P-12 students. Effective use of videotapes in classrooms generally requires selecting videoclips so that particular concepts may be reinforced or learners may construct generalizations. In this example, each of the lesson plans designed by the graduate or undergraduate student, along with documentation (videotape of the lesson) can be incorporated into the appropriate Kentucky new or experienced teacher expectations and learned society competencies. In addition, the graduate or undergraduate students may want to enhance their portfolios by including entries demonstrating the manipulation of the resources and materials into development a product, thus moving into the domain of development.

Integrating technologies within the development domain involves graduate students, undergraduate students, or both forming products by constructing physical forms of media for utilization. These entries or products are then organized by filling in the appropriate area of new or experienced teacher expectations and learned society competencies, thus documenting achievement of standards.
Utilization of these products may occur through opportunities for providing professional development for colleagues, collaboration with colleagues, or through use by P-12 students. Portfolio entries should provide evidence of using a variety of integrated technologies such as productivity tools, hypermedia authoring tools, presentation software, web-based tools, and distance learning tools. Thus, the domain of development involves the synthesis of information into a new product so that a concept is illustrated or problem-solving situations are presented to the learner. This product may contain new text, visuals (e.g., photographs and line drawings) which are created on a computer, scanned, or imported to enhance the text or videoclips selected from film, video, or videodisks. In addition, new video may be produced and edited to further illustrate a concept, to provide oral histories, or to demonstrate a dramatic play. Finally, sound may be selected from previous resources or new sound created to reinforce the concepts. Web sites may be referenced so that the learner (viz., the one interacting with the product) may further investigate/research the concept or topic. Using information synthesized from these searches a web site may be constructed to focuses on the concept.

Summary
All students in the undergraduate Teacher Education Program, the Master of Arts in Education, non-degree Rank II and Rank I programs are required to submit portfolios prior to the completion of their programs. The content of the portfolio is determined by the competencies of the Kentucky New Teacher Standards for Preparation and Certification (1994b), the Experienced Teacher Standards for Preparation and Certification (1994a), and the learned societies of the various disciplines. Entries or artifacts in the portfolios are indicators of the performance and mastery of the competencies by the preservice or experienced teacher.

The use of integrated technologies in the production of the portfolio is strongly encouraged. The technologies must be incorporated so that the infusion of instructional technologies across the curriculum becomes transparent, and the use of the technologies in teaching is automatic. Portfolio entries may be in any physical format such as print, video and sound recordings, transparencies, slides, CD-ROMs, and disks. What is essential is that there be integration of all technologies, used as tools or displayed as products.

Starting from Ground Zero: Integrating Technology in Education Programs

Tina Marshall-Bradley
South Carolina State University

George C. Bradley
Webster University

In teaching, new ideas and teaching methods cycle in and out of favor more frequently. Integrating them solidly into practice, however, may still take several years (Brown & Henscheid, 1997). The idea of using technology in some schools of education has been articulated, but has not always been put into practice. One reason may be a long-standing assumption that when students take a basic course in technology they are prepared to use the concepts as a part of their training in education.

Current technology has allowed us to simplify our lives, become critical consumers of information, and bring the world a little closer to home. Technology allows university faculty to access information and expose students to ideas, issues, and resources beyond the geographic boundaries of their actual location. However, simply placing technology in front of pre-service educators and administrators will not ensure that they use this medium of information acquisition to effectively instruct students or improve the quality of their work.

There is an effort to provide educators with the skills they will need to become knowledge navigators who will pilot their schools and classrooms to the very edge of human knowledge. Educator explorers will reach out and touch experts in the community, in the nation, and around the world as pioneers on the knowledge frontier, and as "hands-on" practitioners. In order for educators to be able to do this, it is necessary for programs that work with educators to incorporate the use of technology as a part of programs being offered.

Several courses being taught in the School of Education at South Carolina State University are utilizing a variety of available technologies in conjunction with cooperative learning and collaborative problem-solving, to deliver the content of the courses, while modeling effective strategies for using technology. Faculty members from a variety of disciplines collaborate on effective methods of presenting information to undergraduate and graduate students using appropriate technology.

Students enrolled in these courses are required to engage in activities that allow them to use existing technology (i.e. wordprocessing, databases, Internet searches, presentation packages) as a part of the learning process. Faculty members present information in the courses using the kinds of technology that will enhance the learning process. Faculty members and students work collaborative to determine methodology that is effective and those areas that are ineffective.

Background Research on Standards and the Use of Technology

Several factors were considered when exploring the possibility of integration of technology in education courses in School of Education. As educators begin to explore how technology will be used in the area of education, it was imperative that issues of relevance are addressed. If teachers' primary use of a computer is to be a reward for students to play computer simulated games or to be used as high tech drill and practice sessions, then less expensive methods may need to be considered. All educators, from administrators to classroom teachers, must resist the urge to give in to the public pressure of having students work on computers because of high visibility media attention or for other non-academic reasons. Higher education programs must be careful not to perpetuate the "use of technology for technology's sake" mentality among its graduates.

While the promise of educational technology promotes sense of both enthusiasm and urgency among public officials and academicians, a key element of the educational process is often absent from these discussions — faculty development. Faculty must include current technologies in their curricula, thereby empowering graduates with the knowledge and understanding of appropriate and productive use of technology. Scholars have advocated integrating computer elements throughout the courses in undergraduate programs (Scherer, 1985; AACTE, 1985; Berger & Carlson, 1988; Billings & Moursund, 1988; Bitter & Yohe, 1989; Callister & Burbules, 1990). Course work in these programs, however, needs to be redesigned to integrate technology in both methods and foundations courses so the technology is...
used in relevant contexts (Todd, 1993). An initial investigation indicates that most faculty members do not have the technical skills to achieve these goals. There also is very little motivation to acquire the necessary technical skills to integrate or require the use of technology in current education courses.

Therefore, as technology should be integrated as a natural part of the education process, it was felt that all educators should be aware of the functionality of technology through an integrative approach. Kovalchick (1997) suggests those elements from both competency-based models and integrative models are blended into a reflexive approach in which students use technology as both learner and teacher. In this way, preservice teacher education students and students working on advanced degrees in administration are challenged through direct experience to generate personally relevant conceptions of technology. When examining the uses of technology, it was imperative to consider the proposals made by Duffield (1997) in that technology should be integrated into existing courses and not seen as separate from the subject areas.

**Primary Uses of Technology**

The school of Education at South Carolina State University offers initial certification programs at the undergraduate and graduate (masters) levels in Early Childhood Education, Elementary Education, and in the secondary areas of English, History/Social Studies, Industrial Education, Mathematics, and Science. The graduate program in Educational Administration offers certification to school principals, district level coordinators, and superintendents. The Educational Specialist Degree and Educational Doctorate Degree are offered through the Department of Educational Administration.

The uses of technology as a part of these programs is focused primarily on the use of: wordprocessing, databases, statistical packages and spreadsheets, the Internet as a research tool, e-mail as a tool for communicating (student to student and student to professor) and presentation software as a part of classroom instruction and class projects. As in many other programs, only a small proportion of faculty is utilizing technology. These faculty tend to be "innovators" or "early adopters" rather than "mainstream" faculty (Frayer, 1997).

The use of technology in the School of Education corresponds with the 1996 National Survey of Information Technology in Higher Education. This report by Kenneth Green notes that the percentages of college courses using various kinds of information technology resources remains relatively low. Table 1 indicates the percentages of technology use in college courses as well as the kinds of technology that is currently in some courses in the School of Education at South Carolina State University.

The Department of Teacher Education provides an undergraduate initial certification program. All education majors must take two courses entitled Introduction to Education (ED 199) and Socio-Economic Geography (GEO 305). Introduction to Education is a survey of current education issues and exposes students to the field of education, while Socio-Economic Geography allows students to study geographic concepts within the context of educational areas. The National Standards are utilized in order to make the connection between public school instruction and instruction at the university level. The use of technology as a tool is also a major component of these courses. Students are required to use a computer based wordprocessing package to complete all written work. In addition, all students have e-mail accounts and the professors poses multidimensional questions via e-mail. Students are required to respond via e-mail and the evaluation and comments on the assignments are provided to students via e-mail.

In addition to student to professor interaction, students are encouraged to use e-mail for student to student interaction to facilitate the communication process as a part of cooperative learning activities. Student groups are required to develop, write and deliver group research projects. The research projects must flow as if one person wrote the paper and the group process is held in equal value to the group outcome. Therefore, students send copies of their parts of the project to other group members for comments and review via e-mail. Some groups chose to use a presentation package, such as Powerpoint®, to present the major points of their project.

Many of the assignments given via e-mail ask students to evaluate the utility of identified web sites in assisting them in understanding classroom concepts, developing class projects, and collecting necessary educational information. Students visit and evaluate web sites as an integral part of learning critical aspects of the courses in...
general and their relationship to the students’ specific areas of study. The emphasis in these courses is certainly not the use of technology. However, students are not only exposed to and required to use technology, they are also given any training they deem necessary to complete identified tasks. If future teachers are expected to integrate technology into their teaching methods, faculty must model the use of technology in courses.

Certain courses at the graduate level naturally lend themselves to the inclusion of technology or already contain technology components. In these courses, Educational Research and Data Analysis (EAR 710), Advanced Data Analysis (EAR 803) and Survey Research (EAR 804), students use the Statistical Package for the Social Sciences (SPSS-X) and Microsoft Excel® to organize and analyze research data. Students also use current databases on CD-ROM to collect relevant literature on current issues in education.

To develop the use of technology in the Department of Educational Administration, a CD-ROM based law library, that is housed in the South Carolina Institute for Research in Education (SCIRE), is being utilized to supplement the current course in School Law (EAM 738). Students are able to search for actual court cases that pertain to education policies, procedures and regulations.

Faculty members utilize the advanced research services available in the Miller F. Whitaker Library on the campus of South Carolina State University. MIL-LINE is the library’s integrated online library system. It allows users to access the library electronically from offices and laboratories using the campus VAX system. Library holdings on MIL-LINE include books, state and national documents as well as CD-ROMS, CD-ROMS on MIL-LINE utilized by School of Education faculty as a part of undergraduate and graduate courses are, Book Review Digest, Education Index, ERIC, and Statistical Abstracts.

**Future Plans for Technology Integration**

Programs that are in the infancy stage of using technology can, because of technology, use the experiences of other educational programs. The information highway allows faculty members to read about the activities of other institutions of higher education, and benefit from their work. In order to address the needs of educators and administrators there are several plans being developed to effectively integrate technology in education courses at South Carolina State University. These plans include: the addition of hardware and software to facilitate the use of technology by professors; faculty development in the area of effective use of technology; and the development of innovative methods of delivering information in education.

One of the classrooms used by School of Education faculty is being converted to accommodate the needs of faculty members who are making technology an integral part of their courses. Although the classrooms were specifically designed for methods courses, faculty members who are proposing innovative uses of technology in their courses are being invited to use this classroom. Technology that is included in the design of the classroom are; mounted television sets, a teacher computer station with a projection unit, several student computer stations, and Internet connectivity. This classroom is adjacent to an eighteen station computer lab. The proximity of the computer lab facilitates the process of students being trained to use specific pieces of hardware or software as the need arises during the course.

A university wide project has been initiated to provide resources that will allow faculty, staff, and students to use campus-wide Intranet and Internet tools to improve academic instruction and student services. The Multimedia Development Institute (MDI) has been established to assist faculty in the design and development of an Intranet of web-based applications, including courses, course materials, and student services information. This Intranet will also include some commercial applications as well. To insure adequate access to this Intranet and to the Internet, an open student lab will be established. Faculty participants in the MDI will receive multimedia development systems and appropriate training for the development of appropriate courses or modules within courses that integrate technology into the learning process. In addition, an Internet security firewall will be established to provide data integrity and ensure confidentiality of student information.

Faculty members are working towards creating asynchronous learning environments, i.e. learning that is time and place independent. These methods would serve the needs of a growing diverse population of individuals and professionals whose needs extend beyond the traditional boundaries of the university setting. Ideas and strategies that are implemented need to be evaluated and analyzed to determine their effectiveness.

It is the belief of a core group of faculty members that technology will allow the School of Education, to improve existing instruction, maximize the use of current resources, and target new student markets. The primary barrier to integrating technology into the programs in the School of Education appears to be in the connection between, what faculty members do, and ways that technology can improve this process. However, with more faculty development being provided, the enthusiasm and drive of a core group of faculty members serving as the catalyst for change and the acquisition of resources to support the use of technology this barrier can be overcome.

AUTHENTIC APPROACHES TO ENCOURAGE TECHNOLOGY-USING TEACHERS

Nancy Luke  
University of Georgia

Joi L. Moore  
University of Georgia

Salley B. Sawyer  
University of Georgia

Technology, effectively used, has the potential to restructure schools, and to empower individuals to solve problems creatively and to interact effectively with complex information (Jonassen & Reeves, 1996; Means, 1994). Although schools must enable students to “become information literate and skilled in using computer-based tools” (Rakes, 1996, p.52), Collis (1996) contends that the teacher shapes “the eventual success or lack of success of any computers-in-education initiative” (p. 22). Teachers are key to putting technology in the hands of students by integrating it into the learning environment. By using technology as a natural and necessary part of classroom practice, teachers can give students the knowledge and experiences they need. For students to be better prepared to learn with technology, teachers need to be better prepared to teach with technology.

Theoretical Framework

There is great interest in the concept of situated cognition as a way to encourage authentic learning. This concept is based, in part, upon a Vygotskyan construct recognizing that knowledge cannot be separated from the situations in which it is used. In an authentic situation, a learner is located at a particular time and place. What is learned in that place is knowledge in context. It is embedded within the activities of that context as well as the meaning derived from that context.

In the forefront of research on the value of situated learning, Brown, Collins & Duguid (1989) argue that learners are hindered in their ability to transfer knowledge when it is not learned in context or in the authentic setting. “Learning and cognition, it is now argued, are fundamentally situated” (p.32).

Helping future educators to perceive technology as meaningful, authentic and necessary for their work as teachers is a goal of many teacher educators. The classroom teacher’s work includes both instruction and management. Those of us teaching and using technology in pre-service courses have an interest in our students’ ability to transfer these acquired skills into their future classrooms. Not only are we concerned with their technology skills, we also want to generate attitudes and beliefs which facilitate this transfer. In this regard, both cognitive and affective domains are significant and must be considered. To a large extent, a teacher’s ability to integrate technology into the classroom depends on the modeling and classroom experience that person had as a pre-service teacher. While there might be some technology modeling in education methods classes, for the most part, the old model which excludes technology still is in place (Ingram, 1992).

Many teacher preparation programs do not place pre-service teachers in the field until their last year of undergraduate study. Therefore, these students have a limited opportunity to explore apprenticeship learning and less opportunity for connecting skills developed in their pre-service classroom to an authentic experience. There are pilot programs that have given pre-service teachers the opportunity to observe technology using teachers in the field and to use technology in their student teaching experiences (Bali & Diggs, 1996; Wetzel & McLean, 1997). These projects have reported a positive effect on teacher candidates in terms of their knowledge and attitudes toward technology. As teacher educators we are concerned with enabling teachers to use technology and to accept and understand technology’s role in the classroom.

Purpose of the Paper

For technology to be integrated into K-12 classroom practice, teacher learning of the technology must occur at the pre-service and in-service levels. It is our contention that it is necessary to address ways to bridge these two stages in the professional life of teachers. This paper suggests three approaches to encourage technology learning and subsequent use by pre-service and in-service teachers: (a) finding the self in the technology (pre-service teacher education); (b) “if you build it they will come” - involving teachers in the development of technology tools to encourage use (in-service teacher training); and (c) helping future practitioners toward a vision of themselves as
technology-using teachers (the bridge between pre-service and in-service).

**Pre-service Teacher Education and Technology**

We believe that in order for pre-service teachers to consider technology as necessary for their future work in their classrooms, they need to perceive technology as essential to their lives at the present time. The technology modeled in their course work must address ways to assist them with their current challenges as students. Teacher educators must be aware of their students' needs in courses and encourage them to use newly acquired technology skills to meet class assignments. This provides an opportunity for the students to use technology in the authentic context of their present moment.

We have observed the importance of encouraging pre-service teachers to use technology as a means of self-expression. When a student is able to use a tool as a means of self-expression, the value of the tool is increased. The objective in these activities is to develop fluency and skill in the use of the technology as a means of creative self-expression. When this occurs, the student begins to regard the technology as a tool that is as essential as the paintbrush is to the artist.

In the context of the introductory technology course, pre-service teachers explore the use of various technology tools and are assigned to use them in ways, which convey information about themselves. Examples of these activities include using a graphics program to create a “postcard” telling what they dream and creating a HyperStudio stack that reflects their growth over the process of the course (i.e. a reflective portfolio). These activities designed to encourage students to use the technology to express the self. Other activities focused on making the technology relevant to their needs as learners in other classes. The goal was to enable the students to use technology to remedy challenges in their current professional situations. One such activity involved a student who learned how to check out and use a portable computer cart from the media center when she needed to make a presentation in her psychology course. Another student created a PowerPoint presentation on her student organization’s marathon dance competition. The presentation helped her explain the dance project to university officials. These students experienced technology as having immediate meaning in their current work. They did not have to save for later the technology skill for “one day, when they will be teachers”.

**In-service Teacher’s Professional Development**

Positive attitudes can influence the acceptance of any type of technology. Making people aware of how the technology can help them perform their job can change attitudes. Installing any type of computer tool will be of little value in an instructional environment without dedicated, motivated, and energetic teachers. Yoon, Guimaraes, and O’Neal (1995) note that the ease of use and learning are directly related to the users’ positive attitudes toward computer technology. The teacher’s perception of computer technologies may depend on whether the computer is viewed as an opponent, supporter, or powerful assistant. Hopefully, when the teachers are involved in the development of computer technology, the computer will be viewed as a powerful assistant.

A study conducted by Zammit (1992) revealed that computer software was not used if it could not support the classroom teachers’ tasks. Software that was judged as being instructionally weak or inappropriate was found to be a major factor for non-usage. In addition, several commercial applications designed for teachers can be too generic for teachers’ tasks. Thus, this study supports the assertion that teachers need to be involved in the design and development of software to meet their specific needs.

Involving teachers in the development phase of a computer tool designed to meet their specific needs can change their perceptions and attitudes towards technology. Their direct involvement in the product’s development enables teachers to envision the capabilities of the technology. The computer tool becomes more meaningful as the teachers experience a sense of ownership. The teachers’ input into the development process also assures a more accurate congruency with their needs. These points illustrate the significance of having teachers’ feedback recognized as a critical component of the formative evaluation process. Their vision of the completed product and its’ anticipated usage acts as motivation for them to accept the technology. This process also encourages confidence building.

Alavi and Napier (1984) describe three different interactions that occur in the rapid or adaptive design process. First, the user-system interaction pertains to how the user’s characteristics affect the system utilization as well as how the user’s understanding of the decision task and its potential solutions can increase by using the system. Second, the user-builder interaction involves communication and collaboration during the system development process. Third, the builder-system interaction occurs when the builder adds new capabilities and functions to the system as a result of evaluations and new knowledge learned in the decision environment.

These three interactions help to deepen understanding of how and why to use the computer technology. By working with the technology’s primary designer and offering suggestions, teachers are being “in-serviced” during the development process. Also, by making design decisions concerning the technology tool, teachers are building a sense of ownership. Training and expert assistance is considered important for encouraging computer usage.
of how technology can support teaching and learning" (Balli
They also saw concrete examples of ways in which technol-
cate and cooperate with the developers of the system
(Vockell, Jancich, & Sweeney, 1994). The knowledge
acquisition process is an important task for the design and
development of technology in education just as it is in the
business environment. School personnel are considered the
experts in this situation and they must be able to communi-
cate and cooperate with the developers of the system
(Telem, 1990).

An example of teachers sharing in the development
process is a university-schools partnership project that
invited classroom teachers to participate in the design of a
computer tool. This computer application is being devel-
oped with a modular and rapid prototyping approach for
middle school teachers who have been involved since the
beginning of the project. An initial prototype of the tool was
presented to the participating teachers. Their formative
evaluation provided important feedback that was used in
refining the prototype. The new prototype was presented
again to the teachers and their suggestions were docu-
mented for future enhancements. The cycle will continue
until all stakeholders are satisfied with the computer tool.

As teachers become confident in using the technology
that they helped to create, the skills acquired during the
development process can be transferred to similar computer
applications. When teachers develop more skill with
computer technology, they may see patterns and similarities
between computer applications. This may help them in
selecting and applying appropriate technology to their daily
work processes, such as guiding student learning. This
ability to see similar patterns allows for possible transference
of what they learn. Heightened motivation is also a factor.
(Bassok & Holyoak, 1993). Authentic usage seems to be
key. When the technology is used in the context of a real life
setting, teachers better understand how to integrate it into
their work.

**Bridging the Gap**

Researchers have provided compelling argument as to
the importance of placing pre-service teachers in the
authentic setting of the K-12 classroom. One pilot project
studied pre-service teachers' placement in an elementary
classroom as part of a field experience (Balli and Diggs 1996).
The students incorporated technology into a practice lesson
that they taught in their observed class. They reported that
selecting and applying appropriate technology to their daily
work processes, such as guiding student learning. This
ability to see similar patterns allows for possible transference
of what they learn. Heightened motivation is also a factor.
(Bassok & Holyoak, 1993). Authentic usage seems to be
key. When the technology is used in the context of a real life
setting, teachers better understand how to integrate it into
their work.

The question of transfer from pre-service to in-service was
an underlying concern of the researchers. It was their
contention that "if pre-service teachers used their newly
acquired technology skills in an authentic classroom
situation, the experience could enhance their understanding
of how technology can support teaching and learning" (Balli
and Diggs, 1996, p.57). The results of the students' technology-enriched field experience showed that they had
a deeper understanding of how and why to use technology
within the structure of the K-12 learning environment.

As the previous description indicated, the authentic
context contributed to prospective teachers’ transfer of
theory into practice. By maximizing the opportunities of a
field placement, pre-service teachers can practice and
observe their mentor teachers using the technology. As
Wetzel and McLean (1997) point out, it is important to place
pre-service teachers in classrooms where technology use is
modeled “appropriately” (p.53). There are some non-
exemplars, classrooms where technology is used in non-
innovative ways (Wetzel & McLean, 1997), minimally, or not
at all (Bosch & Cardinale, 1993). Work in the field is a salient
way to help pre-service teachers experience deep learning of
how to effectively and innovatively use technology in their
future classrooms. In some instances a field placement is
not available to the students when enrolled in the introd-
tory technology course. Although not as optimal as an
actual field setting, there are activities the undergraduate
instructor can employ that challenge the future practitioner
to “think like a teacher”.

It is important to help pre-service teachers develop a
vision of themselves as technology-using teachers. By
helping them “practice” developing effective ways to
implement technology in their future classrooms, pre-service
teachers will begin to build a framework for how to use
technology effectively with their students and as a tool in
their work processes. When they situate themselves in the
role of a technology-using teacher, they can start to develop
an internal sense of how necessary the technology will be in
creating a successful, exciting and active learning environ-
ment.

Pre-service teachers begin to construct the “bridge”
when they describe themselves as technology-using
teachers through narratives, role playing and self-as-teacher
discussions. In an introductory technology course, pre-
service teachers were shown how to use particular technol-
ogy tools such as database and graphics software, video
digital cameras, and HyperStudio. After the instructor
demonstrated these and other tools a discussion of how
these tools might be used in the classroom would ensue.
While the structure of these discussions would vary (think-
pair-share, whole or small group), what was consistent is
that the emphasis was on integrating the tool into K-12
classroom practice. In fact, this concept formed the
theoretical framework for the majority of the activities in
which the students participated. As they placed themselves
in the role of teacher, they attempted to specify ways to use
the technology to help meet their students needs. Other
activities included having students plan technology -
enriched lessons and units as if they were members of a
grade level team. Decisions about curriculum, budget, and
even field trips were discussed within these grade level
groups. The group members also appointed a grade level
coordinator. This type of role-playing gives the students the opportunity not only to behave as a teacher but also demonstrates the importance of collaborating and negotiating among colleagues.

Another activity, which helped to put the student in the role of teacher, was scenario-based discussions. The students were given a classroom setting including a profile of the students and learning setting. They then had to apply solutions using technology as a means (not an end) to solving the problem. They could ask further questions of the instructor who served as a mediator with the "insider knowledge" of the learning situation. Questions ranged from details about the school setting to the technology available for classroom use. These scenarios were discussed in small groups and then shared with the class as a whole. These structured activities can give students who do not have the authentic setting available, a way to practice thinking and behaving like a teacher. The link between pre-service and in-service teaching is further built as students integrate into their personal vision of self-as-teacher, meaningful ways to integrate technology into the learning community of their classroom.

Conclusions and Recommendations

Just as every classroom in every school is unique, so are pre-service technology education programs. The ideas described above are meant to be suggestive only, each teacher educator must decide what activities and approaches are appropriate in their particular setting. What seems important is to continue the dialogue concerning innovative and effective approaches to technology education for pre-service teachers. As future teachers feel prepared to teach in a technology infused classroom they will help their students interact successfully in a technology infused society both inside and outside the walls of the K-12 classroom.

AN INTERDISCIPLINARY, PROBLEM-CENTERED METHODS MODEL FOR PRESERVICE ELEMENTARY TEACHER EDUCATION

Elizabeth Willis
Northern Arizona University

After wrestling for some time with how best to tell the story of EDUC 453/454-553/554, Methods of Integrating Technology in the Elementary Social Studies/Language Arts Classroom, I have chosen to begin with the students' personal narratives and reflections about their experiences. Following a bit of historical and theoretical background I will share my own challenges and experiences in thinking about, planning, and implementing the course, including the strategies that made the “doing” so meaningful for all of us.

Student Narratives, Reflections, and Evaluations

Andrea: Dear Becky,
For the first time ever, I actually feel that I truly learned an immense amount of information that I can take with me and honestly apply in my own classroom. I am no longer terrified of computers and I have no doubt that they will be a large part of my curriculum. I just loved your class and teaching style...how you respected each of us as people, not just students...you inspired me to go that extra mile and to stretch my thinking, while building my confidence. I am not afraid of going into the classroom and teaching, as well as learning. I have so much faith in myself and my abilities now, much more than I did at the beginning of the semester (Personal communication, 1997).

Christie: I wanted you to know I learned a lot from you this semester. I learned not only about strategies, but how to be a wonderful teacher (Personal communication, 1997).

Melissa: Dr. Willis,
This is to thank you for everything!!! I feel like I have grown so much through this course. Being the teacher that you are makes it possible for us, in turn, to become teachers like you have modeled to us. Thank You. P. S. Thank You for the “hand on the shoulder” touch that made me feel cared for as a student and as a person (Personal communication, 1997).

From anonymous class evaluations:
This class was one of the most interesting...I have had to take. Not only did I learn different techniques and strategies of integrating technology into my classroom, but I learned a tremendous amount of information myself. It’s just amazing to me how much knowledge I gained on the rain forest! I think the most beneficial (sic) thing I got from this course, was getting rid of the “fear” and frustration I have always experienced when working with computers. I still get frustrated sometimes because things take so long, but at least I feel confident enough with my computer skills that I know how to do something when I need to without asking someone to help. I realize that this was one of the goals for this course, and I just want you to know that you succeeded! Not only did I enjoy the content of the class, but I enjoyed the style you used to teach it. You are one of the only professors I have had that made me feel like I am not just a student in your class. It seemed as if you actually understood that we were almost teachers ourselves, and treated us all with respect in that way. Thank you for a great semester Becky, I truly learned a lot from you. You are a great role model for developing teachers. I hope one day I will have the ability to make my students feel special and respected as you have done (Personal communication, 1996).

I feel that my biggest area of growth was in computer applications. I have learned of and how to use so many programs that I will be able to use in the class. From participating in so many different programs, I have learned how to manipulate the computer. I also learned a lot on current issues, the need to discuss these issues in the classroom, thematic units (ie Rain forest, and the many perspectives in history). I would have liked to have focused on the areas of social studies more. I enjoyed the way Becky introduced our activities. She gave us brief instructions and left us to figure things out, but was always available when we needed help. Becky is a very supportive person. She treated everyone with respect and always made time for the
students. She is very approachable, and was very flexible with assignments. She provided a very non-threatening learning environment. I feel that Becky possesses a very important quality which is self-evaluation. She not only evaluates herself and units but asks for areas of strengths and improvements. The only area of improvement I see is that she is sometimes too lenient. I feel that Becky held true to a teaching strategy she believes in which is mushroom management. She challenged us and let the students do inductive learning but was available if we became frustrated. Becky has been a wonderful model for me. I hope that I am as accepting, patient, and as dedicated as she is. She also showed me the importance of: having student's understand themselves as well as other cultures; having students evaluate the lessons/units; having closure and discussing what we learned; modeling and flexibility; giving students "hands on" time. I do not think there is one thing that I have not or will not use in my classroom (written class evaluation, 1996).

My Thoughts on the Student Comments

The sampling above, of students' thoughts and candid evaluations of EDUC 453/454, demonstrate that something very powerful happened in this class, something that had happened neither for, nor to, these preservice teachers in their previous educational experience. Several strands I noted running through the messages were (1) respect for the individual; (2) personal responsibility for learning; (3) trust in students' intrinsic motivation to work independently and with others.

Historical Background

Technology in the Curriculum

The United States, as a part of a global society, is fast becoming defined by electronic technology, in the home, in the workplace, at leisure. Education of young people in such a fluid, ever-changing society has become a complex and challenging task for a system based on the outmoded concept that information remains static and can be transmitted and learned in fragmented disciplinary bits. Enmeshed in this system is the classroom teacher who realizes that the job of teaching students to learn in the electronic world is not being accomplished, but who has little background education on which to rely for a new vision of an interdisciplinary curriculum. The view of the mind as a tabula rasa, a blank slate to be filled, was never appropriate, but is even less so today. With the amount of knowledge estimated to be doubling every decade and computer capability every three years, it seems more important that students become able to process, interpret, and evaluate information than to amass specific knowledge (Post, Ellis, Humphreys, & Buggey, 1997).

The Fragmented Curriculum

Heidi Hayes Jacobs (1989) notes that from early on experience in educational environments students begin to define subjects as separate bodies of knowledge with little relationship or links between them. This delineation between disciplines becomes more entrenched as students move into middle and secondary school where subjects are taught in 35-50 minute blocks by specialists, with little modeling of the relevance of one class or subject to another. In "real life," though, these young adults begin to realize that "we encounter problems and situations, gather data from all of our resources, and generate solutions" (Jacobs, 1989 p. 1). Unfortunately, school days fragmented into discrete disciplinary time slots do not reflect reality.

The Class: Methods of Integrating Technology in the Elementary Social Studies/Language Arts Classroom

The purpose of this course was to assist preservice teacher candidates in developing an understanding and appreciation of the many perspectives of the social studies, language acquisition in all its forms (reading, writing, listening), and a vision of the roles and impacts of technology on the social studies/language arts curriculum. Students would ideally begin to: develop expertise in planning particularly computer-based technologies... Training focuses on the mechanics, not on integrating technology in the curriculum...

Teachers lack an understanding of curricular uses of technology and lack models of technology for their professional use (p. 3).

The Transmission Model

According to Cameron White (1996), "Social studies teacher education desperately needs a shot of innovation" (p. 69). The knowledge transmission model of teaching and learning is what most students experience in their own education from kindergarten right on through teacher certification, so it is little wonder that the goal of students in teacher education programs becomes transmission "rather than a process of interaction and construction of knowledge (Brazee & Kristo, 1986; Shor & Freire, 1987). This model with which preservice students have lived for 16 years of education is internalized and becomes the mode of operation, guiding not just the use and integration of technology, but the whole of a teacher's approach to curriculum in their own classroom. The view of the mind as a tabula rasa, a blank slate to be filled, was never appropriate, but is even less so today. With the amount of knowledge estimated to be doubling every decade and computer capability every three years, it seems more important that students become able to process, interpret, and evaluate information than to amass specific knowledge (Post, Ellis, Humphreys, & Buggey, 1997).

The Transmission Model

According to Cameron White (1996), "Social studies teacher education desperately needs a shot of innovation" (p. 69). The knowledge transmission model of teaching and learning is what most students experience in their own education from kindergarten right on through teacher certification, so it is little wonder that the goal of students in teacher education programs becomes transmission "rather than a process of interaction and construction of knowledge (Brazee & Kristo, 1986; Shor & Freire, 1987). This model with which preservice students have lived for 16 years of education is internalized and becomes the mode of operation, guiding not just the use and integration of technology, but the whole of a teacher's approach to curriculum in their own classroom. The view of the mind as a tabula rasa, a blank slate to be filled, was never appropriate, but is even less so today. With the amount of knowledge estimated to be doubling every decade and computer capability every three years, it seems more important that students become able to process, interpret, and evaluate information than to amass specific knowledge (Post, Ellis, Humphreys, & Buggey, 1997).

The Transmission Model

According to Cameron White (1996), "Social studies teacher education desperately needs a shot of innovation" (p. 69). The knowledge transmission model of teaching and learning is what most students experience in their own education from kindergarten right on through teacher certification, so it is little wonder that the goal of students in teacher education programs becomes transmission "rather than a process of interaction and construction of knowledge (Brazee & Kristo, 1986; Shor & Freire, 1987). This model with which preservice students have lived for 16 years of education is internalized and becomes the mode of operation, guiding not just the use and integration of technology, but the whole of a teacher's approach to curriculum in their own classroom. The view of the mind as a tabula rasa, a blank slate to be filled, was never appropriate, but is even less so today. With the amount of knowledge estimated to be doubling every decade and computer capability every three years, it seems more important that students become able to process, interpret, and evaluate information than to amass specific knowledge (Post, Ellis, Humphreys, & Buggey, 1997).
and implementing informed, interdisciplinary practices of teaching social studies/language arts through literature (whole language, the writing process, and student response); create a computer using curriculum based on models, theories, and research; learn habits of inquiry and reflection as lifelong learners and teachers; and build bridges of understanding among individuals of diverse cultural backgrounds, learning abilities and special needs. These were the stated goals and objectives. However, as I talked with students throughout the semester and received their feedback through reflections, evaluations, videotaping, interviews, and observation, the real power of the actual implementation of the course was stunning.

Strategies utilized and modeled were constructivist in approach: hands-on, problem-centered and interdisciplinary, with technology seamlessly integrated into the curriculum. Students participated in a selection of projects relevant to their own future elementary classrooms (i.e., Rain Forest thematic unit, the Lecture Series), learning to use appropriate computer software, from word processing, graphics, databases, spreadsheets, and simulations, to telecommunications and hypermedia. According to Post, T. R., et al, (1997) "Interdisciplinary studies can be squarely placed with the philosophical position that contends that knowledge cannot be transferred directly from one individual to another (p. 19)," but is both personal and social in nature. That is, meaning is individually created by engagement in activity, and, activity with peers "results in an internalization of ideas and the construction of a personalized from of knowledge" (p.19).

Thinking About and Planning EDUC 453-454/553-554

In the Spring of 1996 the Department of Curriculum and Instruction realized that another section of our methods block (elementary social studies, language arts, reading) would have to be in place for the Fall semester to accommodate increased enrollment. To insure a robust, somewhat standardized methods curriculum for this new section of 30 undergraduate and graduate students, the block instructors decided to try something new. We did not hire part time faculty to teach the additional social studies and language arts classes; instead, we integrated the two courses into one three-and-one-half hour class that met twice a week. Students registered for both classes, and I agreed to teach the integrated class, since I had been teaching the elementary social studies methods, "Integrating Technology in the Elementary Social Studies Classroom," and held secondary English certification in New Mexico. Besides, I was excited to put together what seemed to me to be the perfect elementary, interdisciplinary methods model: language arts, social studies, and technology.

What transpired for me next was three months of hard work and thinking: gathering, reading, and reflecting on information about reading and language arts, brainstorming with language arts and reading methods professors, immersing myself in the latest research on curriculum integration and learning in teacher education.

When the course syllabus for Methods of Integrating Technology in the Elementary Social Studies/Language Arts Classroom appeared on my computer a month before the class was to begin, it was, from what students later told me, mind boggling and just scary. For me, it was the rewarding synthesis of months of challenging thinking about the social studies, language arts, and technology. It was the blending into one entity of three content disciplines. This is what the first week looked like in the syllabus:

Curriculum Integration Concepts
- Modeling a thematic approach to curriculum integration
- Modeling the use of whole, small, and individual grouping strategies
- Modeling Action Research: A Pretest Survey
- Modeling Democracy as a classroom experience: reflecting on a philosophy of education
- Using the WWW in the classroom

Computer Concepts and Skills
- loading a program, loading a file, saving a file, formatting a disk, printing
- Using software: telecommunications, word processors, and graphics
- Mac Basics
- WWW

Class Activities
- Introductory comments
- Video: Technology Unplugged
- Email accounts: Dante, Verdi, Paris, Hector, Netscape, ED-554
- Biopoetry: word processing
- Completing an Autobiography using a word processing application
- Creating a Print Shop Personal Sign for Notebook/Portfolio: graphics
- Announcing a University Lecture Series: cooperative group meetings as process
- Web Quest using Netscape

Telecommunications Activities
- Sign onto email
- Send a message to beckyw: All About Me
- Netscape: Web search for language arts and social studies standards

Readings
- Reading, Writing, and Email
- Guide to the Internet, 1-44
- Elementary Social Studies, xvii-27

62 Technology and Teacher Education Annual — 1998
**Assignments**

- Locate biography or autobiography about lecture series personalities for class work
- Begin vocabulary database: symbol systems (brain-storm, Venn diagram, chart, web)

To give the reader an idea of my approach in the classroom, this is what I did the first class meeting of the week: I sat "in the round" with the group to discuss the syllabus. Actually, they were so intimidated by it that we spent very little time then talking about it. Students then completed the Biopoetry form, an introductory activity in which one student interviews another to complete a poem that begins with the student’s first name and ends with their last name; they then introduce each other. This is a wonderful, personal activity that I believe sets the respectful, friendly, supportive tone for the whole semester.

The next activity that day was the completion of a technology survey, modeling that teachers at all levels are, and should be, action researchers. This activity gave me the opportunity to discuss kinds of research in general and appropriate survey participation in particular, and, of course, collect my own data.

Following the survey, email accounts were set up for all students and a brief demonstration of our telecommunication software was given. They had an email assignment immediately...to email me several paragraphs about themselves, which was an extension of the Biopoetry activity. And, to introduce them to the Internet and the World Wide Web, another immediate assignment was the completion of a short-term Web Quest.

Additionally, brief demonstration was given for the computer graphics application *Print Shop Deluxe*. Students then worked to complete a personal sign to be included in their personal portfolio, a further extension of the personal emphasis of the class.

Most of these students had very little computer experience and many wanted, at the outset, to have "cheat sheets" for guidance for the technology activities. What they learned through mistakes and intuition, trial and error, however, gave them one of the most important learning outcomes—self-confidence. Later, no one even wanted me to show, even briefly, how an application worked—they wanted to do it themselves.

What a first day! And so the semester continued...

Based on the national standards for the three content areas, what I planned to have happen was that these preservice educators would experience interdisciplinary activities, they would "be" lecture series planners and understand the power of language through reading, writing, and speaking; they would "do" social studies through research and reporting on the Rain Forest. Further, students would learn a variety of computer software applications to assist them in "being" and "doing." Plus, they would work in cooperative groups, as well as be responsible for individual components of their projects.

When I look at what I have just written, it seems like a huge undertaking, one fraught with danger and doubt as to outcomes. At the time, though, I was confident that my plan was based soundly in learning theory and my own experience with other classes. More importantly, I knew "down to my toes" that students could and would respond positively to the challenge I was offering.

Were these students confused by what was being asked of them at the outset? Yes.

Did they mutter that the work required for the class appeared insurmountable? Yes. Did they see the interdisciplinary "fit" early on? No.

Were they anxious about using computer technology? Yes.

Did they resent my group making? Yes.

Were they concerned that everything was not given a grade? Yes.

But the evaluations, comments, interviews, and videotapes are a testament to what these students in EDUC 453/454-553/554 accomplished, to their engagement in the learning process. After the first week, when they truly understood that their choices, their judgment, their learning was the class priority, the fun really began. Each one of us pushed our individual envelope, teaching each other and ourselves more than I could possibly have planned for us. These preservice teachers demonstrated to me again the fascinating diversity of learners and the power of the learning environment; they learned from me to trust themselves as learners and teachers.

**Importance of the Integrated, Interdisciplinary Model**

In order for preservice teachers to become technology-using, constructivist in approach, and designers of effective interdisciplinary curriculums for their own classrooms, they must experience that environment first-hand. They must participate in hands-on, problem solving, and critical thinking processes as students themselves. Models of integration and knowledge construction must replace the transmission model of education still so prevalent in teacher education if we expect teachers to develop those skills for their own K-12 curriculum. And, for that to occur, teacher educators must be the models for those strategies. Methods of Integrating Technology in the Elementary Social Studies/Language Arts Classroom was just such a model. It became clear through the engagement and voices of the preservice teachers that they became active, constructive learners, who were confident in their ability to integrate technology into an interdisciplinary curriculum when they were presented with an appropriate model in a learning environment that made them responsible for their own learning.

The global information technology revolution and new instructional strategies have the potential to significantly improve the learning environments of K-12 students throughout the country. Despite these capabilities, many of today's preservice and inservice K-12 teachers are not adequately prepared to utilize computing, communications, and other technologies to support teacher-facilitated technology-based learning experiences for K-12 students. Teachers and Technology: Making the Connection, (U.S. Congress, 1995) confirmed this by making us aware that “technology is not central to the teacher preparation experience in most colleges of education. Consequently, most new teachers graduate from teacher preparation institutions with limited knowledge of the ways technology can be used in their professional practice (p. 165).” According to the report, “Helping teachers use technology effectively may be the most important step to assuring that current and future investments in technology are realized” (p. 2). Few preservice programs are sending forth teachers prepared to use technology well as an instructional tool in their new classrooms. We know that helping teachers must continue beyond their preservice programs as well. One of the important factors in the school setting is administrative support. Lack of administrative support is most critical because it is linked to other factors that help teachers such as staff development, resources, and ongoing planning (Ritchie, 1996).

The Illinois State Board of Education (ISBE) adopted a K-12 Information Technology Plan (1996) developed by the ISBE Infrastructure Planning Team and the ISBE Technology Coalition. The Plan presents strategies for closing the gaps in technology in Illinois schools by the year 2000. Recommendation #7 in this document suggests requiring preservice teachers to demonstrate proficiency in the use of hardware, software, and related technologies to receive certification.

Calling for more technology focus in higher education, Lawrence Werner of the Illinois State Board of Education highlighted the following:

The Office of Technology Assessment (OTA, 1995) concludes that reform of teacher education should accompany any significant reform in K-12 education. In addition, teacher education faculty and cooperating K-12 teachers must model effective instructional technology use. The OTA reports that Colleges of Education have much to learn from each other and technology can be the catalyst to make the necessary connections. Colleges, the state and K-12 schools need to work together to develop a set of shared expectations for joint reform efforts.

The PIE-21 Project
Five Illinois universities, the National Center for Supercomputing Applications (NCSA), and Illinois Area IV Learning Technology Hub are collaborating in the Preparing Educators for the 21st Century (PIE-21) program. This HECA/ISBE funded project focuses on providing preservice teachers, administrators, and teacher education faculty with the skills and knowledge necessary to effectively use technology.
information technology. The original grant was funded through the Higher Education Consortium and joined by the Illinois State Board of Education in support of the k-12 participants involved in the projects. Each project includes collaboration between a university and K-12 schools to provide preservice teachers or administrators with training and experiences to effectively use information technology in the classroom. NCSA participated by coordinating the project during its first year, offering technology workshop opportunities, and providing mechanisms for group communication and electronic collaboration.

Key objectives for PIE-21 include the following:

- develop models for teacher preparation that can be adopted at all Colleges of Education;
- prepare faculty, teachers, and students to effectively use information technology resources; and
- establish partnerships within local communities and educational organizations statewide.

Given that each institution is unique, each PIE-21 partner is developing and piloting a different model of integrating information technology into a teacher or administrator preparation program.

**Project at Eastern Illinois University**

The primary objective of the PIE21 project at Eastern Illinois University is to ensure that student teachers emerge from their college career with the skill and knowledge to be able to deal with information technology as they enter teaching careers. To accomplish this goal, learning communities have been established which involve three faculty members of EIU, four cooperating teachers, seven pre-service teachers and students in K-12 classrooms at three Professional Development Schools. Each faculty member has formed a team along with one or two cooperating teachers and 2-3 pre-service teachers. The teams interact on a level of parity with each team member being empowered equally as part of the collaborative team effort. Each team member has three roles:

1. actively engage as a learner of new technological skills,
2. serve as a mentor to assist other team members in enhancing their technological skills, and
3. serve as a mentor to their peers in disseminating new technological skills.

The teams are designing curriculum projects in three areas.

**Special Education.** The team is using technology to develop curricular modifications and adaptations to enhance the comprehension and writing skills of 5th and 6th grade students with learning disabilities. The students will be using the WWW to research a pre-selected topic and, using the computer, will write a paragraph about the topic. After reviewing and editing, each student’s paragraph will be placed on the class homepage to be shared with parents, students, and other individuals.

**Middle Level Education.** The team is developing a website where middle level students can post science-oriented questions. The audience who will answer the questions, may vary according to the classroom setting. Some questions may be posed for peers at the same grade level and some may be developed for younger students. The questions are designed to develop problem-solving skills using the three highest levels of Bloom’s Taxonomy - analysis, synthesis, and evaluation.

**Secondary English.** The team is developing a website specifically focusing on American Literature and analysis of The Crucible. As research is conducted on the WWW, sites pertinent to the project will be linked to the homepage. The various analyses conducted by the students will be posted on the website and made available to other English classes at the High School. Students from an “honors” class and students from a “regular” class will be involved in the collaborative project along with their teachers and student teachers.

The PIE21 project at Eastern Illinois University is meeting with success as the teams continue to work as a collaborative learning community. Many new technology skills have been learned and the teams are anxious for the student teachers to implement the projects and share their skills with the students during their student teaching semester.

**Project at Illinois State University**

The Illinois State University model is based on the integration of information technology into methods classes at both the Wheeling Professional Development School (PDS) and on campus. The ISTE/NCATE recommendations are used as technology guidelines for the program.

Illinois State and the Wheeling Elementary District have developed a PDS that annually includes between thirty and forty senior elementary education majors. During the fall semester, students take methods classes delivered on-site and complete a field experience in their assigned classrooms. Spring semester they student teach in the same classrooms. A joint Illinois State/Wheeling committee planned technology workshops and attendance at a technology conference for these students. The workshops provided students experience with finding information on the Internet, communicating with Eudora, ClarisWorks, and multimedia.

The second focus of the grant is the use of the Internet collaborative environment to expand the field experience of junior elementary education majors. This collaborative environment facilitates the discussion of theory and practice focusing on the areas of language arts and classroom management. The collaborative environment currently used is netWorkPlace developed by National Center for Supercomputing Applications at the University of Illinois. It provides a visual environment for threaded discussion groups, a chat area for synchronous communications, and a library for downloads. A goal of the collaboration is for the
undergraduate students to develop an understanding of the different philosophies of teaching language arts and classroom management. Another goal is to have students use Internet technology in a meaningful way to apply what they were learning in the university classroom. This collaborative environment was used in the following two ways:

1. Off campus, Illinois State student teachers at Wheeling were connected with Illinois State University juniors on the Normal Campus who will be in the Wheeling PDS school the following year. They use this collaborative environment to discuss the application of theory that they have learned and to convey information and answer questions for the future PDS participants.

2. On campus, Illinois State students posed questions and discussed theory with teachers in the field to better prepare them for field experience and student teaching. Students in a Language Arts methods class selected topics of interest to research and developed questions in their area of interest. These questions were the beginning of a dialog between teachers in a graduate Language Arts and Technology class and the undergraduate class.

**Project at National-Louis University**

National-Louis University has been using the ISTE Foundation Standards as a framework to help us move toward greater integration of technology into our preservice programs. That is an ongoing effort at our institution. It is not, however, the ISTE Foundation standards or the Elementary Education program that were the focus of NLU’s PIE-21 project. Our focus was the integration of technology experiences into the Educational Leadership program and identifying the knowledge and skills needed by future principals and superintendents.

The major goal was to impact the Educational Leadership curriculum in terms of technology experience for students and modeling by faculty and to build a community of principals who can learn and work together to impact the use of technology in their schools. Toward this end, our team was made up of 3 faculty members of Educational Leadership Department, 2 principals from member schools of our Professional Development School Network (PDSN), 1 student from the Educational Leadership Doctoral Program, and 1 student from Educational Leadership Masters Program. Finally the team included a facilitator and a liaison to the educational leadership faculty who was a curriculum expert.

During the course of the year, members of the group participated in a variety of experiences geared toward making them more aware of ways in which classroom teachers are currently using technology in classrooms; thus making the administrator more aware of the support and resource needs of the classroom teacher. There were also hands-on opportunities to try out software and to explore the WWW.

Other sessions involved visiting schools and having demonstrated the ways in which technology linked the principal (a member of our team) to his faculty and other administrators and inviting a panel of building and district level technology coordinators to interact with this group of faculty and administrators, present and future. This open conversation on what the panel “wished their administrators knew” had a strong impact on future group meetings. Following that panel they met to formally begin to identify the skills and knowledge about technology use that they believed administrators should have. The draft list of knowledge and skills included the following 11 items:

1. use presentation software to share ideas with an audience;
2. use concept-mapping software for brainstorming process;
3. use computer-based technology to collect, analyze and report data;
4. access and use telecommunication tools and resources for information sharing and information access. this includes the use electronic mail and web browser applications for communication and research;
5. use spreadsheets for analyzing, organizing and graphically displaying numeric data;
6. design and manipulate databases for managing school-related bodies of information;
7. use school management tools to design solutions for a specific purpose;
8. describe strategies for facilitating consideration of ethical, legal and human issues involving school purchasing and policy decisions;
9. impact of technological and societal changes on schools;
10. demonstrate knowledge of ways to assist teachers to learn to apply computers and related technologies to enhance the learning environment; and
11. describe current instructional principles, research, and appropriate assessment practices as related to the use of computers and technology resources.

Members of the PIE-21 team began to examine course content to see where these could best be implemented. During the 1997-1998 year the full Educational Leadership team will examine the implementation process.

For Educational Leadership faculty and the current principals, participation in this group was the impetus for their attendance at their first educational technology conference. The participants attended two local conferences and joined in some the pre and post sessions as well. Three of the principals attended the National Educational Computing Conference in Seattle as well. For all participants it was an awakening as they looked for more sessions applying to administrator education and expressed interest in presenting at such conferences.
During the coming year plans include the implementation of the special interest group for area principals.

**Project at Southern Illinois University-Edwardsville**

SIUE’s now two-year involvement with the PIE-21 grant has been a growth opportunity for all six direct participants. SIUE already had a significant program for technology integration and P12-university collaboration before this grant in three areas: an experimental middle school professional development school with an on-site preservice teacher and administrator cohort, a field-based, collaborative on-campus preservice teacher education program, and a rich science education curriculum. However, the grant brought the on-campus participants into close collaboration with technology innovators statewide and, consequent to this, with each other.

Our elementary education on-campus program has two field-based semesters of methods courses followed by a semester of student teaching. Sections in Field 1 and Field 2 are block scheduled so that the cohort stays together in all of their methods sections. Eight technology integration times are scheduled over a two-semester period, and while the technology coordinator is responsible for these, a collaborative team-taught approach is used. The curriculum is web-published. ISTE Computer Literacy Standards and the new K12 State Learning Standards were used to critically redesign our curriculum, especially emphasizing hypermedia, applications and internet tools in a context stressing collaborative learning, problem solving and portfolio building. This year we have focused on developing the concept of portfolio-based evaluation. Students evaluate their own progress in technology competency and integration at crucial points during the two-semester methods sequence. We are also developing a more focused liaison between the technology integration sessions in the first two field-based semesters and the university supervisors of the student teaching experience. We are hoping to institute UIUC’s Technology Competencies Database in the coming semester.

The Professional Development School at North Middle School is a site-based two-year preservice program for preparing preservice teachers and administrators funded by the Danforth Foundation. The development of this curriculum has been a model of faculty-staff collaboration. For our PIE project, the most significant technology occurred because the ISTE Literacy standards were used to develop the North curriculum and students must choose to achieve proficiency for a minimum of two technology applications each quarter. The cohort has received both campus-based and on-site training in technology applications. Even more significantly, the staff has had a series of inservice workshops on technology use in the classroom followed up by focused project development periods and individualized coaching. We are seeing a synergy for technology use develop between the cohort and the North staff. Two listservs that are in active use have facilitated sharing and collaboration.

SIUE also included some non-education courses in the PIE-21 endeavor. In particular CI 341 (science methods) emphasized modeling the use of technology, required filling out the survey on the student’s understanding and use of technology, required the research paper, charts, and graphs to be computer generated, introduced new technologies into the curriculum, such as using C.B.L.’s for at least one topic, with a pre and post questionnaire about using them, and developed a survey form listing the types of educational technology used during each lesson to be filled out by the instructor. For student teachers the goals were to encourage e-mail as the means of regular communication, to survey both the cooperating teacher and the student teacher on their background and access to technology, and to include as part of the Student Portfolio the Technology Standards Grid assessing the student’s knowledge and exposure.

**Project at College of Education, University of Illinois, Urbana-Champaign**

At the College of Education at the University of Illinois, Urbana-Champaign, we have investigated two uses of technologies for improving the preparation of pre-college teachers. We have implemented and evaluated a new framework for using the Internet to bridge the pre-college and the university environments, which we call “electronic editorial assistance.” Secondly we have implemented and tested an innovative way of using the Web to provide support for the accomplishment and evaluation of accomplishment of a set of technology competencies for our undergraduate teacher education students.

**Electronic Editorial Assistance**

We studied ways in which the World-wide Web can be used to improve preservice teacher education. One of the major strengths of the World Wide Web is that it allows a broader set of people to publish their expertise in a way that is widely accessible. In the past, we have found that publishing exemplary lesson plans developed, implemented, and evaluated by student teachers was helpful to the students, was useful for the next cohort of students (by providing exemplary models), and was widely accessed by people from around the US and across the world. However, student teachers are relative novices - it would be much more useful to publish the expertise of exemplary practicing teachers with many years of experience. However, it is difficult for those teachers to find the time, expertise and motivation to write up their own experiences so that others can benefit.

We have implemented a new framework for student learning, integrated into their student teaching classes, called “electronic editorial assistance.” Undergraduate student teachers are given as a class assignment to work
with their cooperating K-12 teachers to identify a "best practice", something that the K-12 teacher has done successfully in his/her classroom that the teacher is willing to share with other teachers. The student teacher writes up the "best practice", shows it to the cooperating teacher for corrections and extensions, and their work together to develop a finished write-up. The write-ups are submitted as a class assignment and graded by supervising university faculty. These "best practices" are then published on the Web, with the K-12 teacher as author and the student teacher as editor. The best of these "best practices" are featured on the web, but all of the best practices are available so that others can make their own judgments.

We have implemented and evaluated this framework during the 1996-1997 academic year with students in a secondary mathematics student teaching program and with students in a general secondary education student teaching program at the University of Illinois. The response to this framework from student teachers, K-12 teachers, and university faculty has been very positive. The published "best practices" have been accessed by a very widely distributed set of people from across the US and around the world. We are planning to work cooperatively with faculty at other teacher preparation institutions to implement this Electronic Editorial Assistance framework more broadly during the 1997-1998 academic year.

Technology Competencies Matrix

New learning environments provided by technology, such as the electronic editorial assistance framework, require alternative assessment of student learning. We have explored ways in which the World-wide Web can support a more richly collaborative evaluation, through a web-mediated database for communication between students and university faculty. In this computer-supported collaborative evaluation, students can see the current state of their accomplishment, can submit evidence of accomplishing a specific competency, can receive feedback from faculty, and can modify and augment their evidence until they have demonstrated competency. For faculty, this mechanism provides an easy way to see where students are, to receive and evaluate students' evidence of accomplishment, and to engage in a productive interaction to help support the students learning through evaluation. It also is a continually updated source of information for students and faculty, providing access to instances of successful accomplishment.

We have implemented this Technology Competency Matrix (TCM) during the 1996-1997 academic year, and have tested it during the Spring semester of 1997 with twelve students in an elementary education student teaching program at the University of Illinois. Students were motivated to use the TCM because it provided them with an electronic portfolio demonstrating their technology competency that they could use as part of their job search. The portfolio was available world-wide to prospective employers through the Internet. In addition, students printed out the relevant web pages and used them as a print-based portfolio demonstrating their portfolio for job interviews with schools that did not have easy access to the Web. The main drawbacks discovered during this initial use was the slowness of the system under load, issues of interpretation of the technology competencies (the first ISTE/NCATE Technology Competencies for Teacher Education Students), and the fact that the system was introduced so late in their academic year. During the summer of 1997, we have worked to speed up the system and to incorporate the revised ISTE/NCATE Technology Competencies, and during the fall of 1997 we plan to use the TCM with an entire cohort of elementary education student teachers for the whole academic year.

Conclusions

Each of the participating institutions made strides toward their original goals. All were interested in continuing their projects into a second year of the grant. Table 1 summarizes each of the models implemented as part of the PIE-21 program, identifies key characteristics, and describes the transfer of technology.

There were direct benefits to each of the institutions through the PIE-21 monthly team meetings. These included 1) an exposure to current ideas about technology integration and how these ideas were being implemented in different ways around the state, 2) a consequent increased confidence locally in what were and were not fruitful avenues of technology integration and K12/university collaboration, and 3) a demonstration of some of the more technologically complex innovations in educational technology being developed at NCSA/UIUC. Another unanticipated benefit was that one of the grant participants had worked extensively on a model for using the ISTE Foundation Standards as a basis for integrating technology into the college curriculum.

Important developments at individual Colleges of Education have been shared with the other PIE-21 colleges and are in the process of being disseminated statewide. Four products have been developed that will be of use to any organization concerned with the education of teachers and administrators. There has been development of strong partnerships among the collaborating institutions with a real and positive synergy generated by this project. It has added impetus to the individual reform efforts to the teacher-training curriculum at each of the sites while at the same time all groups work together toward the same goals. At each monthly meeting, participants left having learned something about integrating technology into their teacher preparation program. Each of the models has demonstrated the importance of involving all stakeholders in the process of integrating technology into teacher and administrator preparation programs. That is, cooperating teachers, college
faculty, administrators (at both the college and K-12 level) and the students, all need to “buy into” the importance of technology in the classroom and school.

Today's colleges of education and systems of teacher development do not adequately prepare teachers to use technology in their teaching or in their own professional development. The Office of Technology Assessment (OTA, 1995) reported on technology in teacher education and noted significant limitations: 1) faculty do not model the technology, 2) students learn about technology, not with it, 3) field experiences are not designed to model the use of technology, and 4) technology is isolated from the main curriculum and pedagogy of teacher education. The OTA report identified some promising new approaches being used in a few teacher education programs, but new models of preparing teachers for learning and teaching in an age of technology need to be developed.

The need for improved teacher preservice development programs is heightened by the realization that half of the teachers who will be teaching in 2005 will be hired over the next decade and this large scale hiring will continue over the following decade (Gerald & Husser, 1991). In a briefing paper for the National Commission on teaching & America's Future, Linda Darling Hammond (1996) illustrates how this is a critical historical moment for transferring the capacity of the American teaching force by transforming the quality of their preparation.

This paper describes an innovative technology infrastructure for teacher preparation in a land grant university that is committed to a vision of a technology using educator, and has made a substantial investment in reform and infrastructure.

**Background**

In 1993 the University of Missouri (MU) College of Education (COE) made a commitment to a vision of a teacher as a reflective and inquiring professional. The new undergraduate teacher development center (UTDC) was designed through a collaborative process with school districts and members of the government and business communities. The COE has restructured the teacher preparation program to focus on field-based inquiry and reflective practice as two key methods for teacher development. Freshmen in the 1996-97 academic year were the first cohort to undertake this new UTDC program. This commitment to an improved COE undergraduate program is taking place in the context of a university-wide commitment to improved undergraduate education. For example, the Interactive Shared Journal System that allows preservice teachers to capture and share their experiences can also be used by inservice teachers to reduce the isolation of teaching and bring the resources of the education/learning community to bear on the problems of practice.

**Key pieces of the technology infrastructure**

A set of technology markers

Markers refer to milestones or achievements expected of the student. They refer to objectives for the technology infrastructure for the UTDC includes: 1) developing a set of technology competencies for teacher education majors, 2) having each student possess a laptop computer to insure high levels of access to technology, 3) providing faculty with advanced technology, 4) connectivity between the COE and partner school districts, 5) using electronic tools to capture, share and reflect upon experiences, and 6) creating new forms of support for using technology. The COE envisions a community of educators enabled by advancing technology for shared and continuous professional development. For example, the Interactive Shared Journal System that allows preservice teachers to capture and share their experiences can also be used by inservice teachers to reduce the isolation of teaching and bring the resources of the education/learning community to bear on the problems of practice.
competencies and knowledge of the undergraduate teacher education student. These markers are expected to evolve and grow as the faculty gain experience in supporting students to achieve them and as the technology infrastructure grows and improves. The markers are intended to provide a solid beginning for a lifetime of technology use and continued professional development. They emphasize that technology is a means to valued, shared goals of the program: communication, diversity, and inquiry. All phases and components of the UTDC have technology markers that are expected to contribute to the following principle and goals:

Effective teachers use technology to participate in a community for professional development, to engage in personally meaningful inquiry, and to support teaching, learning, and assessment with their students.

1. Use technology to communicate with others, share information, reflect, and engage in professional development.
2. Integrate technology in managing and facilitating instruction, assessment, and learning.
3. Use technology for inquiry in content areas across the curriculum.
4. Explore existing and emerging technologies to determine their potential usefulness.
5. Expand students’ experience and understanding of multiple perspectives through use of technology.
6. Examine the educational, ethical, political, and cultural implications of technology.

**Personal computers for teacher education students.**

Apple Powerbook 1400’s were provided to all 270 freshmen in the class of 2000 and to all 30 faculty implementing the first phase of the UTDC. A similar number of freshmen and faculty have received powerbooks for the class of 2001. The UTDC program has been designed with the expectation that students will have technology competencies and technology capabilities. In order to achieve the high expectations for student outcomes as represented by the markers, it became apparent that individual students each need a mobile and powerful system. To this end each member of future freshman classes will receive a personal laptop computer. The plan is to replace the student computers after 2.5 years with the most current and appropriate version available.

**Support for using technology**

The Reflector is the COE laboratory and support system for applying learning and technology innovations. The Reflector is a learning and performance support center that integrates interactive networked technology with traditional media resources. In most colleges, the Reflector would be called the media center, but the Reflector has been designed around the goal of developing a reflective professional educator. An essential role of the Reflector is to connect practicing educators with preservice teachers, in virtual and actual settings, thereby enabling today’s and tomorrow’s educators to exchange experiences, challenge assumptions and test ideas. The Reflector also includes a team of Learning and Performance Support (LAPS) specialists who provide learning and support on an as needed basis, with the belief in right-time, right-place, right-form support.

**Interactive Shared Journal System (ISJS).**

The ISJS is an Internet-based tool developed in the COE for enabling students to create journals about field experiences and share these journals with other educators in their community of professional development. ISJS integrates a set of Internet-based tools, such as web browsing, e-mail, and chat, with the shared journal tools to create an advanced system for supporting learning from field-based experience. The ISJS will be a core technology for supporting the teaching and learning experiences of the UTDC and will be integrated into most courses as well as for connecting preservice teachers with the experiences of inservice teachers. (Laffey & Musser, 1997 & 1996).

**Connections with Schools.**

The COE has formed a partnership with 19 school districts around the state of Missouri, who form a web of emerging professional development schools. The COE has invested in building a telecommunication system to connect with these schools so that preservice teachers and inservice teachers can form a community for professional development. These connections are just getting underway, but several projects represent tests and prototypes for how the community can develop. The test projects include Project MOST (an NSF/NIE award) http://tiger.coe.missouri.edu/~most/index.html and Project Whistlestop (a Department of Education Challenge Grant award to a consortium of several partner schools) http://whistlestop.org.

**Implementation of the Technology Infrastructure**

Three short case reports will be used to describe how the technology infrastructure is influencing teaching and learning in the college of education. In preparation for these case reports consider two extremes of design. On one end of the spectrum, goals and objectives are set, designers specify pathways from a current status to a desired end, evaluation measures are put into place, and a master plan is executed to systematically eliminate or minimize the prospect of error. This traditional design type works well in steady state environments, where there is a core of experience, and outcomes are predictable. On the other end of the spectrum is an approach called rapid prototyping, where mistakes are expected and lessons are rapidly learned and turned into system improvements. Rapid prototyping is used in organizations when speed to market is essential and when
key parts of the system are novel and the impact is unpredictable. Our approach to implementing a technology infrastructure required both types of design processes. When you are handing out three hundred laptops to freshmen you need to think through a process of installation, testing, and start-up that is efficient and minimizes confusion. You cannot anticipate every problem that will arise, but based on experience you can plan for a certain number of systems that will fail, a number of students who will need extra help, and a need for custom settings and configurations to minimize the level of expertise needed by students to get started. However, you cannot anticipate the degree to which faculty will appropriate technology into their curriculum or what type of support they will need as they start to envision listservs, web pages, mediated presentations, and uses of custom software. You need flexibility to adapt and adjust as opportunities or challenges arise.

Support, Support, and more Support

In less than a four year time span the college of education has moved from classroom and lab access of about 40 computers and less than 100 computers in faculty and staff offices, to approximately 1800 computers in various capacities of use in the college. To support this rapid growth in computer access and use the LAPS team was created and has grown to 6 staff members. In a given month the team logs approximately 300 e-mail and phone work orders. In addition to fixing computers, installing software, and troubleshooting network problems, the LAPS team provides training and specification for new equipment. A system administrator provides a network of listservs, e-mail addresses, webpage maintenance, an other sharing services.

An instructional materials center that historically provided access to materials required by instructors has been transformed into the Reflector. The Reflector is open 7 days a week and provides access to computers in a context of multi-media tools, printers, network and Internet services, and high levels of support from a customer-oriented staff. A typical month in the Reflector has over 20,000 users. The physical space of the Reflector has been designed not as a place of computing, but rather as a place of work and learning that is supported by computing. There are multiple types of spaces facilitating collaboration, production of artifacts, and use of multiple resources including books, computers, and people.

Internet-based Shared Journals

The teacher-education faculty designed a new curriculum emphasizing learning from field-based experience with the goal of developing reflective practitioners. Student use of journals to share their experiences and thoughts has been a commonly used tool for many years among many of the faculty. With a vision of a technology infrastructure providing high access to computing, curriculum goals emphasizing learning from field-based experience, and a shared value among faculty of learning through the use of journals; a software development team created a client-server environment for students and faculty to report, share, and reflect through an interactive, internet-based, shared journal system. The most common journal assignment in the first year has been a faculty assigned task, such as visiting a school site and observing a student or classroom and then reporting on the observation. Faculty then read the journals on-line and have the capability of writing appends (an attached journal entry) to the student entry. Some faculty have encouraged students to share journals by asking them to read and append to fellow student journals.

The use of the journal system has been one of the most challenging features of the new technology infrastructure. On the one hand many faculty and students have appropriated the tool to enhance the way they communicate and make sense of their experiences. Some faculty are developing innovative designs for curricular use, such as creating a journal environment for virtual students, wherein the teacher education students would build a virtual school and describe experiences through the eyes of virtual k-12 students. Similarly, in focus group sessions, students have discussed how the journal, since it is a tool they will use throughout the teacher education program, will help them to look back over their experiences facilitate a better understanding of new experiences. Students have also discussed reviewing entries made by other students to help understand observations they are making in classrooms. On the other hand, however, some faculty are reluctant to use the journal system. There are several reasons for this reluctance, including other preferred ways of working, limited experience with technology, technical problems of the network and journal software which have made it unreliable at times, and just being overwhelmed with all the other programmatic changes.

Mobile Laptop Program

Putting computer technology in the hands of all students and faculty is a technical, social, cultural, business and political process. Our process included testing several potential platforms for supportability and functionality, testing all of the possible system peripherals, developing the program-specific software configuration that replaces the initial Apple configuration, developing mass production systems in order to update each system, and providing training sessions for laptop use. In addition, the process included orchestrating the related business endeavors to purchase, finance and secure the systems. The selected systems include:

**Hardware:**
- Macintosh Powerbook 1400cs
- 16 Mb RAM expandable to 64Mb, 750Mb Hard Drive
- Internal 6x CD-ROM and floppy disk drive
- 800 x 600 Color Display
- 33.6 Modem/Ethernet PC Card
• 133 Mhz with level two cache high performing chip
• Built-in infrared technology
• Customizable Book Cover
• Shoulder or Backpack Carrying Case

Software:
• Claris Works (integrated word processor, drawing program, database, communications program, and spreadsheet)
• Claris Organizer (schedules and contacts tracking)
• Apple Internet Connection Kit (Netscape Navigator, Claris E-mailer Lite, Fetch, NCSA Telnet and NewsWatcher)
• MU Internet Suite (a supplement for the Apple Internet Connection Kit)
• Apple Remote Access (For connection to a desktop or network from a remote location)
• Macintosh Easy Open and DataViz Easy Open (translator for reading and writing PC-formatted floppy disks and PC-formatted files)
• Interactive Shared Journaling System (multimedia journaling application supporting communication among students and faculty in local and remote locations)
• Eudora Pro (user friendly E-mail application)

Early lessons
Many of the lessons learned in the first year can be placed into three categories: technical, access/usage, and curriculum integration.

Technical. Meeting technical challenges provides a foundation for usage and curriculum integration. To a great extent most of the technical components of laptops, software, servers, and networks are well understood, and one could model a technical plan after those used by other organizations. Two of the key drivers for the technical plan were ease of use and mobility. Since many of the students and faculty were essentially novice users of technology, and much of the value of the technology infrastructure was driven by network access, it was important to make networking simple. However, since the students and their laptops were mobile networking was complex; access needed to be supported from within the college of education, in the dorm rooms or in a k-12 school. A custom configuration of network tools and settings were installed on each laptop. Similarly, custom tables were created to make it easy for students during class or in the Reflector to connect to the campus network. This system, however, proved too fragile and students frequently were confronted with error message or unexpected outcomes of trying to make network connections. Problems included: inadequate dynamic allocation of IP addresses, user confusion about when to use the modem or the ethernet adapter, faulty cables, unreliable software, inadequate training of students for what to do when an error occurred, and difficulty in updating software on the laptops when a problem was diagnosed and corrected. Planning the technical installation and resolving problems consumed great amounts of energy and mind share during the first year, but one can look at the technical features of the system and see that technical hurdles are becoming manageable. The combination of technical solutions and a more experienced community of users is progressing toward a sound and effective technical implementation.

Access/usage.
A somewhat naive conception is that access to the technology will inevitably lead to appropriation of the technology. In many ways this simple notion is being borne out. But, a more powerful notion of access sees it framed in a set of conditions, such as to what end and enabled by what support. Access to an appropriate form of support may be nearly as critical as access to the technology. While some forms of group training are required by the need for efficiency, most of our efforts to develop competency are moving away from training models and toward support models. To the extent possible we are designating a technology support person for most groupings, encouraging buddy systems, extending hours of the reflector, creating self-paced explanations and skill building, and leveraging competencies developed by one set of students to facilitate the next set of students. These types of activities need to be planned and coordinated, but in a certain sense they are also organic. As our community becomes more densely populated with competent technology users the process of inducting a next cohort should become easier, just as learning a foreign language is easier if you are among people who speak that language naturally and frequently.

Curriculum Integration. Curriculum integration means both the use of technology as a key component of the curriculum and of changing the curriculum because of what technology enables. Clear progress is being made by many faculty on the use of technology in their curriculum. Like many other newly introduced technologies the technology infrastructure and the journal system in particular are at first being used to replicate existing patterns of work, primarily communication between the teacher and student. As faculty become more experienced with the tools, they start to see other benefits and possibilities, such as the virtual school and collaboration among students mentioned earlier. One initiative underway is to use the journal system to connect preservice science teachers with high school students involved in project based learning. The high school students use the journal system to report on their project work, and the preservice teachers use the journal to “observe” project based learning. One of our science education faculty has developed a methods curriculum that has the science education students use the journal to facilitate moving through various roles of observer, mentor, and teaching assistant for the projects underway in the high schools. The
asynchronous nature of journaling and the Internet wide
basis of the journal facilitates connecting preservice
teachers to innovative k-12 experiences wherever they may
occur across the state.

Conclusion

There is no silver bullet for bringing the benefits of
advancing technology to bear on improving teaching and
learning. However, a technology infrastructure that enables
preservice teachers to learn in a context of computing and
network services seems fundamental to developing atti-
tudes, values and competencies for making technology a
tool of teaching. The technology infrastructure cannot
simply provide lessons about using technology in curricu-
lum, it must enable teachers to learn to use technology for
continuous professional growth and development. The
technology infrastructure of the College of Education at the
University of Missouri, while no doubt still under construc-
tion, is a substantial step towards understanding how to
build and support a technology infrastructure and towards
providing beginning teachers with powerful new concep-
tions and tools for using technology as a part of their
learning and teaching.

THE TEACHER EDUCATION COMPUTER LAB: PLANNING, DEVELOPMENT AND MANAGEMENT

Patricia P. Shopland  
Eastern Nazarene College

Joan K. Kannegieser  
Eastern Nazarene College  
Martinson Middle School

The identification of the need for a teacher education computer lab at Eastern Nazarene College was rooted in (1) the authors’ intense technology-based professional development experiences as registrants in the Lesley College M.Ed. Outreach Program in Computers in Education, (2) the authors’ perceived need for a facility in which teacher education students could experience immediate technology applications of the content of their curriculum and methods courses, and (3) the passing of the 1993 Education Reform Act by the Massachusetts Legislature.

In the fall of 1992, the authors enrolled in the M.Ed. Outreach Program in Computers in Education located in Orleans, MA. Lesley College offers this program in various sites across the country. Instructors are practitioners in K-12 settings and Lesley full-time faculty. Throughout this program the authors became familiar with the many ways in which technology was being integrated into K-12 programs. They experienced, first hand, the powerful instructional impact of multimedia, the value of student-instructor e-mail capability, and the ways in which the Internet could be used as a valuable research tool in professional education and in all of the academic disciplines.

In 1993, Dr. Shopland was asked to teach the undergraduate and graduate courses in educational technology in the Division of Teacher Education at Eastern Nazarene College. After reviewing the “standard” course outline, it was apparent to her that the courses were in need of significant revision. Heretofore, the courses had treated the traditional “audio-visual” learning tools. It was essential that students and teachers of the 90’s also become knowledgeable of the use of computer-based learning tools. During the ‘92 - ’93 and ‘93 - ‘94 academic years, videos and journal articles were used to introduce students to the uses of computer-based learning tools.

Even these modifications proved inadequate preparation for tomorrow’s teachers. Students and teachers also needed to become skillful in the use of computer-based learning tools. While all students had word processing and e-mail privileges in the Information Technology Systems Mac and PC labs located in the library, teacher education students required a facility in which they could learn the skills they would need as classroom teachers managing the use on in-classroom computers. These skills included learning how to (1) install programs, (2) access the control panels, (3) save to the hard drive, (3) handle minor troubleshooting with their computers, (4) develop multimedia instructional materials, (5) use the Internet as a research tool, etc.

In addition they would also need to learn how to integrate computer-based learning tools with the K-12 curriculum. The concept of the teacher education computer lab was beginning to emerge.

The 1993 Education Reform Act, shaped and placed into law by politicians, had called for the integration of educational technology with the K-12 curriculum. This mandate would later serve as a significant factor in communicating to college administrators the need for a teacher education computer lab.

During the ‘95 - ‘96 academic year, two events occurred at ENC that provided momentum for the actualization of the concept of the lab. Professor Kannegieser was employed as an adjunct to assist with the teaching of graduate educational technology courses, which had grown in enrollment in the past three years from 10 students to 26. She worked closely with the Information Technology Department in making the ITS computer labs located in the library more user friendly for education students. Several pieces of educational software became available to students in the lab. Teacher education students were also provided with password access to the Internet. While teacher education students were now able to access computers for professional and course-related purposes, it was impossible for the authors to conduct class in the ITS public use labs.

The building momentum toward a teacher education computer lab was strengthened by the purchase of a $6,000 Proxima computer projector by the Mathematics and Computer Departments for use in their courses. The authors requested and were granted use of the projector in their
courses in educational technology. The projector was very helpful in demonstrating educational software, teaching students how to use various tool programs, and how to navigate the Internet.

**Communicating the Need for a Teacher Education Computer Lab**

The course in educational technology was significantly revised in 1993 with a new text, videos focusing on computer-based learning tools, and assigned readings in current journals treating the integration of computers with the K-12 curriculum. The instructor’s dissatisfaction with the lack of educational software and hardware to enable a much needed “hands on” instructional methodology motivated her to communicate with the key decision-makers regarding facilities and technology planning for the college. These decision-makers included the Chairman of the Division of Teacher Education, the Director of Information Technology Systems and the Vice President for Academic Affairs. The developing concept of a computer lab in which curriculum and methods courses could be taught was first brought to the chairman of the Division of Teacher Education. Fortunately, he was a self-taught computer user who was an e-mail and spreadsheet enthusiast. He accepted and supported the concept and referred Dr. Shopland to the college’s Director of Information Technology Systems. Convincing the ITS Director of the value of such a unique instructional space was not an easy task. Certainly, he believed in the value of computers as learning tools. He was not easily convinced of the need for a computer lab designated for the exclusive use of teacher education courses, students and faculty. The key “selling point” for him was the evidence of a significantly growing market for professional development courses and programs in the greater Boston area, which was the direct result of the ‘93 Massachusetts Education Reform Act.

Once convinced of the need for the facility, the ITS Director has been a significant supporter of the work of the Education Division in regard to program development in educational technology. A meeting was held with the ITS Director, the Chairman of the Division of Teacher Education and all members of the education faculty to discuss the concept and affirm joint support for its actualization.

**Planning the Teacher Education Computer Lab**

The Director of ITS worked closely with Dr. Shopland in developing the following list of hardware to be purchased with funds that became available:

- 10 Power Macs
- 1 Hewlett Packard Laser Printer
- 1 Hewlett Packard DeskJet Color Printer
- 1 Apple Color Digital Camera
- 1 Apple Color Scanner
- 2 Connectix Quick Cam Video Cameras

Software purchases were severely limited by lack of sufficient funds. However, each system was preloaded with Claris 4.0 and ITS added Netscape and NCSA Telenet. Five copies of the Apple Elementary CD Resource Bundle and five copies of the Teacher CD Resource Bundle were purchased. Additional software purchases were limited to five additional copies of Hyperstudio and five copies of MicroWorlds.

Funds were not available to set-up a stationary instructor demonstration station which would include a computer projector. This is a significant limitation of the teacher...
education computer lab at ENC. Instructors must use a portable demonstration station/projector available to all departments and scheduled via ITS. Unfortunately, reservation conflicts are not carefully monitored, and instructors cannot rely on the "reserved" availability of the college's only computer projector.

The teacher education computer lab was opened in the fall of 1996. During the first semester of conducting classes in the lab, it became apparent that each system should also be equipped with a Zip drive. The multimedia projects being developed by students required much more memory than the 1.4-MB available on a floppy disk.

Ten Zip drives were purchased and installed for the Spring Semester, 1997 and students were required to purchase a Zip cartridge. Spring Semester, 1997 students reported significantly greater lab-user satisfaction than did Fall Semester, 1996 students.

Managing the Teacher Education Computer Lab

The effective use of the teacher education computer lab by students and faculty is dependent upon effective management of the lab. The effective management of the lab requires an institutional financial commitment to fund the part-time or full-time position of Director of the Lab. The Director has many responsibilities including (1) scheduling open lab times, (2) scheduling of student lab assistants who monitor the lab during open lab times, (3) training of student lab assistants, (4) development and updating of the lab handbook, (5) follow-up with students regarding log entries noting hardware and software problems, (6) trouble shooting, (7) communication with individual instructors regarding their requests to use the lab and special programs, (8) installation of programs requested by individual instructors, (9) communication with facilities management regarding cleaning and appropriate maintenance of the lab, (10) communication with ITS to request additional technical assistance, and (11) monitoring legal uses of software in the lab.

Faculty Orientation to and Training in the Lab

Voluntary small group and individual orientation to and training in the lab has been provided. All faculty members have attended an initial session. A few faculty members have requested individual training in e-mail and the Internet. No faculty members have requested individual training in the use of multimedia and other tool programs. In addition, no faculty members have requested information related to instructional software that would be appropriate to the courses they teach. While faculty members have been supportive of the design and implementation of the lab, they have not utilized it as fully as was hoped. Faculty survey results have shown that the instructors who do use the lab extensively in their curriculum courses are also the instructors who teach the undergraduate and graduate courses in educational technology. In retrospect, it may have been wise to include the entire teacher education faculty in the planning of the computer lab. Their engagement in this process may have prompted them to develop a stronger commitment to more effectively utilizing the lab in their courses.

Recommendations for Utilizing a Computer Lab in Teacher Education Courses

The recommendations noted below are made in regard to the utilization of a computer lab in curriculum and methods classes, and all other teacher education courses.

In curriculum and methods courses, and other education courses, instructors may use the computer lab to:
1. demonstrate how to adapt a student's use of a particular piece of software to the learning styles and needs of various students,
2. engage students with a particular piece of software using a cooperative learning approach,
3. demonstrate how to integrate subject specific instructional software with a constructivist approach, discovery approach, investigative approach, or direct teaching approach,
4. introduce students to various pieces of instructional software to engage the learner's higher order cognitive skills,
5. introduce students to various pieces of instructional software to engage learners' multiple intelligences,
6. demonstrate various pieces of instructional software engage learners in the "process" of a specific discipline,
7. introduce students to various pieces of instructional software to facilitate the development of learner's writing, reading and speaking skills,
8. navigate the Internet with students,
9. demonstrate how to use the Internet as a research tool,
10. e-mail other professional educators who have published on the Internet,
11. conduct videoconferences with other educators,
12. enable students to share their research with classmates via e-mail,
13. enable students to provide each other with peer feedback regarding course projects,
14. develop K-12 multimedia instructional materials with students,
15. identify K-12 educators with similar professional concerns, and
16. assist students in publishing their own work on the Internet.

This is merely a beginning list of recommendations. Each instructor who makes a meaningful commitment to utilizing computer-based technology as a learning tool in
teacher education courses will be able to add many recommendations to this list.

Acknowledgements

The authors wish to thank the many individuals who have worked to make the teacher education computer lab a meaningful reality on the campus of Eastern Nazarene College. Dr. Robert Kern provided the initial acceptance and support for a teacher education lab while serving as Division of Teacher Education Chairman. Dr. James Knox, current Chairman of the Division of Teacher Education, Professor Lois Knox, Chairperson of the Department of Education, Dr. Paul Nyce, ITS Director, Dr. David Kale, Vice President for Academic Affairs, and Dr. Kent Hill, President, have all provided significant support of the teacher education computer lab.

Patricia P. Shopland is Director of Graduate Studies and Associate Professor of Teacher Education at Eastern Nazarene College, Quincy, MA 02170. Voice, Office: 617 745 3558, Home voice: 781 582 8491. E-mail: shoplanp@enc.edu or shoplanp@aol.com.

Joan K. Kannegieser is Director of the Teacher Education Computer Lab and Adjunct Professor in Graduate Educational Technology at Eastern Nazarene College, Quincy, MA 02170, and Computer Teacher at the Martinson Middle School, Marshfield Public Schools, Marshfield, MA. Collaborative Distance Learning Research for the Phi Delta Kappa National Values Project

William J. Stockebrand
University of Texas at El Paso

Christine Althoff
University of Texas at El Paso

Students in the Educational Leadership Department of the University of Texas at El Paso have been invited to help direct research efforts in high schools throughout the nation as those schools move ahead with the Phi Delta Kappa National Values Project. Under the leadership of senior researcher Jack Frymier, Phi Delta Kappa conducted a national study entitled Study of Core Values and the Schools. In the subsequent 1995 publication, Frymier and his fellow researchers described seven core values identified as important to most people and essential to be taught in schools. These core values were: 1) learning, 2) honesty, 3) cooperation, 4) service, 5) freedom, 6) responsibility, and 7) civility. In addition to the publication, the study also produced a recommendation that Phi Delta Kappa seek external funding to establish and maintain a League of Values-Driven Schools.

The League of Values-Driven Schools

During the Autumn of 1996 and the Spring of 1997, Frymier visited high schools throughout the country, seeking to establish a league “comprised initially of 100 or so high schools in which teachers, students, administrators, and parents make a commitment to develop a values-oriented program of study in their school, focusing on one or more values every year from the seven core values” (Frymier, J., et al., 1995). Research teams would conduct in-depth research, then share their findings with other participating schools through newsletters and a summer conference for selected students from each participating school. Principals would be expected to lend both material and moral support and would be personally involved with other principals in both the planning and monitoring phases of the collaborative national project.

Phi Delta Kappa agreed to work directly with participating schools to develop and share materials and experiences that proved effective in addressing values issues. The main thrust of the project would be to incorporate values into each school’s curriculum and culture in a meaningful and positive way so that students would develop the abilities to: (1) deal in an ethical manner with complex challenges and dilemmas new to the human condition; (2) apply sophisticated knowledge and skills to daily living and occupational tasks; and (3) function successfully in a technologically complex environment.

The Phi Delta Kappa Chapter of the University of Texas at El Paso (UTEP)

Representatives from the UTEP Chapter of PDK attended the initial meetings held by Jack Frymier for potential league high schools. The broad scope of the envisioned research and its logistical realities concerned many of the principals in attendance. Many felt that they needed outside local assistance to carry out the proposed research projects and some formal mechanism to share both ongoing research efforts and the findings of successful projects. The UTEP Chapter of PDK had been searching for a way to return to its original mission of supporting research and providing service to its community and schools. Chapter officers decided to visit PDK International in Bloomington to explore avenues of collaboration that might serve both local El Paso needs and the demands of the national league effort.

As a result of these meetings, the UTEP Chapter agreed to serve at several levels. First, it would seek assistance from graduate students in UTEP’s Department of Educational Leadership and Foundations. These graduate students would be assigned to specific schools to act as catalysts and facilitators for campus research efforts, so they might use parts of the research for their masters theses and their doctoral dissertations if they chose to do so. Their involvement in this project would also reflect their commitment to values-driven education in general. These students would expand their opportunities to engage in a variety of learning communities which value: (1) the intrinsic worth of learning something well, (2) the connections between what students are learning and understanding themselves in the world, and (3) the excitement of exploring that world with others (Sergiovanni & Starratt, 1993).

Second, the UTEP Chapter would establish and maintain an Internet web site whose primary purpose would
be to provide a collaborative forum for league activities. This site would be directly linked to the main PDK International site, as well as to all other known PDK chapter sites throughout the country and any sites that might be established by participating league schools. Thus, research experiences would not be limited to conventional means, but would include opportunities to utilize such innovations as distance learning, internet activities, and field studies. Brownell (1997) notes, “The content of educational technology has changed over the last decade from hardware and programming for teaching of computer studies to the use of technology to enhance educational and professional studies.” These technological advances present new challenges and advantages for graduate researchers and other league participants.

Third, the UTEP Chapter of Phi Delta Kappa would reorganize in ways that would maximize its ability to service the league project. For instance, the officer position entitled “Research” would be elevated to vice-president rank, with several assistants assigned to coordinate local and national research efforts. A position entitled “Director of Technology” would also be established along with the appropriately appointed assistants to build and maintain the web site.

Recruitment of the graduate students began with those who were already members of PDK. An Ed.M. student and an Ed.D. student volunteered immediately to conduct their thesis and dissertation research in the core values area. Several other students, who were not yet at the thesis or dissertation stage, agreed to act as facilitators in the high schools. They assumed that their values research would eventually evolve into personal research studies.

The values research project offers opportunities for adult learners to participate in activities which “facilitate optimal learning and growth” and will allow them to: (1) be involved in the determination of their learning activities by setting learning goals, content, experiences, and evaluation; (2) be considered as individual learners, bringing a varied background of experiences and knowledge to the learning situation; (3) see the values of the learning experiences in knowing that the activities and experiences will be applicable to their work; and (4) see tangible outcomes from the learning activities and experiences, thereby receiving some acknowledgment of their personal achievement toward learning goals (Webb, Montello, & Norton, 1994). The benefits to student researchers would be maximized within supportive professional and educational environments.

Possible next steps

Since UTEP shares the border with Mexico, many students expressed an interest in replicating the original values study in Mexico. Conversations with education officials in Ciudad Juarez and in the State of Chihuahua confirmed that Mexican schools would be very interested in joining the values project, not only from the viewpoint of the study, but also as members of the League of Values-Driven Schools. Sergiovanni (1996) notes that “centers of inquiry foster the sense of community by encouraging discourse among teachers.” One of UTEP’s great advantages lies in the bilingual abilities of many of its graduate students, which optimizes communication opportunities. Thus, collaborative efforts over the Internet could be both bilingual and binational and could provide a solid basis for comparative studies of the values embedded in the high schools of both nations, further encouraging inquiry and research and expanding learning communities.

A second possibility resides in the desire of many local middle and elementary schools to become meaningful players in the league. The web site and ongoing e-mail communication eliminate the need to transport students in order to facilitate collaboration. Thus, distance education has opened doors to the involvement of new league players.

Because of the asynchronous nature of the Internet communication, people who would not be available to work with students during the school day can be called upon as resources and fellow researchers. This could include people halfway around the world as well as those in a neighboring city.

The PDK values project offers opportunities for educators to collaborate in research about values education through technology. The PDK websites, e-mail, the Internet, and other databases provide immediate access to a variety of useful data pertinent to the values research project. Such technology can enhance educational and professional studies and facilitate conversations which create, sustain, and expand a “community of research practice” (Sergiovanni, 1996) at local, regional, national, and international levels.

Call for participation

We would encourage anyone who sees a way to add something to the league efforts to contact the UTEP Chapter of PDK. Project coordinators will attempt to fit your contributions into the national project. Primary contacts can be found on the web site at http://pdkutep.org/

The Historic Pittsford Website - Time travel through our town is a project done in partnership with several groups. Its purpose is to provide students and the community at large a virtual source for the history of the town of Pittsford as it fits into the greater scheme of the region and state. It is particularly valuable for fourth grade students as local, regional and state history is the focus of the social studies curriculum in New York State. The Pittsford Central School staff is also interested in sharing this site and learning about similar efforts in other communities so that linkages can be set up and communities can learn from each other.

Historic Pittsford Website Designers
The design of the Historic Pittsford Website is a partnership of three groups. One is the Pittsford Central Schools Social Studies Standards effort, chaired by Peter Pappas, Social Studies Standards chairperson. Another is the Jefferson Road School fourth grade parents, staff and students. Finally, Mrs. Elisabeth DeGironimo, GIS web consultant at Phoenix Systems & Technology, has designed and produced the actual site.

Historic Pittsford Website Development
The project originated with Mr. Peter Pappas, who through numerous contacts with Historic Pittsford and town officials, linked the fourth grade team at Jefferson Road School with source materials and people for a school project on the history of Pittsford, entitled the Spiegel Project. After a meeting with fourth grade staff, Elisabeth DeGironimo, web consultant at Phoenix Systems & Technology and Mr. Pappas in August 1997, the Historic Pittsford Website project was launched.

Parents were given an initial overview of the project in October 1997. They were then assigned computer lab time periods to come to school and scan photos, maps, and pictures for the project with students. At the same time, Mrs. DeGironimo designed the site and its structure. A database was set up to catalogue the images into the various categories. Students will be adding original material, including interviews with Pittsford officials and business people, reports and multimedia projects.

The Historic Pittsford website is in a GIS format and programmed in HTML. The site has three levels:
- Local - data about the town of Pittsford.
- Region - data about the city of Rochester and Monroe County
- State - data about the state of New York

Users are able to zoom in and out of a location from the three levels and gain a perspective of the relationships among the different geographic levels.

The site also is divided into four areas within the levels:
- Land - data about homes, farms, geographical features of the respective areas.
- Enterprise - data about businesses in each area.
- Community - data about churches, schools and other civic organizations.
- People - data about people at each of the levels.

As with many websites, this one is in its genesis and will continually evolve and be under construction. Future plans call for the inclusion of aerial photos, QuickTime VR movies, and multimedia projects by students.

Catherine Alfieri is a fourth grade teacher at the Jefferson Rd. School of Pittsford Central Schools, School Lane, Pittsford NY 14534, voice: 716-385-6060, email: calfieri@eznet.net or calfieri@mail.monroe.edu.
The deployment of a learning environment requires the development of two components: (a) a guiding philosophy and (b) a system that supports the philosophy in practice. The Electronic Studio is a distributed learning environment based on constructivist and constructionist ideas as explained by Papert (1993), Negroponte (1994) and Resnick (1994, 1996). In the Electronic Studio the support system is provided by a network based computer system. Papert (1993) has argued that people learn more effectively when they are engaged in the creation of objects that are relevant and meaningful to their lives. In this process, students learn more by creating an object after designing its parts than by taking apart something that is handed down to them (Negroponte, 1994; Resnick, 1994). This, by definition, is a problem oriented instructional environment. The characteristics and advantages of problem based learning have been reviewed by Blumfeld et al. (1991). A technologically enhanced system based on a network can support this project-based approach helping learners to solve problems in a collaborative fashion and facilitate the process beyond the confines of space. This makes it possible to extend the notion of constructionism to distributed constructionism, a situation where people who are not working in close physical proximity can collaborate in creation and construction (Resnick, 1996).

This is an overview of how the Electronic Studio concept, developed by Rice University’s Center for Technology in Teaching and Learning (CTTL) can serve as an environment in which project based learning can flourish by facilitating construction, collaboration and sharing of projects and information objects. See (http://ctl.rice.edu). The Electronic Studio has gone through several iterations. The initial phases of the current iteration have been developed and deployed at this point. Other aspects are still under implementation.

Electronic Studio

The Electronic Studio is the result of CTTL’s System-After-Next vision for technology where people, processes, and technology are integrated (Gorry, 1997). The Electronic Studio serves a number of purposes, all focused on the construction and development of projects. It is a workplace, a display area and a repository for tools, data, multimedia, design projects, and personal papers. But because of our use of networking, an Electronic Studio is not bound to a single place. Learners, linked together by a telecommunications network, can work simultaneously within a studio to share notes, assignments, documents, images, video, and sound.

An Electronic Studio provides a unified front for access to remote information sites. For example, students can access information from libraries, and gain access to databases around the world; or students can view the resources at a museum and interact with its curators. Electronic Studios allow groups of learners from different environments to collaborate in the development and exploration of curricula. It permits two way interactive video discovery and enable learners to become builders of common knowledge bases by creating shared repositories of information.

The distributed nature of the Electronic Studio depends on the development a networking infrastructure. That infrastructure enables uses of computing that go beyond the single student to foster the sharing of educational resources between teams of learners and individuals. Because of its nature, the Electronic Studio is a great system for student centered learning, as discussed by Norman and Sphorer (1996), where groups can be engaged in active exploration, construction and problem solving.

Design process

The Electronic Studio concept does not focus on a static environment. It is an environment that is constantly transforming due to of changes in technology and in user interests and needs. Therefore, the development of an Electronic Studio project follows an iterative prototyping approach (Gorry, 1997) with significant involvement of the target population. At the project site, consultation with the users takes place so that their needs and concerns are addressed.
Sample Projects of the first iterations

The Center for Technology in Teaching and Learning has been supporting and developing Electronic Studios at Rice University and at The Rice School/ La Escuela Rice, a k-8 educational institution. These developments have been centered on the creation of rich World Wide Web resources that serve students and instructors as centers for information delivery, exchange and communication. One such endeavor is The Galileo Project at Rice University (http://es.rice.edu/ES/humsoc/Galileo/) which was developed as part of a college level course on the life of the famous astronomer.

Galileo’s Web (http://riceinfo.rice.edu/armadillo/Rice/Galileo/) was the second iteration of the Galileo Project. In this version, the Galileo materials were adapted to the k-8 learning environment of the Rice School/La Escuela Rice. Using a more integrated environment where learners had access to creative materials through a reduced number of entry points extended the Electronic Studio functionality. A website tied several of the distributed classroom functions together, including reference materials, lesson plans, media collections and display materials. The second entry point was provided by a local area network that provided access to locally stored materials and documents.

The Virtual Villas Project in Galileo’s Web represents the kind of projects that learners can develop in an Electronic Studio environment. Here, teams of students designed and built virtual reality villas for Galileo. In the process they learned about the history of science, mathematics and architecture while collecting information and building elements from network repositories and World Wide Web sites (Solis, 1997a).

The Rice University and Rice School/Escuela Rice Electronic Studio projects relied on two technologies: a) the institutional Local Area Network (LAN) and b) the Internet. The LAN provided teams with distributed, shared spaces for tools and documents, as well as with widely accessible private spaces. The Internet, on the other hand, provided learners with access to information resources and a communication system for remote locations. What these two sites lacked was an integrated access system for information and communication. Users were able to access all the necessary resources through the networking systems, but the process required them to become familiar with procedures and technologies, which were in not necessary for the goals of the projects.

Refining the Electronic Studio – higher integration

In a new iteration, the Electronic Studio is being deployed at Hogg Middle School, an inner city school in Houston, Texas. The Electronic Studio model under development at this site takes advantage of new technologies developed after the deployment of the previous iterations. The technological goal for this model is to create a highly integrated interface and seamless environment to enable learners to concentrate on the creative processes and learning. To achieve this, an Intranet component has been added to the support technologies.

What is an Intranet?

The term Intranet is used here to refer to a local or wide area network based on Internet protocols and designed to serve the internal needs of an organization. It may or not be connected to the Internet and typically includes e-mail, file sharing and other basic network services. One of the advantages of Intranets they can be deployed over existing networks and require very little re-engineering. (Khan and Logan, 1996; Brandt and Nash, 1996).

The main differences are that Intranets offer a single point of entry to network based resources and the focus of the development is on the users of the organization involved, not on the global community. This entry point is a World Wide Web page. The Intranet approach has the potential of impacting learning in an Electronic Studio environment as it can create a seamless working environment for the users. In the same way that students walk into a traditional classroom and can interact with tools and materials to develop projects, the unifying approach of an Intranet allows learners to concentrate on the task at hand letting technological nuisance take a back seat. This aspect was important since the reduction of procedural steps facilitates the adoption of technology in organizations that have not relied on it to function (Solis, 1997b).

Several schools and school districts are already using Intranets, but not under this approach. For example, the Hueneme School District and Blackstock Jr. High in Oxnard, California, use an Intranet system for cross-district communications, file sharing and source code implementation (Sowinska, 1997). The Montgomery County Public School system, in Rockville, Maryland, in its “Plan for Educational Technology Implementation: The Global Access Project and Beyond" has established, as part of its core strategies the installation of building wide networks and Internet and Intranet software.

The Electronic Studio at Hogg Middle School

What follows are some projects are already under implementation. These projects take advantage of Intranet technologies such as server based databases and scripts to enable users to participate in a collaborative knowledge base construction to create cross-curricular materials. One of the most important criteria in this area was the desire to enable students and teachers to collaborate in learning, while removing unnecessary steps and fronts in the process.

The Online Personal Journals and The Rainforest Poets

The online personal journals were designed so that students would have a personal writing space that could be accessed at the touch of a button and be worked on from...
any room in the school. Other students could read each other's materials from any room in the building and teachers could reply to student and comment on their materials. All this happened within a browser environment. Students and teachers looked at the same interface regardless of where they were or what computers they were using. At the same time, files were saved at designated spots at the click of another button. In the Rainforest Poets environment, users collaborated in the creation on poetry based on tropical rainforest themes, again, using a web based interface, with more concern on collaboration than with technology.

**WeatherTrackers**

The processes of science rely on data collection and analysis within a research framework. The objective of this project was to enable learners to collaborate in data gathering and to create a distributed database that could be used across disciplines to meet the needs of individual learners. Taking advantage of the wide area network, schools in the district take weather measurements at their sites and enter them into a web-based database. The participating students build a raw data source that can be used to test hypotheses in science classes but can also be accessed by other classrooms not involved in the sampling process and used as starting materials for mathematical and statistical investigations. Because the data are raw, many age levels depending on the questions and problems that the learners are interested in answering can use them.

**The Book Report systems**

This project design was based on previous models deployed at the Rice School/ La Escuela Rice, in Houston. Through a series of web based forms students post book reviews to the web. Using an on line database the materials are sorted according to level of complexity, language and genre. The on line reports are reviewed by teachers but are also used in other content areas such as theater arts to make decision on themes that are of interest to the student population.

**Development site**

The current development of the Electronic Studio is taking place at Hogg Middle School, in Houston, Texas. This is an inner city school, housed in a building that dates from 1926, serves approximately 1,300 students and has about 80 teachers.

This development of the Electronic Studio is the result of a grant awarded to the school by the Texas Telecommunications Infrastructure Fund. (http://www.tifb.state.tx.us/tif.html). The school, with the participation of teachers, administrators and university advisors, established as its goal to deploy a technological infrastructure to facilitate the integration of curriculum and technology.

---

**Creating the technology environment**

**Preparing the learners**

In the past, this school has in the past used computers in a more traditional ways and had no network access. To implement the Electronic Studio at this site is became necessary to train teachers as well as students.

The training model used with the teachers has been successfully implemented before at other k-12 institutions (Solís, 1977b). During the summer of 1997 sixteen teachers from all content areas and grade levels were trained intensively on the use of network technologies in the classroom. They were instructed in curriculum development in a technology rich environment and participated in classroom discussion that focused on teaching practices. After the summer training, monthly workshops were conducted to allow participants to refresh and update their skills. These teachers are now training other teachers in their teams.

Students, on the other hand, learn in this environment through modeling, exploration, construction and by teaching each other. Furthermore, a resident consultant remains with the school and actively participates in the implementation of projects and in the school life in general.

**Network Infrastructure**

Hogg Middle School deployed, as part of this project, cabling for a network capable of serving 550 clients with the help of volunteers and at risk students under the advice of CTIL.

The school is connected to the district WAN and the Internet by a T1 line. All network transactions are handled through TCP/IP protocols. The network system is supported by a Windows NT® that functions as a resource server, a web server, a file storage system, and as a print server. To handle its web services, the system is equipped with Microsoft’s Internet Information Server® (version 2.0 with Microsoft Active Server Pages® installed).

**Classrooms**

There is at least one networked computer in each classroom. Several classrooms have been set throughout the school with four to twenty networked systems. At the completion of this project each classroom will have at least eight networked computers. Due to a staggered influx of systems into the school and changing policies within the Houston Independent School District, Hogg Middle Schools classrooms are populated with a mixture of Apple Power Macintosh® and Windows 95® systems.

Essential to the implementation of the current Electronic Studio model is the uniformity of system configurations. Additionally, applications are carefully chosen, selecting those tools that show a high level of integration with each other. This is what enables learners to share in the production of information objects, regardless of where they find themselves in the schools. Therefore, all systems will be equipped with the same components: Ethernet cards,
Microsoft Internet Explorer® World Wide Web browsers, mail clients and the Microsoft Office® application suite.

Technologies

The employed technologies and provided services are chosen to facilitate the achievement of the desired goals of curriculum integration with technology in a seamless environment. Because of the mix of operating systems and computer models the computing capabilities of the stations are not the same. The web server plays an important role in the integration and collaboration capabilities of the different elements of the Electronic Studio. The platform independence afforded by browser and server based applications overcomes these problems. For the applications developed for the school, many tasks are carried out by server scripts written as active server pages, where the server generates HTML based on user input and the content of server based databases  http://www.microsoft.com/syspro/technet/boes/bo/iserver/prodfact/aspover.htm).

One of the functions of the Electronic Studio is to serve as an area where completed projects can be displayed for others to learn from them. To facilitate this function in a heterogeneous computing environment Adobe Acrobat® (http://www.adobe.com/acrobat) networked printing services were installed in the system. This allows the participants to publish their work in a portable format that will retain all the characteristics of their creations.

Web databases

Web based databases are an integral part of the system since they enable the users to create a dynamic learning environment and to become active participants in the resource creation for the school. Having the learners access and interact with the databases through the browsers helps create a unified front for information, while bypassing the differences in platform and machine capabilities that characterize school environments.

Multimedia Galleries of images, movies and sounds

To support learners in the construction process, a number of resource galleries were put on line. Media galleries such as graphics, sounds and movies were placed on line and accessed through web pages. Previous work with similar groups demonstrated that the adoption of new teaching styles and the inclusion of technology in the curriculum was significantly affected by the number of online support structures provided to the learners (Solís, 1997b). This provides learners with a starter system for project development. Later on, individuals create their own galleries, which they share with others through their own web space.

Web Boarding

An important component of building a collaborative environment for construction is to enable users to communicate within and between teams. In this system two technolo-

This panel will discuss a systematic review of statewide requirements and initiatives for information technology and teacher education. A comparison will be made among three states: Colorado, New Jersey, and New York. For preservice teachers, the study will examine the role of technology in certification requirements: is technology explicitly mentioned? If so, is it considered a separate requirement or integrated into other requirements? How is the issue of technology in teacher education implemented in colleges of education? For inservice teachers, how do states accommodate the changing expectations of teachers’ skills? Is there a systematic method for professional development or is it left to individual districts or to the teachers themselves? Finally, do statewide initiatives for teacher education reflect the new standards for students?

This review will lay the groundwork for a national or perhaps international study of the status of information technology and teacher education. The resulting information will provide a basis for SITE’s development of recommendations for technology and teacher education standards and methods for achievement of these standards.
Distance Education, a section that did not exist just two years ago, is now one of the largest sections in the Annual. There are several reasons for the rapid rise in interest. Those reasons include the Internet’s increasing sophistication and ease of use, a growing number of both students and faculty who have computers and who use the Internet regularly, and a developing anxiety on the part of higher education about rising costs of traditional education. Distance education is, in fact, an “old” field, that was around for more than a 100 years before computers were even invented. But, the development of new technologies, from the Internet to video conferencing, has reinvigorated distance education. That, combined with concern over keeping the costs of higher education in check and serving populations of students who cannot come to traditional campus-based courses, makes distance education today a very active and dynamic field. That is illustrated by the papers in this section.

Several papers describe innovative projects that either demonstrate creative uses of distance education techniques to deliver instruction to teacher education students or illustrate ways of teaching students about distance education. The work of Jostein Tvedte and Svein Lysne at Stord/Haugesund College in Norway illustrates the first type of paper. They describe a sound conceptual framework for thinking about distance education for teacher education students. The paper by Weidenfeld and Leclet, at the Universite de Picardie Jules Verne in France, is another example of the first type of paper. They are creating distance education programs to teach teachers and trainers about multimedia. A third example is the paper by Steve Schlough and Suwathana Bhuripanyo at the University of Wisconsin-Stout. Their paper is about a course they taught over the Internet on task analysis while the paper by Mory, Gambill, and Browning at the University of North Carolina at Wilmington was on training and development.

Harriet Taylor’s paper is an example of the second type of project paper. Her work at Louisiana State University is an interesting way of “learning by doing” in a graduate course. A very comprehensive effort to prepare college faculty to use online learning approaches was reported by Hoffman and Ritchie at San Diego State University. Their work with faculty all over California is the basis for many sage pieces of advice concerning workshops and support for faculty. The paper by Christos Bouras and his colleagues at the Computer Technology Institute in Patras, Greece, deals with an even broader concept – the support of open and distance learning environments across the European Union.

Several papers have asked questions about what constitutes “good” distance education. Barbara Mc Kenzie and her colleagues at the State University of West Georgia approached this general question by developing a list of potentially important teaching behaviors in distance education and asking experienced distance educators how important each behavior was. A similar approach was taken by Donna Everett at Morehead State University in her study of important aspects of the delivery of distance education.

Melanie Hill, also at West Georgia, took a different tack. She describes work on the support system for West Georgia’s distance education program, and concludes that strong support services are critical to success. James Lehman and his colleagues at Purdue University thoughtfully discuss several models of distance education based on their extensive experience with distance education at Purdue. Still another approach was taken by John Cochenour and Carl Reynolds at the University of Wyoming as well as Randal Carlson and colleagues at Georgia Southern. Both these papers provide a set of suggestions and sage advice is based on work in a sizable distance education program at the author’s respective universities. A similar approach was taken by Pan (The College of New Jersey) in his paper. Penny Garcia (University of New Mexico) incorporates several aspects of good Internet practice in her paper on the impact of Web and Internet access in a cooperating public school.

Another type of paper describes specific concepts or frameworks for doing certain types of distance education. For example, Finder and Raleigh at the University of Wisconsin-Eau Claire, describe a framework for introducing...
K-12 teachers to ways of introducing the Internet to their classrooms. Mertindale and Ahern at Texas Tech University discuss the use of concept attainment theory in the design of web-based instruction. Leclet and Weidenfeld, at the Universite de Picardie Jules Verne in France, focus on the issue of how users of distant education resources on the Internet will search for information.

Finally, there are papers that look at a specific aspect of distance education. A good example is the paper written by Ann Barron and Chet Lyskawa at the University of South Florida. They provide a quick overview of the electronic tools available for creating and managing online courses. That topic was also the focus on a paper by Abbie Brown and Lisa Hansen at Indiana University. They systematically developed an assessment procedure to evaluate several different types of electronic tools for creating and administering distance education courses over the Internet. Ruth Gannon-Cook, at the University of Houston, offers a perspective on distance education that emphasizes the role of apprenticeships and storytelling in the understanding of what distance education can be.

A fourth specialized paper, by William Lynch and Michael Corry at George Washington University is on another topic of interest to many of us – faculty recruitment, training, and compensation for distance education. Elizabeth Kirby, at the State University of West Georgia, offers suggestions for supporting distance education teachers and students at the high school level. She based her suggestions on conclusions from a qualitative study of distance education courses for high school students that included facilitators on site and remote teachers who could be accessed via phone. Finally, the paper by Judi Harris at the University of Texas is an innovative look at web page design. Her premise is that we should carefully consider the function of a page and then design the form of the page to support that function.

A MODEL FOR TEACHER TRAINING ASSISTED BY INFORMATION TECHNOLOGY

Jostein Tvedte  
Svein Ove Lysne  
Stord/Haugesund College

The problem addressed in our R&D work is: Is it possible to make a common model for education, without considering the physical location of the students? And if so, does the electronic presentation interfere with the way the curriculum should be presented?

Our R&D work is based on experience from traditional lecturing in the classroom where the teacher plays a dominating role in presenting the material to the students, as well as from experience from Open and Distant Learning (ODL) where the teacher presents the written material and gives advice during the learning process through electronic conferences, e-mail and so on. We have over the past six years worked in the European JITOL (Just In Time Open Learning), which is a project that has been terminated but continues on in the similar Norwegian project NITOL (Norwegian network for Information Technology in Open Learning). Through this projects courses have been gathered into a course pool in cooperation with other educational institutions.

In our R&D work we have tried to take the best parts from each type of teaching, and integrate them in the same learning environment for both on-campus students and distance students. We have found that it may be important, even necessary, to start a course with considerable control on the part of the teacher, and then gradually decrease the time used for lecturing. As lecturing decreases, time can be used to advise the students concerning the assignments and problems in the curriculum. This is based on the idea that we have to bring the student up to a certain level before we can start using a more student-centered problem based approach where the Internet is used as a main system for distributing the curriculum, and to support conferences, information seeking and so on.

How long should this teacher-controlled instruction and lecturing period last? This will be influenced by the level of the course. In undergraduate courses, this period should be longer than in higher level courses. This is natural because in higher level courses we can base the teaching on earlier experiences both concerning the curriculum and the way of teaching.

Initiating an Electronic Learning Environment

Gathering the students in the beginning of the course is important. The students should get an opportunity to get to know each other. This is an important factor in how the virtual classroom shall work later. We find it rather difficult getting a virtual classroom to work especially if the student do not know each other and do not have any ideas of who they are talking to through an electronic conference. Students can sometimes find it rather frightening to ask a question (in writing) in a virtual classroom, where they do not know who is reading the question, and also knowing that the question will be published (and read) over a long period of time. It is much easier for a student to ask a question in a physical classroom, where he or she faces a limited number of listeners, and where the teacher in every sense can help the student to ask the question. As we often see, teaching is a process of helping the students to ask the right questions. Very often they do not know (or can not explain) what they do not understand. The important role of the teacher is to be a catalyst in the learning process.
achieve this in a virtual classroom, it is a great advantage that the student knows and trusts the other students that will read their questions. In regard to this we find distinct similarities in the physical and the virtual classroom.

It can be rather difficult to initiate activity in the virtual classroom if the students do not have any other relationship with the fellow students besides the communications through the virtual environment. We have seen this clearly in different courses we have run, where the students in some courses are presented only to the virtual classroom, electronic conference and so on without any advance introduction, and courses where the student are gathered in the start and can establish contacts and relationships than can continue in a virtual environment. If gathering the students at the start of the course is impossible to arrange, due to for instance long distances between students, an electronic presentation made by each student can be done in order to establish contact, and let everyone get to know who is participating in the course.

Problem Based Learning

One very important point in having a common study for on-campus and distributed studies, is to organise the study in a more problem-based way. Instead of writing long lectures for distribution on the Internet, or trying to write down every word that you would have said in an ordinary classroom session, you define problems to be solved by the student, and in that way specify the curriculum to be learned. The teacher needs to have an overview of important literature, articles, web-sites and so on, specifically where the curriculum can be found, and therefore the role of the teacher is changed. The teacher will be an adviser for the student. This is quite a significant change. The student plays a more important role in his or her own learning process. By shifting from teaching to problem-based learning, we can use the same methods for both on-campus and distributed students. Without concern to the physical site of the student, the two types of students are able to solve the same problems, seek information in the same places, and discuss their theories in the same electronic conferences. The teacher will no longer have the role as the person who delivers the curriculum through lectures on the campus and through written text to the distributed students. Too often we see that the only difference between on-campus lectures and ODL is that in the classroom the teacher teaches the curriculum (mostly orally), and in distance learning he or she writes the same subject matter. Through problem-based learning we can remove this difference between teaching in the classroom and ODL by placing the problem in the centre and changing the teacher’s role from being a speaker in the classroom or a writer in ODL to an adviser in a student centred problem based learning environment independent of the students physical location.

Shift in the Role of the Teacher

The integration of on-campus and distributed studies, and the focus on problem based learning has very clearly shifted the focus in the courses and can in short be summarised as a shift from teaching to learning. This has also changed the role of the teacher. The teachers’ main functions in the learning process are:

1. The teaching in the classroom will focus the main topics in the curriculum.
2. Teaching in the electronic virtual classroom can include the organisation of the electronic classroom, presentation and organisation of the curriculum, literature, articles, web-sites, organisation of information bases, electronic conferences and so on. It entails also being a kind of catalyst where the teacher tries to keep the students involved and interested in the curriculum and the learning process in the electronic classroom.
3. A very important part for the teacher is in the definition of problems related to the curriculum. In problem based learning a main issue is to define the contents of the curriculum.
4. The teacher also has to be an adviser in the learning process. When the students concentrates on problems, the teacher will have to be a resource in the learning process, and an adviser in the problem definition and solving process. In order to fulfil this students demands, the teacher will have to have a overview of different methods, algorithms, strategies and so on, to be able to advise students in many student defined ways to solve a problem.

Shift in the Role of the Student

The most obvious change in the work of the student is that it has shifted from a situation where the curriculum is presented in the classroom, to a situation were curriculum has to be learned out of the need to solve a problem. This is a situation where the students are much more responsible for their learning process. They can get assistance from the teacher which is related to the specific problems in the study. This is an important part because if the time used to lecture is reduced, the students will instead get more contact with the teacher through the problem solving process. The limited contact with the teacher in the classroom will also force the student to use electronic tools to communicate and seek information. This way other students on the course, information bases, search engines and other resources on the Internet will play a major role in solving problems.

The main topics in the students’ work will be:

1. Introduction to the curriculum through teaching, either in the classroom or electronically on the Internet.
2. Introduction to problems which state the most important parts of the curriculum to be learned.
3. Problem solving which includes continuously seeking
of information, assistance from fellow students and teacher, and feedback from the teacher.

4. Feedback on the assignments.

Feedback is important both for the student and the teacher in order to check that only relevant information and curriculum are part of the study. The assignments can be optional and/or obligatory for the student to complete in order to take the finishing exam. Assignments can also be a part of the student evaluation.

A Case Study

A questionnaire was distributed to a group of 35 students in an introductory course on ICT in teacher training. In this group the use of traditional lectures had been reduced to approximately 50%, and the use of problem-based methods was accordingly increased.

Preliminary findings

The students disliked the reduction in time spent on lecturing. They seem to feel more comfortable in a traditional learning environment, together with their teacher. The students are positive in their comments to problem-based learning methods. But almost all the students want the teachers to spend more time together with them in the classroom or in the lab! Not even very frequent use of e-mail or news conferences can replace the presence of a teacher.

The students present mainly formal, well formulated questions on the news conference. We seldom see spontaneous, informal questions. The news conference is a too formal channel of communication, perhaps because it appears so official. Many to many-communication is perhaps the most complicated and challenging area to transfer from the live classroom to a virtual learning environment.

More than 50% of the students in the group use net search, (search engines like Alta Vista and Lycos), in order to solve assignments in their studies. The Internet and news conferences as tools for seeking information seem to be functional and frequently used tools. But these tools appear to be less functional for asking questions and for discussions of ideas. E-mail may be a better tool for private and not so precise formulations.

Summary

By defining the virtual classroom as a combination of the use of Internet, news conferences and e-mail, we find some main points:

- The presentation and seeking of information can in many situations be replaced by electronic tools.
- The interaction seems to be the most difficult part to integrate in a virtual environment by using electronic tools.
- The use of e-mail seems to function best and especially in the one-to-one communication between teacher and student.

- Simple, updated access to information is perhaps even better implemented in the virtual learning environment than in the traditional.

What are the competencies and knowledge needed by teachers and trainers in order to use efficiently the new technologies of information? This paper aims at giving some answers to this question and describes a distance training action which enables to acquire the desired topics. The theoretical knowledge which is needed is first briefly described. Another essential characteristic of this action, the acquisition of the true capacity to realise a real project is then discussed. The second part of the talk is related to the design of a modular, open, accessible from a distance, training action which uses both specific multimedia training supports and conduct patterns based on the telecommunication numerical networks. The design of the multimedia supports specifically developed for this action is also commented.

This action, which registers itself in a larger scope of distant training to multimedia [11] aims at giving to non computer scientists, technical bases allowing them to, either create or round off, training interactive supports. Of course, at these two levels of targeted tasks, there are very different technical uses, and one of the essential characteristics of this training is its modular aspect: the contents are sliced into elementary units called “modules” accessible independently.

Another essential characteristic of this action relies on the acquisition of the true capacity to realise a real project. Thus the teachers who take part in this training are not just inclined to acquire a new diploma (related to the acquisition of a full set of multimedia knowledge offered to them), but rather wish to improve their competencies as far as conception and realisation of educational tools are concerned.

The global target is therefore to conceive a modular training, open, accessible from a distance, for such activities as conception, conduct and realisation of multimedia projects intended for training. This communication tends to present the plan of action which is now under development. This plan uses both the multimedia training supports and conduct patterns based on the telecommunication networks.

The peculiarity of this training is that it introduces a “double entrance”:

- The first one corresponds to a classical approach through “themes” : the knowledge is accessible through a thematic organisation which is explained. However this knowledge is gathered into modules, it gives it a flexibility when being brought into play and allows to adapt the progression to the inter-individual variations.
- The second one corresponds to a complementary approach through means of “jobs”. Thus, the way to explore the information network built this way constitutes a professional entry. It is the description of the multimedia training products conceivere/director’s “job” which supports a contextual approach the content: one can, starting from a professional practice, have access to the necessary knowledge for its achievement.

Multimedia competencies and the development of training supports.

In order to acquire knowledge with the purpose of the acquisition of multimedia competencies various subjects have to be taught. The following subjects are then necessary:

Technical topics related to the multimedia domain

The following are examples of technical topics that are useful for designing educational products. In our opinion, project designers have, at least, to be aware of the current stage of advanced technology in the following domains. The courses related to these technical topics will provide the amount of information needed to communicate with other (technical) partners in the project

- Computer graphics and computer images: generalities about computer pictures (modes, formats, compressions,...), picture transformation with 2D and 3D algorithms, technics of realistic transmission systems
and of picture analysis and processing.

- **Networks**: network technology and the various transmission modes are studied. The purpose is to present the technical features that may be necessary for explaining some behaviours of information transmission on the web. One key point is to understand the constraints on large files (images, video, high resolution sound) transmissions.

- **Interfaces**: software ergonomics, design of friendly user interfaces, the use of agents and basic knowledge of Java language.

- **Knowledge basis**: type of data, organisation of data sets connected to the objectives, representation of knowledge, the acquisition of knowledge, multimedia and knowledge representation.

- **Documentation systems**: the electronic management of documents, the various way for indexing documents and the associated methods of information retrieval. The navigation process and the use of hypertext and hypermedia.

### Methodological contents related to projects analysis and management

The next topics are directly related to the practice of project design and management.

- **Project management methods and tools**: Significant multimedia developments are always undertaken by a team of people having various competencies (technical, artistic, pedagogical, content expertise, marketing,...), and also various behaviours and habits. Project management methods are needed in order to take this heterogeneity into account. Practical management tools will give a concrete meaning to these methods.

- **Needs analysis**: It is related to information extraction from experts and trainers and evaluation of benefits deriving from the use of new technologies. As an example:

- **Extension of training to a larger number of participants**:
  - Greater availability of training
  - Improved costs/benefits relationship
  - Improved transfer of skills
  - Individualised instruction
  - Possibility of self-paced learning
  - Reduction of individual learning time

- **Multimedia design methods**: Adaptation of some method used for analysis in computer science and software applications may be useful for the design of educational products. Among these methods, object oriented and knowledge description approaches are prominent,

### Computers in education

The use of computers for education and training did not start with multimedia or the internet. A lot of developments have been made in the last thirty years and it seems important to have a good perspective about their successes and failures. A survey of CBT, simulations and microworlds will hence be useful for designing new generation multimedia educational products.

### Tool handling

Practical knowledge such as picture scanning, sound or video digitalisation, multimedia script organisation by means of a simple authoring tools, etc... may be useful for project designers, even if other people are in charge of realisation. This type of knowledge is, in itself, the least complex to teach. However, in the case of distant teaching, it becomes very delicate to put up. On the other hand, this knowledge, taken as a whole, takes quite a long time to acquire. Moreover, all of it is not useful and strongly depends on the professional project to be realised. In fact, a training project consists in the building of a system allowing the web surfing through this knowledge in regard of the project’s needs.

As a support of the training action, we are in the process of building a large hypermedia system including all the topics mentioned before which will be used for distance training. This work will now be described.

### Interactive multimedia supports for distance training

The training action discussed here is part of a more general distance training action, dedicated to general multimedia knowledge and competencies. This work relies on the design of interactive supports that can be used in several ways. The paths that will be explored by trainers and teachers is determined by their own needs. The overall project is briefly summarised in this section.

### Design of Interactive supports related to multimedia topics

In order to put into place the distant training plan, various stages have been considered:

- At first, the writing of two books, one bearing the title “Technical basis for the multimedia” [10] and the other one “The management of multimedia projects” [1], have been made as paper class support.
- Secondly, creating hypermedia books is now a major priority. Compared to the paper version, these hypermedia books have two major plus:
  - **Indexing**: it is not difficult to provide a user with several types of indexes for multimedia material. Multiple ways of indexing enables several browsing approaches, according to the various « thematic » interests([2],[8]).
  - A complementary browsing method is provided by an additional linguistic work on the index. A
The former slicing is obviously inspired by the management of an individual degree course. This elaboration will take into account the acquisitions and the objectives of each one. In the end, it comes to the global suggestion of modules and/or to the suggestion of supports to be studied, as well as an evolution within this study.

Moreover, for each of the modules taken into consideration, there will be an allocation of individual tutoring for two hours. This tutoring will allow:

- The correction of the applications and activities offered in this module.
- Regular communication, through e-mail, between the tutor and the learner. This e-mail (with mail and talk facilities relies upon the installation of an access server accessible from the university servers)

Besides the individualised help given to the learners, this e-mail will make the updating of so-constituted knowledge easier. Therefore, the message exchange format will include such elements as:

- The information, by the learner, about the reference of the chapter(s) regarding his question.
- The information, by the tutor, of the general interest “level” of his answer (circumstances or deepening compared to the existing contents).

This information will not only allow the collection of quantitative data, but also, after the validation of the project leader, the putting into place of hypertext links so that the next group of users will have access to this correspondence.

### Conclusion

The action described here is still in progress and the first objective is to set up the distance learning course. During the next academic year availability of learning material will enable us to start an experience with a significant amount (over 30%) of distance interaction. During the 1998-1999 academic year the final version will be completed, with some experimental and evaluation features.

Another direction is to adapt the described method to other contents. Business managers make intensive use of information and they need to acquire information retrieval abilities [9]. We are actually looking for an adaptation of the system described here in order to fulfil these needs.

The Development and Evaluation of the Internet Delivery of the Course "Task Analysis"

Steve Schlough  
University of Wisconsin-Stout

Suwathana Bhuripanyo  
University of Wisconsin-Stout

The course, Task Analysis, is one of the required courses in the Bachelor of Science degree in Vocational Education, the specialization in Training and Human Resource Development, as well as the Master of Science degree in Training and Development at the University of Wisconsin-Stout. The course is offered by the Communication, Education, and Training Department.

Normally, the course is delivered by the instructor to students in the form of lectures in a traditional classroom. In the summer of 1997, the method of delivery was changed from traditional learning to asynchronous learning, using the Internet. This was a means of delivering the course content to meet the needs of a cohort of students who were teachers at the Milwaukee Area Technical College, and enrolled in the Vocational Education undergraduate degree at the University of Wisconsin-Stout. Milwaukee is approximately 265 miles from the UW-Stout campus. Many of the courses for the program had been delivered to the students face-to-face on weekends in Milwaukee, but it was felt that they needed more flexibility to complete the program. The Internet is considered the fastest growing educational phenomenon in the history of the world (Dryli & Kinnaman, 1995). It allows students to learn anywhere, at anytime, as well as to access content at their own pace. Therefore, a WWW-based instruction program on the subject of Task Analysis was developed using the authoring software, ToolBook II Instructor, in order to deliver the content to students enrolled in the Task Analysis course in the summer 1997. In addition to content delivered via the WWW, additional resources were placed on a Lotus Notes Domino server. The course was offered in two separate sections. The first section consisted of UW-Stout undergraduate students who were in the Vocational Education Program and were employed as teachers at the Milwaukee Area Technical College. Students who were pursuing undergraduate and graduate degrees at the University of Wisconsin-Stout were included in the second section.

Literature Review

The literature review for this study (Bhuripanyo, 1997) started out by looking at computer-based training. The section reviewed tracking students responses (Campbell, 1993), students controlling of sequencing (Kearsly, 1983), and the differences between classroom instruction and computer-based learning (Steinberg, 1991).

The next section of the literature review dealt with authoring systems. Yeager (1993) addressed the four areas that an authoring system should handle: presenting information, judging answers, branching, and managing instruction. Hefner (1996) discussed the features of an authoring system and reviewed Authorware, IconAuthor, CBT Express and ToolBook Instructor II. The rest of this section discussed ToolBook Instructor II (Hall, 1997) as it provided a solution to convert authored content to HTML so that it could be accessed over the WWW.

The last section of the literature review examined the use of the WWW in education. Relan and Gillani (1997) addressed different methods in designing instructional strategies using the WWW. Driscoll (1997) provided an in-depth discussion of web-based training and compared web-based employee performance support, asynchronous virtual classroom, and synchronous virtual classroom. Hall (1997) compared the advantages and disadvantages of web based instruction.

The review of 1996 and 1997 studies by Chamlongsupalak laid the foundation for the research design.

Methodology

The research study was designed to assess the effectiveness of a Web-based instruction program in the delivery of task analysis content. The program was partially developed using Asymetrix ToolBook II Instructor software. In evaluating the program, all students enrolled in the Task Analysis class were asked to complete the evaluation forms. The form was used as a research instrument to evaluate the effectiveness of the Web-based instruction program.

The program was presented and delivered on the Internet during a period of eight weeks in the summer of 1997. To inform participants about this research study, the
researcher sent out cover letters along with the evaluation forms on July 15, 1997. Each participant was asked to fill out the evaluation form and return it in the provided envelope by the 30th of July 1997. A total 13 evaluation forms were sent back to the researcher. In order to increase the response rate, follow-up letters and evaluation forms were mailed out to the participants who did not complete the forms in the first mailing timeline. The second timeline allowed participants until the 10th of August 1997 to respond. Nine evaluation forms were completed and returned to the researcher. There were 22 (57.89%) returned evaluation forms from both mailings.

**Findings**

The respondents were asked to rate each of the following statements a 5 point Likert scale with a point range the included: 5 (strongly agree), 4 (agree), 3 (no opinion), 2 (disagree), and 1 (strongly disagree). The mean scores for each statement follow.

Table 1.

In addition to the data gathered through this study, graduate students enrolled in the course performed an analysis of the WWW delivery system. A summary of their discussion follows categorized under the headings: strengths of the course, weaknesses of the course, and recommendations.

**Strengths of the Delivery from Students**

- The delivery provided convenience to the learners both in terms of freedom of time and freedom of space.
- It promoted individual learning yet allowed for group learning activities.
- It allowed learners to process course material at their own speed.
- Opportunity to read classmates' opinions through postings to the Lotus Notes Learning Space CourseRoom. Each posting brought new insight because of the diversity of the students.
- The clarity of the on-line content provided exactly what you needed to know. In classroom experiences the professor often provides more information than what is needed and the student is left wondering what is important and what isn't.
- Using the telephone to discuss projects with the instructor allowed for a sense of connection.

**Weaknesses of the Delivery from Students**

- Required the learner to be self-disciplined.
- The delivery was not appropriate for all learning styles.
- Despite on-line discussion groups and contact from the instructor some students who did not work in pairs or groups felt isolated and the delivery has the potential to be impersonal.
- Although the WWW content portion of the course that was evaluated in the study was considered relatively easy to use, the Lotus Notes Learning Space section was considered to be confusing to some users.

**Student Recommendations**

- Make sure that all participants understand the nature of the course and it's limitations.
- Participants should be encouraged or required to work in small groups.
- Improvements in the Learning Space application suite.
- More in-depth orientation to the course and the software.
- Provide a print version of instruction to software use.
- Set up a chat room so students can dialog in real time.
- Have students find an Internet site relating to the course and report back to the class on it.
- At the end of the course have a face-to-face meeting of the students.
- Have a mid-term meeting or teleconference.
Summary and Recommendations

Based on this study and other evaluations of the course, it was found that this is a viable way to deliver teacher education instruction to students at remote locations. However, there are some concerns in making Internet delivery a viable alternative to classroom delivery. To better understand the study, it is important to look at the students who took the course and served as participants in the study.

The vast majority of the students in this course were employed as full time teachers in the Wisconsin Technical College System (WTCS) and had associate degrees in a technical area and were completing an undergraduate degree to meet WTCS teaching certification requirements. They were not given other alternatives in taking this course. They were asked some questions regarding the assumptions of this study before it was decided to offer the course in this format. All the students indicated that they had sufficient knowledge and skills related to the use of computers and that they had experience using the Internet. This did not prove to be the case. There were some miscommunications on the availability of adequate computers for them to use at their site and misunderstandings about the level of support available. These issues caused the students some problems as they were getting started. Based on these considerations, the findings of the study, and other input, the following conclusions can be drawn and recommendations made regarding the Internet delivery of the course Task Analysis.

Internet delivery of this course and others shows much potential. It is important that students know the nature of the course before enrolling. For some students, it would be possible to enroll and start at any place and anytime if they have adequate computer skills, can work in isolation, deal with ambiguous situations, and are self-motivated. Students were provided with a checklist, relating to these issues for self-evaluation before beginning the course. Even though students responded positively to this list, many expressed a desire for more support as they proceeded through the course. There is a balancing act in trying to provide as much support to the students as possible and yet allowing them freedom of completing the course at their own pace. It appears that a face-to-face orientation session is important to most learners. There was a three-hour orientation session provided to all students enrolled in the Milwaukee cohort, although one hour of this time was spent in registration and other procedural items. There was also an optional orientation session available to students enrolled through the on-campus section.

The first recommendation would be that the course be offered 4 times a year with a one day orientation session. This orientation would be offered at different sites throughout the State of Wisconsin on a rotating basis. The first half of the orientation would familiarize the students with the delivery and the content of the course. During this session the students would be allowed to split into project teams if they wanted to work together. If they chose to work alone, they would be paired up with a "buddy" so they would have someone to contact in addition to the instructor if they had concerns as they progressed through the course. The second part of the orientation would deal with the computer and Internet skills. The students would be provided with hands-on training in using existing on-line instructional packages. This would ensure that they could log on and maneuver through the program. They would also be provided with some background on the Internet and the World Wide Web as some frustrations were caused by not understanding how Internet browsers function and are configured. This computer training also allows for the introduction of more advanced WWW features that allow for better connectivity and submission of projects. A printed guide to the software should be developed as those students who had the most problems with the software were the least comfortable using on-line help. In addition to being partnered with someone in the class for support, each student should have a technical mentor to help them with technology-related problems and a content mentor to provide them with subject-matter related support.

There is a need to include more information in the content section. This would make the course less dependent on print resources. The interface should be evaluated to see if it is as effective as it could be. Although, all complaints on interface design centered on the Lotus Notes Learning Space portion of the course, there may be ways to better integrate the content section of the course with the Course Room and the quizzes. It should be noted that this course was offered shortly after Lotus Notes became WWW enabled and there should be improvements as new versions are released. It would also be possible to use the Notes client software but that was avoided to make the course easily available at more locations.

The idea of mid-term teleconference and end of the course videoconference should be explored. One disadvantage to this is that it would take away some of the flexibility that was offered to the students, as they would all have to complete the course at the same time.

The course should also be marketed to potential students who are more computer proficient. This market would not require the orientation and would allow for more experimentation with a more open-entry open-exit delivery system.

The potential for the Internet delivery of courses should continue to grow as more people have Internet connections and become more proficient in the use of the Internet. It should provide an excellent avenue to provide courses to educators in the field, but probably has less potential for those aspiring to become teachers.

The purpose of this study was to examine the experiences of two university graduate students while taking an on-line course over the Web, in order to identify issues of design, implementation, and motivation from a users' perspective. With the rapid growth and increasing accessibility of the Internet, numerous universities are making on-line telecourses available to students (Barnard, 1997; Kearsley, Lynch, & Wizer, 1995; Stahlke & Nyce, 1996). While researchers are beginning to examine the design and implementation aspects of on-line instruction (Berge, 1997; Couples & Luke, 1996; Eggers & McGonigle, 1996; Pisik, 1997; Trentin, 1997), few studies have documented the experience from an online student's perspective.

Data collection included descriptions of course content, page design and presentation, assignments and tests, communication techniques, schedule of events, and student/student and instructor/student interactions. Experiences were documented through the use of questionnaires, interview data, and student's annotated experiences during the course semester. Issues of course design and delivery, communication restraints, logistical uncertainties, motivational needs of learners, and technical problems will be discussed.

Description of the Course
The on-line course was a graduate class on the methods and techniques of training and development. The course was part of a funded university project in eastern North Carolina in which twenty-five existing university courses would be moved to the Web. The course was the first of its kind offered by the Training and Development program of the university using the Internet as the medium of delivery. The course contributed to the program's philosophy to demonstrate alternative delivery modes while providing students with the opportunity to experience such methods as designer/developer and learner.

Structure of the On-Line Course
Course information was provided through Internet connection via the student's computer. The course incorporated regular interactions between the instructor and students and between students. Major course requirements, expectations, schedule, assignments, and other information were organized through designed web links to individual parts of the course. No on-campus student attendance was required. Communications between student and instructor could occur using e-mail, the discussion group, telephone, fax, and surface mail. Students were also welcome to schedule conferences on campus or via the Internet during the semester.

The basic core of the instruction was organized into ten lessons as listed in an on-line course syllabus. Each Internet lesson included common elements of an introductory narrative, assigned readings from required textbooks, supplementary resources, key point/concept explanations and discussion, applications and examples to support key points, self-evaluations, discussion questions, and assignment/evaluation. Each of the ten lessons had its own web page. Most lesson pages consisted of text and diagrams to illustrate the main points. One lesson included presentation slides. Students printed out each lesson in order to read and study the web page lesson notes as a supplement to textbook readings. Each lesson ranged from approximately 13 to 38 printed pages in length. The purpose of the course was to prepare training and development professionals. By the end of the course, students were to recognize that effective training is based on an understanding of how people learn and differences in types of learning in order to make objective decisions as instructional designers and deliverers of training to result in performance improvement.

Course Requirements
Students were given detailed explanations of several main course requirements. Table 1 presents an abbreviated overview of these requirements.

Assignments and other required course work were submitted to the instructor through a student file. The student file was password protected so that only that student and the instructor could access the file. As students completed an assignment, they moved it to the student file and notified the instructor via an e-mail message. The instructor evaluated each assignment within approximately
three days and placed it back into the student’s file with a grade and evaluation comments. Students were responsible for completing the lessons in order and according to specified and assigned due dates.

Table 1.
Course Requirements.

| Prepare a synthesis paper and describe relevant applications. |
| Prepare a background paper/executive summary and lead a class discussion. |
| Prepare three detailed session and lesson plans. |
| Demonstrate effective group instruction through a videotaped training session. |
| Use an assessment/evaluation instrument to gather data and analyze. |
| Complete a series of concept/principle quizzes. |

Communications and Help

In order to allow group work and class discussion of topics and issues throughout the course, learners were instructed to follow a sequential progression through modules according to a common calendar. Discussions were managed with the Internet software tool, NetForum. Communication was open to all students enrolled in the course, secured by individual student entrance passwords. Each of the lessons required students to give initial responses to two discussion questions of the students’ choice from a given list. Students could answer additional questions and respond to other students’ answers.

“Extended class discussion” was facilitated for students to ask additional questions about the lesson or to make comments about their individual learning experiences related to a given topic. Any information placed on NetForum could be read by all students and the instructor. If students wished to communicate only with certain individuals in the class, they were directed to use individual e-mail addresses provided by a link from the home page.

In terms of technical help, students were to review hardware requirements and Internet procedures that were developed by the university. Special links were provided for technical assistance needs. Course information and assistance was provided through the instructor’s e-mail.

Schedule

Students were presented with a set of “ideal” completion dates for beginning each lesson. Students were allowed to complete assignments and activities earlier if they chose, although initially only three lessons were on-line, with subsequent lessons added each week as the semester progressed. Table 2 contains the basic course schedule.

Students were advised that the tenth of December was the last date for completing and submitting materials. The instructor forewarned that “extensions for completing course requirements beyond the ending date are seldom granted and only for unanticipated circumstances beyond the control of the student.”

</tbody>
</table>

Evaluation

Each requirement was evaluated by the instructor based upon the criteria for individual assignments. Each requirement received a point total and grade; however, only the point total was recorded by the instructor. Grades on each requirement only reflected the relative position of the student in relationship to other students in the class based upon total performance on the particular requirement. Points were accumulated during the semester to determine the students’ final point total for all activities. The total at the end of the semester was analyzed based on the percentage of total points possible and the range and frequency of scores of all students.

The listed set of percentage points for each requirement is shown in the table below.

Table 3.
Evaluation.

<table>
<thead>
<tr>
<th>Description</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synthesis Paper</td>
<td>20%</td>
</tr>

<td>Assessment/Evaluation report</td>
<td>5%</td>
</tr>
<tr>
<td>Concept quizzes</td>
<td>15%</td>
</tr>
</tbody>
</table>

In addition to the total percentages, the quality of class participation beyond the completion of the identified requirements could influence the students’ final grade by plus (+) or minus (-) 5 percent.
Student Experiences

Subjects
The two students who participated in this study were graduate students working toward doctoral degrees in instructional technology at the same university. Both students were familiar with the use of computers and the Internet. Both students were taking the course from a city approximately 180 miles from the university campus using IBM-compatible computers. The two students both held full-time jobs in the same city, teaching courses involving the uses and applications of technology to preserve teacher education students and providing technical support in computer hardware and software. Both students had to commute between their jobs, homes, and to other classes at the university offering the on-line course.

One student commented near the end of the semester about how a course such as this should be developed specifically for non-traditional students, reflecting upon how this on-line version of the course was or should be different from the version taught in the classroom. This student had a student colleague who was taking the regular in-class version of the same course during the current semester. This traditional student related that even the in-class version of the course required a great deal of effort in order to keep up with the amount of required readings and outside assignments. The on-line student felt that anyone taking a course from a distance would likely be someone in a situation that made it difficult to travel to the university campus to meet in a classroom every week. Many of these students would not be able to attend the university as a full-time student due to a variety of constraints such as family, work, and relocation or commuting costs. This student raised the question as to whether an on-line course such as this should contain the same workload as a course that met face-to-face in a classroom each week, suggesting that the course should build in less workload to compensate for the extra time involved in students’ managing their own instructional time and being totally responsible for the pace and synthesis of the presented topics.

On-Line Communications
When asked about the discussion groups that occurred on-line using NetForum, both students agreed that discussion among students was beneficial. Both students answered the required minimum two questions and participated in comments about other students’ answers. At one point during the semester, a student at another site had a continued debate with one of the subjects concerning a topic. All students could read all other student responses. Positive aspects of this type of discussion was identified by the two subjects as (1) being able to read other students’ answers and comments and (2) having time to reflect upon what was being said before reacting or responding. Further, (3) posting of answers and comments provided a record that allowed for more open pacing and review of topics. Students could return to discussion items at any time to review previous discussions and reflect further. Students also were allowed to read other students’ research papers as they were entered on-line by the instructor and became part of the content of the course.

The downside of using discussion groups via NetForum was that it did not provide real time communication. This took away any “normal” spontaneity that having face-to-face discussions would allow, adding to a feeling of separation in time and a lack of visual contact. One subject remarked that he felt that there was an artificial politeness in the written interactions of students. Students’ being overly polite or diplomatic, combined with the delay in communicating via the electronic written word, resulted in a loss of typical class dynamics including immediate emotional responses on various discussion topics. There was no way to react to a comment as one would do if one placed in a regular classroom with other students present and with real time communication.

The students did comment that in general the communication with the instructor was good, predominantly utilizing e-mail communications and telephone calls. The instructor provided an excellent turnaround rate of responses to students’ questions and concerns. Of course, even with such a good response time, the logistics of communication did not allow immediate turnaround, which meant that students would have a lag time delay before getting answers or help to their questions. One student commented that he did get to meet the instructor in person on campus about three weeks before the semester ended. This meeting seemed to make the instructor more personable to that student.

Motivation and Self-Discipline
A major problem that seemed to effect all students taking the course was in individual pacing and a continual effort to keep up with the schedule. Initially students remained on-track with the “ideal” completion dates scheduled for requirements. However, as early as late September, both students began to find the multiple tasks required by the course to be daunting. One student said that in order to discipline himself, he would formally sit down at the same scheduled time of the class each week, even though he would not be required to participate on-line at a given time. The other student divided his time between sometimes meeting with the other student at the class time and completing on-line work from home. After the completion of the first paper (requirement 1), both students began to get progressively more behind.

By the end of November, all students in the course appeared to be several weeks behind schedule. One student was very stressed-out by the fact that there were only two weeks left in the semester, yet the students in the class were only “halfway through” the assignments and requirements.
While the instructor was cognizant of the problem and would send students reminders about the remaining requirements and time constraints, the instructor did remain firm to the amount required and the original timeline. The two subjects were forced to scramble during these last two weeks to complete all the requirements before the December tenth deadline. This period also involved each student's making a videotape of himself or herself teaching a lesson. These tapes were then sent to the instructor via surface mail. Viewing the videotape was the only opportunity the students had to allow the instructor to gain a visual impression of their presentation skills.

One student thought that the most difficult part of keeping up with the course requirements lied in the fact that all the information for the course was in the form of text and graphics that had to be read and studied individually by each student. In a typical classroom setting, instruction can be varied to include presentations by the instructor, vocal discussions between students, visual cues and stimuli to vary the instructional presentation pace and gain attention to more important aspects of the topics, and the dynamics of real time delivery. The fact that these on-line students had to read lengthy assignments in the textbook, at other websites, and then print and read an thirteen to thirty-eight page set of review and summary notes and submit discussion questions on each lesson required an inordinate amount of time. This was on top of writing research papers and other more “traditional” assignments of a graduate course. The time spent reading and synthesizing these different sources of information vastly out-shadowed the amount of time that would be spent if the instructor was able to present and summarize the information in a regular classroom setting. When the instructional delivery was combined with the other assignments of responding to the questions and other students’ responses, writing research papers, making a videotape of one’s teaching, writing lesson plans, and taking quizzes, the students felt overloaded and over-whelmed.

One student in particular felt that his learning style was such that he needed more visual and auditory stimuli, rather than just “read, read, read.” This student missed the dynamic interaction of being in front of the instructor and with other students. Even the informal discussions that naturally occur outside of class among students was unavailable due to the more “formal” communication of writing over e-mail and in NetForum discussions.

The quizzes that the students were required to complete were e-mailed to them. Each student was on an honor-system trust to complete the exam in one hour without using any notes or other resources. When the test was completed, the students would return the quizzes to the instructor as an attachment to e-mail. One student felt that because there was the problem of taking the exam under such a trust, one should not do “too well” on the exam or the instructor might assume that that student had used notes or had taken longer than the allotted time frame to answer the questions (i.e., cheated). Thus students felt that doing well on the exam would become suspect due to the circumstances of the administration of the test. This created unnecessary test performance anxiety.

Technical Problems

Given that this was the first administration of such an on-line course at the university, there was great potential for problems to occur. At least twice while the two subjects were on-line, the university’s server went down. This occurred while the students were entering their responses to the NetForum discussion questions. Students then lost all the information that they had entered and had to begin again after the server was back up. The effect was multiplied when considering the number of total students on-line and the multiple comments and interactions that were lost as well. Presumably one’s initial responses and comments to another’s answer would lose intellectual spontaneity and focus if at first lost and then subsequently re-thought.

Conclusions

Results of this study indicate ways designers designing a web course, instructors teaching a web-based course, and students taking a course online can employ instructional strategies to insure the greatest probability of success. The participation in a web-delivered university course was the first experience in taking a course on-line for the two subjects of the study. From their resulting experiences, the following recommendations can be made for designers of web-instruction, consistent with current research in web-design considerations:

1. Provide a detailed schedule timeline, but provide external cues and imposed deadlines to help students stay on-track.
2. Obtain data and evaluate student reactions to the course throughout the semester to gain insight into the amount of load a student must handle at any given time. Instructors should use such data to revise and adjust course load and simultaneous assignments and readings as necessary to maximize student success.
3. Provide adequate technical support for the instructor and students. Any down time during such a course has major implications for the students and instructor and will influence the outcome of the course.
4. Provide a variety of presentation formats. Include a variety of media such as video, graphics, sound, and other cues to gain and maintain student attention and continuing motivation. Provide visual impressions of the instructor and other students if possible.

DISTANCE EDUCATION BY DISTANCE EDUCATION: PUTTING THEORY TO PRACTICE IN A GRADUATE EDUCATIONAL TELECOMMUNICATIONS COURSE

Harriet G. Taylor
Louisiana State University

Graduate students in a telecommunications in education class participated in a collaborative project in which they implemented and practiced the curricular models that they studied during the course. The students used distance education to support learning about the field of distance education. They used the Web and other media for background information and visited distance education centers. To provide in-depth insights on the topic, they participated in e-mail exchanges with on-line experts, each representing a different model of distance education. The students created a unique Web site which contains not only the information gathered from the experts but links to Web pages that are good general resources on the topic of distance education.

This experience allowed the educators to become immersed in a study as a group and to develop their own models of collaborative learning supported by telecommunications. Many of the educators themselves had directed their students in such activities, but rarely had they participated in such a project. The project confirmed for the educators the value of such shared experiences and the richness and depth of learning that can occur. They also witnessed the motivational value of a real project with a real audience and the complexities of working as a team. The project clearly illustrated to them the value of distance education both as a vehicle for education and as a field of study.

Related Research

As computers and communications networks have become more common in K-12 schools, a great deal of research has been done on uses and effectiveness of electronic discussions within educational settings. From a teacher education perspective, these often focus on two populations, pre-service teachers practicing in the field or in-service teachers who are geographically distant.

Numerous studies (Hoover, 1994; O'Neill & Coe, 1996; Russett, 1995) have illustrated the value of e-mail based communications involving pre-service teachers. The models include journal writing, mentoring on decision making, and simple social interaction with peers for support. Typical benefits included enhancements in reflective practice and decision making and reduction of feelings of isolation.

Discussion lists and listservs (Anderson & Perry, 1995; Espinoza & McKinzie, 1994) on which participants post e-mail messages to targeted groups of subscribers have also been effective educational tools. Discussions often include pre-service teachers, in-service teachers, and education faculty (Anderson & Perry, 1995). Espinoza & McKinzie (1994) set up discussion lists for graduate students to confer on issue of mutual concern.

Many studies point to common benefits of instructional activities involving electronic mail exchanges in teacher education. Among these are more active participation by students (Wolffe & McMullen, 1995), students taking responsibility for their learning, greater equity of participation (Wizer & Beck, 1996), decreasing feelings of isolation (Casey & Vogt, 1994), building of virtual communities for support and collaboration (Casey & Vogt, 1994; Hoover, 1994), and internalization of the methods into teaching practice.

Participants

The participants in this project were all graduate students in a telecommunications in education course. A prerequisite for the course was a prior technology course or equivalent experience. Therefore, the participants were not novice technology users. There was a wide range of experiences and competency levels in the group, particularly prior experience using telecommunications. The students were typically enrolled in graduate programs in curriculum and instruction or administration or were classroom teachers wanting to learn more about telecommunications.
Course Content

The course included many of the standard instructional activities associated with a dedicated educational telecommunications class. Activities included use of electronic mail, Web searching and research, Web page design and development, Web page evaluation, curricular uses of telecommunications, and exploration of emerging technologies. These topics were taught from a constructivist point of view, using student projects as the focus of class time and the class develops a Web site to display their work (Webcom Project, 1997).

To reinforce many of the curricular concepts of the course, the instructor "taught" the topic of distance education by using the on-line and collaborative techniques the students had studied. The project, Distance Education by Distance Education, provided real experiences that engaged the students in self-directed and collaborative learning and assisted them in clearly differentiating the domains of educational telecommunications and distance education.

Distance Ed By Distance Ed Project

Project Goals

The Distance Education by Distance Education Project had the following goals and outcomes for students:

1. Differentiate distance education and telecommunications as disciplines
2. Identify ways in which telecommunications is used to support distance education
3. Use curricular models found in K-12 schools
4. Practice collaboration and group processes
5. Examine a variety of resources and media
6. Apply on-line strategies to an authentic learning task.

Project Preparation

The preparation for the project included conducting readiness activities for the education students, developing project design and planning materials, locating on-line experts for the group, and locating relevant resources as starting points for the study. The project activities took place during the last six weeks of the course as a culminating experience to reinforce many of the principles and methodologies discussed and evaluated earlier in the semester.

The class component of the project began with a group discussion of the term "distance education" and what it meant to each of the students. This evoked a variety of first, second, and third generation distance education models (Jones, 1996) in which the students had participated.

To prepare for a deeper investigation, students were assigned readings (Hirumi, 1996; Jones, 1995; Jones, 1996; Sherry, 1995) which provided excellent summaries of the evolution of distance education. They were directed to explore selected Web sites (Distance Ed, 1997) that provided good overviews of the field. They were given a broad description of possible project activities and asked to prepare to collaborate on the project in one week.

Project Activities

During the project, the graduate education students participated in a range of activities to support their study of distance education. These included class field trips, group discussions, practical experiments, simple video conferencing, on-line searching, and e-mail exchanges with experts.

A considerable portion of each class during these weeks was allocated to the distance education project. The class visited the new campus distance education facility and engaged in discussions with the Distance Education Coordinator. They experimented with video conferencing. They conducted on-line research and shared results. They also decided as a group to develop a Web site to reflect their learning in this project.

One of the more interesting experiences happened quite early during the project. The students were instructed to locate on-line professional development opportunities appropriate for themselves. By this point in the term, the students fancied themselves as experts in Web searching. They used sophisticated searching techniques often involving elaborate refinements. During the discussion of the resources they located, it became clear that one method had yielded far better results in terms of quantity and usefulness than any other. The student who had been the most successful had simply followed the already-compiled indices of a popular Web search engine to a list of sites. Thus, sometimes the simplest and most obvious approach is quite adequate even for Web research.

Expert Mentors

The graduate students had studied projects in which children engaged in on-line discussions with others about topics of mutual concern, including most of the models of on-line interpersonal exchanges identified by Harris (1995, p. 130). They had located sites for soliciting pen pals and collaborators for students and teachers. To underscore the positive effects that this type of experience can have on learning and motivation, the professor arranged an electronic exchange for the graduate students.

The professor contacted colleagues around the world and asked them to serve as on-line experts for the students. Each of these individuals was involved in a different type of distance education activity or unit. They included a professor at The Open University in the UK (The Open U., 1997; Thomas, 1996) which serves a student population of over 200,000 students totally by distance, the director of a regional service center which offered television courses by satellite to secondary students across the United States (Contreras, 1993; TI-IN, 1997), a computer science professor teaching a course to multiple campuses using com-
pressed video, an Australian instructor using a variety of
distance education methods with teachers, a professor in an
educational technology doctorate program that included a
significant on-line component, and an educational
technology doctoral student participating in on-line
courses.

Ground rules were set to limit the amount of time each
of these busy people was asked to contribute. The dialogue
was limited to three exchanges, with students posing a
maximum of four specific questions on each exchange.
Each expert was asked to reply to the students within one
week of the receipt of a message.

The professor matched the students to the mentors,
based on the students’ backgrounds and professional
interests. Each student was given a sheet with contact
information and background information for the mentor as
well as links to Web pages put out by the institution or
entity connected to the mentor and recent research
published by the experts describing their activities. They were
directed to start by studying these resources and seeing
what they could learn from the information at hand before
developing interview questions for the experts.

The students discussed their mentors and findings and
collaboratively identified topics to focus on with each
expert. Each week, the students discussed results and
determined where to head next. The major topics of interest
included student populations served, recruitment of
students, comparison to traditional teaching methods,
assessment procedures, charges for the courses, hardware
requirements for the students, certification and accredita-
tion issues, materials and class preparation by the instruc-
tors, time demands on instructors, and overall appraisal of
the distance education experience.

Representations of Learning

Since this project was a component of a real course,
some structure had to be established for assessment and
documentation of participation. Simple documentation
was done in two ways, observation of the contributions by
each student to the weekly discussions and summaries by
individual students on the progress and nature of their on-
line exchanges.

The professor considered the dilemma of capturing the
dialogue precisely for research analysis and participation
verification versus the freedom of allowing personal
discussion that is not monitored. Since the participants in
this project were all adults, there were other issues about the
privacy of their exchanges and the appropriateness of
requiring copies of all messages. The decision was modify
the practice used by Broholm and Aust (94) and have the
students create personal journals or summaries of their
discussions rather than copy the actual messages to the
professor.

The students were charged with designing more
meaningful, in-depth representations of their learning as
individuals and as a group. Their initial ideas included
holding international video conferences or creating
volumes of printed matter. The final decision was a more
moderate form, a Web site (Salcedo, 1997) which could be
shared and serve as a resource to others in the future.

The Distance Education by Distance Education Web
site (Salcedo, 1997) was designed and constructed by the
students, with the students organizing themselves into
working teams to develop the site. It includes individual
contributions by the student on the interactions with their
mentors, group overview and findings sections, and links to
other resources. Since this was a course component, the
Web site development also had to be completed within the
timeframe of the course. The site (Salcedo, 1997) went on-
line seven weeks from the date of the beginning of the
project.

Professor in the Background

The professor acted as a facilitator of the project as well
as a learner herself. She provided the initial vision and
structure of the project and a set of foundational resources.
She also served as the liaison between the students and the
mentors, maintaining contact with both groups electroni-
cally to monitor progress and address problems. She
rearranged the traditional course structure to include group
collaboration and discussion time weekly and provided a
framework or stimulus for the discussion each week. She
served as a resource and mentor as needed and as an
enforcer when necessary for the group to meet schedules.
Her main contribution, however, was to stay in the back-
ground and watch with delight as the students took
ownership of the project.

Results

The project and its experiences allowed the graduate
education students to become immersed in study as a group
and to internalize their own models of collaborative
learning supported by telecommunications. It easily
attained the baseline goals of differentiation of distance
education and telecommunications, practical application of
K-12 curricular models, practical experience with collabo-
ration and group processes, examination of a variety of
resources and media, and application of on-line strategies to
authentic tasks.

The project allowed the professor to transmit or
illustrate concepts and principles that are often difficult to
fully explore or appreciate using traditional teaching
methods. The students gained an enormous amount of
insight into project management from the model of the
professor and their experiences in managing their project.
They saw first-hand the motivational benefits of active
learning that has a real purpose. They also experienced the
joys and frustrations of a telecommunications project as
they encountered many of the normal problems that are associated with such projects. For example, the network went down during times planned for on-line activities, Web sites appeared and disappeared, and mentors responded at different rates.

The project also supported the findings of Wizer and Beck (96) and others of greater equity of participation. The graduate student population in this study included two students who were not native speakers. This project gave them an active role and provided direction for their discussion. It also allowed them to communicate on-line at their own speed and illustrate in written form their distinct way of communicating. It connected them to the group and let them share their unique perspective on the topic.

As in other studies (Casey & Vogt, 1994; Hoover, 1994), a camaraderie and support system developed among the students in the course. They continue to support each other in a variety of ways and actively collaborate on curricular projects. One student’s project has turned into a major community project (Anderson, 1997b) with students at schools around the city adding educational resources and research to the Web page of a local historical site (Anderson, 1997a).

The project also suffered some of the persistent problems which have been noted in other studies involving on-line educational practices. Those not regularly on campus experienced difficulty with access from their schools and access to facilities at times convenient for them (Broholm & Aust, 1994; Casey & Vogt, 1994; Wolfe & McMullen, 1995). Likewise, equipment problems, technical support, and network down time (Broholm & Aust, 1994; Davis, 1995; O’Neill & Coe, 1996) also proved frustrating for the graduate students.

Issues

While the project was an overwhelming success by most measures, several issues emerged that need further investigation.

1. The role of the professor. Do the K-12 models of facilitator/guide work in graduate education? How should they be modified to reflect the maturity and academic level of the students? How can the professor become a learner in the process as well? What are the additional time demands on professors for facilitating such projects, maintaining regular e-mail contact with many students, providing on-going support and feedback on student progress, and preparing project materials and structures? How are these accounted for in terms of academic workload and evaluation?

2. Location of experts/mentors for graduate students. While there are numerous sites for locating K-12 collaborators, those directing university level on-line interpersonal communication projects have needed to be more creative in locating appropriate experts and on-line collaborators. It is not reasonable to rely on personal colleagues to support such projects. It may be that university faculty need to use methods such as solicitation from specialized listservs, collaborating with distant colleagues to find compatible groups, as well as developing Web sites for recruiting collaborators at the university level.

3. Maintenance of confidentiality/privacy of mentors. What methods need to be used to insure confidentiality of mentors as well as to insulate them from further solicitation by others? How does one illustrate the validity of the research and expert contributions without publicly exposing direct information about the experts? Is this problem more serious in an on-line study involving a widely available Web site than it would be if the final product were a printed article?

4. Modifications based on class size. Since the class involved in this project was relatively small, it was not difficult to arrange for a mentor for each student. What models should be used if classes are larger or if only a few experts are available? Should the entire group concentrate on one project or should there be several projects? How are students grouped and organized for projects? Can this approach be modified for any class or are there practical limits to the class size?

5. Network access outside class. Technical problems and access to network resources are still major barriers in on-line projects. Is it fair to assign projects that require that students have or find regular access? How do you handle or prepare for network difficulties when classes are planned around on-line activity?

6. Appropriateness of the experience for graduate students. Is this type of project appropriate and reasonable for a graduate class? How much class time should be allocated versus outside time? Should graduate credit be given for courses with such practical components? The course and its projects clearly tested the bounds that many have set for graduate scholarship.

7. Permanence/maintenance of Web site. How long should this Web site and others created by students be kept on-line? Who should maintain them? Who owns or should control this intellectual property? Is it acceptable for future students to extend the academic product started by others?

Conclusions

The Distance Education by Distance Education project was an excellent vehicle for graduate study and for providing students with an insight into the practical impact of using technology to support instruction. The basic model works well in a graduate setting and can be replicated or modified easily with similar results. Electronic message sharing is a technology that is not new but is still a
fundamentally sound and exciting way to use technology to support learning.

Through expert mentors and on-line resources, the graduate students in this project were able to explore their research topic in ways not possible if limited to traditional methods using materials at hand on campus. They became excited about learning and learning together. They took responsibility for their learning and continue to seek more learning opportunities, courses, and challenges.

TEACHING AND LEARNING ONLINE: TOOLS, TEMPLATES, AND TRAINING

Bob Hoffman  
San Diego State University

Donn Ritchie  
San Diego State University

The 22-campus California State University (CSU) system recently sponsored an on-line faculty development institute to help college instructors learn how to create pedagogically sound on-line instruction. The workshop is now available to interested faculty and institutions throughout the world. This paper describes the genesis of the online workshop, describes the underlying instructional principles, presents an overview of the workshop modules, and reviews the lessons learned from the project.

How the Online Workshop Came About

Higher education faculty are content experts. Most were not hired for their teaching ability or teaching experience. Few were screened for their computer skills, and it's probably safe to say, almost no search committees include web development skills in their criteria. Once on campus, faculty are busy teaching, researching, and performing community service. Those with the inclination to develop web-based courses almost certainly don't have the time to do so, particularly if they are young, enthusiastic, and untenured. That a few faculty do develop web-based material is remarkable, but their exceptional successes prove the rule.

As educational technologists, we were interested in providing an environment in which faculty can continue to be what they are—content experts, with perhaps a feel for and, ideally, some experience in teaching. That meant providing significant support both for developing sound pedagogy and for the technical aspects of web development. To try to meet these requirements we decided to put together a suite of templates that reflected both “best practices” from an instructional design perspective and simplicity and robustness from a technical standpoint.

Underlying Design Principles

Toward this end, the workshop was designed to foster immediate success and encourage incremental development of online course materials. Faculty could begin with just a page or two, work up to a course module, and eventually understand the scope of effort necessary to scale their online modules to a full online course. The workshop facilitated faculty as they developed online course modules by providing templates to help create a course “marketing” page and instructor home page, then moving on to course pages such as a schedule and information page, and finally creating an instructional module using both innovative and traditional instructional strategies.

Distance Education — 113
eyes for a moment, and notice what you “see” when you think of a course you teach regularly. Did you “see” a kind of abstract diagram with a bubble or “chunk” for each week or each class session? Did you “see” your syllabus? Did you “see” the room in which you last taught the course, along with the students and the entire classroom environment? Did you “see” yourself talking with a series of students who have taken the course in the past?

Whatever you “saw” when you thought of your course is probably closely related to what we mean by your “mental model” for that course. It’s what helps you organize the course in your head. Students, too, have mental models of their courses. They may be related to the materials, such as texts used in a course; to the physical space, such as a classroom, they associate with the course; to the other people involved in the course; or perhaps to timelines of assignments or coming due or the course meeting schedule.

These mental models are what help both instructors and students organize their experience of the course. A clear mental model will presumably help instructors create clearer courses and help students organize their course work more effectively. In any case, we realized that students taking online courses have mental models as well. We hypothesized that by creating a clear course structure, we could facilitate students generating a clear mental model of the course, in turn helping them succeed. We further reasoned that if the course structure reflected the course pedagogy, or instructional design, it would further help both instructors and students think clearly and usefully about the course.

**An Overview of the Workshop**

To this end we devised a course design based on a simple pedagogical model. We designed each module in our online workshop around this five-step model, which we call the “I CARE” system. I CARE stands for “Introduction, Connect, Apply Reflect, and Extend.” I CARE is distilled from basic instructional design practice, adapting various systems or “steps of instruction” to what seemed to us to be particularly useful components for an online course.

Synchronous, face-to-face courses usually entail regularly scheduled meetings, and course syllabi are typically organized around that schedule. Since many online courses tend to have a strong asynchronous component, or even be entirely asynchronous, we divided our course into “modules” or “sessions” rather than “weeks” or “dates.” This recognized learners’ prerogative to organize their course time around work, family, and other commitments, while maintaining a modular structure of “do-able chunks” arranged in a progressive series.

Each module, in turn, represented a pedagogically complete “lesson” that can be completed in roughly the equivalent of the time a student would devote to a face-to-face class session and corresponding out-of-class work. Thus, in our online workshop, each module or session was implemented using the I CARE system. Each of these sections are designed to enhance students’ learning opportunities.

**Introduction**

The introductory section serves to place the present module in the context of the course as a whole, and enliven learner’s prior knowledge with regard to the content that is about to be presented. This section should include clearly stated objectives for the module so that learners know exactly what they are supposed to be “getting” from the module. The introduction may also provide motivational elements, such as a scenario that poses a familiar or relevant problem for learners that may be used in subsequent sections as well.

**Connect**

The connect section is primarily for presenting new information in context. It may consist of online text with appropriate visualizations, such as charts, diagrams, illustrations, visual analogies, and other media elements such as sound or appropriate virtual environments. Alternatively, it may consist primarily of instructions to read offline text material, view a videotape, or listen to a sound recording. The connect section should be designed to help learners organize the new material in the context of what they already know, and prepare them to apply this information in the next section.

**Apply**

This is the practice section of the module. It might involve writing a short paper or a section of a longer work. It could involve a hands-on project such as classifying rock samples (virtual or actual), analyzing earthquake patterns, or developing a web page. It might be an individual or small group project, or involve students interviewing local subjects or subject matter experts. You might implement the apply section using a WebQuest (Dodge, 1997), a prompted writing tool, an interactive online experiment, or simply provide instructions for an offline activity you wish students to complete. Students might create a concept map or draft a plan. In short, any activity that gives learners a chance to try out their new information in an appropriate context is fair game.

**Reflect**

Often the least valued—and frequently one of the most needed—stages in a pedagogically sound lesson is to give students an opportunity to reflect on their newly acquired skills and knowledge. This might take the form of a thoughtful response to a carefully crafted question from the instructor, or a peer exchange about lessons learned, insights gained, and so forth. It might be implemented through an online chat or a more deliberative online forum. You might ask learners to keep an electronic journal to submit or use in a later assignment.
Extend

Like the introduction, the extend section has many possible functions. It can provide closure, prompt further exploration and learning, assess students’ skills and knowledge, give students an opportunity to evaluate the course itself, or all of the above. This is a good place to provide references or resources “for further information” or for advanced work on the topic.

The T3 online workshop describes the I CARE system, models it for workshop participants, and provides other examples of I CARE and other pedagogically sound systems for organizing online learning. The workshop consists of a five-module on-line course featuring:

2. Document preparation for on-line courses: Using specially designed templates for helping professors quickly and easily mount course-related web sites. The I CARE (Introduction, Connect, Apply, Reflect, Extend) system. Using HTML editors; preparing graphics and media files. Converting existing text (word processing) files for delivery via the world wide web.

3. On-line student learning activities: Organizing selected course content around on-line learning activities. Best practices in on-line learning. Creating activities that are easy to implement and maintain. Questing the web in search of content, activities and other resources.

5. Management of on-line course resources: Developing and maintaining course-related on-line publications and activities. Strategies for increasing personal productivity as an author and manager of on-line course resources. Developing a plan for gradual improvement of on-line course-related content and activities. Identifying local campus support for web-based publishing.

This approach is applicable to the development of on-line courses in all disciplines, but is particularly suited to teacher training and school leadership development courses because it models sound teaching and learning practices. In addition to the original 40 or so CSU faculty who developed course modules as part of their participation in the Faculty Development Institute, we have received requests from a number of individual faculty and faculty development coordinators at a variety of universities throughout the country who are interested in using the online workshop on a personal or institutional basis. The course is free, entirely asynchronous, and will be maintained indefinitely on SDSU’s web servers.

The T3 online workshop is located at http://clipt.sdsu.edu and click on “T3.”

In addition to the many examples by workshop participants (click on “People” in the T3 menu bar), several examples of entire courses developed using the T3 approach are also available for scrutiny.

One such example is the course “Technology for School Leaders” that provides K-12 principals, technology coordinators, and lead teachers with the “big picture” of school technology integration (pro and con). It helps them “speak the language,” assess their schools’ specific technology needs, and plan for effective classroom implementation. The course may be viewed at edweb.sdsu.edu/courses/edtec596r/index.html.

Lessons Learned

We understood from the beginning that a team approach to online course development would be useful. Our experience developing and implementing the online workshop underlined that idea again and again.

During the development phase, for instance, we benefited greatly from the collaboration of a team of three faculty and four graduate students. The faculty were able to help generate, review, and revise another’s work. The graduate students helped draft modules, implement web page layouts and visuals, and provide technical support for tasks like web page-database interactions.

On the workshop participant side, our intention was to foster strong campus development teams by training and supporting strong lead faculty and staff on each campus, who in turn would coach and support additional faculty. To this end we attempted to screen prospective lead faculty and staff for their past experience with online course development or related tasks. On some campuses, however, adequately experienced volunteers were not forthcoming, and we “settled” for less skilled, albeit highly enthusiastic, substitutes. This resulted in mixed success for the initial workshop. On the majority of campuses, where lead faculty were both proactive with respect to their leadership role and already had at least a modicum of experience in web development, the workshop flourished and faculty participants raved. On a few campuses, where lead faculty themselves were floundering in technical problems or failed to provide leadership for the other faculty, the workshop fizzled. We concluded that, while the idea of screening onsite leadership is sound, the implementation, including followup support, is crucial and should not be compromised.

This and other evidence also led us to conclude that we had been over-confident about faculty ability to author online courses. As noted above, we aimed the course at faculty with little or no web development experience (with the exception of lead faculty), which describes most of the
faculty in our institutions of higher education. We hypothesized that by providing easy-to-use tools (such as Claris HomePage for web page authoring), instructionally sound templates for courses and course modules, and training consisting of the online workshop itself with coaching from lead faculty and staff on each campus, that faculty could successfully author good quality online courses.

This proved only partially true. While many participants raved about the I CARE system and the workshop as a whole, others reported occasional to chronic frustration. The experience of one participant is instructive. A history professor who joined our workshop was an outstanding teacher who had participated in experimental two-way interactive video courses in past semesters. He was enthusiastic about putting parts of his course online and plunged into the T3 workshop with characteristic energy.

Despite his background as an instructor with a proven track record teaching with technology, his computer got the best of him. In the context of his interactive video course, the technology was handled by a team of video production experts. He had only to adapt his teaching style to the constraints and affordances of the technology. In our workshop, he was asked to actually handle the technology himself. He did not give up easily. He solicited and received the support of his campus T3 staff person, who visited him in his office and tried to help him work out the technical problems he was experiencing. Nevertheless, the technical problems did not go away. Eventually he threw in the towel and reluctantly resigned from the workshop, explaining that he had come to the realization that he would need to spend an inordinate amount of time simply getting his computer system up and running in a useful way, and that he was, rightfully, unwilling to commit that time in addition to the time it would take to participate in the course as well. While this was an extreme case, it is probably familiar at least in kind to anyone who has attempted this type of development.

This and other participants' experiences led us to reformulate our thinking about how best to foster online course development in higher education. We realized that most faculty not only don't have the requisite instructional, media development, and technical skills to single-handedly author online courses, but that they are unlikely to develop those skills to any significant degree through a workshop such as ours. The overall success of the T3 workshop was probably more a result of self-selection by faculty who were already sufficiently "technology-ready" and able to either provide or seek out adequate technical support. They probably represent a minority of current faculty, and that demographic seems unlikely to change significantly in the near future. Moreover, it is probably not useful to expect most faculty who are not at a level of technological sophistication to author online courses by themselves. Like our history professor, it is probably too time-consuming, and perhaps in some cases altogether impossible, to acquire those skills lacking the requisite aptitude. The solution to this problem seems to be the return to the team approach as described in the beginning of this report, but with an even greater emphasis and support.

In addition to the team approach, there appear to be four additional skill sets required for successful online course development. The first is expert content knowledge as provided by a faculty member. Content expertise is what they were trained to do by their degrees, hired to do by their peers, and regularly assessed for with respect to promotion and tenure. That said, we would suggest that even here there is much to recommend a team approach. With several faculty on a development team, there is more opportunity for quality assurance through collaborative generation and peer review of both content and pedagogical strategies. Since online and other distributed learning courses will potentially be seen by many more students than a similar face-to-face course, with the correlate that the institution as a whole will be judged to a greater degree on the overall merits of these course "products," it seems worth the extra effort and expense to ensure only high quality offerings in the online arena, particularly with respect to content.

The second skill set, instructional design, is a little more ambiguous. While usually untrained in teaching, many faculty have nonetheless become good or even great teachers, and others are willing and able to learn to become good pedagogists, particularly in the context of systematic development of online courses which does not rely heavily on personal characteristics such as charisma or "presence." But in cases where faculty may not have sufficient experience or interest in pedagogy (or time to devote to it), the course development team should include a professional instructional designer. Instructional designers are trained to work with content experts, media developers, and technicians to develop instructional programs or products, and are often skilled in project management as well.

The generation of media products is the third skill set. Online courses depend almost exclusively on media products, be they books, web pages, videotapes, or CD-ROMs. Neither faculty nor, for the most part, instructional designers, are trained in media production methods such as graphics, video, and multimedia development. These require competent artists, video production personnel and multimedia developers. This may be a team of 30 to 40 people at one extreme (as is the case in British Open University development teams, for example), or merely a skilled graduate student or two. In either case, these individuals are typically not trained in instructional graphic, video, and multimedia development, and need to work together with faculty and instructional designers to create effective online courses.

The fourth skill set emerges out of the present state of online course development, which is characterized by an
expanding tool set of primarily computer-based technologies. What was once limited to inserting a few strategic HTML tags has become a rather staggering array of far more complex technologies, such as Java and JavaScript, Shockwave movies and their requisite "plug-ins," CGIs, forms, web page-database interactions, frames, layers, image maps, archived and real-time streaming audio and video, and much more. While these technologies offer useful strategies for online teaching and learning, the sheer number and complexity of these new tools leave most of us gasping for air. Serious online course development efforts must include dedicated technical support staff to set up and maintain servers, load and maintain software, and to consult on bandwidth and compatibility issues.

These four "skill sets" (content expertise, instructional design, media production, and technical support) seem to be the basic components of effective online course development teams.

Another lesson learned from developing and implementing the T3 online workshop was the value of various methods of support. As described above, most participants in the original workshop were either screened by T3 staff or self-selected, probably to a large extent for technical aptitude. Even so, several faculty participants needed direct support from the T3 staff. One tool we found particularly useful for direct coaching in technical areas was screen sharing software, in our case, Timbuktu (Netopia, 1997). On several occasions T3 graduate assistants or faculty in San Diego assisted workshop participants in distant parts of the state by accessing their computer screens on our own screens, and even controlling their mouse and keyboard to demonstrate techniques while talking with them on the telephone. This software was easy to install and use, and worked flawlessly, even across platforms, with reasonably fast Internet connections being the only requisite.

Finally, throughout the time we have been developing and implementing the T3 online workshop and other online courses, we have become aware of a kind of "natural" taxonomy of development activities. We could describe them as development on the "learning activity" level, the "course" level, and the "program" level.

Most faculty and even institutional effort, including the T3 workshop, is focused primarily on the course level, dealing with the practical concerns of getting courses online in much the same way we put a course into the classroom. But one of the lessons learned from veteran distance learning providers is that we would do well to think also in terms of whole programs, when viewed from a "marketing" perspective. If one of our goals is to attract new students (in order to enhance quality, diversity, revenue, or all of the above), they are more likely to come to an integrated certificate or degree program than they are to seek out a single interesting course.

At the same time, perhaps the most manageable realm in which to develop is the "learning activity" level. Almost any individual or small group of faculty can manage development of small, well-designed online learning activities. Wonderful examples of these are the Virtual Flylab and the Virtual Earthquake (http://vflylab.calstatela.edu/Welcome.html). This level is particularly appealing because online course developers could potentially pick and choose these activities for their online courses in the same way we pick and choose journal articles for reading packets. Drawbacks to this level of development activity include figuring out how to pay for it (grants? subscription fees?) and server and software maintenance issues.

The rapid technological advancements and their impact were recognised by the European Union which assigned the task of investigating the various trends and of defining the needed actions to the Bangemann Commission. The commission in its report defined ten sectors to which priority should be given and in which the teleworking and distance education activities were included.

The aim set by the Bangemann Commission for the area of distance education is the provision of a continuous educational process which will satisfy the needs imposed by an ever shifting and changing society. The achievement of this aim is envisioned through the following actions:

- The establishment of distance education centres. These centres are expected to fulfil their purpose by making extensive use of Telematics and network-based distance education software.
- The establishment of advanced distance education techniques to schools and universities.

The application of the above structures is expected to offer advantages to:

- the industry, especially to the SMEs, and to the public sector since it will allow the education of staff members with lower costs and with better utilisation of the finite available educational resources,
- the employees who need to upgrade their knowledge and skills,
- the people who are either unable to move outside of their houses or reside at remote geographical areas,
- the students who seek to have access to educational material of higher quality than the offered one.

The trends noted above result in a need for training people in the use of the New Information Technologies (NIT). Significant help, towards the satisfaction of this need, can be acquired by the use of Telematics.

The TRENDS Project

The TRENDS Project aims at the development and efficient delivery of in-service training to school teachers. The methodology focuses on the enhancement of existing ODL techniques, in the area of multimedia telematics. The objectives of the project are:

- The development of an in-service, school based teachers training system, based on multimedia telematics, to support the continuous improvement of teachers’ skills and capabilities in Secondary Education, in Europe.
- The implementation of distance learning techniques, to provide viable and cost-effective school based training.
- The establishment and operation of a European Teachers’ Training Network, to provide the distance training.
- The validation of the distance training services, by training 2,400 teachers from 120 European public secondary schools.

Training Centres: A Centralised Architecture

For the uniform provision of the services that will be offered by the TRENDS Network at a pan-European level and the enhancement of co-operation of the participating countries in various educational issues, the six national sites, in Greece, Italy, Spain, Portugal, France and United Kingdom, will be interconnected through mature network technologies (Euro-ISDN, TCP/IP protocol suite), so as to act as service providers to the teachers in their schools.

The basic idea of the TRENDS network is that the six Training Centres (one per participating country) will have to interact with each other transparently and will play the role of the educational services provider in their National Teachers’ Training Network. The same idea could be applied to every organisation planning to offer similar educational services, either to a national or international
The establishment of an educational network. The Training Centres approach to the realisation of Open and Distance Learning Environments is a centralised architecture with the following advantages:

- The Training Centre can be hosted on the premises of an educational authority, who will be responsible for the content and the model of the offered services.
- The technical support will be much more efficient if the hardware and the software modules involved reside in the same place.

The establishment of a Training Centre should be preceded by a feasibility study, aiming at defining the context into which a Training Centre will operate. The following parameters have to be considered as critical elements to be discussed and investigated, in order to cover the aspects considered as most important in the Feasibility Study for the establishment and operation of a Training Centre aiming at supplying Open and Distance Learning Services.

A Training Centre should be considered as a distance training services provider that is going to address the needs of the client (society), for the provision of educational services in the context of the life-long learning.

When devising, developing and putting into practice services (or training services, as it is happening in the TRENDS context) three major elements need to be taken into consideration: the implementation environment representing the context into which learning technology products and services are placed; the implementation design comprehending the analysis of the opportunities present in the implementation environment, the formulation of implementation strategy and plan of action; the action occurring as a result of the implementation design and corresponding with service delivery.

The concept of implementation environment includes the understanding and characterisation of some other components which are necessary in order to develop properly the feasibility study. This is to say, the factors involved in the implementation, the "market" structure and the related socio-economics dynamics. What is intended for "market" structure is obviously influenced by the institutional context in which training takes place.

Once the scenario is created in which the Training Centre is supposed to supply its services, the other side of the coin to be surveyed consists of the innovation dimensions which come up and affect the creation of a feasibility study.

They are respectively technical, economic and organisational. Another basic innovation dimension is the pedagogical one. A training model should be established that is a model through which the training services are going to be offered. This training model is a very important phase in the feasibility study of a Training Centre. It will affect the content of the training material used and the evaluation method of the trainees. It is deemed imperative that the training model needs to be decided, applied and monitored by education experts.

Here it is worth saying that, from this standpoint, any effort will have to be done to put into operation some general principles underlying the design process:

- to make explicit the new educational concept underlying learner-based systems which are centred on the learning-paradigm rather than the teaching paradigm, namely on knowledge acquisition rather than knowledge transmission;
- to guarantee a maximum level of interaction between trainees/teachers and among the trainees themselves (this in the perspective of an evolution towards distance training systems of third generation);
- to foresee communication flows to collect bottom-up suggestions.

When selecting a technological configuration for a certain learning environment, the technical feasibility involves the consideration of some factors such as:

- learning functions (transmission of knowledge and information communication among trainees, tutoring, guidance, exercises, etc.).
- key features (real time, delayed time, one-way, two way, one to many, many to many, use of text, use of sound, use of still images and use of moving images).
- technology components (they cover a full range of delivery mechanisms based on information, telecommunications and multimedia technologies).

The economic feasibility can be considered from two different viewpoints: the former concerning the provision of services, which is more focused on the survival of the product/service, the latter concerning the adoption of the product/service and more focused on questions about cost, economic efficiency, risks and investments.

Finally, the organisational feasibility requires to foresee the necessary measures to prevent organisational problems from being obstacles in implementing the training scheme and to design roles and functions to maximise efficacy and compatibility of it within the organisational context of implementation.

Also in this case, as in the one of the pedagogical dimension, the respect of some general principles underlying the design process needs to be guaranteed.

This is to say that:

- the outcome of the services offered from the Training Centre has to work as an engine for additional/complementary initiatives at regional/local level,
- training practices based on networks and distributed systems have to be embedded in the mainstream of re-
education activities, and
training services need to be consistent not only with
present competencies that are required but also with the
ones they may be required by the coming rapid reforms
concerning the working class of the years to come.

WHAT ARE THE MOST IMPORTANT TEACHING BEHAVIORS FOR DISTANCE INSTRUCTORS? PERCEPTIONS OF FACILITATORS, INSTRUCTORS AND COORDINATORS

Barbara K. Mc Kenzie

Distance education is a rapidly developing instructional approach used by educators through the world. For this teaching technique to be highly effective, it is imperative that those using the system for instruction be trained appropriately (Barker & Dickson, 1996; Moore & Kearsley, 1966; Willis, 1994). Over the past decade distance educators have increased the development of guidelines for what constitutes effective distance instruction (McKenzie & Davidson, 1997; Ciardulli, 1996; Dilllon, & Walsh, 1996; Thatch, 1995; Wolcott, 1995). A review of the literature, however, found nothing dealing with the identification and validation of the most important teaching behaviors displayed by distance instructors. The purpose of this study was to twofold: (1) to validate a list of distance teaching behaviors collected by the research team and (2) to develop training guidelines on the most frequently observed and the most important behaviors of distance instructors.

Methodology
A validation instrument was designed by the research team. Forty-one teaching behaviors: extracted from an extensive review of the distance education literature, discussions with distance trainers, teachers, and researchers, and the research teams’ observations of distance classes. The instrument used a 5-point Likert scale. Respondents were asked to indicate on that scale how frequently they had observed the distance behaviors and how important they felt the behaviors were in delivering effective distance classes. On the importance dimension a 5 on the scale indicated that the behavior was “critical, required or necessary”, 4 = “very important,” 3 = “important,” 2 = “somewhat important,” and 1 = “unimportant.” On the frequency dimension a 5 indicated that the behavior occurred “very frequently,” 4 = “often,” 3 = “sometimes,” 2 = “seldom,” and 1 = “never.” This paper will report only on the importance findings.

The survey was distributed to thirty college and university distance education sites in Georgia in the spring of 1996. Distance coordinators at each of the sites were asked to complete and return a survey as well as to distribute three surveys to distance instructors and facilitators at their institution. Two hundred and ten surveys were mailed.

Analysis
Seventy three surveys were returned to the research team. Of these only sixty eight were used in the data analysis due to missing demographic information. The data were analyzed using SPSS to compute the mean scores and standard deviations. The mean scores on the importance dimension were then ranked from the highest to lowest.

Demographic Findings
The majority of the respondents were distance learning coordinators, female, and from comprehensive universities. Most of the respondents had observed/taught one distance class. This was followed closely by respondents who had observed two to five distance classes. Table 1 below summarizes the study’s demographic findings.

Important Behaviors Findings
One of the forty-one behaviors was considered to be “critical” to effective distance instruction. This behavior dealt with arranging for materials such as handouts to be delivered to off campus sites as needed. The majority of the behaviors (N = thirty-five) were considered “very important” while five of the behaviors were considered “important.”
Table 2 summarizes the importance findings. It is interesting to note that all of the distance behaviors scored above a 3.0 on the 5-point Likert scale and that the majority of the behaviors dealt with classroom management behaviors (N=17) followed by instructional (N = 14), technical (N = 5), assessment (N = 4), and dress (N=1) behaviors.

<thead>
<tr>
<th>Conclusion</th>
</tr>
</thead>
<tbody>
<tr>
<td>The results of this study, while no means conclusive, are a beginning in what will be a difficult and continuous process of identification and validation of what constitutes the uniqueness of effective instruction in the distance classroom. It is the researchers' hope that this work will be useful for training, evaluating/assessing, and/or improving distance educators and what they do in the classroom.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Where to Next?</th>
</tr>
</thead>
<tbody>
<tr>
<td>More research on a variety of issues regarding instruction in distance education is needed. Prominent among those issues are these:</td>
</tr>
<tr>
<td>1. What do students in distance education courses identify as the most effective teaching behaviors of instructors?</td>
</tr>
<tr>
<td>2. How do effective behaviors identified by different groups (students, facilitators, trainers, etc.) compare?</td>
</tr>
</tbody>
</table>

3. Are there (a set of) generic teaching behaviors all instructors in distance education must master in order to be effective?
4. Does teaching style alter what constitutes effective teaching behaviors?
5. Does the content of the course to be taught influence what is considered to be effective teaching behavior?

As the world grows smaller the need for more educational opportunities for more people in more places will become epidemic. Effective distance education programs led by effective distance instructional specialists will have to be one of the cures.

TAKING INSTRUCTION ONLINE: THE ART OF DELIVERY

Donna R. Everett
Morehead State University

The notion that people seek to make meaning out of their world, whether it is the classroom or the living room, is not a new one. Educational philosophers and learning theorists have attempted to explain how learners learn and construct meaning from instruction or the classroom. Stimulus-response theorists (Thorndike, Guthrie, Pavlov—as cited in Hilgard & Bower, 1966; Watson, 1960; and Skinner, 1960) view learners as reactive, passive robots only responding when stimulated by something outside of themselves. Reese & Overton (1970) propose to call this the mechanistic world view—any change in the learners comes from outside of themselves. Organismic theorists (Dewey, Tolman—cited in Kingsley & Garry 1957; Lewin, 1951; Combs & Snygg, 1959; Bruner, 1968; and Freire, 1970), on the other hand, contend that learners are active, organized entities who seek meaning from their own experiences to solve problems; to create relationships between signs and desired goals; to manipulate information and knowledge to fit new tasks; and to evaluate whether the way they have manipulated information is adequate to the task. The desire for self-actualization is the driving force which motivates the behavior of organismic learners.

Constructivism is a theory about knowledge and learning that draws on a synthesis of current work in cognitive psychology, philosophy, and anthropology (Kuhn, 1962; Piaget, 1970; Sigel & Cocking, 1977; von Glasersfeld, 1981; Bruner, 1985; Gardner, 1991). Constructivist theory defines knowledge as temporary, developmental, socially and culturally mediated, and non-objective. Learning from this perspective is a self-regulated process which seeks to resolve inner conflicts that arise from concrete experience, collaborative discourse, and reflection (Brooks & Brooks, 1993). Simply stated: learners construct their own internal understandings of the world in which they live.

The concept of adults as learners emerged both in this country and in Europe shortly after the end of World War I; however, only in the last few decades has the theory of adult learning matured. Knowles, Thorndike, Sorenson, Tough, Lindeman, Cross, Darkenwald & Merriam, and Houle, among others, have written extensively on the idea of the adult learner. The term, andragogy, has appeared as the label which differentiates adult learning theory from pedagogy, youth learning theory. The andragogical model of the adult learner is based on the assumptions that adults need to know; adults have a self-concept of being responsible for their own decisions and for their own lives; adults come into education with a greater volume and a different quality of experience from youth; adults come ready and motivated to learn what they need to know in order to cope; and while adults are aware of external motivators (better jobs, promotions), it is internal pressures (job satisfaction, self-esteem, quality of life) that are the most potent motivators (Knowles, 1990). Adult learners cannot help but try to make sense of their environments.

Distance Learning Theory

Distance learning seeks to provide education at a distance. Inherent in this telecommunications technology is the introduction of activities, tools, and instructional designs for which the learner may have no frame of reference. The normal model of one teacher and a single class of students in the self-contained classroom does not fit the distance learning training model. The television camera provides the teacher a view of multiple classrooms in which various kinds of learning media must be implemented. The old classroom star configuration—the lecturer reaching a finite number of students—does not apply in a situation where the teacher only has face-to-face interaction with students via the television screen. Student and teacher learning and interactions are changed (or, at the least, modified) in the distance learning environment.

Tough (1979) has suggested that when learners approach a new learning task [e.g., understanding the distance learning classroom], they cast around for some analogous situation from the past to give guidance as to how to approach this new situation to determine the benefits to be gained in learning from it. Students trying out this medium for the first time receive little guidance about how to participate, organize their lives, interact with online materials, reflect, express themselves online, and use the online experience for successful completion of the course. Smith (1982) has suggested that learning-how-to-learn...
(LHTL) strategies may assist students and teachers to make sense of a new learning environment. LHTL is defined by Smith as "possessing or acquiring the knowledge and skill to learn effectively in whatever learning situation one encounters" (p.19). LHTL theory suggests that learners rely on a "bag of tricks", tried and true approaches, prior learning strategies and tactics, and what worked in other situations to make sense of a new environment. Eastmond (1995) has indicated that these factors may include prior experience, the role of the support person, a frame of reference, relationships between and among students and teachers, acclimation to information and sensory overload, role of participation, and processing the small picture.

Recently, Sherry and Wilson (in Khan, 1997) have offered another view of learning: transformative. The transformative view of learning combines the ritual view of instruction which communicates and perpetuates tradition with the transmission model of instructor-as-expert deliverer of instruction. In the transformative view, both the teacher and the student alike are transformed into learners by the process of communication. A two-way dynamic comes into being as distance learning modalities are used to deliver instruction. The learner can pause and reflect on what he or she is learning; the instructor can develop new understandings of the subject and the learner.

This paper focuses on the process of preparing and delivering courses using compressed video by considering research related to how learners adapt in new environments, the approval process, the environment, and course delivery techniques. Implications for pre-service and in-service instruction, graduate teacher education faculty, and faculty and staff development will be offered.

**Methodology**

Over a two-semester period, a survey has been administered to students in distance learning courses to address the issues of adjustment to the environment and technology, methods and interactions utilized by the instructor, and related experiences which provide the framework for adapting to the distance learning classroom. Specifically, the survey has focused on answers to the following questions:

1. How do students make sense of distance learning technology?
2. What mechanisms do students employ to adapt to a media-rich learning environment?
3. What external or internal motivations allow students to succeed in a media-rich learning environment?
4. What social interactions are employed to help students master and use the technology in the distance learning classroom?

Based on the findings from the surveys, implications for training of faculty and suggestions for techniques for taking courses and methodologies online are offered.

**Findings**

The survey instrument entitled, *Adapting to the Distance Learning Environment*, produced results in three areas: feelings about the distance learning environment, factors which helped make sense of the distance learning environment, and technologies of the distance learning environment. The population for the surveys were all students enrolled in distance learning courses taught by compressed video instructors. Statistically significant results from the surveys were determined using the chi-square analysis. Since the responses to the questions on the surveys yielded frequency data, the chi-square analysis was appropriate.

**Feelings about the DL environment**

The first part of the questionnaire asked students to describe their feelings about the distance learning environment on the first day of class and on the last day of class. The factors used in this part of the survey were gathered from the literature related to the conceptual framework for this paper. The responses from the students to the statements in this part of the survey reveals the following results:

First day results. From the responses to the factors, data in Table 1 show that eight factors appear to describe the students' feelings about the distance learning environment on the first day of class when analyzed by gender. Demographics show that 68.6% of the respondents were female, 30.4%, male. Only two of the factors are mentioned by both groups—comfortable and motivated.

Table 2 shows the feelings of the respondents when analyzed by age. Demographics show that the students were represented by the following age groups: 18-25 years of age, 41%; 26-35 years, 33%; 36-45 years, 18%; and 46-54 years, 8%. In this instance, nine factors appear to have significance for the students; however, none of the factors was the same for both groups.

Last day results. Students were asked to denote factors which appear to describe the feelings of the students on the
last day of class in the distance learning environment. Table 3 illustrates that nine factors appear to describe the students’ feelings on the last day of class; none of the factors was the same for both groups.

Data from these four tables have significant bearing on the training and delivery of instruction in the compressed video classroom.

Factors which helped make sense of the DL environment

When asked in part two of the survey which factors helped them make sense of the distance learning environment, the students responded to a series of 41 statements gathered from LHTL theory and distance learning research. Table 5 exhibits the factors which appear to have helped students cope with making sense of the distance learning classroom when presented by gender. Only one factor—encouraged to participate—was mentioned by students in both semesters. Each of the other nine factors was different for each semester.

Table 6 demonstrates the feelings of students related to adjustment to the DL when analyzed by age. This table shows that seventeen factors appear to have statistical significance. Only two of the factors—on-site support and encouraged to participate—were mentioned by both groups. The other fifteen factors also appear to have vital significance for delivery of instruction via the compressed video environment.

Technologies in the DL classroom

In part three of the survey, questions dealt with the technologies of the distance learning environment. Specifically, students were asked to identify the technologies the distance learning instructor used during the course and the technologies they used and mastered during the course. Additionally, students were asked to identify the technologies they had seen used outside of the distance learning classroom.

It appears from the responses by the students that instructors used computers (83.1%), the document camera (76.7%), the TV (71.6%), the podium tablet (70.3%), the VCR/Video (65.9%), e-mail (59.8%), and presentation software (52%) in the distance learning environment.

Distance Education — 127
However, the only technology students used was the computer (73.6%). To a lesser degree, students used e-mail (47.3%), the Internet/WWW (44.6%), and the TV (43.9%). It is interesting to note that the students used the Internet/WWW more often than the instructors (33.1%, instructors versus 44.6%, students).

When asked which technologies students felt they mastered during the distance learning course, students felt that, to some extent, they mastered the computer (32.1%) and e-mail (30.7%). Outside of the distance learning classroom, students saw the following technology used: computer (80.1%), the Internet/WWW (66.2%), VCR/Video (65.9%), TV and word processing software (62.2%), and spreadsheet software (57.4%).

**Recommendations for Taking Instruction Online**

Results from the two iterations of the distance learning survey indicate that the following techniques may prove to be helpful for instructors in the compressed video environment:

1. Instructors must have training which focuses on the apprehensions, fears, and coping mechanisms which students exhibit and apply during the first days in the distance learning environment. Learning students' names, providing explicit directions for completing assignments, encouraging students to use the site

facilitators for technology instruction, and encouraging students to participate are only a few of the devices which may prove helpful to students.

2. Instructors must meet certain guidelines for adapting courses to the distance learning environment in their course syllabi. Specifically, introducing students to the technology in the distance learning environment and how it works may allay some students' fears; providing a technology back-up plan when the technology fails is essential; requiring students to use the technology in the classroom from the very first day begins to ease students' fears and apprehensions—introducing themselves at the podium by looking into the camera and using email are two critical technologies for the first day; and continuing to require students to use and master the technology will prepare them for the high-tech classroom and workplace. Approval of courses should not be forthcoming until and unless the instructor has proven that adaptation factors and technology factors have been adequately addressed.

3. Instructors also may assist students to make sense of and adapt to the distance learning technology through interaction with peers, being encouraged to participate in discussions, and relying on their own internal motivations to learn independently, to monitor their own learning, to use life experiences, and to employ a high degree of autonomy. These findings support the adult learning and LHTL theories which formed the conceptual framework for the study.

4. Instructors must take the time to employ a wide variety of teaching methods to assist students in the distance learning environment. Small groups, individual presentations, asking questions, classroom discussions, and inter-site group work are possible and successful in the compressed video environment if the instructor will take the time to think through the process. Relying on the star configuration in the compressed video environment will not get students involved and excited about their learning.

5. Instructors must learn and introduce new technologies into instruction. Email is becoming a very common way for students to communicate outside of class with instructors—it also provides the opportunity for instructors to extend learning and require students to reflect on in-class exercises and materials. However, other Web-based discussion thread sites are available to instructors. In these discussion thread sites, students can read other students' thoughts and reflect on and respond to the discussions in an appropriate manner. To this end, continuing education for DL instructors is imperative.

6. As students in the DL environment are surveyed about their feelings and coping mechanisms, instructors will need to adjust materials, methods, and technology to continue to meet the needs of students. A certain level
of maturity can be noted in the differences in the responses of the students in this research.

Distance learning holds the promise of overcoming time and distance restraints for learners; for improving course design and delivery techniques; for focusing intense attention on learners' needs; for reflecting on how teachers teach and prepare instruction; and for determining how individuals adapt to new environments. All of these are compelling reasons for learning as much as possible about distance learning as a training delivery system and how all of the participants in the distance learning classroom adapt to the environment.

BUILDING A SUPPORT SYSTEM FOR DISTANCE LEARNING STUDENTS

Melanie Hill
State University of West Georgia

Student support services are generally the greatest predictor of the success of a distance learning program. Yet at many institutions, student services in distance learning take a backseat to technology purchases, instructor training, staff development, marketing campaigns, and other building blocks of a distance program. Faculty may receive weeks of training, but students simply show up, receive a few handouts and a short talk, and begin class. Sometimes student services are “innocently” underdeveloped because of a lack of funds, inadequate staffing, or time pressures. But without support services, the entire investment in distance learning becomes very fragile. The symptoms of an institution without adequate student support systems in place may include declining or static distance enrollments, disgruntled faculty, apathetic students, inaccurate registration figures, or students who lack basic services such as ID cards, text, or library access until a course is well underway.

The State University of West Georgia (UWG) has the seventh largest graduate teacher education program in the United States. Each year, the number of graduate education students taking courses via distance learning (two-way interactive videoconferencing or on-line) nearly doubles. The top priority for the distance learning department at UWG during 1997 was to develop a comprehensive support system for these students.

Each quarter, distance learning students at UWG are surveyed regarding course satisfaction. Although the survey’s Likert-scale questions are directed towards teaching and technology issues, the survey also includes an open-ended portion where students can discuss what they like most and least about the course. In many instances, students in past years complained about not receiving materials timely, communicating with the university, and receiving knowledge about schedules, financial aid, and upcoming courses.

Components of Support

As a first step, the distance learning department developed a 10-minute video to acquaint students with the technology and to provide success tips. The video is shown to all distance learning students during the first class meeting, and features footage from actual distance courses to demonstrate proper classroom protocol. Although the video helped students to prepare themselves for the responsibilities of distance learning, they still complained that they had no single reference point from which to obtain help.

Thus, the next step was to write a comprehensive handbook for all students and develop a web site. At a minimum, students were to have information regarding registration, financial aid, parking, library access, names and phone numbers of contact persons, calendars of university deadlines, a guide to technical issues, course information, and advisement procedures. In addition, the handbook and the webpage included a section for frequently-asked questions (FAQs), that sought to provide students with empathy and understanding concerning frustrations they might encounter. Future plans for the web site include an interactive introduction to distance learning for students.

The third prong of the UWG student support system became a telephone help-line. Students can make one call to get receive assistance on any administrative or technical problem they have. Thus far, most questions received have been inquiries regarding upcoming distance courses. Surprisingly, students have thus far needed less technical assistance than anticipated. Although the phone is presently staffed only during regular business hours, future plans are for extended hours.

Finally, all distance courses are assigned a student assistant who serves to relieve administrative responsibilities of the instructor, provide technical support, and serve as an additional contact person for students. If an on-line student has been inactive for several days, the student assistant may contact him or her by phone or e-mail to see if assistance is needed.
Evaluation

At the end of Fall quarter 1997, a sample of distance students were invited to participate in a focus group, where they were asked if they believed their needs were being met. They were also asked if they had suggestions about further steps the institution should take to prepare them for the distance learning experience. Most students said the presence of a telephone help-line made them feel more secure as distance students, whether or not they actually used the service. There were no substantial suggestions for improvement in terms of student support, although this may be due in part to the fact that most students were new to distance learning, and had not been involved long enough to encounter administrative problems or issues. A follow up focus group is planned for Spring and Summer quarters.

Melanie Hill is the Coordinator of Distance Learning Programs at the State University of West Georgia, Carrollton, Georgia 30118. (770)836-4647. E-mail: mhill@westga.edu.
Distance learning is emerging as a critical opportunity and challenge for institutions of higher education throughout the United States and the world. With growing pressure to provide distance learning opportunities, many institutions of higher education are rushing to put courses and programs into place. But, what sorts of distance learning experiences are appropriate? What delivery systems will best meet students’ needs in a particular situation? These are fundamental instructional design questions that are best answered by applying a systematic approach that takes into account the subject matter and students’ needs. This paper focuses on models of distance learning that emerge from application of systematic instructional design concepts to instructional problems. Examples of distance learning for in-service and pre-service teacher education, taken from the authors’ own experiences, are highlighted.

Today, we are experiencing a boom in distance learning. The traditional college student population pool is beginning to decline, but opportunities for reaching non-traditional students are expanding. As a result, universities are pursuing distance education with increased vigor. The U.S. Department of Education (1997) recently released a survey of distance education college courses. According to the survey, in the fall of 1995 a third of all higher education institutions in the U.S. offered distance education courses, led by 62% of public four-year institutions. A total of over 25,000 distance education courses were offered in the 1994-95 academic year reaching over three-quarters of a million students; 45% of that total was offered by public four-year institutions. The most popular delivery methods reported were two-way interactive video (57%) and one-way video (52%). However, one-way video with two-way audio and the Internet were each reported by about a quarter of reporting institutions. While attesting to the growing popularity of distance learning, this survey almost certainly fails to capture the full extent of current efforts because, for example, of the rapid growth of the World Wide Web and delivery of Web-based distance learning in just the past two years.

Because of the pressure to provide distance learning opportunities, institutions of higher education are rushing to put courses and programs into place. Our institution, Purdue University, is no exception. Although Purdue has a long history of distance learning initiatives, a new Office of Distance Learning was created just within the past year, and there are many efforts underway to develop new distance education courses and programs across the campus. But, what sorts of distance learning experiences are appropriate? What delivery systems will best meet students’ needs in particular situations?

Planners of distance education must consider the choice of media and methods in light of the potential impact on student attrition, the quality of the experience, its educational status, and cost (Keegan, 1990). Fundamentally, questions about appropriate distance education approaches and methods are questions of instructional design. These fundamental instructional design questions are best answered by applying a systematic approach to the development of instruction that takes into account the nature of the subject matter and needs of the learners (Cyr, 1997; Dick & Carey, 1990; Newby, Stepich, Lehman, & Russell, 1996). While there seems to be a tendency today for people to jump on the bandwagon of whatever is the latest technology, a systematic approach to instructional design calls for matching media and methods to the needs of a given situation and group of learners. By asking basic questions at the outset, it is possible to identify appropriate models of distance learning that fit the situation.

Applying Instructional Design to Distance Learning

When taking a systematic approach to the design and development of instruction, one can view the instructional process as a set of interrelated components. On a simple level, these components form a PIE model — planning, implementing, and evaluating (Newby, et al., 1996). Planning focuses on designing instructional materials and learning experiences to meet the specific needs of the learners, the content, and the context. Implementing puts into practice the plan to help the learners achieve their
learning objectives. Evaluating involves assessing the level of learning achieved by the learners and/or the effectiveness of the instruction.

Let us focus in particular on the planning component of this process because, with appropriate planning, many missteps can be avoided. Dick and Carey (1990) elaborate that the initial planning steps of the process should include: identifying an instructional goal, analyzing the type of learning required of the learners, and analyzing the characteristics of the learners. These planning steps can be addressed by asking:

- What is the overall instructional aim?
- Who are the learners and, in the case of distance education, where are they located?
- What sorts of learning experiences should the learners have?

By answering these three questions, many of the important issues in planning for distance education can be resolved. For example, if the overall instructional goal is the transmission of basic information, any of a variety of relatively simple media (e.g., print-based correspondence material, videotapes, the World Wide Web) might work just fine. However, more complex aims would likely lead to a need for more complex and interactive distance learning technologies.

Likewise, the nature of the learners and their locations has a significant impact on the planning process. Novices in the use of computer, for example, are likely to be poor subjects for a Web course. We learned this the hard way when, some years ago, we made our first attempt at using computer-mediated communication (CMC) for delivery of an introductory computer class to inexperienced in-service educators. While ultimately fairly successful (Cheng, Lehman, & Armstrong, 1991), the course was fraught with difficulties because the inexperienced users were not able to use the computer network effectively. The medium must be able to reach the learners where they are located, and it should match the characteristics of the learners.

Finally, it is very important to consider what learning experiences you want the learners to have. In face-to-face instruction, nearly the entire repertoire of instructional strategies is available to the teacher. You can make presentations, perform demonstrations, or have class discussions. Students can work with computer software or view videotapes. Students can be teamed to work cooperatively, and so on. At a distance, some strategies are almost always constrained by the limits of the technology. So, it is important to ask, which are the most critical learning activities? If demonstration is a crucial element of the learning process, as it might be in a woodworking class, then the distance learning medium must support that; videotapes or live video might satisfy such a requirement. If discussion is a key element of the learning experience, then having appropriate tools for communication becomes an overriding consideration of the distance learning system.

**Models of In-Service Distance Learning**

Let's examine how consideration of these basic instructional design questions has led to different models of distance education at our university.

**Northwest Doctoral Cohort Program**

Launched in 1995, the Northwest Doctoral Cohort Program is a special graduate program in educational administration. (See: [http://www.soe.purdue.edu/cohort/home.html](http://www.soe.purdue.edu/cohort/home.html)) Let's examine the three key questions and how they were answered for this program.

**What is the overall instructional aim?** Broadly stated, the aim of the program is to help school administrators simultaneously become certified for a school superintendent's license in the state of Indiana and obtain a Ph.D. degree.

**Who are the learners and where are they located?** The learners in this program are individuals seeking to become school superintendents. In most cases, these individuals are already school administrators, e.g., building principals, assistant superintendents. The greatest concentrations of school administrators can be found where there are the greatest concentrations of schools and people. In our state, that means the Indianapolis metropolitan area or northwest Indiana near Chicago. Both sites are distant from the Purdue University main campus.

**What sorts of learning experiences should the learners have?** At the advanced level, educational administration is largely an issues oriented field of study. While there is content (e.g., school law, finance), much of the curriculum deals with issues of leadership and the problems of managing the large educational enterprise of a school district. As a result, it is important for the learners to see examples of a variety of problems and issues, grapple with them, and come to appreciate new perspectives on them through discussion and reflection.

So, what does this tell us about the nature of this program? In this case, several factors together affected the decision to structure this distance learning experience in the way that it now exists. Because of the concentration of potential students, the decision was made to begin the program in northwest Indiana. This decision was supported by the fact that Purdue University’s Calumet regional campus is located in the area. Because the Calumet campus is not authorized to grant Ph.D.'s in educational administration, a distance learning program was conceived. But, what sort of program would it be?

School administrators are busy individuals. Because of the distance to the Purdue University main campus, travel to the main campus was out of the question. So, the decision was made to offer classes early in the evenings at the regional campus. Because of the need for these
individuals to grapple with issues and see a variety of perspectives, a cohort program was devised. Participants move through the program as a group, and the individuals become resources for each other. Further, in order to permit a high level of dialog and discussion in classes, two-way interactive video is used to deliver the courses to the regional campus. As a result, the instructor on the main campus and the members of the cohort group on the regional campus can discuss issues and present materials as if they were all together in the same room.

This example illustrates how consideration of the basic instructional issues can lead to a decision to structure distance learning in a particular way. In this case, the model is composed of a coordinated sequence of courses, delivered from the main campus to a regional campus by means of two-way interactive video. In the last year, the program expanded to include a site in the Indianapolis area so that it now reaches both major population centers in the state.

Topics in Educational Restructuring

Other programs offered via distance learning have relied upon other approaches. Beginning in 1993, one of the authors has taught a graduate level course EDCl/EDFA 591, Topics in Educational Restructuring. (See: http://www.soe.purdue.edu/~lehman/edci591/intro591.htm). Let's examine how the answers to the basic questions compare in this example.

What is the overall instructional aim? The aim of this course is to give interested individuals the opportunity to learn more about the many issues and concepts involved educational reform and restructuring.

Who are the learners and where are they located? Unlike the Doctoral Cohort Program, the learners in this course can be quite diverse. Individuals interested in course topics often include: school administrators, inservice teachers, curriculum coordinators, college faculty, and education graduate students. Students can have varying backgrounds, abilities, and schedules. They can be located almost anywhere from on campus to schools within the state to more far-flung locales.

What sorts of learning experiences should the learners have? The issues surrounding educational reform are complex and intertwined. To give students an opportunity to come to grips with the concepts and issues, they need to read current literature in the field and interact with others to encounter multiple perspectives. What is needed is something like an on-campus seminar but at a distance.

Given these considerations, what is the nature of this distance learning model? In this case, the factors that influenced course design included: participants' schedules and locales, course content, and the need to approach topics from a variety of viewpoints and in depth. The methodology that was chosen was computer-mediated communication (CMC). CMC has been touted as an excellent medium to promote meaning making in distance education (Jonassen, Davidson, Collins, Campbell, & Haag, 1995).

CMC provides a mechanism for extended dialog on topics. With it, we could reach participants who had access to a computer and a modem almost anywhere. When we first began the course, we used a computer network called IDEAnet that was available to any educator in Indiana through toll free dial-up access (Lehman, McInerney, & White, 1993). We purposely chose to use the "lowest common denominator" technologies — mainly e-mail — because, when we first started, 2400 baud modems were the norm. Readings were initially supplied as a print packet that was mailed to participants. As the Internet matured, the course matured and changed with it. As a result, in a recent offerings, we have had participants from as far away as Norway, and we have been able to rely on readings available on the Web rather than printed copies of articles. A Web site now supports the course, although the heart of the course, the on-line discussion, still takes place through e-mail. For our educational goals, the discussion remains our primary vehicle for learning.

These examples illustrate how different distance learning solutions may emerge when basic instructional design issues are considered at the outset. By applying systematic approaches to the selection of media and methods, we can arrive at appropriate solutions for particular situations. While these examples have addressed in-service education, we have extended the concepts to pre-service education as well.

Applications to Pre-Service Teacher Education

We can examine our pre-service teacher initiatives by first looking at the same basic instructional design questions. What is the overall instructional aim? Distance learning is clearly rise in K-12 education as well as higher education. Therefore, our basic aim in these initiatives is to give our teacher education majors exposure to and experience with common distance education methodologies. Who are the learners and where are they located? Our students in these initiatives are on-campus teacher education majors. What sorts of learning experiences should the learners have? At a minimum, we want them to experience distance education methodologies as learners. If possible, we want them to also leave our program having had some experience teaching at a distance.

Several projects are underway. With the success of e-mail and the World Wide Web, a number of our on-campus courses now make use of e-mail discussions to extend dialog beyond the confines of the class period. In another project, education students at Purdue use electronic mail and UNIX chat to tutor students in a community about two hours from the Purdue campus. In addition, one of the classes in the Northwest Doctoral Cohort Program enrolls undergraduate students who are pursuing a computer
With careful selection, effective distance learning experiences can arrive at appropriate solutions for particular needs. The most extensive pre-service teacher experience in distance learning takes place in EDCI 260, Introduction to Computers in Education. This course is an undergraduate elective (soon to be required) in educational technology with an enrollment of about 150-250 students per year. During the 1996-97 academic year, a major initiative was launched with funding acquired by school-based colleagues Kathleen Steele and Dawn Colavita in the Crawfordsville Schools, Crawfordsville, Indiana, a community about 45 minutes south of the Purdue main campus. In Indiana, many K-12 schools have two-way interactive video distance education capability through Project Athena, a statewide initiative supported by equipment grants from Ameritech. The Crawfordsville Schools have the nearest Project Athena site to Purdue. They worked with Purdue to initiate this project as a way to begin exploring their own use of this capability.

At the outset of the activity, students in each of the EDCI 260 course laboratory sections experience distance learning via the two-way interactive video as learners. Students come to Purdue’s Ameritech Distance Learning classroom, a facility located in the Liberal Arts and Education Building and supported by PictureTel digital video equipment and ISDN telephone lines. There they are treated to a program in current educational technology content. They then return to their school and work with a cooperating teacher in the Crawfordsville Schools. Through the interactive video equipment, the students conduct a conference with the teacher to plan a lesson for the teacher’s high school class. The students then spend about two weeks to prepare a lesson on line. Finally, on a pre-scheduled date, the student team meets with the Crawfordsville class online and conducts a short distance education lesson. Thus, the students are able to leave the course having not only experienced distance learning as learners but also have planned, implemented, and evaluated a distance learning lesson.

Conclusion

When basic instructional design issues (goals, nature of the subject matter, and needs of the learner) are taken into consideration, different distance learning models may emerge as appropriate for different learning situations. No one method is correct or best. Rather, by applying systematic approaches to the selection of media and methods, we can arrive at appropriate solutions for particular needs. With careful selection, effective distance learning experiences can be constructed for both in-service and pre-service teachers.

Of course, evaluation must be an on-going part of these programs. After a couple of years of experience, for example, we have determined that two-way interactive video may not be necessary for every class in our Northwest Doctoral Program. The rich, reflective dialog which can come from CMC may suit our aims as well or better and at much less cost. So, we are looking to make adjustments. Some of the dialog in the cohort classes will be shifted to CMC while we will use the video for what it does best, allowing for presentations and face-to-face interaction.

With clear thinking and a systematic approach, we can continue to take advantage of the exciting opportunities that distance learning provides.

Distance Education — 135
INTEGRATING COMPUTER TECHNOLOGIES IN DISTANCE 
LEARNING AS PART OF TEACHER PREPARATION AND INSERVICE:  
GUIDELINES FOR SUCCESS

John J. Cochenour  
University of Wyoming

Carl Reynolds  
University of Wyoming

Since Wyoming is sparsely populated with communities separated by large distances, distance learning and communication systems are in great demand. The delivery of teacher inservice especially, requires the use of distance learning technologies. It is not uncommon to respond to inservice needs that include a small group of twenty or fewer teachers spread over 300 miles apart with as few as two-three persons per site. Practicum sites for undergraduates are sparsely distributed throughout the state as well. Conventional delivery systems, face-to-face inservice courses and on-site supervision of undergraduate practica, are becoming increasingly difficult to justify because of the time commitment required for travel. In addition, people in a globally based economy will find it necessary to use computer mediated technologies to access information and communicate with others (SCANS, 1991).

Distance delivery requires extra effort to insure that students’ basic information needs are met and that as more complex computer technologies are introduced, a stronger support system for solving problems is needed. Incorporating the use of the Internet, course web pages, and computerized “chat rooms” adds a complex set of problems that can overwhelm some students. Problems can and likely will arise which, if appropriate support systems are not in place, will negate learning.

The purpose of this paper is to introduce guidelines that can contribute to the successful delivery of distance instruction to teachers using a variety of delivery technologies. These guidelines have evolved from extensive experience in teaching and administration of distance delivered courses, student evaluations, research studies conducted upon previous courses, and from the literature. Factors that seem to make a difference in the quality of distance instruction have to do with planning, instructional design and management, facility and support for teacher-student and student-student interaction, reliable technical support, empathy for student needs, and instructor training (Willis, 1993). The interesting finding is that these factors are the very same ones that are essential for success of a conventional face-to face delivered course (McKeachie, 1986).

Guidelines
We have organized these guidelines under the following categories: course design, general delivery strategies, computer strategies for delivery, student and administrative considerations, and evaluation. Within each category the guidelines are offered not as an exhaustive recommendations, but rather as examples of considerations or techniques intended to make a distance delivery experience more successful.

Course Design
A systematic method of planning developing, managing and evaluating the instructional process is basic to effective and efficient distance education, or any instruction for that matter (Kemp, Morrison, & Ross, 1998). But what should be included in thinking about such a systematic development of instruction? The traditional umbrella categories of analysis of the learning situation and the learner, delivery strategies, and evaluation must of course be considered, but three specific areas that should be considered for good distance delivery of instruction are suggested below.

The course design should help resolve the balance between formal structure and interactive dialogue. Including more dialogue can develop more interaction and community. Doing this has resulted in evaluation comments that were very positive from some students. Such comments usually remarked on the opportunity to “see a topic through its course,” or “understanding another’s position with greater clarity.” Using lots of dialogue can result in negative comments however. For example, students sometimes remark on “time wasted in unrelated topics.” This tension between time on task and time devoted to student interaction and community must be
addressed to provide both dialogue and structure in appropriate amounts.

The course design should be attentive to developing a learning community. Many hours can be devoted to designing course content and massaging subject manner, but equal time should be given to developing a learner-centered course that allows learners to build a support community within the class. Success in distance instruction is positively correlated with a sense of ownership and community among the students. Distance students at remote sites who have neither often drop out of courses and programs. Building community and ownership requires the use of learning strategies that are flexible and adaptive and the use of delivery strategies that incorporate interaction and dialogue.

The course design should identify goals, instructional processes and distance delivery procedures. Separation tends to heighten students concern regarding what is expected of them, so it is essential to provide learning structures such as a detailed syllabus that includes a course calendar, clear goals and objectives, assignments, grading policies, deadlines, and other expectations. Determine specifically activities such as registration and collection of fees, distribution of class materials, receipt of student papers, use of copyrighted multimedia and print materials, responsibilities such as grading, and other protocols and procedures the educational organization may require (Rezabek, Cochenour, Bruce and Shade, 1994). It is also very useful to determine the optimum conditions for instruction. Such considerations include: class size, number of sites, number and length of class sessions, variety of delivery modes, and other issues related to the course.

**General Delivery Strategies**

**Preplanning Group Sessions.** When planning group sessions, it is important to communicate the process as well as the topic/issues that will be addressed. Prior planning includes such items as developing a list of discussion questions or readings for reaction that can be sent to participants by email or posted on a web site. Another strategy is to create a scenario or case study for reaction. Sometimes, a videotape or satellite broadcast is available as a discussion item. A course web site can also be used to post a multi-media slide presentation produced by the instructor.

In planning and communicating distance delivery technology procedures, it is essential to increase the time interval before sessions actually occur. One convenient strategy is to send an email to all participants several days prior to the next group session with reminders of assignments, readings, or other key information to prepare for the session. Announcements, tips, or supplementary information can be communicated in this way to encourage consistent use of the technology.

**Promote interaction and collaboration.** We require at least three students per remote site and encourage these students to work together and develop a small learning community that can rely on each other for support throughout a course or program of study. Peer learning can support both the novice and experienced distance learner. These groupings often promote students to select learning projects of local interest, thus increasing the relevance and real-world applicability.

Another way to promote interaction is to restrict the use of lectures. Ten minutes of lecture over a distance delivery system appears to be the maximum time for a didactic presentation. Instead of more lecture time, we would suggest a variety of instructional options be incorporated. These options are viewing and listening (such as in lectures), writing, and speaking. Writing strategies would normally include the use of an interactive study guide, specifically posed questions or learning journals.

**Speaking strategies could include discussions, presentations, and role playing.**

Discussions can be held among all class members or among sub-groups established for that purpose. Sub-groups can be at a particular site, or from members assigned from specific sites. Regardless, sub-group discussions should be followed by a return to the class as a whole for summarization and further discussion. Discussion strategies require sufficient time to satisfactorily complete the discussion, which means a limitation to one or two specific issues. Individual and/or group presentations and projects are quite feasible in distance delivery situations. However, the course design should have a portion of class time built in for students to practice their delivery skills where feasible. As with discussions, role playing can occur within a site or across sites. Case studies, scenarios, and videotapes are effective starters for a role play. Again, planning and time controls are essential for successful role plays, and often instructors need to be proactive in getting role plays started. For example the instructor might need to ask someone from a specific site to take part, “I’d like someone from Casper to be a risk taker today and to take part in creating a scenario with me. We’ll role play a situation to start a class unit on conflict mediation” (Rezabek, Cochenour, Bruce and Shade, 1994).

Group projects and presentations promote collaboration and can build a learning community. We have experienced students developing a group identity simply by having common experience in successfully overcoming the limitations of distance technologies. To encourage this process students should have opportunities to work directly with the delivery technology and to help one another with the mastering of each of the methods used in a course to connect students and instructor. Connecting and collaborating with peers in the distance education environment encourages student persistence, celebrates new learning,
and provides constructive feedback (Burge, 1994). Also, several students noted an increase in self-confidence resulting from communication with people at different locations who acknowledged their ideas.

An important practice to follow is to design assignments that are practical and have application to the students’ experiences. These activities should be designed for “think it through” level that have a reasonable time frame for completion. Also, it is important to provide time for students to share their work with each other for interaction. The assignments should be designed for reflectivity to allow a vehicle to express honest thoughts or concerns about the topics, issues, or any aspect of the course delivery.

Facilitate with spontaneity, balance, and humor. One student commented, “I really had to plan my responses and be ready for a pause in the discussion, so I could break in with my answer.” This comment demonstrates the potential difficulty in facilitating spontaneous interaction at a distance, and hot topic discussions can become competitive. An instructor needs to periodically break into the conversation, if necessary, to widen the group by restating questions and responses or offering feedback before directing the discussion to another site or person.

It is very important to balance participation among the remote sites. Instructors should not show favoritism to any particular site or person, nor should any site or person be allowed to monopolize discussion. Without sufficient thought and preparation, it can be difficult to balance the participation among all sites. Another aspect of balance and participation is the tendency for students to conduct side discussions. As one student remarked, “Our group had to be made to talk with the entire class. Most of the time we tended to talk among ourselves at our site.” Many learners need to participate and respond in order to feel a class session is a fruitful one. Side discussions can be acknowledged by incorporating local discussion time, and by insuring that each site has an opportunity to share during large group sessions.

The appropriate use of humor and self-revelation can be employed to create trust among participants and to humanize the distance environment. The use of appropriate humor can assist in establishing a warm, receptive learning environment. It can also enhance the climate for creativity, risk taking, and brainstorming; and can reduce anxiety at each site (Rezabek, Cochenour, Bruce, Shade, 1994).

Use questioning techniques that force learners to be actively engaged. Call on students by name and rotate questions among sites and students so everyone can expect a reasonable chance to contribute. Another technique is to use a random number approach to call on participants for response. Ask students to introduce themselves by name when they respond. Don’t be afraid to wait after asking a question; give students a chance to think about the question and position themselves to use the telecommunications technology. Check occasionally to see if everyone can hear or see. Students are notorious for not identifying technical problems until after class is over, so encourage them to speak up rather than accepting poor quality transmissions.

Computer Technology Strategies for Delivery

A wide range of computer technologies can enhance the distance delivery of an inservice course or aid in communication with a practicum student. An effective way to communicate with a group or an individual is through use of email. The technology is fairly user-friendly now and most people have access to a computer and modem hardware. A group mailing list or listserve is fairly easy to establish. Email provides an effective way to interact among participants and the instructor. Reflective journals, responses to discussion questions, submission of assignments, and issues of concern can be communicated effectively. Email software is now available which makes the management of group mailing lists, and archival of documents simple to handle.

The Internet has probably caused the most excitement related to distance technology in recent years. Several strategies may be used to facilitate distance delivery of information. Web sites can provide a convenient way to distribute essential course information, class schedules, assignments, reading lists, and supplementary materials. Simultaneous web conferencing provides a powerful strategy for conducting discussion groups and reporting of professional experiences that can be interactive for all participants. Also, several multi-media applications make it possible to create visual presentations that can be posted to a web site. Participants in an inservice course can download and view the material as often as they wish. When used in conjunction with either email or a web conference, the communication can become interactive as well.

Another strategy that works well is to encourage the use of the Internet as a tool for information searching. However, the random way in which information may be posted on the Internet frequently causes problems with locating quality information desired for a topic. By designing assignments that provide guidelines and hints for conducting keyword searches, the chances for successful information retrieval is enhanced.

Student and Administrative Support

One of the most important set of guidelines learned for distance delivered activities relates to student support. Without extra effort in this arena, frustration levels peaked so quickly that negative impact on learning quickly became dominant. Technical assistance, cheerful “customer service”, and non-threatening problem solving services are essential. Technical assistance before, during,
and after sessions is a must for success. Conventional communications systems need to be available as a backup for support to aid the participant in solving problems. For example, access to friendly assistance through a toll-free telephone number, and ability to talk to a "real person", is probably the most effective way to reduce frustration levels. The administration and support service personnel must realize that a facilitative and forgiving atmosphere must be maintained at all times. It is essential that the participant is led to feel that the institution cares about the individual being successful in the distance delivery of the program.

A shared responsibility for technical assistance should be accepted by the administration and the instructor. The administration includes clerical personnel, technicians, and administrators of the program. Anyone who may have contact with the student must assist with a facilitative and forgiving atmosphere and project the “customer service” orientation at all times. Assumptions about the expectations of students’ technical expertise and responsibilities should be minimized. Quick feedback with problem solutions is essential. An atmosphere of willingness to coach participants through problems and repeat as many times as necessary must be adopted by all administrative, clerical, and technical support personnel. It is important to make follow-up contacts to determine any particular problems that may have occurred rather than wait to hear from a frustrated customer.

In spite of all the best planning and technical support, problems will arise that cause frustration. The instructor must be prepared for these events and maintain a sense of humor and exhibit empathy for the participants. Alternative communication backup systems must be in place when these problems arise. Contingency plans must be communicated in advance to prevent high levels of frustration and fear from occurring. Clerical staff as well as instructors must be willing to fall back on conventional methods such as telephone and mail to communicate essential course information and technical assistance. At times, detailed step-by-step procedures are needed to insure success.

Additional effort is required to prepare for a distance-delivered activity. Clerical support is needed to send mailings and make personal telephone calls to insure that everyone is prepared and properly coached to join the activity. Adequate lead-time is needed to mail course packets and technical instructions to participants. Sometimes, practice sessions with the particular technology are needed to insure success for everyone. If possible, local technical support should be arranged to facilitate delivery.

Instructors should be accessible to students. There are a number of ways to accomplish this, but one method that has been successful for us is electronic office hours. These office hours are accomplished through a variety of approaches. First, the use of email and published email addresses allows students to access instructors 24 hours a day. This should be qualified by clear standards regarding the instructor’s schedule, workload, and turnaround time for reading and replying to email. Don’t raise student expectations above the reality of an instructor’s ability to respond. Second, post office hours during which an instructor will be available by telephone to distance students only. Distance students deserve a period of time each week when communication between student and instructor can occur. Third, have a fax number that students can use to send materials to an instructor. Other communication aids such as 1-800 numbers, answering machines, voice mail, willing secretaries, and a policy of promptly responding to student needs can assist in accessibility and student satisfaction.

Class size and electronic delivery sites should be of a reasonable number. Our opinion is that student to instructor ratio should be no higher than 25 to 1. This derives from constraints created by student email and the need to facilitate a class in a pro-active manner. We have also found the optimum number of sites in an audio or video teleconference to hover around seven. We have experienced as few as one and as many as fourteen, but instructor’s ability to effectively manage an interactive and collaborative class becomes severely taxed as these numbers grow. Also, issues of system operations, remote sites and facilities, and other infrastructure items can limit numbers.

**Evaluation**

This is a critical element in the effective delivery of distance education. No course in which we have been involved has ever approached perfection. In order to learn from a specific experience, feedback from those involved is critical. We recommend two formative evaluations, a formal one conducted at the mid-point of a course and a number of informal evaluations done at the conclusion of each class. If a few minutes at the end of each session are given up for informal formative evaluations, immediate feedback can assist in making changes in approach or content before following sessions. We also conduct the usual end-of-course summative evaluations, but it is important to seek feedback to specific concerns and questions. Students are also encouraged to respond to difficulties and problems by providing immediate feedback to the instructor or to the responsible administrative unit.

Formative evaluation during course delivery and after-course summative evaluations have played a part in the development of the guidelines suggested here. When asked whether they preferred face-to-face instruction or distance delivery, our students have been roughly divided into thirds. One-third preferred the face-to-face, one third preferred the distance delivery option, and one-third indicated that using both methods would be their preference. This result is perhaps tempered by the recognition that face-to-face instruction is not a true option for many of
the students, however our students have indicated a high comfort level with the distance technologies. Most of them have been overwhelmingly positive about their experiences in distance education (one of our graduate students is working on her Ph.D. at a distance and has received both her B. A. and M. A. at a distance). As one student commented, “The good points pretty much compensate the bad.”

Conclusions

We shouldn’t assume that computer literate students do not need training and support to effectively use distance learning technologies. Developing an attitude of openness to new education technologies is an important step for everyone. Distance delivery problems require the presence of backup systems and an instructor with a proper frame of reference, i.e., a sense of humor, and skills in managing stress.

A majority of our students, indicate that they believe distance technology is an important, if not essential, educational tool and resource. Many have spontaneously generated ideas for further use of the distance delivery during their education. These suggestions include talking with teachers and students in other states and nations; mentoring student teachers in the field; conducting job interviews and/or admissions interviews; and other conferences.

Web-based instruction (WBI) is at the cutting-edge (sometimes called bleeding-edge) of both today's technology and instructional design methodology. It offers significant opportunities — opening up education to the unserved or underserved, providing new tools to enhance learning, and increasing convenience for learners in terms of effective use of place and time.

But before beginning any discussion of WBI, it is imperative that the underlying motivation for beginning this discussion be explored. Instructional leaders must resolve the "Why do we want to do this?" issue before moving on. The answer will drive your response to many related issues. Possible answers to this key question include:

- provide more convenient access to education.
- serve a previously unserved/underserved population.
- protect your share of the instructional market.
- expand your share of the instructional market.
- become a national leader in WBI.

Presuming that the institution successfully resolves the answer to the preceding complex question and decides to proceed with this project, we see the need for action focused on institutional commitment, instructional design and development, and student issues.

Institutional Commitment
Commitment is the place to begin. WBI must be intentional and purposeful. Campus-wide systematic planning is of the utmost importance to this endeavor. To successfully implement this type of a program, an institution should make a significant, long-term commitment concerning co-involvement of institutional units, resources, and faculty reward structure.

Co-involvement of Institutional Units
The institution must develop partnerships within its existing units because each possess the expertise and resources that may never exist within individual cooperating units. The administration from the President on down must support this project, because without their support, the inter-unit partnerships that are required to enable program success may never develop. An institution-wide leader must be appointed who has not only the expertise to complete the project, but also the power to make it happen (Shore, 1997). Specific organizations that will greatly impact this process are the computer center, organic centers for instructional design and development, student services, and programs which contain content expertise.

Resources
Critical resources may be grouped into two general classes, personnel and technology. Personnel will be needed to develop and manage the WBI. Development requires specialized training and expertise which is slowly acquired. Initially only a handful of faculty and staff may have the necessary skill sets. Of course, outside hires or consultants are possible solutions, but this still requires resource commitment. The commitment doesn’t stop once the WBI is developed, though. It continues throughout the life of the course, a much longer time than the development period.

One of the major resource areas that must be explored prior to beginning instructional development of web-based courses is the technology. Problems including service volume, compatibility, training, and technical support must be solved before one can begin to successfully develop web-based courses.

WBI, by design, will significantly increase the load on the institution’s web distribution capability. Planning must be accomplished for this increased traffic to preclude total gridlock when students of WBI courses are trying to access information. Problems including incompatibility between
student and instructional hardware and software systems and slow internet connections must be taken into consideration when developing web-based courses. Faculty and staff who are developing the courses need access to computers and software that are capable of handling the various tasks necessary to develop the multimedia elements required to support a web-based course. These elements include, but are not limited to video, sound, and graphics.

At the other end of the spectrum, students will need a system and software to display all the components of the courseware. Courses will need to be developed in such a way that they can be delivered regardless of what system is available to the student. The software necessary to run various parts of the courseware must be made available for the student to download either on- or off-site. Bandwidth also becomes a problem. An uncompressed one hour movie running at 30 fps at a resolution of 640x480 requires 100 GB to store. Time to transmit using a 28.8 kbps modem is 320 days (Fryer, 1997). These problems make hybrid designs (combinations of CD and WBI) attractive.

Another problem area is training in the capabilities and limitations of the web and its use by both the faculty who are developing the courses and the students who will be expected to take the courses. Most faculty do not possess the technical skills necessary to develop courses for delivery over the web. This is currently mitigated by the fact that instructors who are developing on-line courses at this time have some knowledge and interest in computers. Students will need to acquire the necessary skills to configure their system to run the WBI courses. Once the courseware is developed, hardware and software for distribution is necessary.

Technical support becomes critical as faculty with little or no technical training become involved in developing courses for delivery over the web. As this type of instruction becomes more commonplace, one can expect more involvement from faculty with less computer knowledge. “Those involved in on-line learning initiatives report that robust technical support is crucial to the success of courses.” (ed tech, 1997)

**Faculty Reward Structure**

Faculty commitment to delivering a WBI program is at the heart of any program’s ultimate success or failure. They must feel that it is a valued enterprise through the existing reward structure, with significant credit toward promotion/tenure. Faculty productivity, as measured by usual standards, may be severely impacted, posing a risk, especially to non-tenured faculty and faculty below the rank of Professor.

It appears that in many institutions the faculty reward system fails to address critical issues associated with using technology for teaching and learning, and in some cases, actually seems to discourage innovation in technology-based instructional delivery through disincentives.

Cummings (1995, 1996) refers to these as faculty resistance barriers, and notes that “when teachers express the belief that for them, implementing ET [educational technology] offers more risks than rewards, their resistance is easy to understand” (1995, p. 14). In considering the design and delivery of web-based courses, some of the key questions related to these issues include:

- Will all faculty be required to design and deliver web-based courses?
- What effect will this time and energy commitment have on promotion and tenure?
- How does the concept of course load change with the use of the web for instructional delivery?
- Will faculty be offered any rewards (monetary or otherwise) for course design and delivery?
- What kinds of training will faculty be given in terms of the technology utilized for WBI delivery?
- Will instructional design training also be provided or will the institution provide instructional designers to work with faculty?
- What other resources will be available to faculty as they work through this process?

In terms of traditional faculty rewards and incentives (additional monetary compensation, reduced course load, etc.) it is somewhat difficult to make general predictions about the relationship between these extrinsic motivators and faculty willingness to participate in the design and delivery of a web-based program. These are, however, internal issues that the institution itself has a high degree of control over and thus are issues that can and should be addressed from the beginning of the planning process. (Connick, 1996)

**Instructional Design and Development**

The key to success for any learning environment is the effectiveness of the instruction. WBI is presented in a format that differs significantly from traditional instruction. To maximize the learning opportunities for this presentation format requires a shift in pedagogy. WBI alters not only the method in which information is presented to the learner but also changes the way in which the learner interacts with information. The essence of this shift focuses on instruction within the constructivist paradigm. Rather than designing instruction that is intended to deliver information to the learner, it is necessary to design instruction which engages the learner in interactive activities (Sherry, 1995). Careful planning is required to establish that learning is a process in which the student actively participates.

The amount of time and effort that must go into the design and delivery for web-based courses should not be underestimated. Overviews of the major components of this process have been discussed by Odasz (1994) and in *Learning on the Web: An Instructor’s Manual* <http://...>
Each facet requires specialized expertise to produce effective instruction. The initial phase of course design would include a team organized to conduct a needs analysis. Academic units need to determine if existing courses and course sequences are suited for on-line offering, if existing programs could be modified, or whether new programs are more appropriate. Content experts, instructional designers, end-users or practitioners, graphic designers, web page designers, program administrators, and university administrators all need to be included in various phases of the design process. The British Open University has been involved in distance education for over 30 years. Each course offered by BOU is designed by a team of experts which may include as many as 20 or more individuals (Moore and Kearsley, 1996).

Media should always be selected on the basis of the effectiveness of the medium to deliver the content. An initial planning decision involves the appropriateness of WBI for course content. The design team must determine that the instruction can be effectively delivered via computer capabilities. An analysis of course content must be conducted to determine course topics that require other or additional delivery methods. WBI tends to be heavily text dependent. There are many other media including audio, video, photographs, graphics, and charts that can be enlisted within the course design to ensure that the content is being effectively delivered. The design team must ensure that the instruction utilizes the most effective feature of online instruction — its interactivity and is not just a series of lectures, or written text.

Development of the courseware requires specialized expertise and time. Recognized industry standards are from 30 - 600 hours of development time for every new hour of instruction delivered (Golas, 1993). The wide variance is due to the mix of complexity of the subject matter and the type of media and method that is chosen. If we were to choose to teach a relatively low-level skill with some interactivity and utilize a multimedia environment, one may find that 100 hours development time per new hour of instruction may be required. Given that a three semester hour course has 45 contact hours, then the required development time may be 4500 hours — over two person years. The industry also recognizes that a startup project would require much more than the average figures and incurs a risk much higher than normal.

**Student Issues**

Even before development begins, administrators should decide how the course is to be managed — enrollment in cohort or on-demand. Once the course is developed, ongoing management is required. A faculty member or graduate assistant must be designated to assist and assess the students. Computing resources must be allocated sufficient for the enrollment. Tuition charges must be managed. Typically, tuition costs for these courses are significantly higher than normal courses because of the higher development and management costs. These charges can be potentially adjusted downward through competitive forces as more courses are offered.

As students and faculty must make significant adjustments in the way that they approach instruction in a web environment, so must the administration. In fact, administrators must be active in the development of any institution-wide move to WBI. Support for the development of the instruction must be available. Resources must be allocated for the development of the instruction. Examples may be:

- load adjustment to provide faculty course development time,
- staff direction to provide assistance in instructional design and development,
- administrative time to develop course management, and
- specialized applications for course development and web management.

**Scheduling**

One of the important decisions that must be made is the enrollment or scheduling model. Current models of scheduling for traditional students are the batch or course-based model. Students choose the course that they will enroll in based on degree requirements and accomplish the courses during a formalized period that are designated semesters, quarters or terms. This scheduling model is appropriate regardless of the instructional model chosen — a course supplement model or a virtual classroom model. The course supplement model uses the WWW to augment conventionally delivered courses, while the virtual classroom model is one where all instructional aspects are delivered via the WWW and students and teachers may never meet in person (Saltzberg & Paxton, 1995). Nontraditional students may also be in degree programs and thus choose their courses based on program requirements, but a larger number of them are non-degree students who choose their courses based on personal perceived needs and time availability (Butler, 1997). Both traditional and nontraditional students may opt to erase the artificial boundaries created by batch scheduling. These types of students may prefer an open enrollment model that allows students to begin courses at any time and complete them as time is available.

Admission, advising, and registration procedures must also be addressed. These procedures are somewhat tied to the enrollment model. If scheduling using the open model, admission and advising should be flexible. Procedures may be developed to accommodate enrollment, advising, and scheduling via the WWW. Batch scheduling can also take advantage of the convenience afforded by accomplishment via the WWW, however, because it is quite traditional, this method need not be used.

*Distance Education — 143*
Student Management

Student management procedures must also be developed. Entirely web-based courses may struggle with security because the student is unknown. Admission requirements must include screening strategies to identify the students. Ascertaining who is accomplishing the work is problematic. As students engage in the learning process, additional measures must be devised to identify the students as they proceed through various course activities. The outcomes of a program are dependent on the student demonstrating specific skills or knowledge as a result of the instruction. Without a method of determining student identity, the integrity of the program is in jeopardy.

Transfer policies must be developed. Because convenience and appropriateness for the learner’s needs receive a high priority in these situations, the learner may not be persistent in programs. They may “shop” for the best or most convenient course and look at transfer as a means of eventually consolidating courses into a program. Another problem may be how to handle the occasional “convenience course” that is taken to replace a course in a traditional program. How should the course content and administration be verified?

Another student management issue is evaluation. Even if the security issue is ignored, keeping track of the participation and assignments for a web-based course is a challenge. If there are many students enrolled at different sites, the scoring, recording, and providing feedback can be a daunting task for the instructor. There are courseware such as Asymetrix’s Librarian that can assist in the record-keeping, but the workload potential still remains. If the open enrollment model is used, there must be an instructor to provide services to the student, regardless of the number currently taking a “course.” This may make student to instructor ratios extremely variable.

Student Support

Threlkeld and Brzoska (1994) categorize student support in two ways. The first category is non-content related institutional support, consisting of services such as admissions, registration, financial aid, counseling, and technology assistance. Typically, on-campus support services are available through a variety of offices, providing individual counseling, small group sessions, and written materials to help support the needs of learners. In a web-based learning situation, a distance learning coordinator or facilitator may perform some of these functions, and serve as a student resource person. (Sherry, 1995) The Education Network of Maine Online web site <http://www.enm.maine.edu/> is a good example of both the range of support services available to distance learners, and an effective way of communicating the availability of the services. The second category contains two areas of academic support. The first subsection includes support from faculty, which may include services such as expanded office hours, e-mail contact, and extended syllabi. The second subsection of academic support comes from classmates, and may include provisions for small group work and listservs. One category of academic support services may be added to Threlkeld and Brzoska’s list: support to help students learn to become better learners. Students may need assistance in study skills and bibliographic (or library skills) instruction. These foundational support skills may make the difference between success and failure, especially in a situation where students may be highly motivated but lack experience in web-based learning.

Learning Issues

One of the barriers students may face when considering distance learning opportunities is lack of experience and expertise with a range of rapidly changing technologies. It is very easy for an instructor to tell a student to “Sign on to the listserv and participate in the group discussion. Then e-mail me your assignment in ASCII format” without even considering the possibility that a student may not have the expertise to accomplish these basic tasks. Adequate, ongoing support must be provided to help students overcome their anxieties about the technologies used for distance learning—students should be spending time on course content, not worrying about how to attach a document to an e-mail message. Access to on-campus technology support personnel should also be available for more challenging problems.

Students who are successful in a distance learning environment tend to be mature, highly motivated, and possess well developed self-directed learning skills. At the same time, Moore and Kearsley (1996, p. 155) suggest that “Most adult learners also experience a considerable degree of anxiety about learning. There is a considerable fear of failure.” Given this, it is important that students who lack essential learning skills or who are high of anxiety about web-based learning be given opportunities to master the necessary skills and overcome their anxiety. While maturity and motivation cannot be directly taught, they can be indirectly fostered as a result of the development of self-directed learning skills. Even experienced students face challenges in a new kind of learning environment and they may find that skills that served them well in a traditional classroom are inadequate for learning via the World Wide Web.

Marketing

Finally, marketing issues have to be addressed. Where are the students going to come from? What are their interests? Why should they take your courses? As more and more institutions offer WBI programs, one needs to determine what would attract the student (consumer) to a small institution when a big name institution offers the same program. The program must then direct their efforts...
toward filling that perceived need. Accreditation is important in this instance (edTech, 1997).

Conclusion

WBI offers significant opportunities for institutions to open up education to the unserved or underserved, provide new tools to enhance learning, and increase convenience for learners in terms of effective use of place and time. The institution must make a commitment and systematically plan to implement this new form of instruction and faculty should also be aware of the additional time and effort that will be required to ensure the success of these initiatives.

References

The Internet continues to grow in education. In the past few years, the use of the Internet among university faculty and students has soared. Listservs, Web-based courses, and e-mail have become an important aspect in college-level courses. Internet developments, especially the World Wide Web (WWW or the web) offer a great potential to improve instructional practice. A wide variety of tasks may be designed and developed by teachers to integrate the web into curriculum and to engage students in dynamic activities such as exploration, research, discussion, planning, cultural awareness, and publication.

Although many people hold a high hope that the Web will bring tremendous changes in education, in reality, using the web for instruction is not an easy task. There are many obstacles for web implementation in the school. Lynch and Horton (1997) highlight a few weaknesses the web has presented—being awfully slow, demanding lots of memory, bandwidth limitations, and the expense required to upgrade and to maintain. Monke (1997) also describes the common reality and frustration in school uses of the web, “The education community has been bombarded with hype about the information highway. But in practice, the connections are often unreliable, the interfaces unintuitive, the documentation unintelligible, the information unfindable. And when we do get the systems working, the technology changes so fast that we never feel fully confident about what we are doing.” (p. 30)

**Issues and concerns**

The integration of the web in instruction should involve the following types of tasks: finding resources on the web, retrieving resources from the web, communicating, developing teaching and learning activities using the web, and publishing on the web. These tasks match what Flake (1996) identified as the four key areas of the Internet skills. To integrate the web into instruction successfully, we must take into consideration many concerns and issues related to real life practice. In addition to the above-mentioned issues of the stability and speed in web implementation, many other issues such as resource appropriateness, pedagogical and curricular considerations, designing and publishing effectiveness, and the cognitive impact are of equal or even more importance and deserve much attention. These issues and concerns are presented as follows.

**Finding sufficient time and developing good plans are critical for web integration.**

Cruising on the web to search for resources can be time-consuming. Developing or maintaining web pages is even more time-consuming. To integrate the web for effective instruction requires thorough planning and extensive experimentation. For example, to engage students in active exploration on the web, teachers should develop learning activities that can link the learning contents to students’ prior experiences. Teachers will have to explore all the potential web resources prior to students’ exploration. As another example, to develop a good web page, one should plan ahead of time and develop a template containing necessary components so that the web page will meet the intended expectation and can be easy to maintain. Sound web pages will require constant modifications and maintenance.

**Students’ involvement is the key to the success of web implementation.**

When using the web for instruction, students should not be the passive information receivers. To engage students in active learning, teachers should assign students to explore resources, to formulate discussion, and to organize their own information for on-line publication. An elementary school technology coordinator in the southeast Wisconsin, for example, trained some enthusiastic fourth and fifth graders to become technology class helpers who constructed web pages for teachers, classes, and the entire school. They also functioned as teachers’ technology assistants. These students, functioning as seed students, continue to grow, help, and influence other students and teachers. Before long the entire school became heavily involved in the web implementation.

**Useful web resources are hard to come by.**

Teachers should be careful in examining the resources retrieved from the web to ensure that they match the teaching and learning objectives. Many web-using teachers share a serious concern about the inadequacy of the web information to meet the instructional needs. Although there are many resources on the web, most
teachers probably will agree that it is difficult to locate pertinent information to serve the instructional needs. Often times the contents of the resources found on the web are irrelevant, incomplete, or inappropriate.

To locate useful information, critical thinking and problem-solving skills need to be incorporated into the learning process. Users need to develop good strategies of using the on-line search engines to simplify the tasks. Users should learn to choose a proper keyword or combination of keywords for smart search. They sometimes will have to choose different search engines to locate what they need to find. Finding web resources requires time, patience, and practice to excel.

**The web should not be used solely for disseminating course materials**.

Some administrators advocate saving printing costs by promoting a practice of using the web to display instructional materials and course information. According to such an advocacy, instructors do not give out handouts in class, instead, they put instructional information and materials on the web. Students are required to log onto the web to browse the information as needed. In most cases, as a result, students simply log onto the web, find the information, and print it out from the school printers. It cost even more than using the Xerox machine. Such a policy does not provide students any good motivation to explore the web for learning. Incidentally, such a practice will take teachers plenty of time to put information on the web.

**Access to the web is essential for curriculum integration**.

An urban school district administrator boasted that his school district had the Internet access way ahead of other school districts. In fact, the teachers from this district revealed the truth that they had only one slow phone line connection in the library which no teacher could access. Inconvenient access is equal to no access. If we want to fully exploit the power of the web for instruction, learners must be provided with an easy access to the web. At present, schools are not well-equipped with the web technology. Most teachers do not have an adequate access to the needed hardware and software resources to support the web-based instruction. In addition, poor scheduling and time management often aggravate the situation.

To increase Internet access, an innovative approach may be developed through cooperation and collaboration between school, community, and universities. Writing small grants to seek community and business contribution may result in financial support to the web access in the school. Teachers and university professors can also work together to explore potential collaboration such as enriching public school students’ learning experience by taking a field trip to the university computer lab, or to develop a continuing project that connects the college professional development experience with the public school via the web.

**School should create a policy for proper use on the web**.

The web has opened a door for misuses. The web is an untamed area where we could bump into almost anything that we may imagine. With the vast variety of the web, two main issues that concern education are the security issue and the copyright issue. Most people believe it is not safe to do transactions on the web. Many teachers, parents, and administrators have expressed their concerns about releasing individual information such as names, addresses, phone numbers, and pictures on the web. Many individuals become aware that a third party in cyberspace might be looking while they are browsing on the web. Individual information becomes vulnerable and insecure.

The problem of pornography, another serious issue, has become pervasive and controversial. Several computer companies have formed the Information Highway Parental Empowerment Group to create standards for software filters that make it possible for teachers and parents to restrict children’s access. The controversy over privacy and freedom of speech versus the cyberporn restriction may become a debatable issue and remain unresolved for many years to come. However, an appropriate guideline must be in place to restrict undesirable behavior.

Also, many teachers are concerned about the quality of homework such as the research paper. Individual users can easily copy the resources they have browsed. To fulfill the assignment requirement, students may log into the web and retrieve a portion of an article and paste it into their own research paper. A clear school policy about fair use regarding copyright and plagiarism violation should be established. Copyright issues should be clearly addressed with students so that they know the differences between free resources and copyrighted materials, and know how to properly use and cite other people’s work or ideas.

**Design a web page with a good purpose**.

After learning how to construct a web page, a practicing teacher commented, “Although the process of generating a web page has been made easy, it is still very difficult to develop a good and useful web page.” Simply putting text, graphics, or multimedia elements onto a web does not necessarily make it a meaningful and worthwhile product. To make a significant web page, we have to design the page by taking full advantage of the unique characteristics the web can provide. For example, one of the most exciting aspects of web-enhanced instruction is that teachers are able to organize instructional information and include all the relevant references by easily linking to other well-developed sites.

Another important element for a good web page is the inclusion of valuable content to satisfy users’ needs. We have to think from the users’ point of view about what they
like to see on the web. Since we have seen some web pages as considered as a waste of time or of no value, why do we want to create the same kinds of junk pages? Teaching students to compose a web page, teachers should focus on not only the mechanical part of the designing and development, but also the meaningful contents as well as the global hypertext structure that allows users to cruise around to find relevant information easily.

Other rules of thumb include the basic instructional design and screen design theories. For example, the web page should contain more depth and interactivity for the resources so that teachers can engage students in extensive exploration and collaboration. In addition, the web page should be made intuitive and self-explanatory. The web page designer should also be sensitive to the needs of hardware and software on the users' sides. Undesirable or irrelevant, big graphics should be avoided, and alternatives for unsupported functions or plug-ins should be provided. A good web page for instruction is not only good-looking, exciting, considerate, but also conducive for learning.

**Good practice to exploit the web**

Good practice to implement the web for instruction requires good planning so that students can concentrate on learning materials and activities within budgeted time. As witnessed by the author, a group of college students were sent to the computer lab to research a certain topic on the web. After an hour, they reconvened in the classroom to talk about what they had learned. Surprisingly, most students did not seem to have achieved much in their experience. They could only contribute to a shallow discussion. With limited time for exploring, it is difficult to stay focused unless a well-organized plan is provided. Otherwise, students will very likely be distracted by other items that caught their eyes.

The web has facilitated an exciting way to engage students in active learning. Contrary to the traditional lecture and factual information memorization, the world wide web as an instructional tool allows student-centered learning where exploration and discussion may inspire students to find information to satisfy their curiosity. The web-based learning can meet individual’s needs, motivate students to find resources, and to publish with a creative mind. It also promotes cooperation and collaboration.

Properly integrated, the web can make a huge impact on instruction. However, in many cases today, the web application in instruction still focuses on the mechanical aspect of learning. The courses place a great deal of effort on the following tasks: studying the new terminology, learning to use the web, cruising and finding information on the web, and composing and publishing on the web. Although these tasks are important, the web should not become an independent element in education. Instead, it should function as a supporting element to enhance the content teaching and learning.

**Suggestions for optimizing the Web for effective instruction**

The web has provided a great potential for instruction. However, in order to maximize the power of the web, we must carefully design and develop instructional activities so that students can benefit from using the web without wasting time. The following are some suggestions derived from the above discussion.

- **Plan web-based learning activities ahead of time.** Gather needed information. Organize meaningful learning activities to support the web exploration. Schedule needed computer time. Browse through all the suggested web resources before students do it. Prepare a Plan B just in case of the bad connection or some other unforeseen events.
- **Relate the web resources with the learning contents and develop instructional activities on the web.** Students should explore the web with a clear goal. Random or unprepared exploration on the web often result in a waste of time.
- **Watch for proper use of the web resources.** Discourage students from pirating ideas or materials from the web.
- **Conduct formative and summative evaluation on students’ performances.** Browsing on the web does not necessarily constitute effective learning. Teachers should conduct needed assessment to monitor students’ performance and progress.
- **Encourage communication via collaboration and cooperation.** The web is a great tool for students to share their own experience. The web-based activities should emphasize the importance of sharing. Teachers should encourage students to engage in active discussion, and creative and critical thinking which in turn may increase students’ multicultural awareness.
- **To increase efficiency and effectiveness for web exploration, ask students to keep a log about what they have experienced and narrow the focus to the desired resources only.**
- **When organizing and publishing web pages, authors should consider the needs of the audience.** Put only useful and relevant information on the page. Minimize the multimedia elements which may consume too much computer resources to load. Organize information in a proper layout.

**Summary**

Although the world wide web has become a popular tool in education, to implement the web across the curriculum will require teachers to invest a tremendous effort. This paper addressed various issues regarding the use of the world wide web as an instructional tool. Based on the discussion, some suggestions are provided for optimizing web-based instruction. To sum up, we must overcome the
obstacles of the web access. We should develop innovative instructional activities to motivate students by maximizing the power and advantages that the web can provide.

The current fascination of educators with the World Wide Web (WWW) is indicative of a fundamental change of perspective rather than mere curiosity about the hot topic of the moment. This change is occurring at three levels: communal, organizational and personal. Levin (1976) states that one of three motivators for educational change is through internal contradictions such as when indigenous changes in technology lead to new social patterns and needs. This communal level deals with society at large as the Internet with all of its inherent technologies redefines humanity’s relationship with, access to, and even definition of, knowledge. Virtual communities are creating new social relationships across distances, gender, and economic levels. Usage of the Internet creates new opportunities for research, defines a new style of discourse and demands new means of composition.

Change is also occurring at the organizational level. At this level, the Internet is a powerful tool with the capability of circumventing the anachronistic hierarchical structure that defines today’s public schools. McDonald (1996) identifies this preference for central control in cellular institutions as one of five items on an “unlearning agenda”. Such a structure denies the individual school the ability to establish a purposeful community where common standards can be articulated, a vision can be developed reflecting a collective image of excellence, and staff, parents and students come together to form a learning community.

Finally, on a personal and professional level, educators’ interest in the Internet reflects a growing acceptance of the constructivist learning model. Technologies can support school reform if they enable teachers to implement new models of teaching and learning (O’Neil, 1995). Roblyer, Edwards, and Havriluk (1996) list five characteristics of constructivist learning:

- Authentic problem solving activities;
- Wide variety and format of resource materials;
- Collaborative work groups;
- Emphasis on problem solving process rather than product; and
- Authentic qualitative assessment methods.

These characteristics can ably be facilitated through thoughtful Internet usage. Harris (1994) and Brehm (1997) divide educational telecommunication activities into four categories: computer mediated communications (CMC), resource retrieval, collaborative projects, and content generation. It is important to note that many educators embrace a constructivist learning model because of their growing awareness of how they, as adults, learn in their everyday life. Therefore, facility with the Internet is seen not only as necessary for their students but also as relevant in their own personal and professional lives as well.

Background

Double Eagle Elementary School in Albuquerque, New Mexico, opened in the fall of 1996 under the auspices of an ambitious collaborative between Albuquerque Public Schools and the University of New Mexico. The core of this collaborative was aimed at creating a vibrant learning community incorporating pre-service teachers, in-service educators, university doctoral students, and university professors. Additionally, ten staff members completed on-site masters’ degrees in technology integration during the first eighteen months of this project. Two main goals of this project were collaborative curriculum development and the integration of technology into that curriculum. The emphasis for the first year of the collaborative was on collaboration and working with teachers to increase their comfort level with the use of technology.

The second year has seen the continued growth of the teaching staff in willingness to assume a collaborative stance in a community of learners through bimonthly focus groups centered on reflective practice and action research. Two master teachers at grade levels two and four have become mentor teachers for four university interns placed in double classrooms. Two doctoral students from UNM are on site at the school daily to assist in curriculum development and technology integration while university personnel conduct monthly workshops on campus as well.
In the first year of the project, the majority of classrooms were housed in portables while construction continued throughout the 1996-97 school year to complete the main buildings. This issue prevented full development of the local area network (LAN) at the school. However, by the fall of 1997, construction was completed and the school was projected to be fully networkable for both communications and media purposes.

The emphasis on this networking was to enhance teaching and learning by both the students and the staff. A national study, Model Nets: A National Study of Computer Networking in K-12 Education, completed in 1996 by Los Alamos National Labs and sponsored by the U.S. Department of Energy, concluded that networks spark motivation among teachers and students, facilitated on-line information services and enabled intrastaff, intrastudent and intercommunity e-mail communication. However, professional development for teachers in how to plan curriculum that utilizes computer networks as an integrated portion of student learning is often overlooked.

Therefore a major goal for the 1996-97 school year was to concentrate on providing the structure and professional development needed to encourage and support full use of the LAN by both teachers and students in grades 3, 4, and 5. Additionally, through discussions with staff, the need for staff to feel comfortable with the WWW was apparent, as was the need to feel competent in their ability to publish on the WWW. Therefore, a grant was sought from the Corporation of Public Broadcasting Next Step Project to provide the needed software, hardware, and monies for teacher release time. A group of four in-service teachers and one doctoral student wrote the grant application and notification of acceptance was received August 1997.

Project Description

This project was conceived as a means to further the building of a community of learners at Double Eagle Elementary School. It was envisioned that joint participation in designing a website for the school would bring together staff, students and parents. Because a survey indicated that a majority of families at the school had Internet access at home, a website seemed to be a natural communication link. Additionally, many parents indicated that they would like to have the ability to e-mail their child’s teacher with questions and comments. Teachers, as well, felt that the site could prove to be a valuable tool in their classroom curriculum.

A website was designed and developed through the coordinated efforts of school and UNM collaborative staff, giving all teachers the opportunity to participate in the design of the website. To facilitate getting the site up and running in a timely manner, a software template developed for Intel was used as the basis for design. This precluded the need for time consuming instruction in HTML and staff agreed that a more personable design, unique to the school, could be developed over the upcoming months. However, staff did have available Microsoft FrontPage and Adobe Acrobat for construction of their personal web pages. A digital camera was purchased and, using the Jigsaw II method by Slavin (1990), certain staff members volunteered to become experts in the operation of the camera as well as ‘experts’ with PhotoShop software.

The basic website includes a weekly calendar of events, the cafeteria menu for the week, and general announcements. A library page includes suggestions of reading material for children and parents as well as book reviews written by students. A student art gallery gives young artists a place to display their work while another page features a different class each month for a feature presentation. This portion of the website is kept up to date by both staff and parent volunteers.

Parents have contributed to the website by volunteering to serve as ‘page parents’ charged with updating the basic information databases. The Parent Teacher Organization has a page on which their minutes are posted, the parent community is queried, and the needs of the school are presented. Other parents have begun construction of a page with links to information sources on such items as parenting issues, special needs, and health and development issues.

Individual teachers were given the option of creating their own pages as links to the school site as well. Many teachers chose to move beyond a basic biography approach to this page. Some chose to post long-term assignments on their page as well as to embed links that students could use as on-line research resources. Pre-service interns at Double Eagle, as part of their on-site UNM math methods course, created a math page with links for parents, students, and teachers.

Originally envisioned was a school intranet to provide a virtual space where teachers could meet to plan collaborative on-line projects centered around Writers’ Workshop with emphasis on integration with the social studies and science curriculum. HyperStudio stacks, perhaps started in grade three, would be archived to both serve as a learning resource for the student community and to stimulate continued study within that interest as the students moved up through the grades.

Thus was authentic assessment embedded in the growth and depth of understanding demonstrated over a course of time through these HyperStudio projects while encouraging connectivity across grade level curriculum.

Staff received assistance in learning the mechanics of using the LAN/WAN for e-mail capabilities, uploading and downloading files, and conducting research by WWW searches.

Sessions for all interested staff members were conducted on website design and constructing web pages using Microsoft FrontPage. Individuals who volunteered as ‘experts’ received instruction on use of the digital camera,
conversion graphic formats in PhotoShop, use of the scanner, and basic HTML skills.

Professional development activities were conducted on the effective use of the WWW in the elementary classroom. Teachers had the experience of participating in a WebQuest and later were assisted in developing one for use in their classroom. Excellent collaborative projects on the WWW were demonstrated and explored. Teachers had the option of participating as a member of the I*EARN Learning Circle projects.

**Change**

Development of a website at Double Eagle Elementary did demonstrate change across three levels: communal, organizational and personal. Most staff members signed up for an e-mail account on the district WAN and learned how to access and manage their accounts. Many joined educational listservs and began to participate in discussions on educational issues with other teachers around the world. Classrooms began collaborative projects with other classes under the I*EARN Learning Circles program. Indeed, the scope of the classroom world did become redefined for these students and teachers.

The bimonthly focus groups did continually emphasize the need for increased staff facility with the WWW. Teachers self-selected the content area of their focus groups as well as their membership in any group. Content areas to be explored in the groups ranged from mathematics to music to poetry to science. However, no matter what the content area selected, discussions within the first three sessions of the focus groups led each group out onto the WWW. Whether it was the need for information, the need for classroom collaboration, or the need for a publishing medium, each group of teachers saw the potential of the Internet as a tool to support their curriculum. Some were not quite sure of just what was the WWW while others, a little more sophisticated with technology, knew how they used it in their personal life but were seeking guidance in how to use it with their students.

Collaborative construction of the website opened up areas of discussion among staff, students, and parents. Acceptable use policies were debated. Discussion was initiated aimed at creating a vision of excellence for the school. Censorship issues came to the forefront with students and parents. Standards for publication for the local site became a focus of teachers and students. Thus, the very structure of the school organization began subtly shifting.

The collaborative design and development of the Double Eagle WebSite involved teachers with a hands-on approach to the technology. Constructing a site, building the pages and mastering rudimentary HTML and web authoring tools combined to give a sense of confidence to each participating member. Additionally, the complexity of the WWW was demystified. By presenting an authentic problem to be solved (create a school website, making available a wide variety of resource materials (software, hardware, and other tools), and coming together in collaborative work groups to accomplish the solution to the problem, constructivist learning was both practiced and modeled.

The collaborative design and construction of the Double Eagle WebSite served as a focus agent in building dynamic school community. It supported organizational change by providing a focal area for discussion and debate. It challenged current definitions of school community by extending the walls of the classroom into the world beyond. Finally, the very act of collaborative website design stimulated discussion of constructivist learning through a dynamic interaction with the five defining characteristics of its methodology.

**Bibliography**

**Penny Garcia is a doctoral candidate specializing in Instructional Technology within the Curriculum and Instruction Department, College of Education, at the University of New Mexico, Albuquerque, New Mexico 87131. E-mail: pegarcia@unm.edu or pegarcia@roadrunner.com.**
The World Wide Web! It’s hyper, it’s dynamic, it’s complex. It’s overwhelming! As K-12 teachers or preservice teachers struggle with integrating Web resources into classroom assignments and projects, it’s often difficult for them to focus with yet another wonderful resource only one click away. The advantages of using the Web; however, make it imperative that teachers be able to use it effectively. As we work with K-12 teachers, preservice teachers, and education professors, we have found that looking at Web resource use in the following framework has proven beneficial. After introducing the Web in this way in an educational media course, one of the graduate students, a fifth grade teacher, said:

At the recent teacher’s convention I attended two Internet sessions, and both facilitators handed out a list of Web resources and said, “Explore.” Applying this framework to Web resources will really help as I develop Web assignments for my fifth graders. I wish I had had this structure before I did the exploring at the convention.

Expanding on the Web levels of use as defined on the “Courses on the Web” page at Oregon State University (http://www.orst.edu/fe/extendu/couviaf), we devised the following structure which emphasizes assignments based on Web use while de-emphasizing the glitz of the Web. The educator purposefully designs a Web-based assignment which adheres to the unit objectives and is appropriate to the environment in which it will be used. Therefore, assignments will be varied according to connectivity, accessibility, student skills, and, of course, classroom goals and objectives.

The Framework: Levels of Web Use

The “levels of Web use” background helps prevent teachers from experiencing that overwhelmed feeling. It allows them to begin with tightly focused assignments that make small and appropriate use of on-line resources, then builds to more complex assignments as they experience success and develop confidence in their ability to use Web resources effectively. What follows is a description of each level of Web use and URL’s that exemplify that level of use.

Level One: Informational Use of the Web

This level of Web use contributes to the teacher’s ability to disseminate information in on-line form. It is often used to post syllabi, assignments, reviews, sample exams, frequently-asked-questions about an assignment, and even personal and student-friendly information about the teacher. It often takes the shape of a teacher’s personal home page. Initially, the information posted may also be distributed in print form to the students, thus making the on-line form an optional source. If, for example, (or should we say when) a student forgets assignment information at home, the student can access the information on-line, preventing teacher interruptions. Vice versa, students and parents with at-home connectivity can access the assignment via the Web.

Posting information on the Web has advantages for both the teacher and student. It is an easy way to become involved in Web use and aids in developing Web navigational skills while teaching students the basic mechanics of Web browser use. In Wisconsin, all it takes is a small blizzard to upset schedules! Adjusting assignment procedures and timelines posted on-line is quick, efficient, and could possibly be done from the teacher’s home during the blizzard!

Here are some examples of the informational Web use level:

- Mount St. Joseph High School Foreign Language Department: http://www.msjnet.edu/for-lang.html
  This site provides information about the school’s foreign language department. It lists the languages taught and explains the school’s language requirement, facilities, and placement policies. Current and future students, parents, counselors, teachers, and administrators can make use of the information.

- Elementary School Media Specialist Home Page: Jennifer Burger: http://comp.uark.edu/~jb burger/
  Ms. Burger’s home page invites students to get to know her better. Note her use of color, cartoons, and catchy
link titles. Students can develop a sense of Ms. Burger's personality so when they go to the Media Center they may already feel some rapport with her. This site not only helps teachers and students gather a "sense" of Ms. Burger, but Ms. Burger also provides some easy to use links for both teachers and students, thus, providing additional information and resources.

- Dr. Linda Shadiow's Home Page: http://www.nau.edu/~cee/faculty/l.shadiow/l.shadiow.html
  This Northern Arizona University professor's home page is a good example of how the informational Web use level can be used for distributing information on preservice education courses.

**Level Two: Supplemental Use of the Web**

Supplemental Web use implies that Web resources are used in addition to traditional resources. A well-designed assignment does not fail if Web resources cannot be employed; however, accessing the Web resources through a live connection may enhance and enrich the assignment. It may also provide additional motivation for students to complete the assignment. Web resources can include basic information published by the teacher, but they also can be part of a required or optional assignment to use resources others have placed on the Web. In fact, the majority of supplemental uses include accessing already published Web pages. Some examples of supplemental use encompass using a Web page as one resource, along with print resources, when researching a topic; using a Web page for resource evaluation and critical thinking activities; and locating Web resources through simple key-word search techniques. Students may also be asked to go to a specific site and locate/read/summarize some specific information or a Web-based document.

Some examples of sites that can be used at the supplemental level include:

- Currency Converter: http://www.oanda.com/cgi-bin/ncc
  A middle school business education teacher uses this site as she teaches her students spreadsheet basics. Each student chooses a country and for two weeks tracks the currency conversion rate for that country. The students enter their data in the spreadsheet program and then produce a line graph using the data. The line graph also includes a flag of the country found and downloaded from a Web site. Although the assignment would be successful using non-Web data, the combination of using the currency converter and bringing in images from the Web enriches the assignment.

  Two kindergarten teachers who develop their units around a housing theme, chose the Whitehouse as their theme for February, Presidents' month. The students partake in an on-line field trip, a virtual, historic tour of the Whitehouse. Following the tour, the students design a president’s home of their own, naming the rooms and assigning room locations. In addition, the students compose an electronic mail message to the President.

- The Nine Planets: http://www.seds.org/billa/tnp/
  This site is one of several sites preservice students choose from as they complete a Web resource evaluation form. The site critique form involves critically analyzing the site, including appropriate vocabulary for the age level the site is designed for, appropriate linkages, linkages placed appropriately, site continuity, currency, quality and accurate information, and diverse site use.

**Level Three: Dependent Use of the Web**

In level three, classes continue to meet in a traditional classroom; however, the Web becomes a critical component of a course, a project, or an assignment. Often a majority of the course materials and resources are on the Web, and students can access the material only through the Web. The Web provides access to simulations, exercises, and forms. Links to Web-based activities and resources are usually provided from the teacher's home page or a course home page. Links to relevant resources may also be provided and a certain number of Web-based resources may be required in a research project or presentation. One note of warning, however, as we develop more complex Web projects, we need a back-up plan just in case the technology goes awry, or the sites that we plan to use disappear, move, or change content.

Some examples of dependently used Web sites include:

  Upper elementary teachers use the Sea World Animal Information Database as their students study sea mammals. Each student group chooses a sea mammal and writes a report which must include particular facts they extract from the Sea World Web resources about the sea mammal. At a related site, students learn the Latin prefixes for sea mammal features. In art class, each student uses the Latin prefixes to create and then draw a unique sea mammal. This art lesson, including the Latin prefixes, can be found at the second URL listed for this example.

- Real-Time Relative Humidity Activity: http://www-kgs.colorado.edu/rt_clouds.html
  This project requires students to gather actual humidity data and submit it as part of a nation-wide weather information data gathering activity. Students engage in real scientific data collection and come to understand the weather scientists' role while learning about the range and effect of humidity in their location.
that incorporates interaction between the students, between
disciplines. Success requires a carefully planned course
every topic or discipline but can be successful in a range of
courses for high school students as well.

directed to adult learners, there are good examples of these
demonstrate a high tolerance for on-line glitches. Although
Learners must be self-motivated, good time managers, and
take a greater share of responsibility for their learning.
required. Fully developed Web courses force learners to
interaction (email, discussion lists, Use Net News, Internet Chats, or
with one or more forms of computer-mediated communica-
tion, and administration is Web-based. In each case, the
content, assignments, communication, and administration is
primarily handled on-line. Second, fully-developed Web
courses can stand alone. Students and instructors never
meet. All content, assignments, discussion, communication,
and administration is Web-based. In each case, the
course may be supplemented by traditional resources such
as books, print library resources, and videos. Timelines
differ according to course objectives and purposes. Skill
with one or more forms of computer-mediated communica-
tion (email, discussion lists, UseNet News, Internet Chats, or
groupware) is expected and assumed; Web access is
required. Fully developed Web courses force learners to
take a greater share of responsibility for their learning.
Learners must be self-motivated, good time managers, and
demonstrate a high tolerance for on-line glitches. Although
most fully-developed Web courses we have seen are
directed to adult learners, there are good examples of these
courses for high school students as well.

Fully developed web courses are not appropriate for
every topic or discipline but can be successful in a range of
disciplines. Success requires a carefully planned course
that incorporates interaction between the students, between
students and course content, and between students and
faculty. Other keys to success include availability of
technical support in case of difficulties; sufficient
interactivity provided by the Web-based course content,
and a highly-motivated and supportive instructor (the first
time through this will involve a LOT of work!).

Many fully-developed courses require a password in
order to access the course itself. The following URLs
provide access to the opening pages of fully developed
Web courses.

Advanced Placement European History: http://
www.cesa10.k12.wi.us/clustera/apeb/index.htm
The Cluster A Consortium Schools (five rural Wiscon-
sin School Districts) currently offer this on-line course
to qualified students in all five schools. Individually
each school would not have sufficient enrollment for
the course. Together, they have filled the course and
have a waiting list.

Cool Math 221: http://www.uwp.edu/academic/
mathematics/cool.html
As stated on the Web page, “COOL stands for Calculus
Offered On Line. Offered to students via the World Wide
Web, its purpose is to reach out to mathematically
prepared high school students across the state of
Wisconsin and offer them an outstanding educational
opportunity.” Taught completely on-line, the course is
designed to provide students who otherwise might not
have it, the opportunity to study calculus before
entering college. A math textbook and the software
Mathematica are integral to the course.

Flexible Learning System: http://f1s.cll.wayne.edu/f1s/
welcome.htm
In creating a Web 101 course, the educators at Wayne
State University have provided an opportunity for K-12
educators and preservice educators to analyze the
structure of an on-line course. What are the issues when
developing such a course? What considerations must
the developer keep in mind? How many graphics
should be used? Does graphical format matter? How
does a developer incorporate interactivity in an on-line
course? Students have a chance to send their feedback
to the developers.

The Home Education Network: http://www.then.com/
Since its inception in the Fall of 1996, The Home
Education Network (THEN) has provided over 135
courses to its adult learner audience. Sponsored by
UCLA Extension, THEN continually updates its courses
and adds new ones.

Advantages of a Context for Web Use
Defining various levels of Web use expands the array of
possibilities for educators in a meaningful way. K-12
educators, preservice education students, and university
education professors now have a way of categorizing Web
use that will help them manage Web-inclusive assignments.

Distance Education — 155
The levels of Web use framework helps educators focus on clear objectives, well-planned, easy-to-follow activities, and distinct outcomes. This way of looking at Web use aids the teacher who is feeling pressure to use Web resources by providing a growth structure where the teacher starts gradually, simply, and comfortably at the informational or supplemental levels. After some initial successes, dependent Web assignments will not seem overwhelming. Another advantage of focusing and planning through this framework is the ability to create interdisciplinary and intragrade assignments. Language arts and math, social studies and music, science and art represent only a few of the combinations that can be made via the Web. A fifth grader may help a kindergartner develop a Web page; two third graders may create art for a sixth grader’s story, a group of preservice education students may divide the task of creating a Web page into writer, coder, image digitalizer, editor, etc. As you can see the possibilities are endless.

We cannot overemphasize the importance of focus and planning. The levels of Web use framework helps educators developing Web assignments to focus, plan, and structure assignments and learning to keep the emphasis on the learning and away from the wow, gee-whiz-bang nature of the Internet.

To see more examples of the Web levels of use see Finder and Raleigh (1997). Web Applications in the Classroom [On-line.] Available: http://www.cesa10.k12.wi.us/districts/augusta/levels.htm.

Kathy Finder is the Technical Training & Documentation Specialist in McIntyre Library at the University of Wisconsin-Eau Claire, Eau Claire WI 54702-4004. Office phone: (715) 836-2865. Email: finderks@uwec.edu.

Donna Raleigh is the Technical Training & Instructional Design Coordinator in the Media Development Center at the University of Wisconsin-Eau Claire, Eau Claire WI 54702-4004. Office phone: (715) 836-5162, fax (715) 836-6001. Email: draleigh@uwec.edu.
Using the Concept Attainment Model for Web-Based Interventions in Self-Paced Classes

Emery S. Martindale
Texas Tech University

Terence C. Ahern
Texas Tech University

Self-paced, learner-autonomous instruction is rapidly proliferating, particularly due to the growth of the World Wide Web. The effectiveness of this self-paced instruction has been and is currently being researched with varied results and conclusions. This paper describes a pilot study using the concept attainment model of teaching as Web-based intervention for students in a self-paced class.

With the rapid expansion of distance education and self-paced learning there is a need to examine and modify traditional instructional methods in the context of distance education. Using HTML, the investigator created a Web-based concept attainment intervention strategy to be used in a self-paced class. The concept attainment model of teaching can be defined as the search for and listing of attributes that can be used to distinguish exemplars from non-exemplars of various categories. The model requires students to compare and contrast exemplars that contain characteristics (called “attributes”) of the concept with exemplars that do not contain those attributes. Exemplars are a subset of data from a data set. Positive exemplars are the subset examples that share one or more defining characteristics that are missing in the other examples. It is by comparing the positive exemplars and contrasting them with the negative ones that the concept is learned.

Learning by concept attainment involves two phases. First, the concept name is presented along with labeled examples of positive and negative exemplars. The learner integrates these exemplars and generates a hypothesis about the concept definition. The student then states a possible definition in terms of essential attributes.

Secondly, the student identifies additional unlabeled examples as positive or negative exemplars of the concept. The student hypothesis and definition is either confirmed or corrected, and a correct definition of the concept is given. The student then generates more concept examples. By following this model the student learns the concepts related to the instructional content. This particular concept attainment intervention was used for reinforcing concepts related to particular subject matter. For this pilot study the subject matter was telecommunications.

Review of Literature

There exists a wide range of studies that consider different kinds of academic interventions. Some may be considered behavioral in nature, in that the intervention addresses behavioral problems or desired modifications within the student. Often the study involves a particular population which may be considered at risk or disadvantaged in a particular educational facet. For example, increased locus of control has been identified as an predictor of academic success. In a study comparing locus of control in very young boys and girls, Bernhard (1994) used a computer-based intervention to try to increase the internal sense of control in both groups. In a study of Black engineering students in South Africa, Meyer (1990) recommended identification of potentially “at risk” students very early in the academic year, and to have explicit provisions of intervention mechanisms to assist such students. Following up with the same population, Parsons (1990) implemented a successful intervention focusing on the teacher/student relationship, perceptions of textbooks and notes, and the nature and role of tests and examinations.

In a meta-analysis of intervention studies that considered the individual students’ learning styles, Dunn (1995) found that students whose learning styles were accommodated could be expected to achieve 75% of a standard deviation higher than students whose learning styles were not accommodated. Dunn summarized the results as following:

1. Students with strong learning-style preferences showed greater academic gains as a result of congruent instructional interventions than those students who had mixed preferences or moderate preferences.
2. Studies conducted with small sample sizes showed greater academic gains than those with large or medium sample sizes.
3. College and adult learners showed greater gains than elementary school learners or secondary school learners.
4. Examination of socioeconomic status indicated that middle-class students were more responsive to learning-style accommodations than were lower middle-class or upper middle-class or lower class students.

5. Academic-level moderators indicated that average students were more responsive to learning-style accommodations than were high, low, or mixed groups of students.

6. Instructional interventions that were conducted for more than one year showed stronger results than those conducted for several days, weeks, or months.

7. The content area most responsive to learning-style accommodation was mathematics, followed by other subjects and language arts.

Another meta-analysis of career education interventions on academic achievement found a small positive effect size for these types of interventions. Career education was significantly but not necessarily practically supported as an effective academic intervention (Evans, 1992). For adult learners the use of computer-based counseling interventions is widely used in the area of career counseling, particularly for those workers in transition due to economic factors (loss of jobs, layoffs, etc.). Marin (1991) found that career counseling is most effective with the computer plus the counselor rather than just the computer-based intervention.

Computer-based interventions have also been attempted with elderly institutionalized adults. McConatha (1995) found that computer interaction was an effective tool for increasing older adults' cognitive abilities and daily living skills and decreasing their levels of depression.

Many academic interventions are designed to teach or enhance students' learning skills. There exists a large body of research on study skills and how they may be effectively taught. In a meta-analysis Hattie (1996) classifies these studies as focused on either task-related skills, self-management of learning, or affective components such as motivation and self-concept. Hattie’s results support the notion of situated cognition, whereby it is recommended that training other than for simple mnemonic performance should be in context, use tasks within the same domain as the target content, and promote a high degree of learner activity and metacognitive awareness. Nelson et al. (1993) found that knowledge of learning-style preferences increased community college students’ achievement and reduced their drop-out rate. Freshmen taught to use study skills responsive to their unique learning styles achieved significantly higher grade-point averages and were more likely to remain in college than freshmen who studied according to traditional guidelines.

Interventions may also be aimed at student retention, particularly within distance education courses. Kember (1990) developed a model to derive such interventions to help reduce drop-out rates. The model includes components of background characteristics, motivation, academic environment, and the family, work, and social environment. Kember derived a series of recommendations for the design of distance education courses. Primary among these recommendations are: enhancing intrinsic motivation; reorienting student conceptions of knowledge; and improving collective affiliation.

In a similar study of interventions for low achievers and potential drop-outs, Kriner (1992) described an initiative for college freshman involving the university counseling center. This study involved a proactive approach by the counseling center staff, as opposed to waiting for the student to seek help of their own initiative. The counseling center identified low achieving freshmen and initiated academic and personal counseling. Results showed a significant increase in grade point average for recipients of this type of counseling intervention.

Short term interventions have been implemented with mixed results. Schultz (1992) describes a model program that would provide interventions designed to assist students to:

1. Develop discipline
2. Understand academe and improve study skills
3. Manage emotions and relationships
4. Develop skills in communication, assertiveness, decision-making, and values clarification

Schultz points out that additional research might focus on implementing this kind of model as part of a long-term program. Research is also needed to investigate interventions that incorporate all facets of students’ environment (Schultz, 1992).

Methodology

Participants in this pilot study were 152 college students enrolled in a self-paced computer literacy class at a large public university in the Southwestern United States. The students represented many different colleges and majors, and ranged in age from 18 to 55. All were taking the class as a general degree requirement. The course itself involved the completion of ten modules, with approximately ten days to two weeks allowed for each module assignment and test. A print-based manual guided the students through the module assignments.

General demographic information was obtained at the beginning of the class, as well as information regarding weekly computer usage and Web and e-mail experience. Midway through the self-paced course the students were required to complete a module on telecommunications. The investigator selected three concepts from the course manual to be reinforced with the on-line intervention. These three concepts were telecommunication software, Internet uses, and on-line databases.
When each participant completed the module work, he or she was directed to the class Web site to complete the intervention before being tested over the material. Upon completing the intervention the participants were required to send the investigator an e-mail message giving feedback about the usefulness of the intervention and about the self-paced nature of the course. For many of students this assignment was their first use of the Web and e-mail.

Results and Discussion

One hundred forty-eight of the 152 students were able to complete both the print and Web-based portions of the self-paced module. Of the 148 students completing the module, 140 (95%) were able to pass the module test with an acceptable score after a maximum of three attempts, in accordance with the class syllabus and policies. 83% of the successful students passed on the first attempt, while 14% passed on the second attempt and 3% passed on the third and final attempt. The 95% success rate on the module compares very favorably with other print-based modules of the self-paced course, where passing percentages normally range from approximately 80% to 90%.

Part of the Web-based intervention required students to give feedback on the perceived effectiveness and quality of the intervention itself. Generally the comments were very favorable in terms of ease of use, intuitiveness, and relevance to the subject matter. There were particular suggestions that the participants offered which are helpful in designing future iterations of the concept attainment Web-based intervention. The participant comments were also revealing in terms of learning more about the situated context of this particular participant audience. Participant difficulties and suggestions for improvement are summarized in the following points:

1. Access: Some participants were new to using the Web and e-mail and had difficulty entering a URL and navigating through a Web page. Also, due to the self-paced nature of the class, some participants were ready for the Web intervention much earlier than slower-progressing participants.

2. Graphic Design: Experienced Web users expected pages filled with graphics and possibly animation, while in fact the pages were quite bland and simple in appearance.

3. Difficulty Level: Some students were very familiar with the Web and the subject matter (telecommunications) and found the intervention too basic and remedial. Some students requested more details on how to complete the intervention, having not been previously exposed to the concept attainment model.

Most participants found the intervention to be very helpful and relevant, and the high passing rate for the module test indicates the participants were very successful in mastering the instructional content. Future research will be focused on addressing the aforementioned shortcomings of the Web-based intervention, and on comparing interaction effects of student characteristics such as cognitive tempo, previous academic record, and socioeconomic status.

Distance Education — 159
The use of internet in a training context modifies implicitly the trainer’s behaviour and role. In a traditional training action, one may notice that sharing of the roles between the teacher and the students has been significantly modified. Indeed, in the digital era, new technologies make new ways of working and studying together possible. For example, both collaborative and cooperative work can be facilitated by the use of computers and telecommunications resources. These new and emerging technologies seem particularly supportive of constructivist teaching principles such as authentic instruction and situated learning, as suggested by Jonassen [8].

One area where constructivist principles seem particularly appropriate is distant learning. However, this is a new and quite different type of teaching and learning environment when the power and diversity of electronic communication tools are used. Both the student and the teacher must take on quite different roles. This paper describes the competencies one must acquire in order to teach and learn in technology-rich distant learning environments.

The information system within Internet

The information system available for a trainer is mainly characterised by the nature of pieces of information which may vary in many ways. In fact, a triple heterogeneousness can characterise the information:

A. The heterogeneousness of the type of information. It expresses the physical diversity (text, picture, sound or video) and the formats diversity of a same object (diversity of origins and freshness).

B. The diversity of possible indexings. It can be indexed, for example, by the name or the title, a literal description or a keyword set, a criteria set satisfied in a relational structure, semantic links defined by the authors, etc...

C. The origins diversity: local or distant information basis, proximity (means of contact) of the transmitter, etc...

One of the obvious consequences of this heterogeneousness is that research strategies and use of information can only evolve over time [15].

Strategies for the search and use of information

It seems obvious that the above A., B., C. points will influence the strategies for the search and use of information.

a. Thus, the diversity of research modes, which is possible on the Internet, is a counterpoint to the heterogeneousness mentioned in point A.

b. Moreover, the strategies for the search for information, become then very different, depending on the assumed capacity of the user when making out the question. We will particularly distinguish three cases: the case when the needed information is precisely known (query); the case when the sole domain is precisely known (query and browsing); and the case when the information searched for is not a priori identified (pure browsing).

c. The strategies for sorting and discriminating the information can also be guided by various considerations (the adequacy of information to a pre-defined model, the rareness of information, its cost, its quality, etc...).

d. At last, the strategies for the management of information will, among other criteria, depend on the knowledge of data structures and on the task frequency.

The above mentioned points make up a sort of minimum knowledge required to be able to use the Internet, and are prior to any use in an educational context.

Specific knowledge for domain specialists

It seems obvious to us that the knowledge needed for optimal use of Internet, which is rather related to concept, cannot be taught to non-specialists quickly and in a traditional way. The descriptions of information and of strategies to be used, which have been introduced at 2.1, enable to derive the needed competencies for the information management. This approach can be used for the training of general information management specialists, but it cannot be directly applied to the training of domain specialists. Indeed, these are not, a priori, interested in becoming information or communication specialists. Thus, a re-wording of the training objectives, using words proper to the domain, must be done. Comments on a set of “cases”, illustrating all of the previous contexts, seem necessary, and can help to understand and manage the needed knowledge.
The next section is dedicated to the description of a building method for such cases, that we elaborated the domain of *New Technologies of Education and of Multimedia*.

**A building method...**

The content of indexed sites on Internet quickly evolves over time. There needs to be some form of at least partial automatic of the process of searching for information if we are not to be overwhelmed by the sheer vastness of the Internet. Recent achievements, based on agents technologies, is an appealing possibility. The global action includes four phases:

1. Conception and development of an information research method related to the multimedia development tools and to the co-operative work.
2. Evaluation of the obtained results and of the automation possibilities.
3. Conception and achievement of a co-operation scheme between operators and software agents.
4. Agents definition and implementation.

The starting point of this action is a formalisation of the *New Technologies of Education and of Multimedia* expressed through a thesaurus.

**The domain**

The first phase, which permits to model the domain, consists in setting a *thesaurus*. In fact previous works ([20], [22], [23]) published about multimedia, distant training activities, have come to some formalization of the domain expressed by:

1. A plan including four deepness levels.
2. A thesaurus including a « representative set » of key words related to the synonymies among themselves. The thesaurus elements are, case wise, linked to a chapter, to a section, to an under section or to a paragraph of the evoked plan (cf 1.)

The result is a hierarchical structure whose higher level elements will be referred to trough « main key words ».

Starting from this thesaurus, we have built up again *questioning situations* corresponding to the crossing of the cases referenced in 2. (from A to C) and to the points commented in 2.1 (from a. to d.). Thus, we get a dozen of different situations, and, in each one of them, we can build up instances which are also different.

**Elaboration of an information research method**

The search for information, by means of search engines, starting from the *main key words* previously defined, provides thousands of possible references. The method uses as a starting point consists in defining processes for the information filtering in order to methodically extract from it relevant information. This work was inspires by approaches used in electronic documentation and in particular from dynamic links in hypertext ([1], [3], [19], [21]). The result comes under the following forms:

1. A set of information research processes characterised by:
   - Each process is associated to a set of objectives (pedagogical) pre-defined (and parameterable).
   - Each process uses a set of parameters from which some are noticeable within the hierarchical structure evoked above.
   - These processes must be, later on, able to be automatically generated (or according to co-operative methods).
2. For each of these processes, a set of sites or web pages, concrete results of the considered process.
3. An evaluation scheme about the filtering relevance compared to the objectives.

Finally, we show that it is always possible to extract from this virtual corpus a set of significant examples. We focus among them, *questioning which ends up* in a site comprising the searched information and *questioning which does not come to an end*, but where the failure can be explained. The comparison between these different situations helps us refine the search procedure.

**Evaluation of the results and an automation possibility thanks to agents**

The comparison between sites, or identified pages, and the pedagogical objectives assigned to the corresponding information researches will be tested by *experts*. The results of this *user* test will allow the evaluation of the advocated research method relevance (starting from the scheme 1., 2., 3 evoked in 3.2). This evaluation will have to be able to convey specifications for the conception of a collaboration scheme between human operator and agents, and a precise definition of agents.

Indeed, the multi agent approach is the basis for a technical solution. The multi-agent formalism is based on "autonomous agents", able to act over their environment and to communicate in order to accomplish collectively one or several tasks [2]. These agents are not supposed to have apprenticeship abilities, but they are autonomous and proactive: they are able to take some initiative and do not react only at the environment’s request [5].

There is a *main agent* which is the first to be activated and which activates the others. However other agents may communicate together without going through the main agent or even without informing it. On the contrary, the main agent will receive all the lost messages. This definition is derived from Ferber’s *purely communicating agent* [6]. For example, in our case, we could have an agent, who will:

A. know information about other agents: an agent could scrutinise part of the indexed site and would warn an other agent in case of information changes.
B. Be able to communicate with other agents: an agent...
would warn another agent in case of a site disappearing.

C. Possess its own resources, which would tell it when to be active, inactive, etc...

D. Have objectives and manage to achieve them, eventually under human control [14]. This is the main point which secures the agent’s contribution to a cooperative activity.

Thus, all these considerations allow us to oversee favourably, an implementation of our approach under a multi agent formalism [9].

**Conclusion**

The approach settled upon allows an efficient and precise way of defining a method. It meets the necessity to put into place an almost permanent information research method within a distant and open training system, using the Net information. We are on the way to new tools which turn out to be essential on distant learning platforms.

In parallel to this work, we are in charge of putting into place a distant and open learning platform for a postgraduate training course to multimedia. The conception of dedicated supports, and in particular the description of the multimedia jobs professional practice have allowed to settle a strong link between this project and a case based model about multimedia projects management ([10], [11], [12], [13]).

Underlying theoretical and methodological aspects to the distant training project have been described in the various articles, especially ([24], [25]). In order to bring it into action, the development of numerous interactive supports has been started in co-operation with Masson Editors, and the putting into place of training management devices is done in co-operation with the Distant Teaching National Center (CNED). This project is the basis for a cooperation, under progress, with Sussex and Rouen University in the scope Rives-Manche INTERREG actions.

A REVIEW OF TOOLS FOR DEVELOPING AND MANAGING ONLINE COURSES

Ann E. Barron  
University of South Florida

Chet Lyskawa  
University of South Florida

The number of distance learning options offered by universities and colleges is increasing at a rapid pace. In the past, the primary technologies used to deliver distance learning courses were two-way interactive video and one-way prerecorded video (Lewis, Alexander, & Farris, 1997). Although effective, these technologies have their limitations. For example, two-way interactive video requires expensive equipment, and prerecorded video does not offer interactions with the instructor.

The Internet and the World Wide Web offer a new, accessible mechanism for delivering instruction to students. In a study conducted by the U. S. Department of Education, 79 percent of the higher education institutions indicated that they planned to offer courses through Internet-related technologies (U. S. Department of Education, 1995).

Advantages of Internet-based Delivery

Delivering university courses via the Internet offers a wide variety of advantages, offering students new, flexible means of interacting with instructors.

Asynchronous Learning. Technologies such as E-mail and discussion groups allow students and teachers to communicate at times that best meet their schedules.

Synchronous Learning. In many cases, synchronous learning can be accommodated through technologies such as chat rooms and audio conferencing. The software and hardware necessary for these types of communication are minimal.

Minimal Software Requirements for the Students. America Online and other commercial Internet providers now offer full, unlimited Web access for approximately $20.00 per month. In addition, most universities can offer free Internet access for their students.

Minimal Hardware Expenses for Universities. In order to deliver Internet-based education, universities must have Web servers and the associated infrastructure. In most cases, these requirements already exist on campus.

Ease of Course Updates and Maintenance. With Internet-based courses, instructors can upload course assignments and maintain student records simply by connecting to the Web server. Records of the number of times the students have signed in, the amount of time they have spent online, and the scores from quizzes, can be automatically generated.

Decreased Travel Requirements for Students. Access to the Internet has become commonplace for a good portion of our society. With Internet-based courses, students are no longer required to drive to campus at a specific time each week.

Worldwide Audience. Statistics show that hundreds of countries are now connected to the Internet. The audience for a course is limited only by access to telephone lines.

Vast Resources of Web. In addition to providing course assignments, instructors can mine the Web for information on almost any subject matter. Bookmarks or links to relevant sites can be secured for students.

The Need for New Software Tools

Despite the increased pressure on faculty members to produce Internet-based courses, the options for developing the courses have been limited in the past. Very few faculty members have the time (or experience) to develop entire courses in HTML or other Internet-based programming options such as JavaScript, Java, or Shockwave. In addition, the management and record-keeping aspects of online courses often require sophisticated programming.

To meet the need for the development of online courses, several software programs have been developed and tested in the last few months. These tools provide an easy, effective means of creating, maintaining, and updating courses. Many of them also offer features related to student and faculty collaboration such as chat rooms, discussion groups, and videoconferencing.

Features of Software Tools for Internet-based Courses

Course development tools can provide both the framework and the back-end programming to make the task of delivering instruction via the Web easier by providing:
Web templates, chat rooms, testing, tracking, registration, etc. When investigating a tool, consider the following features:

- Ease of use by faculty
- Ease of use by student (intuitive interface)
- Include various media (text, graphics, video, audio)
- Support alternate character sets (mathematics, foreign languages)
- Various communication models (one to many; one to one; many to many)
- Threaded discussions
- Full text search
- HTML links within courseware
- Application links within courseware
- Student tracking
- Student registration
- Quizzes and online testing
- Automatic student reporting
- Tracking of time/hits/etc. per student
- Ability to access remotely (faculty and students)
- Cross-platform delivery
- Ease of updates/revisions
- Security and password access
- Real-time communication (chat, videoconferencing)
- Online help and phone help (800 line)
- Time limitations feature (set display for 2 weeks, etc.)

**Overview of Current Software Options**

The software for online education is still evolving, and several new products have recently appeared on the market. This section provides an overview of the features of the following programs: Learning Space, Top Class, Web Course in a Box, and WebCT.

**Learning Space**

Learning Space is IBM's contribution development tools for Internet-based courses. The software is based on Lotus Notes, using the Lotus Domino server to provide a secure environment for Web-based applications. The application includes five specialized Domino databases that provide for the management and evaluation of online courses. For more information, visit http://198.114.68.60/novox/. The features of Learning Space include:

- The Schedule database. A module designed to enable students to navigate through course materials and assignments, to take tests, and to participate in surveys.
- The Media Center. The media center can act as a virtual library, providing all type of multimedia resources, articles, reports, and links to Web resources.
- The Course Room. This is an interactive environment for students and instructors to partake in discussions. It also assists in the student collaboration on projects.
- The Profiles database. The Profiles databases includes student and instructor descriptions with personal information, such as addresses, phone numbers, e-mail, etc.
- The Assessment Manager. This is an evaluation tool for instructors. It provides an environment for instructors to create quizzes and tests, track students, and record grades. At the time of this writing, the quiz generator did not have the ability to generate random questions.

**Top Class**

Top Class is distributed by WBT Systems. The software is database-driven and allows for remote access, management, and tracking. Top Class runs on multiple operating systems (UNIX, Windows NT, Windows 95, and Macintosh), while supporting numerous browsers. See http://www.wbt.com for more information. The features of Top Class include:

- Collaborative environment. Top Class includes built-in threaded discussion, file attachment, multi-leveled discussion boards, and e-mail components to provide for student collaboration on assignments and projects.
- Online authoring. The instructor interface is designed for ease of use and is based on open HTML standards.
- Security. Top Class provides a robust environment for both individual and group security. It also has remote password protected access for students with all types of browsers.
- Plug n’ Play. Top Class includes plug n’ play capability to facilitate the transfer of classes from server to server.
- Auto testing. Student testing can be customized to suit student needs, allowing course material to be accessed according to student performance.
- Management. Integrated management allows for personalized coursework, testing procedures, security tracking, and student progress.

**Web Course in a Box**

Web Course in a Box (WCB) was created by the Instructional Development Center at Virginia Commonwealth University. The software is a template-based authoring tool and is available for download and use at no charge to educational institutions. For more information, visit http://www.madduck.com/wcbinfo/wcb.html. The features of Web Course in a Box include:

- Easy authoring. The user interface is very intuitive, requiring little knowledge of HTML to create and design classes. The system includes interactive lesson builders and quiz builders to facilitate course design by instructors.
- Collaboration. Discussion forums, file attachment and archiving features, self-correcting quizzes provide a learner-centered environment for collaboration, encouraging small group work.
- Security. Access control is placed into the hands of the instructor. The only maintenance required is the creation of instructor accounts by a WCB administrator.
Modularity. Webs are template driven and can be transferred to any system. WCB integrates easily into any standard Web server.

Support. Subscription support is offered by madDuck. Support includes a user guide and on site training, if desired.

WebCT
Web Course Tools (WebCT) was developed in the Department of Computer Science at the University of British Columbia. WebCT has been used in the beta test stage by several universities and is now a commercial product. See http://homebrew1.cs.ubc.ca/webct/ for more information. The features of WebCT include:

- Integrated Course Tools. WebCT provides instructors with a host of course tools, accessible through icons, including: e-mail, timed quizzes, conferencing system (chat rooms), grade storage, online grading, student presentation areas, student progress tracking, course glossary, etc. Tools can act in conjunction with one another. For instance, e-mail can be used to send grades to students.
- Testing and evaluation. Quizzes can be designed by the instructor, uploaded, and delivered on a particular time and date. Web CT can also track how long the student spends on the exam and mark it online.
- Student management. Class lists can be entered one student at a time or the entire class list may be entered at once. Student accounts are created by the course designer.
- Design issues. Course pages can be customized for individual classes and/or pages. Templates are provided with multiple choices in terms of banners, counters, course tool icons, etc.
- Tracking. In addition to student progress tracking, access to the class as a whole can be monitored. Instructors may determine who visited individual pages during a particular period.

Conclusion
The selection of the most appropriate tool for creating online courses is a major task for colleges and universities. The investment must be measured both in the cost of the software and in the cost of the time required to create and maintain online courses. This presentation will offer "lessons learned" with several available tools and provide a comparison of features, costs, and limitations.

SOFTWARE TOOLS FOR DISTANCE LEARNING: THE BENCHMARKS PROJECT

Abbie Brown
Indiana University Bloomington

Lisa Hansen
Indiana University Bloomington

Distance education has emerged as the latest wave in educational practice. It is currently the fastest growing form of domestic and international education. Course delivery via the World Wide Web is receiving a great deal of attention from educators and administrators, but questions on how to implement and administer Web-based coursework have been left largely unanswered.

The major problem facing Web-based instructional development today is the development process itself. This process is time-consuming and requires a certain level of computer competency to be performed adequately. New tools being developed to create Web-based learning materials are helping this process along, but a new issue has arisen. Which software should a teacher use to create online materials? Which tools work best? What elements are required in a Web-based course, and what software tools perform that function?

Beginnings of the Project

The Center for Excellence in Education at Indiana University Bloomington facilitated the formation of a small group interested in addressing the problem of categorizing and evaluating software. The group members, who dubbed the project “Benchmarks,” were self-selecting, with expertise in software evaluation, and considerable experience in teaching and in facilitating faculty use of technology. The group began by conducting a pilot evaluation of on-line “chat” tools, and by developing a taxonomy of distance-education software, a set of evaluation protocols, and a sample Web site putting these protocols into practice.

Successive prototypes of the evaluation protocol, and the apparent soundness of the taxonomy, led to an increased interest in the project’s completion and incorporation into a larger, university-funded Web site developed for educators interested in emergent technologies. The project received funding after ten months of volunteer effort, and has since developed and tested a formal evaluation protocol.

In a combined effort to meet the needs of faculty members asked to develop on-line instruction, Indiana University’s School of Continuing Studies and the Center for Excellence in Education encouraged and ultimately funded a project to document and evaluate the software necessary to Web-based course delivery.

The Need for Web Tool Categorization and Evaluation

The need for organization and classification of software by type, as well as evaluation of the various software packages within each type, was clearly identified by those educators under pressure to produce distance education courses. There has been little previous research in this area, nor have evaluation protocols been established for distance education development software.

There is a definite need for the organization and articulation of Web-based development tools. First, simply understanding the variety of tools available provides insight on what is needed or possible for a Web-based course. Second, by providing this organization and articulation, instructional designers can reduce the amount of time needed to develop on-line instructional materials, by sharply reducing the sampling and discarding of various tools by uninformed instructors. Teachers already have huge demands upon their time; to require instructional development, modestly estimated at 100 hours of development for one hour of instruction, may prevent many schools and teachers from delivering courses on-line.

Having identified the need for software evaluation, expert review presents itself as the most efficient and effective method. Expert users have little fear of difficult or obscure interface idiosyncrasies and, as designers themselves, are quick to recognize common mistakes made in software design. Expert reviewers are capable of standing in the programmer’s shoes, as well as the user’s, and are comfortable identifying problems that arise from faulty software as opposed to faulty software use.

Developing the Taxonomy

Originally the Benchmarks team focused its attention on review and assessment of current on-line collaborative activities, particularly those that involved k-12 classroom groups or individual learners in k-12 settings (e.g. projects...
offered by TERC, and the Monarch Butterfly Watch project. The focus changed when the School of Continuing Studies requested review and evaluation of tools relevant to their instructors developing on-line courses; additionally, it was decided that the focus would be on tools available at Indiana University.

**Figure 1.** Taxonomy of Web tools.

We began to discuss these collaborations in terms of their shared traits - we noticed that each collaboration required a series of component applications, and that we could categorize these application components in terms of three major concepts: their purpose in facilitating the collaboration (purpose) their relationship to other applications (package) and the time-frame in which they operated (process).

Each application (for example: word processing, on-line chat, e-mail) could be thought of as part of the purpose, package, and process of the collaboration.

**Purpose**

What a software product does is its purpose. A Web tool will fall into one of three categories: creation, communication, or administration. A fourth category used in the Web site is multipurpose tools, those tools that combine in some way the previous categories.

**Creation** (development) — creating physical Web elements

Creation tools are those that are used to create the "physical" elements of a Web site: Web pages, graphics, sound, video, image maps, forms, etc. Currently we provide information about the two basic development tool types, HTML editors and graphics tools.

HTML editors are often what people think of when they think of using a tool to develop Web pages. From the Web site, one can better understand that HTML editors are merely part of a much larger whole. However, the uses of an HTML editor are obvious, and using a good HTML editor makes the process of Web development much easier.

A graphics tool can perform many or few functions. However, larger is not necessarily better when it comes to a graphics program. If you only need to save a graphic as a Web-compatible file (a GIF), then you really don't need a program that is extremely complicated. On the other hand, if you are creating or scanning images, a larger graphics program with more functionality will be more useful.

**Communication** — interaction and information-sharing among class participants.

This category of tools includes chat, conferencing, e-mail, file transfer, and newsgroups. A key element to any course is communication between participants, including teacher-to-student (and vice versa) and student-to-student. These tools provide a variety of communication options, including live versus time-independent, group communications versus one-on-one, and file and news sharing. While many tools can perform more than one function, they often fall primarily into one of the following types.

Conferencing is a vital component to an on-line course because it provides the means for dialogue and discussion as a group. Indiana University is currently reviewing a variety of conferencing tools for potential adoption. File transfer programs are used to move files from a local computer to a shared remote computer, such as a Web server. The step of file transfer is usually the last step in creating a Web site. Newsreaders are not as commonly used for on-line courses; however, they do provide a low-bandwidth alternative to chat and conferencing applications. E-mail applications enable a user to read, compose, send and manage e-mail messages. Users send and read messages at a time of their choosing, without needing to coordinate time with other parties. It provides individual communications (useful for answering questions privately), but can also be used for general announcements and informal discussion, in the form of listservs and distribution lists, and as a convenient interface for file transfer.

**Administration.** Administration tools for faculty developing on-line courses are often provided by the school — in this case, IU Bloomington. However, there are several commercial products as well. Currently, we have reviewed testing and grade reporting applications.

**Multi-purpose.** Multi-purpose tools are those applications which are specifically designed to do a variety of things, in order for a developer to work more efficiently. These tools fall into two groupings. Web browsers are just that — Web interface programs. All-in-one course creation tools are those applications which were created for the purpose of developing on-line courses. These tools have much of the functionality of smaller, more specific applications; their advantage is that they are designed to work together. However, all-in-one tools vary widely in their functionality.

**Package**

Package is that feature of the program which indicates how it is used. An independent program is a stand-alone program that is completely self-contained, requiring no other programs to run. It is often a single packaged file. In contrast, an integrated program is one that is part of a larger package, such as a spreadsheet program that is integrated with a word processor. Integrated programs are often more difficult to use, because they require the user to learn both programs. However, they are often more powerful, because they allow the user to work with different types of data in a single environment.

166b — Technology and Teacher Education Annual — 1998
application. An interdependent can stand alone, but is
designed to work with other applications; an example
would be Microsoft's Word, Excel, and Powerpoint.
Dependent tools require the use of a larger application; for
example, using America On Line's chat tool is only
possible when using America On Line itself.

Process
This element is more applicable to those on-line
application tools that have time as an important compo-
ent. This is particularly important for communications
tools and collaborative development tools. Asynchronous
tools are time-independent; participation occurs at users’
convenience. Synchronous tools are time-dependent, and
require simultaneous participation by users.

Evaluation Protocol and Design
The resulting evaluations covered more than 30
creation, communication, and administration tools. We
focused primarily on applications available to faculty at
Indiana University, since they were our target audience. We
developed benchmark tests that were used to evaluate these
tools. These tasks were written such that they generated an
ordinal number grade; each task was reviewed with the
same scale. The scale is defined as such:
1. Very poor capability to perform listed task; feature not
available or does not perform as intended.
2. Performs task with only limited success.
3. Performs task adequately, but improvement is
4. Performs task well and with few problems.
5. Performs task extremely well; the task feature was as
well designed as could be hoped.

The evaluation results were presented in three types of
pages. Features reviews examined basic features such as
platform, availability, and interface. These reviews included
tools that were not fully reviewed but represented popular
software available. Evaluations pages were comparative
results of benchmarks tasks. Figure 2 below is an example
of an evaluation page report. Profile pages were individual
reviews of software, with comments from reviewers
included.

The site was also designed to be easily expanded and
new reviews included. Because of the size of the site and
the potentially large number of software reviews that could
be added, it was deemed important to design the site in such
a way that future reviewers could add material easily.

Whoever is still awake at the end of a night of stories will surely become the wisest person in the world. An old family blessing. (Estes, 1996).

Recent studies by Harvard Business School professor, Dr. Gerald Zaltman, report findings that would not have surprised a tribal chieftain a century ago, namely that storytelling successfully teaches important lessons to its students (Lieber, 1997). Other ancient customs, like apprenticeships, are also being viewed as possible solutions for problems facing contemporary educators.

At the heart of this research is a quest to discover more insights into human behavior. Several methods of sharing insights and lessons have been passed down through both civilized and indigenous peoples which include stories and apprenticeships. Ancient legends of child kings learning from the tutelage of wise mentors remind us of these traditions, stories like Mentor, friend of Odysseus and teacher of his son, Telemachus (Cavendish, 1992); tales of King Arthur and his wise teacher, Merlin. Fairy tales like Cinderella relate Cinderella’s pygmalion transformation through the magic of her fairy godmother. Modern day legends conjure up familiar feelings with tales like Star Wars, where Luke Skywalker trains to become a Jedi warrior under the tutelage of his mentor, Yoda. These stories exemplify and perpetuate the human connection through generations and may even resonate some deeper, metasymbolic understanding we have yet to discover (Smith, 1997; Salomon, 1997; Baeten, 1995). The compelling question is whether these stories can be harnessed together with the modern technology that often conveys them to provide richer learning experiences.

The intent of this study is to look at how culture and communication are transmitted via storytelling and apprenticeships. Avoiding abstract concepts by honing in on an engaging story, and by using testimonials, becomes important as one person shares her/his stories with others. Working and sharing knowledge with others is a natural extension of this process. Dr. Gerald Zaltman’s study of stories and testimonials had been conducted initially for marketing purposes, to find out what made consumers buy certain products. But what he discovered in this study had more far reaching implications. As a result, Dr. Zaltman established a Metaphor Laboratory to look at storytelling and testimonials to see what other information people conveyed via stories. His findings revealed that people wanted to tell their story, to give testimonials about what worked successfully. And, since this method of sharing knowledge has worked so successfully across many centuries, the likelihood that it could continue to work successfully seemed strong. It remained to be explored whether the stories communicated in person would have the same impact when transmitted electronically.

There may have been more to the legends that old shamans passed down to their progeny than good fireside stories. The youths in those legends lived and worked alongside their elders. They heard their stories and their emotions and psyches were touched by them. They had the opportunity to follow the examples of their elders. Now, research like that of Dr. Zaltman’s, suggests that this type of reinforcement can be beneficial to contemporary lifestyles.

‘You have to start with proof, not theory, and the proof comes from the stories” (Lieber, 1997). Testimonials and stories become extremely important as one person shares and passes along his/her experiences with others.

So what does this have to do with technology? Particularly distance education? Distance education is changing the fibre of higher education by its accessibility, but more important, by the actual delivery of its academic messages. Currently most distance education courses are delivered electronically, via cable television, in a linear mode of transmission, or via the internet. It is the belief of this author that academic curricula will increasingly be designed for on-line, internet, courses, thus increasing courses offered in a virtual venue of education (Gannon-Cook, 1997a; U.S.A.I.D., 1995). Accordingly, it will become important for future curriculum designers to understand both the delivery vehicle, as well as with the internet courseware. Apprenticeships, or internships, can provide an opportunity to...
familiarize the students with this virtual venue of distance education (Dick, 1995; Willis, B., 1995). They could also help students to construct and scaffold their knowledge of curriculum design. But most of all, these apprenticeships/internships could help students adapt to the constantly changing environment of technology, and prepare them to be change agents by giving them the legacy of shared experiences with their elders. These elders could be sixty or twenty-six, sitting next to them in the room, or a thousand miles away (Chalmers, 1997).

Distance education, particularly in higher education, is no longer limited to students at remote locations. Nor is distance education limited in geographic area, social status, or academic qualifications. Higher education is no longer limited to the elite of the academically advantaged, but is now available, virtually, to everyone (Blair & Caine, 1995.)

Today’s college students don’t have to sit in a classroom to learn or to earn college credits. They have options; they have cable-transmitted classes, videotaped classes, and on-line courses that allow them to complete part, or all, of their degrees on-line.

They are no longer boxed in by a limited degree from an American university, a remote Canadian university, or some exotic university in Australia’s outback. Students are also no longer relegated to the choices available to them at their local community colleges (League of World Universities, 1997). But the question that is still crucial to on-line, distance education, will be: will this on-line, computerized, box provide comprehensive education? Will it also provide educational access that removes socially constructed inhibitors to many who could not, otherwise, receive a college education? Or will it be the proverbial Pandora’s box that spills out a legion of nightmarish demons and backlashes onto the educational world? The ramifications of these new on-line choices are more pervasive than we can now postulate.

The challenges to curriculum and instruction designers in the next ten years will be very different from the challenges of the last fifty years. These challenges may be more akin to those facing educators in the time when the printing press was invented, or when the industrial revolution had just begun in America (Danesi, 1993; McLuhan, 1976; McLuhan, 1968). In each era the paradigm shifted, incorporating the vehicle of communication and content material into the curriculum and the instruction. In each era the availability of education also shifted, providing more information to masses of people who, previously, did not have access to such information. (Stevenson, 1993; Dant, 1991, McLuhan, 1970).

**Ancient Storytellers**

Just as Gutenberg books were passed on to villagers who had never learned to read, and as children of immigrant factory workers learned in factory modelled schools, the students of today’s on-line classes will complete their virtual lessons in their environments and cultures. What this will mean in educational terms, and what this will mean culturally, societally, and politically in the world as we know it, is not discernible yet. But if the medium of conveyance really does become the messenger (McLuhan, 1976), then the messenger will very likely include a hybrid of every country’s educational system and curriculum, every career profession and technology, and every philosophical and political form of government (DelRio & Alvarez, 1995; Wertsch, 1985; MuLuhan, 1970).

What helped people survive radical paradigm shifts in the past? There may be few traces of each civilization and era, but what does remain, in addition to some buildings and artifacts, are their legends and stories. Marcus Aurelius related narratives of ancient Rome, gypsies told stories of Czarist Russia, tribal holy men passed on ancient traditions through their initiates. If academia eschews the generational conveyors of traditions and cultures, can future generations rely solely on the archived databases that will be their legacy? Or might these disks resemble indecipherable cuneiform tablets a hundred years from now? The traditions of stories, legends, and apprenticeships, while not favored as educationally acceptable conveyors of information in more sophisticated educational venues, do uphold the oral traditions of generations past (Donmoyer, 1997a; Greene, 1997; Eisner, 1997; Gallini, Seaman, & Terry, 1995). And it is likely, at least in homes and communities where cultural traditions are still maintained, these traditions will continue, at least as long as there are elders to keep the traditions alive. So what does this mean to technology? Will there continue to be parallel forms of communications, oral and technological, or can the twain meet? It already has in technologies like the telephone, television, and the internet. So, how can this convergence combine the oral traditions of storytelling with the newest technological innovations?

**Modern Storytellers**

A way to begin looking at how to merge the two realms could be to look at how some of the rebel technology innovators are designing their work environments. It is not unusual to see huge open spaces in lofts of buildings or in warehouses and many pods or clusters of computers huddled around each other so that the people using them can communicate with each other while working in their virtual environments. A senior person (whose age could range from 17 to 95, plus or minus) is available to help each pod member and spend time mentoring her/him. And, if each member is encouraged to share ideas and experiences, it can encourage storytelling and testimonials. There are also opportunities in environments, like academia, to foster interaction by using apprenticeships and small group learning experiences to pass on rich information to recipients that might, otherwise, be overlooked (Ferris,
Why Apprenticeships Have Survived

Apprenticeships have been used to train artisans from the days of the dark ages. Stories were handed down from elder to apprentice as they worked together skinning hides and drawing pictographs. The apprenticeship practice was adopted by clerical educators and passed on down through time, to contemporary craftsmen and masons. Internships fill the same function as apprenticeships, allowing the intern to shadow senior workers and to learn their roles and responsibilities. An apprenticeship is defined as “someone learning a craft or trade from an employer to whom he is bound for a specified period, a learner.” An internship is defined as “serving as an intern for a period of time.” (While the two terms are similar, the term internship, however, is seen more often in education, so, it will, hereafter, replace apprenticeship when used in an educational context in this study. [New Lexicon Webster’s Dictionary, 1992].)

Internships allow the students to spend time with an instructor and learn more about that person’s duties and responsibilities. As the students get to know the instructor better, they begin a dialogue that includes both stories and testimonials. Often a student can learn important information from informal conversations about how something works, especially in cases where hands on learning and/or equipment are involved (Warner, 1997; Lane, 1992). “Stories researchers tell about themselves often have implicit within them fundamentally different stories about teaching, learning, school organization, and the politics of education” (Donmoyer, 1997b; Smith, 1997). The success of the intern/apprentice will depend on the teacher’s expertise and facilitation, so he/she will need to “teach the criteria of quality so thoroughly that the apprentice workers can use them on their own” (Peel & McNary III, 1997; Abramson et al, 1997; Burns, 1995). When structured this way, the model of internship could work in a distance education environment as well as in a same space environment, where the students are either literally or virtually apprenticing with the instructor(s).

Technology Internships

A technology internship can give the student the freedom to learn, and the freedom to construct her/his own knowledge, in both environments (Willis, J., 1995; Jonnassen, 1994). Moreover, whether that internship is on-site or virtual, it can provide a firm knowledge base more global in scope than mere classroom theory (Fernlund, 1995, Stevenson, 1993). No longer boxed in by any delimiters, the student can benefit from the close working relationship with the teacher and eventually learn to create new virtual venues for her/himself. Educational internships in specific areas like curriculum design could provide future curriculum designers with hands on experience, where they might, otherwise, not have that opportunity. (Once they have graduated, the exigencies of work and/or teaching often prevent the graduated students from having a mentor and a safe venue where they can continue learning.)

Technology Corporations, like IBM, purport that education will become more self-directed in the corporate environment, “shifting control of the learning to the student with distance education technology playing a key role in supporting this vision...diverse student base—different ages, cultures...information overload...pace of technological change...all dictate the need for nonlinear (educational solutions), transferable across language/cultures” (USAID, 1996; Lane, 1992).

In an internship, particularly in a distance education environment, students would quickly learn what does and does not work by working closely with an experienced teacher who would answer their questions, share stories with them, and work side-by-side with them. They could work on videos, courseware, cable configuring, and creating curricula for distance education courses under the tutelage of an expert in that field (Gannon-Cook, 1997a). Ultimately, they would become comfortable experimenting and developing their own zones of proximal development (Chalmers, 1997; Fernlund, 1995; Davydov & Radzikhovskii, 1985). And, while students working with a teacher half a world away may not learn quite as much in that virtual environment as students working next to their instructor, there would still be a relationship, a human bond based on the sharing of experiences and stories. If the human factor was encouraged and emphasized, both the instructor and student would derive the maximum benefit from their interaction as well as learning more about their career field.

Currently there are experimental internships, like the one at the University of Houston, Division of Distance Education, in conjunction with the College of Education, that provide doctoral students an opportunity to intern in Distance Education (Gannon-Cook, 1997b, Brande, L., 1993). Internships like these could provide onsite opportunities to help students see firsthand, and assess what constituted good distance educational course design. Over time, information gathered from this research could help students who will be designing distance education courses to scaffold their own knowledge of what would constitute good distance education courseware.

The hope is that, since educational courseware is now assessable through universities almost everywhere in the world, interns could, ultimately, be placed at other universities offering distance education programs anywhere, literally, or virtually. And, with technology changing so rapidly, and its messages transmitted to the far reaches of the globe, the benefits to curriculum designers who are...
knowledgeable in state of the art distance education could be invaluable.

A firsthand experience by this author placed her at Cambridge University through the University of Houston. There I had the opportunity to spend time with an instructor from that hallowed university. I was able to ask him questions, listen to his stories, share anecdotes, and participate in what my instructor called The Cambridge Experience.

Part of the inspiration for this study came from my Cambridge adventure. I will never forget one of Brent’s (Dr. Robinson’s) folktales, based on the Sabertooth Curriculum (Robinson, 1995). The story told of how, for years beyond the extinction of the sabertooth, cavemen still taught the art of sabertooth slaying. One day a brave teacher stood up and began to teach buffalo slaying instead of sabertooth slaying. And the cavemen survived. Brent’s eyes lit up as he shared the enthusiasm of that buffalo teacher, and Brent’s wisdom infused all of us in ways we have yet to discover. While I personally felt that physically being there was an invaluable experience that could not be replicated in a virtual realm, there could, no doubt, still be significant benefit in this type of apprenticeship in a virtual environment (Gannon Cook, 1996). The Cambridge course continued in a virtual mode after returning home, thus offering a combined real and virtual experience. This type of internship could provide the optimum learning situation for both students, instructors, and university sponsors.

Messengers of Human Legacy

As educators, we must anticipate and plan curriculum and instruction based on the successful models of the past. Just as the examples of the printing press and industrial revolution extended learning to a broader base of learners, mass delivery of education begets access to unlimited numbers of learners. In the example of the worldwide internet, mass delivery of distance education will extend to infinite numbers of learners from every country and culture. It is incumbent on distance education designers to be knowledgeable about what is and will be available to learners, both in-house at their home universities, as well as globally at other learning institutions.

The future of education will, likely, include even more technology. Higher educational programs that give students the opportunity to learn both the technology and the theory of instructional design optimize their learning environments. Internships like that of the University of Houston provide a rich environment for learning and exploration. While the messenger or delivery vehicle of distance education may be technology, the educational message is still created and presented by a human designer. Internships can help aspiring designers to get a perspective of how the process of design integration occurs, not just in theory, or on paper, but in practice, from inception to ongoing operation (Moore & Kearsley, 1996; Loyola, 1994).

A Matter of Course: A Discussion

Ongoing training will continue to be necessary in technology because of its ever-changing nature. Training will be particularly important in distance education venues, or future curriculum designers will be ill-equipped to design courses in those venues (Moore & Kearsley, 1996). Internships and apprenticeships could provide neutral learning zones for not only students, but also, ultimately, to corporate and other interested parties who might be serious seekers in search of a safe learning harbor (Blair & Caine, 1995; Stevenson, 1993). The legacy of passing down stories of what works...and what doesn’t, through intern apprenticeships, might offer students a multi-sensory, nurturing, venue for learning. Incorporating ancient traditions like storytelling and testimonials into technology might help transmute teacher/student hesitation or resistance into acceptance, or at least predispose them to set the course for technology adoption. The hope would be to provide the teachers and students with a legacy of learning that has been successful in the past, and will sustain and thrive in future environments, both real and virtual.

Acknowledgements

An intervening factor that made this internship even more memorable was the untimely demise of our instructor upon our return from Cambridge, Dr. Brent Robinson. But, because of this wonderful experience, his stories and legends will live on. They will forever color my teaching and commitment to distance education, along with the others who participated in the course. Special thanks to Dr. Jerry Willis for co-creating this course with Dr. Robinson. Sometimes the educational benefits of internships far surpass one’s most creative anticipations.

Distance Education — 169
The Virtual Classroom is a metaphor that has been used to help reconceptualize the methods by which education and training is facilitated from kindergarten through graduate school and into the workplace. It suggests that the organization of learning need not occur in the traditional spaces that all of us have historically associated with educational activities. The metaphor is useful for many reasons; it enables us to think about classrooms, to think about organizational alternatives, and to think about how learning might occur when activities are actually separated from their traditional framework. The virtual metaphor fails us, however, when it conjures up a notion of things that are “not real.” Education and training will always involve “real people” promoting and pursuing a “real activity” called learning. It is only the metaphor itself which is virtual.

Recognizing the “realness” of the people, the activities, and the outcomes of organized learning is important because it is on these “real” factors that our attention must be focused ever more intently. While there are many aspects that need to be addressed relative to the new roles of faculty and students for distance education, the purpose of this paper is to help recalibrate our strategies for faculty recruitment, training, and compensation.

Distance Education and Learning Defined

Although Distance Education has been defined in many ways, for the purposes of this paper, Distance Education should be understood as planned experiences which result in changes in a client’s cognition, affect, and/or behavior when the learner is physically separated from the sources of knowledge and instruction. Distance Learning is the set of activities in which clients participate which results in changes in the client’s cognition, affect, and/or behavior when the client is separated from the sources of knowledge and instruction. These definitions are important because they imply faculty roles which are not necessarily explicit in traditional faculty job descriptions, but are characteristic and desirable in distance education. The three major roles for faculty include: curriculum planning and design, instructional management, and evaluation.

Faculty Recruitment

Traditionally, faculty have been hired to come to a campus or school building. This often required a deep financial and logistical commitment on the part of the organization and the individual to develop and sustain a relationship. Universities and colleges have historically treated faculty hiring as a decision which would have significant and long term impact on the educational direction of the academic unit. Hiring a full-time faculty member was as much a philosophical decision about programmatic futures as it was a personnel action. Employment was not an action entered into lightly by either the institution or the individual. Adjunct professorial hiring added some flexibility to the activity of faculty recruitment, but the pool was usually limited to local talent. In non-metropolitan areas, finding qualified adjuncts was at least difficult, if not impossible.

Distance technologies and the paradigms of distance learning created new possibilities for staffing. Although universities have been hesitant to exploit these possibilities, a number of options are inherent. Distance technologies include media which makes it possible to “record and/or distribute” expert knowledge in ways which expand upon the use of traditional books and papers. Video and audio recording, computer based instruction, telephone based audioconferencing, compressed video, satellite transmission and other media make expert knowledge accessible to not only appropriately equipped classrooms, but thousands of remote sites, including home or office. Even when they are hired on a very limited basis these experts greatly enhance the expert content of any class. The same experts can also be hired to conduct an entire class as an adjunct faculty member even when they live hundreds or thousands of miles away. Full-time faculty also
benefit directly from greater flexibility when they need to be away from campus for field research, conferences, or other travel reasons. Additionally, these approaches can be combined in collaborative teaching models to permit faculty from multiple campuses to teach together to a group composed of representatives of each home campus and others. Whether these options will be explored will be decided by faculty themselves, and the demand of market forces (Denning, 1996).

The new options evolving from distance technologies create opportunities for innovative recruitment strategies and options. All institutions, even small remote ones, can advertise nationally for expert faculty to expand or complement their core faculty resources. Recruitment can be designed to attract faculty to teach entire courses or special modules, which only require modest time and effort, but special expertise. A more diverse faculty can be attracted to cover topics from a unique regional or cultural perspective. Retired faculty can continue to participate in the life of the university as they are needed, and as they desire, from wherever they may have relocated. Large numbers of students in one class can be managed by one regular faculty who manages the course and others who contribute their special expertise and share the load for interactivity and evaluation. Some faculty can be hired exclusively for course design, while others are hired for instruction. Whether the model is individually oriented or team oriented, distance technologies mean that a more diverse, better qualified, more talented, and flexible pool of potential faculty become available to all institutions.

The net result of more faculty and more institutions vying for their participation will be more competition. Institutional loyalty and proximity are still factors in faculty decision making, but incentives will become increasingly important especially as a professional group of free-market distance educators emerges. Institutions that wish to recruit the best and the brightest faculty will be well advised to follow traditional lessons in the context of a new reality. Faculty teaching at a distance will not be enticed by a move to a cultural center or research facilities, they are more likely to be enticed by situation which provides them a great deal of flexibility. They may be motivated by an institutional affiliation with an institution renowned for excellence in traditional and distance programs, but they will certainly be motivated by those institutions with the most interesting curriculum options, best support services, and most enticing compensation packages.

A recruiting strategy which uncovers high quality faculty who are available, skilled, and willing to follow institutional policies is essential and must be carefully planned and executed. Involved in this process is advertising, a review procedure for credentials and work products, a detailed list of performance specifications, and a work agreement.

Faculty Training

It is likely that the largest and best financially endowed institutions will have an advantage in recruiting not only the most knowledgeable faculty, but also the most skilled at distance education. Institutions of all kinds, however, will need to pay attention to faculty training. While some education and training can be delivered at a distance by even the uninitiated, normal communications skills are inadequate to achieve effective learning results across the diverse methods of distance education.

To achieve a high performance solution, it is imperative that a systematic approach be applied to the planning and development of distance learning materials, instructional methods, and communications infrastructure (Laney, 1996). Traditional course preparation ranges dramatically among higher education faculty. Many faculty prepare little more than a topical syllabus and allow lessons to emerge from classroom interaction coupled with the personal expertise of the faculty. Other faculty prepare learning objectives, activities, and materials, but few have training in these endeavors. It is precisely because clients and faculty are physically separated that course structure and materials must be developed in a systematic manner that reduces the possibilities of misinterpretation and confusion.

Adding to the complexity of the task is the fact that distance education is not one style of education, but a collection of styles dependent on diverse media and methods. Preparing faculty for teaching in variety of distance settings with a variety of communications media requires both common and unique methods. Obviously, the many media available to distance educators can be combined to provide a rich multiple source media learning environment. For the purposes of this paper, however, the media will be limited to four: videotape for asynchronous delivery, compressed video for synchronous delivery, World Wide Web based text with graphics for asynchronous delivery, and computer based conferencing for asynchronous delivery.

Before exploring these four categories is important to restate, that while traditional faculty roles have included course conceptualization, course preparation, course delivery, course management, and evaluation components; it is not necessary that one faculty perform all these tasks. Collaborative efforts focused on differentiated staffing emphasizing individual strengths may indeed be one of the sweet fruits of distance education. Too many expectations for faculty without appropriate training and support can create a significant barrier to faculty use of technology (Boettcher, 1995). Institutions should provide convenient and supportive faculty development opportunities aimed at high quality educational experiences.

In general, the best technique for learning to use distance education technologies is practice. Skill develop-
ment evolves over time in real life situations. It is a good idea to have faculty participate as learners or observers in settings which use distance education strategies, then have them contribute information or lessons to an existing class. Finally, allow new distance faculty to design and develop a lesson without the pressure of having to deliver the actual lesson. A great deal will be learned by actually going through “all” the steps involved.

Generally, new faculty need to learn how to establish and maintain contact at a distance. They should attempt to create situations in which they reach out to the clients personally as though they were writing a letter. They should think about engaging the clients and communicating to them by anticipating their questions and confusion. Finally, new faculty should determine how they can best evaluate learning in a distance context. The signs are different, but the students needs are the same. Obviously, the institution should provide as much help and support as possible to these efforts on the part of faculty, but it is the individual that must do the thinking.

Videotape for asynchronous delivery involves some kind of studio or field production of a presentation, electronic field trip, or demonstration and variations on these themes for delivery to clients to view at their convenience. Faculty should watch several examples of high quality examples (within the production guidelines of the institutional producer) to begin conceptualizing the kind of production that can and should be accomplished. Next the faculty should work with a director to create several simple samples of on camera work, listening carefully to the director’s advice. The samples should be reviewed with the director and redone for comparison purposes. Finally, some samples should be created and shared with colleagues and students for feedback. The production guidelines for each institution will dictate a good deal about what can and can’t be done, but these should always be stretched in the interest of good quality instruction.

Compressed video for synchronous delivery is the use of a two way audio and video connection to a remote site or sites in real time. Compressed video has the advantage of seeing and hearing how students react to the faculty presentation, but because it is in real time more can go wrong and often faculty are in complete control of the process. As with videotape production, good planning and materials preparation are essential, and screen presence techniques are similar. In compressed video however, the instructional situation must be managed at the same time as content is delivered. Faculty should practice with different groups and to video tape for later study. Coaching during the initial learning phase is essential and faculty should be open to suggestion. As with videotape production, however, practice will deliver its reward.

World Wide Web based text with graphics for asynchronous delivery is the distribution of HTML documents through the Internet for remote viewing and reading. Skill development with the World Wide Web is different that with video production; most important for faculty is the ability to plan and design learning resources that work well within a hypertext and hypermedia environment. This is most efficiently accomplished through the use of an instructional designer or similar support person. Faculty may also want to develop skill in HTML coding, in order to quickly update documents and add resources. HTML knowledge is not essential, but should be provided as a support resource by the institution for document creation.

Computer based conferencing for asynchronous delivery is the use of a computer based system for communicating through the use of electronic mail, newsgroups, or web based conferencing. Almost all faculty now use some form of electronic communications for sharing information. There are techniques that need to be developed to make this work effectively. Most important is the development of a careful communication style that does not inadvertently offend. It is also essential that skills in file transfer and attachment be developed as well.

Faculty are not likely to seek out assistance in learning these techniques without some motivation and encouragement by the institution. It is imperative that institutions establish a comprehensive faculty development program and require those faculty who want to participate in distance learning to participate. Faculty with well developed skills and experience will work with confidence and effectively represent the institution.

**Faculty Compensation**

One of the most challenging questions to confront those familiar with traditional models for compensating faculty is how to convince faculty to engage in the extra work, responsibilities, and time required by the typical distance education project. While there is no single solution to this problem, a number of creative responses will be presented from which administrators and managers can construct fair and enticing methods for compensating faculty fairly.

Compensating faculty is and will continue to be a complex problem. There is no question that on a course to course comparison with the same number and same quality of students, a course formatted for distance education requires more time, thought, creativity, and effort, than a similar classroom based course. Issues of equity, measurement, quality, cost and revenue all come into play. There appear to be three basic institutional responses to the question. One model is to offer distance education through a division or school of continuing studies with a separate faculty or separate compensation structure, a second model is to pay faculty overload salaries, while a third approach offers faculty a percentage of the revenue generated from the courses. Each response has a strengths and weaknesses dependent on the institutional context in which they are implemented.

**Distance Education — 173**
While aspects of these three models may work well for individual institutions, the position offered here is that of a differentiated staffing model. This simply means that an individual faculty member would become part of an instructional team comprised of specialists in different aspects of the distance education provider responsibilities. Each of these team members, (e.g. subject matter expert, course manager, video producer, instructional designer, evaluation designer, technical support personnel) would negotiate compensation based on their contribution to the project. Part of the negotiation on the part of the faculty would be a decision as to whether the tasks were part of their basic teaching load, an overload, or a form of service for supplemental compensation could be provided.

The team approach guarantees multiple inputs into the development process, does not infringe on academic freedom, reduces the burden of distance learning on the individual faculty, and creates a common practice from which a standard design quality emerges without inhibiting creativity. Unlike the traditional conception of classroom based instruction, approaches to distance education vary widely and each design ought to be treated separately to guard against the whole endeavor collapsing into a single standardized approach.

The success of Distance Education will require a dynamic approach to problem solving and policy flexibility on the part of organizations. The significance of the roles that faculty will play in this process cannot be underestimated and clear thinking in advance will avoid many problems in the future.

Strategies to Support Effective Distance Education Programs in High Schools

Elizabeth Kirby
State University of West Georgia

Distance education, when defined as an educational transaction between a teacher at one location and a learner at another, dates back to late nineteenth century correspondence courses. Today, distance education encompasses a myriad of delivery systems that provide learning opportunities to students of all ages (Moore & Kearsley, 1996).

During the past decade, American high schools began using distance education technologies to offer students courses in math, science, and foreign languages. These courses often use a teacher-facilitator-student model where the teacher is at a remote site and the facilitator and students are in a local classroom (Tushnet, 1994). Teachers and students have always been major components in educational systems, but the classroom facilitator represents a new component. Little is known about roles classroom facilitators play in distance education, how they affect other components in the system, or how they affect system outcomes (Willis, 1992).

This study was initially designed to identify the roles of classroom facilitators and students within the context of a high school distance education course and to examine how those roles affected student performance. However, it quickly became apparent that the school itself played an important part in facilitator and student behavior and achievement. Consequently, the focus broadened to reflect a realm of variables, including school attributes, that influenced distance education in this setting.

Design of the Study
An ethnographic, multiple case study research design was used for this study. Three classrooms from different high schools (South High, Central High, and North High; all fictitious names), each taking the same nationally-offered distance education physics course during the 1994-95 school year, participated. The course was delivered live, via satellite. Telephones and a computer keypad system connected the students with the remote teacher. The course design included 30 minutes of instruction and other activities provided by the satellite teacher, as well as a 20 minute off-air period during which the facilitator and students did homework, discussed problems, or did labs.

The research methodology included extensive classroom observation, informal and formal interviews with classroom facilitators and students, and review and analysis of student work products, extant documents and resources used in the course. Each participating physics class was observed daily, in its entirety, for two consecutive units of study. A third unit of study was observed later.

A purposive sampling strategy designed to provide maximum variation was used to select the participants. Case variations included (a) facilitator certification (science, social studies, not certified); (b) facilitator distance education experience; (c) class size; (d) student demographics; (e) match of the school and distance education course bell schedules; (f) number of distance education courses offered by the school; and (g) location of the school (two adjacent states, three school districts).

An inductive constant comparative method was used to analyze the data. Collected data was transcribed, compiled, and coded; and then compared and contrasted to identify patterns and trends. Triangulation of data collection methods and data sources was used to enhance reliability and validity.

School Impact on Facilitator and Student Roles and Performance
The schools in this study had a major effect on facilitators and students. The high school calendar, including student and teacher holidays, and special events scheduling such as pep rallies and assemblies, affected how frequently students missed regularly scheduled distance education classes. This, in turn, affected facilitator roles in terms of planning for students to make up missed coursework. In one school the facilitator just taped the programs and made them available to students; in another the facilitator showed the makeup tape during a later class period; and one facilitator had to plan special make-up periods outside class. Ultimately, student performance was affected by...
when, and if, classes were made up. This was particularly
evident at South High where many school holidays failed
to match the distance schedule, and where a number of
special activities disrupted class. In addition, over half the
students at South High missed Physics once a week for an
entire semester as a result of another class. As the South
High facilitator noted, "If they miss it and don’t make it up,
and then they get lost, it’s a wipeout. They never catch up.”
Thus, the school calendar had an adverse effect on student
learning in Physics if it meant students missed classes to the
degree they got behind and couldn’t (or didn’t) catch up.

The school bell schedule also influenced student and
facilitator activities. At North High a German class was
scheduled at 9:00 a.m., just as the off-air Physics time was
beginning. As a result, physics students went to the media
center for the off-air segment and the facilitator stayed with
the German class. This meant the facilitator could not
participate in off-air activities with the physics students,
and she felt this was detrimental. During previous years,
she had used off-air time to encourage students to call the
physics teacher with questions they did not understand, or
had encouraged them to do homework together on the
chalkboard. These activities allowed students who were
having difficulty to get help, either from the physics teacher
over the phone, or from the other students in the class.
However, the 1994-95 North High physics students were
reluctant to call for help unless the facilitator actually
placed the call. Due to the scheduling of the 9:00 German
class she was rarely able to do this. Cooperative learning
through mutual homework review rarely occurred because
students spent the off-air time in the media center visiting
with each other rather than doing homework. Students in
the media center were also unable to complete lab or other
activities that required equipment access. At South High
School, the bell schedule split the off-air period into two
short segments that tended to be wasted by the students.

School registration procedures had a major impact on
North High students in terms of pre-requisite skills. The
physics course required Algebra I and II as pre-requisites,
but a number of North students were misadvised and did
not meet these requirements. As a result, most of the North
High students had poor math skills and were unable to
perform the algebraic procedures required in Physics.
Consequently, their acquisition of physics skills suffered.
While the facilitator became aware of the algebra deficien-
cies early in the course, she had no way of providing
remediation.

Prior school experiences also affected physics students.
North High students had chosen Physics because they had
heard, from other students or the chemistry teacher, that
Physics was easier than the alternative chemistry course.
So, their expectations were that the course and the work
required of them would be easy. While a number of the
students at South High perceived that Physics was a more
difficult science, the amount and kind of work they were
used to putting into courses did not prepare them for the
effort required by the distance education physics course.
Many lacked adequate study skills and discipline. The
South High facilitator observed, “I think this class requires
more from them than they’ve been used to. They need to
look at Physics every night, and they just did not do it.”

And while all but one South High student met the algebra
pre-requisites on paper, most believed that the skills they
had acquired in their algebra courses at South High were
inadequate.

School drop policies for distance education courses
affected some students. None of the three schools allowed
students to drop distance education courses after tuition
had been paid to the course provider. But, several students
at South and North High Schools indicated they would
have dropped the course had that been an option, since
they were doing so poorly in it. The drop policy may have
indirectly contributed to a test retake policy at South High
and a lenient homework policy at North. Both policies
provided an opportunity for students to improve their
grades although the policies did not support student
learning. Generally, the South and North High facilitators
did whatever they could to help students pass the course
since they could not drop it.

Other school responsibilities affected the amount of
time the South High facilitator actually spent in the
classroom. The South High facilitator was a full-time
school administrator, and as a result she periodically missed
entire classes for several days or a week due to meetings,
workshops, or other school obligations. Since she was an
administrator, substitutes were not hired to take her place as
facilitator. Missing classes meant she had to catch up on
what had been covered in Physics, determine what students
had or had not done, and then decide how students would
make up missed activities. South High students indicated
they did not stay on task and found it difficult to pay
attention when the facilitator was away, so the regular
learning process was always affected when she was absent.

Facilitator Roles and Their Effect on
Student Performance

Facilitators at all three schools agreed that their primary
focus was on classroom management and climate, but noted
they engaged in some planning and instructional tasks.
Logistical planning and implementation was a major
responsibility. All three duplicated instructional materials
developed by the physics teacher and distributed them to
the students. They maintained lab equipment and prepared
the classrooms for lab activities. They also decided how to
accommodate deviations between the school and physics
calendars and schedules. The physics teacher delivered
most of the instruction, but occasionally the facilitators
provided supplemental guidance or feedback as they
responded to student questions. The South and North facilitators occasionally answered informational questions directly, but more frequently directed students to other resources such as other students, teachers, or the telephone tutors. The Central High facilitator had a science background and was able to answer student questions personally. The North and South High facilitators played a major role in gaining (and maintaining) student attention during class and in eliciting student performance during labs and other in-class activities. The Central High students tended to stay on task, paying attention and participating independently, so the Central facilitator rarely had to assume these roles. All three facilitators implemented the testing and student assessment activities planned by the physics teacher. Each facilitator instituted grading policies and procedures that they thought were appropriate for their students and instructional setting. For instance, at South High students were allowed to retake tests for extra credit and at North High students were allowed to turn in homework long after it was due.

All three facilitators assumed classroom management roles, although the North and South facilitators were more active in this area. The Central facilitator reported, and classroom observation confirmed, that Central High students were mature and required little supervision, while the other two facilitators were continuously working to keep South and North High students on task, paying attention, behaving appropriately and participating in classroom activities. At South High the facilitator constantly reminded them to pay attention and participate in class, and she always coached or guided students through labs, since they tended to sit idly without her direct intervention. The students themselves reported that it was difficult to pay attention when the facilitator was absent. At North High the facilitator sat among the students to keep them on task, and frequently interrupted student conversations or other off-task behaviors to get them to focus on Physics. Students at North High indicated that they found it hard to concentrate and pay attention and relied on the facilitator to keep them on task.

The facilitators also assumed classroom climate roles, displaying positive attitudes toward the course and instructor, encouraging positive student attitudes and trying to build supporting relationships with and among the students. The South and North High School facilitators tried to work with other teachers in the school to make them aware of special needs or dispensations the physics students required as a result of their participation in the distance ed course. In all three schools, facilitators maintained indirect contact with parents through mid-term grading period progress reports. The North High facilitator also maintained direct personal contact with several parents who were concerned about their child's performance in Physics. Students at all three schools attributed their positive attitude toward the class to the facilitators enthusiasm.

**Other Factors that Affected Facilitator and Student Roles and Performance**

Individual student aptitudes and other academic skills and experiences also affected the physics students and facilitators. At Central High, many of the students had taken Physics because they were interested in the subject. The facilitator observed that most of these students were gifted, and that all had a great deal of initiative and self-responsibility. The Central students stayed focused and attentive during class, rarely had trouble grasping concepts, and found the pacing of the physics class to be satisfactory. They had good study habits, recognized the importance of solving homework problems rather than copying answers, and had good test-taking skills. They also took responsibility for making up classes they missed by taking tapes home or viewing them before or after school. Consequently, their academic performance was good, and the facilitator rarely had to intervene or provide direct support for class activities.

This contrasted with the students at South and North High, most of whom were average students with average academic backgrounds. They had more difficulty staying on task and paying attention, inadequately utilized instructional resources, occasionally found the pacing of the course too fast, frequently copied homework answers just to get credit, and employed educated guess strategies when taking tests. They tended to accept less responsibility for their own learning, relying on the facilitator to help them focus or to make sure they did their homework or labs. While some of the students at North High reviewed tapes for classes they missed, only one South High student routinely made up missed classes without direct facilitator intervention. Facilitators at these two schools provided a great deal of support and guidance during class to help students to pay attention and participate in class activities, to actively help them complete assignments such as labs, to make sure they turned in homework, and to encourage students to utilize supporting outside resources such as the tutors. While some of the South and North High students performed satisfactorily on tests suggesting that they had mastered physics skills covered in class, a number of students at these schools relied on homework credit and good lab scores to pass the course.

Facilitator backgrounds also contributed to facilitator roles. Since the Central facilitator had a science degree, she could usually provide immediate answers to any content-related questions students might have. The other two facilitators might be able to answer some physics questions — based on things they had learned in previous years — but their more frequent information/feedback role was to direct and encourage students to use other resources to find answers. Some of the South and North High students indicated that they called the tutors and found them helpful, but many were reluctant to call or found it difficult.
to communicate with the tutors. And, since a student's ability to clarify and resolve conceptual or procedural questions ultimately affects student learning, the Central High students’ physics performance was influenced to some degree by their facilitator's ability to answer their (infrequent) questions. Of course, Central High students also turned to each other for help. At South and North High Schools, the students had frequent questions; and whether their facilitators could answer the questions, or direct them to an alternative information source (and get the students to use the resource), also affected student learning. Unfortunately, the South and North High School students rarely took advantage of these resources.

Implications for Theory and Practice

This study supports the position of theorists such as Shale (1990) and Garrison (1989) who contend that distance education, while morphologically different, does not constitute a distinct educational process. The same factors that affect student learning in a traditional classroom also affect student learning in a high school distance education class; that is, learner skills, knowledge, beliefs, attitudes, and course/lesson design.

The study also suggests that responsibility for the quality and outcome of high school distance education courses is shared among all components of the distance education system; the course provider, the high school utilizing the program, and the local facilitators and students who are participating in the course. Specifically, the course provider, instructor, and designers, are responsible for providing effective, efficient instruction in the form of courses that maximize student achievement. This includes designing, developing and providing instruction, materials and activities, that, when utilized as prescribed, result in student mastery of clearly defined objectives. This also includes clear specification of desired student outcomes, required student entry skills (perhaps a specific prerequisite skills test rather than designation of required prerequisite courses), instructional materials and activities, a prescribed plan for course implementation, and other student support as required.

The responsibilities of the local school include assuring students possess the pre-requisite entry skills, and supporting utilization of the course as designed by the course provider. This includes fully implementing the complete range of instructional activities in the sequence designed by the course provider. Or, if the school can not implement the course exactly as designed, it must assure that other components in the system can compensate for the instructional elements that were not implemented as designed. Specific school responsibilities include registering (and pre-screening) students, establishing school calendars, bell schedules, and selecting and establishing facilitator availability. These are all factors which contribute, directly or indirectly, to facilitator and student roles and performance. Since two of the schools participating in this study deviated to some degree from the course provider’s implementation recommendations (i.e., student prerequisites, off-air activity block scheduling, and facilitator availability), this may provide evidence that one of the challenges high school distance education course providers will face is getting schools to utilize courses as designed. This is similar to the problems instructional designers have traditionally faced in getting schools to use courseware as designed (Burkman, 1987).

Finally, the study suggests that in addition to course design and school factors, facilitator roles and performance requirements will be defined by the needs of the students themselves. Students who are high on the motivation and willingness continuum but low on the ability continuum may require facilitator support in the form of instructional assistance (if the facilitator has subject area expertise) or encouragement and assistance in using telephone tutor or other external support (if the facilitator does not have content area expertise); whereas students who are high on ability but low on motivation and willingness will require facilitator support to help them stay on task and participate in class activities (Hersey, Blanchard, & Johnson, 1996).

FORM FOLLOWS FUNCTION: DESIGNING WEB PAGES TO SUPPORT EDUCATIONAL PROJECTS

Judi Harris
University of Texas at Austin

Curriculum-based telecollaborative projects happen both across and within participating school sites; they have no one geographic location. It is helpful, therefore, to create a central, virtual space for sharing information about project-related activities. Many online project directors use World Wide Web pages for this purpose.

Eliel Saarinen (1873-1950), a Finnish architect and city planner who moved to the United States in the 1920’s, was quoted in the July 2, 1956 issue of Time magazine as having said:

“Always design a thing by considering it in its next larger context— a chair in a room, a room in a house, a house in an environment, an environment in a city plan.”

(Tripp, 1970, p. 149)

Saarinen’s words convey wisdom to those of us planning curriculum-based educational telecomputing projects that will be supported by Web pages. The “next larger context” for project page design is the variety of functions that designers intend the WWW site to serve and support. Project pages should be designed with these functions in mind. Before offering Web documents to an online community, we should answer questions like these:

• Who will be interested in exploring the site?
• What types of information should be available at the site to address different audiences’ interests?
• How should this information be presented, so that it is maximally helpful to project participants and/or Web strollers?

Currently, Web page design is addressed primarily in terms of form and content, rather than function. We consider, for example,

• layout options (i.e., “Should we use frames?”);
• overall structure (i.e., “Should the site be one long page with links to subsections or multiple, shorter pages?”);
• transfer time (i.e., “How many graphics should I put on this page?”);
• browser differences (i.e., “Will Lynx users be able to benefit from my site?”);
• readability (i.e., “Does this combination of background pattern and text color make the page difficult to decipher?”);
• aesthetics (i.e., “Is the combination of colors, items, and spacing pleasing to the eye?”).

In this paper, I will suggest that we also consider project-related functions as we design WWW documents. Any architect (including Mr. Saarinen) would strongly suggest that “form follows function.”

Project-Related Page Functions

In this section, I will examine aspects of a few Web-based educational telecomputing projects to illustrate ten different project page functions. More information about each curriculum-based effort is available on the Web, using the either the project URLs provided below or a site containing links to examples of each function. This centralized page function resource can be accessed online at: http://ccwf.cc.utexas.edu/~jbharris/Virtual-Architecture/.

Project Overview

Web sites can serve as succinct introductions to the goals and operational structures for educational telecomputing projects.

iEARN’s ongoing Rope Pump Project, for example, which brings clean water to villages in Nicaragua in the form of a rope-operated water pump, is described on the project’s Web page as follows:

In rural villages in Nicaragua, many children and adults are subject to disease and death because of lack of access to clean water. Through the Rope Pump Project, we are collaborating with an organization called El Porvenir (“The Future”) which worked on small water projects in Nicaragua. Students in iEARN have raised over $10,000 to fund the digging of wells and the installation of rope pumps in villages where people were drinking from polluted streams or from wells that had been contaminated by dirty buckets being thrown into them. We have received numerous letters from children in those villages, thanking our students for providing the materials (the Nicaraguans provide the labor) for their wells and pumps and describing their lifestyles and
goals. We are in the process of setting up a system whereby students can communicate with children in those villages on a regular basis. (http://www.iearn.org/iearn/projects/pump.html)

The page also provides information on the ages for which, languages in which, and dates that the project has been functioning, along with an E-mail address to use to write for more information.

**Project Announcement**

Web sites can announce curriculum-based projects, inviting participation and providing links to relevant networked resources.

The well-organized and well-detailed announcement for the Boreal Forest Watch project in Saskatchewan and Manitoba, Canada, for example, offers clearly-stated explanations and descriptions of purposes, plans, and collaborators for this ambitious ecology project.

![Figure 1: Boreal Forest Watch Project Announcement](image)

As you can see in Figure 1, many aspects of the project can be learned about using its Web site, including descriptions of component activities, information about participating schools, plans for creating the database of observational data, and announcements of upcoming project-related events. There is also an index of similar projects and content-related information on the Web provided for the site’s visitors.

**Project Instructions**

Web sites can provide specific instructions to telecollaborators on how to participate in the educational project.

i*EARN’s excellently organized Learning Circle global classroom projects (http://www.iearn.org/iearn/circles/lc-home.html), for example, are supported by a hypertextually linked set of carefully crafted and information-rich Web pages, which provide specific step-by-step instructions for project participation. A small section of the main page at this site appears in Figure 2. Please note the many active links to documents supporting each stage of project work.

![Figure 2: Instructions for Participation in i*EARN’s Learning Circles](image)

The page also contains information on joining i*EARN, links to conferencing spaces in which project partners communicate, links to custom-designed Web page publication aids, and a chronologically organized timeline for the current session of Learning Circle telecollaboration.

**Information Repository and Exchange**

Web sites can serve as virtual places for project participants to exchange information.

KIDLINK’s long-term Multi-Cultural Calendar database creation project site (http://www.kidlink.org/KIDPROJ/MCC/) cross-indexes student-written depictions of hundreds of holidays and festivals from around the world.

![Figure 3: KIDPROJ’s Multicultural Calendar Project Main Page](image)

As you can see in Figure 3, the holiday descriptions are accessible by month, holiday name, country, author, and user-supplied keywords. A World Wide Web-based form is also available at the site, so that new entries for the holiday
database can be submitted more easily. A portion of this form is included in Figure 4.

![Form Image]

Figure 4. KIDPROJ's Multicultural Calendar Holiday Entry Form Excerpt

**Context for Project-Related Communication**

Web pages can be co-constructed by project participants, creating an open-ended form of **multimedia communication**.

The Electronic Emissary telementoring project (http://www.tapr.org/emissary/), which “matches” volunteer subject matter experts with students and teachers interested in inquiry-based learning in the experts’ specializations, has seen a few electronic teams co-create Web pages to facilitate their virtual interactions. This is especially effective when pictures or diagrams need to be concurrently viewed, and can be supplemented by real-time audio/video interaction using **CUSeeMe**.

For example, a meteorologist working for the National Center for Atmospheric Research in Colorado helped a sixth-grade class in Texas learn about atmospheric science, in part, by suggesting an experiment that required the assembly of a device that would help them to “measure radiative processes.” The scientist posted a picture of the device on the common page, as a beginning to an ongoing, multimedia discussion of the results that the planned experiment yielded.

**Project Support**

Web sites can serve as organized collections of **project-related resources**.

CoVis’ rich and well-organized site (http://www.covis.nwu.edu/) offers a plethora of materials that can be used by participants as they explore geosciences in telementoring contexts, “learning through collaborative visualization.”

![CoVis Main Page Image]

Figure 5. CoVis Project Main Page

**Welcome to the Hobart-Malang E-Mail Project**

![E-Mail Project Header Image]

Figure 6. Hobart-Malang E-Mail Project Header

The key to making project support sites maximally useful to project participants is to organize the materials offered for quick and efficient access. CoVis’ main menu, shown in Figure 5, reflects the care and thought that project coordinators have put into the functionality of the project’s Web site.
Project Chronology

Web sites can present chronologies of past and ongoing project work.

The rich and varied nature of the Hobart-Malang Electronic Mail Project (http://www.tas.gov.au/fahan/Compute/indo.html) is excellently reflected in the project’s detailed and visually appealing Web site.

This multi-year, multi-class, multifaceted, emergent keypals project involved Year Four students in Hobart, Australia and Malang, Indonesia, who wanted to learn about each other’s cultures, countries, and ways of life. Many topics were discussed, many sets of materials were exchanged, and many learning products were created in the course of the exchange. Much of this is available for perusal at the site, richly illustrated with children’s works, photographs, project artifacts, and descriptive text. Hints of the incredible variety represented can be discerned by looking at a portion of a list of active links to project-related materials, as pictured in Figure 7.

Figure 7. Hobart-Malang E-Mail Project Partial Page Contents

Showcase of Participants’ Works

Web sites can provide viewing space to share project participants’ creations.

Marian Herman’s International Peace Museum (http://www.ih.k12.oh.us/ps/peace/), is a thematic project for students in kindergarten through grade 3.

Figure 8. International Peace Museum Virtual Entrance

The project invites young children to “think about peace and the importance of peace,” as its creator has said.

This Web project and the museum that it creates might actually be able to affect the future of the world in some small way. It’s an exciting thought. (http://www.hmco.com/hmco/school/projects/peacemuseum.html)

Participating students in different schools from around the world are asked to read books about peace, discuss the ideas they encounter in class, then “decide what peace means to them,” writing a statement or poem and illustrating it. These creations are then posted at the Peace Museum site, but in a creative and educational way. Contributions from other classes are organized into wings of the virtual museum, as seen in Figure 9.

Figure 9. International Peace Museum Map

In the North Wing, for example, are links to collections of peace works from other schools in the United States:

Figure 10. International Peace Museum, North Wing
Students at the Manaugh School in Cortez, Colorado, for example, created a mural and poem that illustrates the potential power of thematically-organized projects such as these:

We at Manaugh have a dream...
That Native American, Hispanic, Hawaiian, and Caucasian kids can all play together on the same monkey bars.
That all kids are treated equally.
That no one shall fight anymore.
That everyone can share friendship, harmony and peace.
Freedom is all that matters.

Mrs. Herrick’s Reach Class, Cortez, Colorado USA
(http://www.ih.k12.oh.us/ps/peace/cortez/cortez.htm)

Project Center
Web sites can serve as multipurpose centers, combining several of the project-related functions listed above.

The home page for Noelle Kreider’s Read to Write Project (http://www.itdc.sbccs.k12.ca.us/projects/kreider/index.html), an effort to inspire students to immerse themselves in particular literary genres first by reading, then by creating and publishing that type of writing, shows a selection of current, future and past topics for exploration.

Yet once one of these options is selected, we see how engaging language, white space, and well-placed illustrations can be used to make a resource-rich project center quite easy to navigate. The main page for the Historical Biographies section, for example, illustrates well how many of the page functions mentioned earlier in this section can be combined to create an information-rich, facilitative, multipurpose “virtual center” for an educational telecomputing project.

As you can see by the list of topics in the left-hand menu in Figure 13, this project’s schedule, participants, online discussions, student works, resources, registration, and instructional suggestions are easily accessible from this well-presented page.

Project-Spawning Service
Web sites can offer electronic services that can help to initiate new curriculum-based telecomputing projects.

A growing number of services that help teachers and students locate information and interpersonal contacts with which they can begin new projects are now available on the
Web. Notable among these are keypal and global classroom partner locators, such as:

- the Intercultural E-Mail Classroom Connections service (http://www.stolaf.edu/network/iecc/)
- eMail Classroom Exchange (http://www.iglou.com/xchange/ecce/index.html)
- Classroom Connect's Teacher Contact Database (http://www.classroom.net/contact/)
- Keypals International (http://www.collegebound.com/keypals/)
- Mighty Media's Keypals Club (http://www.mightymedia.com/keypals/)
- Dave's ESL E-Mail Connection (http://www.pacificnet.net/~sperling/guestbook.html)
- and Virtual Handshake (http://ananke.advanced.org/3174/), shown in Figure 14, which offers interpersonal connections in seven different languages: English, Spanish, French, German, Afrikaans, and both SJIS and romaa Japanese.

![Virtual Handshake](http://ananke.advanced.org/3174/vh.html)

Figure 14. Virtual Handshake Language Selection Menu

Curriculum-based project planning tools are beginning to show themselves online, also. Notable among these is Pacific Bell's Filamentality (http://www.kn.pacbell.com/wired/fil/), a well-executed instructional design tutorial that helps its users to create WebQuest-like teleresearch sites to be used for instructional purposes. In the words of its witty creator,

**What Exactly Does this Filamentality Do?**

Maybe it doesn’t slice, dice, or chop, but Filamentality does blend your learning goals with the outrageous resources available on the Web. How does Filamentality do it? By guiding you through the complete instructional design process. Okay, okay, we'll tell you in real English: Filamentality works its magic with online ideas to help you shape your ideas around whatever specific goal you have, and then, presto change-o, gives you your very own Web page on the Internet. (http://www.kn.pacbell.com/wired/fil/)

Sound too good to be true? If so, why don’t you go to Filamentality’s site and check out the resources there for yourself?

**The Next Next Larger Context: Purpose**

Hopefully, the ten Website functions explained and illustrated above will help you to allow function to drive form as you design Web pages to support current and future educational telecomputing projects. I would be remiss, however, if I did not urge us all to continue to follow the pattern of Saarinen’s sage advice by considering function in terms of its next larger context: purpose. For, as Norbert Wiener wrote in 1954 in *The Human Use of Human Beings,*

> There is one quality more important than “know-how”...This is “know-what,” by which we determine not only how to accomplish our purposes, but what our purposes are to be. (Tripp, 1970, p. 524)

In the context of educational activity design, the next next larger purpose always refers back to curriculum-based content and process goals. Telecomputing is not, and should not be treated as, another curriculum. Instead, it can serve existing and emerging teaching/learning goals in rich, authentic, and forward-thinking ways.

Diversity. Is it another educational fad? Is it exclusively about and for minorities? Is it about global awareness? Or is it just another politically correct catchword? What exactly is diversity? And why should the SITE 1998 Annual have a section on diversity?

Defining diversity is like defining humanness. Everyone knows what it is, but everyone explains it differently because they focus on a different aspect. Thus there are as many definitions of diversity as there are books on the topic. Perhaps diversity is so difficult to define because it is about the nature of humanness.

Many equate diversity with differences in inherited racial and ethnic attributes. However, this perspective portrays a very limited view of diversity. Humans are complex, dynamic entities who differ from each other in numerous ways. We differ in our educational background, geographic location, income, gender, sexual orientation, age, physical abilities, marital status, parental status, and religious beliefs. In addition to cultural and socio-economic differences, we also differ in how we prefer to learn, how we organize ideas, and how we view the world. Given the countless differences among people, it is not surprising that people often misunderstand, fear, mistrust, and discriminate when they come into contact with those who are different from themselves. These emotional and social barriers result in academic inequity, economic favoritism, emotional devastation, social dissonance, and human ignorance.

As our world experiences increasing demographic changes, the need for justice, equity, and harmony become acute. Diversity will not disappear or be dissolved in the great melting pot that makes everyone the same. Similarly, social inequities will not disappear unless there is intercultural understanding that leads to social activism for equity. Because human diversity is a valuable resource that strengthens society and enriches individual lives, educators have a growing concern with diversity, multiculturalism, global awareness, and social advocacy.

So why a separate section on diversity in this Annual? To assume that all people approach technology in the same way, have the same perceptions about technology, or have the same access to it is to ignore human diversity. The expanding use of technology in education, across disciplines and academic levels, makes research on diversity and instructional technology imperative. Moreover, by placing papers on diversity into a separate section, the Annual demonstrates not only a valuing of diversity, but also a clear interest in diversity and technology issues. Though diversity permeates much of what we do as educators, without a separate section devoted to diversity much of that knowledge would be diffused and subsumed.

The papers in this section address diversity from a broad, encompassing perspective. The first two papers focus on issues of diversity and technology access. Chisholm, Carey and Hernández's University Minority Students: Cruising the Superhighway or Standing at the On-Ramp explores access to technology among minority and low SES university students. This paper presents disconcerting national statistics on technology access and discusses on-going research. Their study stems from collaboration between the faculty researchers and university administrators. The second paper, Gender Equity Model: High School Female Students and Technology Awareness by Beasley, Wark, and Zimmerman, examines female students access to technology. These authors delineate a program model for developing career awareness among high school girls through the integration of technology throughout the program. They report their findings after their first year of successful implementation.

The third, fourth and fifth papers convey a global perspective of diversity and technology. In their paper An International Comparison of Computer Perceptions, Attitudes and Access, Chisholm, Irwin and Carey submit preliminary findings from an on-going international study of university students. This paper summarizes results from a questionnaire administered in China, Ghana and the United States and provides some cultural and educational implications of their findings. The next paper, Using Live Teleconferences to Promote Diverse Perspectives by
Cynthia Anast Seguin, demonstrates how live teleconferences between geographically distant schools can promote multicultural knowledge and cross-cultural understanding. This project linked middle school students in Juneau, Alaska with students in Burlington, Kansas. Collaboration between school teachers and university faculty made this project feasible. The fifth paper, Julie Qiu Bao’s *A Multimedia Comparison of Value Orientations between Chinese and American Elementary Textbooks*, examines the cultural values conveyed by Chinese language arts and American social studies textbooks. The author discusses how explicit or implicit values education reflect prevailing moral principles and national beliefs. In addition, the author provides suggestions on using presentation software in disseminating research findings.

Like Bao, Ryan, Sweeder, and Bednar investigate values education. Their paper, entitled *Technology and the Moral Sense: Re-Wiring Moral Education*, identifies four universal moral values: sympathy, duty, fairness and self-control. The authors provide an overview of current trends in moral education and suggest how educational technologies and moral education can be integrated.

The last two papers approach diversity from the standpoint of individual differences in teaching and learning. Norton and Sprague in *Teachers Teaching Teacher: The Belen Goals 2000 Professional Development Project* document a district plan for teacher technology education that follows a teachers-teaching-teachers model. The project called for collaboration between a university faculty member and the school district personnel. The authors present the results of this project as measured by a pre- and post-test questionnaire. Similarly, Nancy Wentworth in *Technology Inservice: A Powerful Change Force* discusses a technology inservice project that followed Michael Fullan’s eight basic elements of change. This inservice project was a collaborative effort between a university teacher education program and a public junior high school. Wentworth relays program results based on data from interviews, journals, and logs.

The scope of these papers mirrors the complexities and magnitude of diversity. As educators continue to explore the convergence of technology and diversity, and as we begin to translate research findings into classroom practices, all our students will be better served.

Jane Carey  
Arizona State University West

Anthony Hernández  
Arizona State University West

We entered the century with pencil and paper; we leave it with computers able to figure thousands of times faster than the human brain.  
—Carol Sue Fromboluti

Universities can no longer remain aloof, ivy-covered towers of erudition and elite stature. Shrinking budgets, changing student demographics, and public demands for accountability have altered the traditional academic climate. Institutional response to the changing social and economic pressures has led to paradigm shifts, realignment of university missions, and instructional transformation. Among the instructional transformations embraced by many institutions is the incorporation of information technology as both a mode of instructional delivery and as a means for student learning and performance.

The prevalent movement towards increased use of information technology is not, however, primarily aimed at improving the quality of higher education. In reality, our institutions have found that they must turn to “information technology to stay in business” (Barone, 1996, p. 28). Research suggests that instruction delivered through computer or distance learning is not only economically effective, but also instructionally effective (Castellan, 1993). To ignore or avoid technology at our institutions is to “drown under its weight” (Alvarez, 1996, p. 26).

Technology in Higher Education

In today’s competitive market the use of electronic information resources is becoming a distinguishing attribute of institutions that pride themselves in offering the highest academic standards (Ringle, 1996). In fact, the presence of information technology is a critical asset in recruiting quality students and faculty, as well as in attracting external funding. Understandably, university students and their parents seek quality and low-cost education. At the same time, outstanding faculty are drawn to those institutions that provide them with the electronic tools for communication, information and research. In turn, it is the reputation of an institution’s students and faculty that ultimately attracts external funds to support a university’s growth and development.

Consequently, technology plays an increasing role in course design, delivery, and content. In 1995, between 20 to 30% of instructors in higher education used some form of instructional technology in course delivery (Goggin, Finkenberg, & Morrow, Jr., 1997). The number of college classes that use electronic mail rose from 8% in 1994 to 25.0% in 1996 (Green, 1996). By the same token, in 1996, about 9% of all college courses used WWW-based resources to support instruction (Green, 1996). In addition, according to Tapscott (1996), there are over 2,000 courses currently available on the Internet. Not surprisingly then, approximately 31% of all institutions of higher education have a computer competency graduation requirement and one in six institutions requires or strongly recommends that students purchase a computer (Cartwright, 1993).

Casualties on the Superhighway

While computers and the electronic superhighway are transforming higher education, university and college campuses are encountering a changing student population. Fewer than half of the nation’s undergraduates are traditional 19 to 22 year olds (Cartwright, 1993) and minority student enrollment increased from 15% of all students in 1976 to 23% in 1993 (NCES, 1996c). These students bring with them a rich array of experiences and knowledge about the world. However, those experiences and knowledge may not have included the computer and multimedia technology.

Many students from culturally, racially and ethnically diverse backgrounds, as well as nontraditional students, come to higher education with fewer technology experiences and less computer expertise than their majority counterparts. As Krupar (1996) points out, a large
proportion of these students is "technophobic" and lacks the necessary background and skills to fulfill computer-related assignments. These students find themselves unable to meet faculty and institutional performance expectations and to take full advantage of their university education.

National data bear out the differences in computer access and experiences among our students. As of June 1996, approximately 40% of all American households had computers, 21% of these had CD-ROM drives and 18% had modems (Famighetti, 1997). Thus, contrary to popular belief, most households do not have computers and fewer still have Internet and e-mail capability. Further, the number of computer-owning households is unequally distributed across race and ethnicity. Whereas 49.4% of White undergraduate students have computers at home, 27.0% of African American students and 27.3% of Hispanic students do (NCES, 1996a). Of those with home computers, only 36.4% of White students, 41.3% of the African American students, and 31.4% of the Hispanic students had a fax or modem (NCES, 1996a). Even more revealing is that 48.7% of the White population use computers at work, but 36.2% of the African Americans and 29.3% of Hispanics have that opportunity (NCES, 1996b).

This inequitable access to technology leads to information-poor segments of our society. Robert Bauchspies (1996) defines the information poor as those who exhibit one or more of the following characteristics:

- Illiterate
- Unable to determine their information needs
- Unable to discern value or relevance of information to their needs
- Unable to develop information seeking strategies
- Unable to afford access to information
- Unable to access information due to cultural or physical barriers

Bauchspies' definition highlights the urgent need to increase access to information technologies for those who either cannot afford the hardware and software costs for entering the Superhighway or who have been prevented from access through cultural inequities or physical barriers. Our institutions of higher education cannot ignore their obligation to prepare students who are literate professionals. In our increasingly technological society, literacy includes technological literacy.

The question of equitable access to technology and the superhighway becomes an ethical and academic issue. As Krupar (1996) states, more and more faculty require students to correct their spelling and grammar, use graphic presentations, and use several data bases in researching topics. Universities often function as if all traditional-age students are computer literate, can afford to purchase a computer and value computers (Krupar, 1996). However, low socio-economic families are less likely to purchase computers. Black and Hispanic households continue to have an average income that is approximately 60% of that of white households (NCES, 1997). Unwittingly, institutional expectations for technological competence and computer ownership may lead to many causalities on the information superhighway.

Though there is much information about the inequities in computer access in grades K-12 (Coley, Cradler, & Engel, 1997), there seems to be very little information on this issue in higher education. One study that does explore this issue is an informal survey by Mendoza (1995) of students enrolled in a composition course. Mendoza found that the 25% of the minority students who owned a computer considered themselves middle class. Of the 75% who did not own a computer, almost half identified themselves as lower-income. However, the small sample size in this study limits generalizability.

Hypotheses and Instrumentation

To gain an increased understanding of access issues, three researchers began to explore the question of accessibility to existing campus technology by low socio-economic, nontraditional, and minority students. They posed the following questions:

- Do nontraditional, low socio-economic and traditionally underrepresented college students in higher education have the same access to computers and information technology as traditional majority students?
- Do nontraditional, low socio-economic and traditionally underrepresented college students in higher education have the same computer training and information technology background as traditional majority students?
- What factors are associated with access and frequent use of information technology?
- Do nontraditional, low socio-economic and traditionally underrepresented college students in higher education have the same attitudes towards computer technology as traditional majority students?

To answer these questions, one of the researchers created a multiple-choice questionnaire during the summer of 1997. During Fall 1997 the three researchers reviewed the instrument and revised it. In addition, the staff of our Information Technology Office, the Associate Vice-Provost for Extended Instruction, and members of the Information Technology Advisory Committee reviewed the instrument and provided suggestions. The researchers incorporated their suggestions into the instrument.

The questionnaire currently has seventy-two multiple-choice items. Several items on this questionnaire also allow open-ended responses. Twelve items collect information on gender, race, ethnicity, and socio-economic background. Some of these items gather information on family background. For example, one item asks respondents how long their family has lived in the United States. Another item asks if the respondent is the first person in their immediate family. One or more of the following characteristics:

- unable to access information due to cultural or physical barriers
family to attend college. Other items ask for direct information about the respondent. For instance, one item asks the respondents if English is their native language. Another item asks the primary source of financial support for their education. Yet a third item asks if they currently work full or part-time while attending school.

Nineteen items address computer access both on- and off-campus. Nine items focus on hardware access. For example, students are asked whether they use computers on campus and how frequently, whether they have a computer at home, the type of computer owned, and if they use a computer at work. There are also questions regarding on-campus multimedia facilities and their use. Four items examine computer software access. These items include questions on the types of programs used at the university computing center and at the campus library. An additional six items center on Internet and e-mail access. These items ask students if they have e-mail or Internet access at home, their frequency of use, and their purpose in using the Internet.

Twenty-three items on this instrument explore students’ current computer use. Thirteen of these items ask for types of software applications used regularly, their frequency of use, and the purpose for using the software. Ten items examine classroom and course use of computers. For example, students will indicate whether their courses and program of study require computer use and whether their instructors use computers. In asking students if instructors use computers, the researchers hope to glean information about students’ perceptions of faculty computer competency and faculty modeling of information technology use.

Another set of questions on the survey probes computer skills and training. To illustrate, students self-report their degree of computer knowledge, confidence, and number of courses about computers. Students will also indicate if they have taken courses over the Internet.

A final set of questions explores students’ computer perspectives. Sample questions include whether respondents believe that all students at our institution have the same opportunities to use technology, whether computers are essential to their academic life and professional life, and whether scholarships should provide for computer purchase.

Sample

Arizona State University West is an upper division university with some 5,000 students enrolled in junior, senior or graduate level courses. Because ASU West does not offer freshman and sophomore classes, many of our students first attend one of the local community colleges. ASU West students enroll in Bachelor’s and Master’s degree programs in five academic areas: the College of Arts and Sciences, the School of Management, the College of Education, and the College of Human Services, as well as the Division of Collaborative Programs. Our students are largely female, 64%, and nontraditional, 65% are 25 years or older. Most, 63%, are also part-time students.

During the third week of the Spring 1998 term, a stratified random sample of 500 Arizona State University West undergraduate and graduate students will receive and respond to the survey. Since larger numbers of ethnic and racial minority students on our campus tend to enroll in specific degree programs, such as Bilingual Education, Global Business, Women’s Studies and Social Work, stratification of the sample by program areas and ethnicity will ensure that a significant number of minorities on campus are included in the sample.

Procedure

Inasmuch as Arizona State University West is currently expanding the number of asynchronous course offerings, providing faculty development in Web page creation for distance learning, and preparing a university-wide five-year strategic plan, the researchers approached the administration with the idea of collaborating in a campus-wide survey. Consequently, the ASU West Office of Institutional Planning and Research is providing staff support and absorbing the cost of survey duplication.

During the third week of the Spring 1998 term, the researchers will administer the survey to students in selected classes from each of the five academic areas on campus. These classes, selected on the basis of enrollment, will include a racially and ethnically diverse student population. The Office of Institutional Planning and Research will then data process the responses and the three researchers will analyze the data.

Implications

Collaboration between university faculty and administrators can yield valuable information for institutional long-term planning, while adding to our knowledge base on technology and diversity. This study demonstrates how faculty scholarly endeavors can provide answers to essential administrative questions. The research will widely disseminate the results of this survey across our campus. They will share the findings of this study with the Provost, the Vice Provosts, Information Technology, the Advisory Committee for Information Technology, the Campus Environment Team, the Office of Student Affairs, the Deans of each of our colleges, the Academic Senate, the Senate’s Student Issues Committee and the Strategic Planning Committee. The results will help shape the future of technology use on our campus.

In addition, this study will serve as a basis for a national study on technology among diverse university populations. National data will offer a broader view of the current situation and help college and university educators discern the issues more clearly. The researchers believe the findings will provide information for administrators and faculty across the United States. The findings will help in planning for multimedia integration, distance learning, and
technology policies that will provide broad access to information technologies. Unless we know the problems, we cannot begin to address them. Furthermore, unless colleges and universities recognize the severity of the problem, they will unwittingly contribute to the academic failure of historically underrepresented college students (Krupar, 1996). Without adequate information, our institutions will perpetuate inappropriate computer pedagogy and obstructive administrative policies.

Ultimately, the ability of higher education to provide quality education for all students in a high-tech environment is a matter of planning for technological equity. Increasingly institutions of higher education allocate part of their limited financial assets to expanding and upgrading their multimedia technology resources. Clearly, technology will continue to play a critical role in higher education during the next century (Ward, 1994). As our institution cruise along the Superhighway, we need to make room for those who are standing at the on-ramp. To fail to do so is to abandon a growing portion of our student body to becoming the technologically illiterate.

A powerful force in today's technology field addresses such issues as equitable educational environments, student motivation, and systemic approaches to decision-making processes involving secondary, post-secondary, and career awareness. The current Gender Equity Model evolved from these critical issues based on findings such as those from the AAUW Report Executive Summary (1992):

1. Girls from low-income families face particularly severe obstacles to academic success. Socioeconomic status, more than any other variable, affects access to school resources and educational outcomes.
2. Test scores of low-socioeconomic-status girls are somewhat better than for boys from the same background in the lower grades, but by high school these differences disappear. Among high-socioeconomic-status students, boys generally outperform girls regardless of race and ethnicity.
3. Too little information is available on differences among various groups of girls. While African Americans are compared to whites, or boys to girls, relatively few studies or published data examine differences by gender and race and ethnicity.
4. Differences between girls and boys in math achievement are small and declining. Yet in high school, girls are still less likely than boys to take the most advanced courses and be in the top-scoring math groups.
5. The gender gap in science, however, is not decreasing and may, in fact, be increasing.
6. Even girls who are highly competent in math and science are much less likely to pursue scientific or technological careers than are their male classmates.

With these findings in mind, a model for gender equity in a rural Appalachia school system is approaching its second year of implementation at the high school level. This model focuses on equity issues, student motivation, and nontraditional course work. In addition, it addresses career awareness for females, including a strong emphasis on technology and the sciences. Specific objectives are the following:

1. To establish higher expectations of female students in both academic and vocational classes.
2. To implement career exposure activities that provide female students information on nontraditional careers.
3. To provide women students with a curriculum which integrates academic and work experiences.
4. To provide female students with career and social guidance and counseling.
5. To evaluate female students' progression through motivational and attitudinal assessments.
6. To include multiple resources in creating a gender equity program.

Selection Process and Qualifying Criteria of Participants

The selected participants demonstrated interest in such areas and courses as Technology/Manufacturing, Principles of Technology, and Integrated Systems Technology. These courses enable students to work as individuals and in teams on designing and constructing projects using plastics, pneumatics, hydraulics, robotics, electronics, metals, metal testing, foundry, welding, and technical drafting. This course work also emphasized computer skills throughout. Female participation and enrollment is generally low in these specific courses (i.e., 10% or less). Other classes viewed as important in this selection process include science courses with a focus on technological labs using electronic evaluations and experiments, and various agricultural and horticultural fields.

Another factor considered in the selection process includes a focus on a targeted population of females. This targeted population consists of those students who are from economically and socially disadvantaged backgrounds, as well as students who possess future expectations and goals for a post-secondary education.
The Three Stages in the Gender Equity Model

The Gender Equity Model funded through a federal grant, is in its second year of implementation. The model is composed of three distinct stages for the enhancement of courses and careers in nontraditional fields for females. The first stage requires career interest surveys and assessments, a pre-test on school interests and motivators, and the forming of individual student advisory committees. The second stage involves activities and a ropes course for the enhancement of team activities in problem-solving and decision-making processes, goal-setting, team building, and communication processes. The third stage requires hands-on job experiences and placements requiring a minimum of fifty hours work with local employers in the interested, nontraditional fields of study for females.

Stage One

In conjunction with additional goals and objectives within this particular high school setting, this equity program assisted in creating a complete computer lab that includes an entire course and a career counseling program. The career and counseling center will assess students' interests and potential in a wide range of courses and careers. Student schedules will be applied to match students’ academic needs and expectations. To provide smooth transitions between grades, the center will also focus on assessments from middle-school course interests and data. The equity program supplied career software to the middle schools that feed into the targeted high school. The middle-school software matches that of the high school, except it is on a middle-school level and in a simpler format. Students at all levels learn to utilize computer skills in the computer lab setting as personal student data and assessments are collected.

In order to implement a usable and friendly program, first-year female students participating in the equity program viewed various programs prior to the purchase of the current program. These students gained extensive experience in a variety of career assessment programs. Currently, computerized surveys assess participants’ career interests as they explore and learn about various nontraditional careers for females. This software program also offers extensive data on needed secondary and post-secondary course work. In addition, information is available on universities offering such degrees, the need for individuals with these degrees, salaries, and available scholarship money. This information becomes part of the criteria for students as they consider future choices and career paths with counselors and parents.

A second part of the initial stage in the equity program involves an assessment on student motivation and attitude toward school. Subscales include motivation for schooling, academic self-concept, student’s sense of control over performance, and student’s instructional mastery. This attitudinal and motivational assessment serves as a pre-test and as a post-test of the participants.

In addition to these preliminary activities, the program assigns students to advisory committees which can consist of school guidance counselors, teachers, parents, business mentors, equity and school partnership directors, and the student.

Stage Two

The second stage of the model promotes activities and initiatives to enhance student motivation, morale, and self-confidence. Activities in socially-arranged groups range from student luncheons, helpful videos related to nontraditional careers and course work, team building games and activities, to a ropes course. Specific goals of these activities relate directly to problem-solving and decision-making processes, goal-setting, team building, and communication processes.

The literature on group interactions and group dynamics, which are considered a vital part of the growth in a group, provides support for these activities and their outcomes (Bertcher, 1979; Bertcher & Mapel, 1977; Dye, Gardner, Underwood & Clark, 1987; Fraus, 1979; Griffm & Patton, 1971; Kamii & DeVries, 1981; Reeves, 1970). Shaw (1981) states that the results of group interactions include higher levels of energy focused on goal attainment, along with more motivation to achieve group goals. Shaw explains that higher levels of trust are created when group interactions occur, causing group cohesiveness. Motivational factors continue to be stressed as a vital component of learning experiences and the acquisition of knowledge within a social context (Bandura, 1986). According to Cartwright (1968), other positive outcomes of group interactions are effective group interaction involving decision-making and group problem-solving processes, greater participation, and higher self-esteem. Ancona, Kochan, Scully, Van Maanen, and Westney (1996), refer to group decision-making as advantageous over decisions made by individuals, particularly in today’s competitive world. Advantages include greater access to information and knowledge within a group of individuals, the enhancement of coordination among the various parts of the group, and the establishment of a communication network to facilitate problem-solving. As these outcomes relate to the specific program objectives of creating an awareness and involvement in nontraditional roles for the female participants, the authors assess them through the motivational and attitudinal tests, along with qualitative data.

Stage Three

The third and final stage of the model requires hands-on job experiences and placements requiring a minimum of fifty work hours with local employers in the nontraditional fields of study for females. The majority of these placements promote knowledge and application of various technology skills in a wide range of fields such as drafting,
architectural landscaping, the formation of one's own business, and several work experiences in technological communication.

**School Staff and Community Awareness**

Another component of this equity model incorporates the utilization of various community resources including local businesses and employers. Through this partnership, school staff receive professional development in such topics as gender and technology issues; integrated teaching, learning, and motivating through the use of computers; and the use of newly-purchased software and technological hardware. Administrators, counselors, and teachers have been active participants in this staff development. Community awareness is enhanced through the communication and involvement of students working in the community and with local businesses.

**Continuous Research on the Equity Program**

Following the first year of implementation of this model, results were analyzed through both quantitative and qualitative methodology. Findings from qualitative data (through student presentations and interviews) reflected a high success rate on career awareness and self-confidence in relation to the attainment of set goals. Several of the high school seniors made definite decisions, following their experience, to pursue a post-secondary education in the areas of their personal nontraditional experiences.

Quantitative data reflected improvement and gains in various areas, as obtained through the School Attitude Measure (American Testronics, 1990). Analyses of this data showed the ninth grade class demonstrated the greatest gains in overall school attitude, specifically in the first subscale which focuses on motivation for schooling. This subscale contains statements concerned with the student's motivation for working hard in school, desire to perform competently in school, and the student's perception of the importance of school and how it relates to future plans. Tenth grade scores indicated improvement in both academic self-concept, performance and reference based abilities. These scales assess a student's feelings about school performance and confidence in academic ability. In grade twelve, greater gains were shown in a combination of two areas, academic self-concept performance based and the sense of control over performance. The sense of control subscale measures the amount of control a student feels she has over school outcomes. General components include willingness to take responsibility for school outcomes, self-reliance, and independence in school. Overall, across all grades and subscales, 61% of the female participants demonstrated an improvement between the original pretest and posttest scores.

This equity model program is beginning its second year of implementation. The authors will continue to conduct research on many of these same students, along with the new participants in the program. In addition, research will include interviews and surveys conducted on the graduating participants as they continue their education on a post-secondary level in a nontraditional career for females.

**Future Use of Equity Programs**

Due to the newness of research on such programs, it is difficult to predict the outcomes that each individual experiences and will experience in the future, but the analyses of this model suggest that equity programs, such as this one, are in great need and demand within our educational system. This model incorporates equity issues with nontraditional career decisions through technology awareness and discovery. As many participants enter, continue and graduate from the program to pursue education and careers in the various nontraditional fields for females, additional findings will emerge from the program.

As in many cross-cultural contacts, the importation of technology into another society often creates initial cognitive dissonance, disrupts established behavior, and steadily introduces new patterns of response and organization. As a cultural artifact that expresses the culture of its creators, the computer organizes knowledge, reshapes work, changes learning environments, and expands information access in ways that mirror western heuristics and logic. Tallah (1996) noted a two-way cultural infusion “whereby the technologically rich nations draw from and inject into the societies of the less endowed” (p. 2). Thus the introduction of computers, especially into non-western and third world countries, will likely affect changes in interpersonal behavior, communication, and education (Darr & Goodman, 1993). The result of these changes is, at best, an unsettling co-existence in developing nations of the indigenous culture and the imported scientific culture (Yakubu, 1994).

Nevertheless, “one cannot talk about development without talking about computers” (Darkwa, 1996, p. 4). Computer literacy is vital in the effort to participate in and benefit from the global exchange of information, trade, and technology. Developing countries face a myriad of problems compounded by the issues of need and accessibility. Those nations at the periphery of world technologies must enhance “their ability to access, produce and use information as full and equal participants of the global community” (Tallah, 1996, p. 1). By implication, their competitiveness on the world market is increasingly dependent on computers and communications technology.

The acquisition of computer technology is, nonetheless, a massive financial burden. The dependence on western-made hardware, software and expertise keeps third-world nations with fragile economies economically subservient (Dixon, 1995). The acquisition of technology will require significant amounts of capital and technical skills, both meager commodities in most developing nations.

By the same token, social, cultural, and political factors influence how computers are perceived, used, dispersed, and experienced. Given the dependence on wealthier nations for hardware and software, as well as the computer’s intrusion into traditional socio-cultural patterns, attitudes and perceptions toward computers in developing nations may be ambiguous at best. Moreover, the level of exposure to and experience with computers will likely influence individual perceptions and attitudes.

Research suggests that negative attitudes and unfavorable perceptions of computers may adversely affect computer literacy (Chen, 1986; Marcoulides, 1988). Similarly, limited computer experiences are related to computer anxiety and lack of confidence in computer use (Chen, 1986; Huang, Waxman, & Padron, 1995). Given the significant role of technology in national economic development, we embarked on an interdisciplinary investigation of attitudes and perceptions towards technology and technology training among college freshmen in China, Australia, Ghana, Mexico, Puerto Rico, and the United States. This paper presents preliminary findings from China, Ghana and the United States. Data on the other participating countries in this study will be reported at a later time. Within this paper, the authors discuss the implications of their study for cross-cultural technology training and education. In addition, the authors draw conclusions based on this preliminary data regarding the development of technological competency within the framework of computer culture and national culture.

International Comparisons

In 1996 the People’s Republic of China had a population of over 1 billion with 67% of its population between the ages of 15 and 64 (CIA, 1996). Mandarin is the official language, but seven distinct dialects and several minority languages are also spoken (CIA, 1996). Between 1978 and 1994 the annual economic growth averaged 9.4% (Jianguo, 1997). Yet in 1994, China had an external debt of $92 billion (CIA, 1996). Under Deng Xiaoping, national educational reform tried to narrow the gap between China and other developing nations; the government focused education on new technology, information science and
advanced management (U.S. Department of the Army, 1994). As a result of the government’s emphasis, Internet access is spreading quickly (Qiang, 1995). China has some 900 e-mail users; the small number reflects the comparatively high fees for this service (Qiang, 1995).

Ghana, a largely agricultural country, has a population of almost 18 million with 51% in the 15 to 64 age range (ITA, 1997a). English is the official language, but several African languages are also spoken (ITA, 1997a). Ghana has twice the per capita output of the poorer countries in West Africa, but its economy centers around subsistence agriculture (ITA, 1997a). As in other developing nations, Ghana seeks the benefits of telecommunications technology. During 1996, the Ministry of Education created 36 science centers, equipped with computers, in selected senior secondary schools (Peprah, 1997). Nevertheless, Africa remains the least computerized continent; computers have as yet to penetrate many important sectors of the Ghanaian economy (Darkwa, 1996). Many Ghanaians lack computer skills, from basic knowledge to advanced knowledge and computer management (Darkwa, 1996). This lack of computer competency and lack of Internet access limits success in technology adoption. As in many developing nations, insufficient resources in the form of well-trained computer technology personnel and the capital to train them handicap Ghana (Morwenna & Parker-Jenkins, 1994).

Currently the United States has over 268 million people (U.S. Census Bureau, November 1997) with 65% between 15 and 64 years of age (ITA, 1997b). In 1992 an estimated 83.4% of Americans were White; this group is projected to be the slowest growing among the five racial/ethnic groups in the national census (U.S. Census Bureau, 1997a). Blacks comprise 12.7% of the U.S. population, Hispanics 8.9%, Asian and Pacific Islanders about 3.3%, and American Indian, Eskimo, and Aleuts 0.8% (U.S. Census Bureau, 1997b). Though English is the common language, 13.8% speak another language at home (U.S. Census Bureau, 1990). American schools have more computers and a higher ratio of computers to students than schools in other countries (Anderson, Beebe, Lundmark, Magnan, & Palmer, 1994). However, gender, ethnic and racial inequalities in computer access continue to persist (Coley, Cradler & Engel, 1997).

Hypotheses and Instrumentation

The researchers posed the following null hypotheses:

• Preferred ways of learning about computers do not differ across cultures and countries.
• Attitudes towards computer technology do not differ across cultures and countries.
• Perceptions of usefulness of computer technology do not differ across cultures.
• Increased access to computers is not related to more positive attitudes toward computer technology.

To test their hypotheses, the researchers developed a four-part questionnaire to address computer training preferences, computer attitudes and perceptions, and computer access. The first part, consisting mostly of multiple-choice questions and some open-ended questions, gathers demographic information such as sex and college major. The second part, also containing multiple-choice and some open-ended questions, gathers information about computer access and training. The third part, a twenty-seven item four-point Likert scale, elicits attitudes and perceptions toward computers. Part four, a four-point Likert scale with thirty-six items, explores training preferences and perceptions of computer technology.

A Spanish- and a Mandarin-speaking faculty translated the questionnaire into Chinese and into Spanish. Then they translated these back into English to ensure accuracy of translations. Results of a pilot administered to American college students majoring in business and education at a metropolitan university in the Southwest helped refine the instrument.

Sample

The Chinese sample consists of 53 Business majors and 44 from various other majors who attend Shandong University in Jinan, the capital of Shandong province in the People’s Republic of China. Shandong University, with approximately 10,000 students, is a doctoral-granting institution and one of 37 key universities in China. The United States sample consists of 59 Business and 39 Education majors enrolled at Arizona State University West, an upper division, Masters-granting university in a large metropolitan area. The Ghanaian sample consists of 25 Business majors, 26 Business majors, and 48 from other disciplines who attend Cape Coast University. This institution is considered the premier university in Ghana.

The size of the sample is similar for each country, but the mean age of students in each is very different. The U.S. average age is 28.6 years, the Ghanaian average age 21.61 years, and the Chinese average 19.86 years. The age difference is due to the near absence of “adult” education in China where students are traditional age. The American sample comes from an upper division university where most students are “non-traditional” adults.

There are 27 females and 72 males in the Ghanaian sample; 63 males and 34 females in the Chinese sample and 34 males and 63 females in the U.S. sample. The high number of females in the U.S. survey is due to the many female undergraduate Education majors in the U.S. The percent of Business students in both U.S. and China who are females is quite low, plus the typical percent of female students in Chinese universities is below 50%.

Racial and ethnic backgrounds are almost homogeneous in each of the three national samples. Among the Chinese, there were 95 Han and 2 that indicated “other” ethnic
minority. The sample from Ghana consisted exclusively of Ghanaians students. The United States sample consisted of 71 Caucasians (non-Hispanic), 15 Hispanic Americans, 3 Asian Americans, 3 African Americans, and 5 undeclared individuals.

The samples are essentially convenience samples and, therefore, it is difficult to generalize from this data. The numbers are almost equivalent to percents due to sample sizes of almost 100 in each country. The U.S. data was collected in February of 1997; the Chinese data was collected in June of 1997 and the Ghanaian data in April of 1997.

Procedure

The researchers mailed copies of the final questionnaire to collaborating faculty at participating universities in each designated country. The collaborating faculty also received specific instructions for administering the questionnaire, as well as a cover letter to students ensuring their anonymity. The faculty administered the questionnaire to one hundred Education and Business freshmen at their institutions. The researchers personally collected the U.S. data from students attending Education and Business classes.

Results

The number of students who own their own computers is very different. Only five Chinese students and six Ghanaians students in our sample have a computer at home. However, 76 of the 97 U.S. students have computers. Though few Chinese and Ghanaians students can afford to own computers, they feel as positive towards computers as the U.S. students do. The data support the second, third and fourth hypotheses.

Forty-one (42.3%) of the Chinese students and thirty-one (31.3%) of the Ghanaians students preferred to share the computer with another while working on it in the university labs. The limited number of computers among Chinese and Ghanaians students dictate that they share computers when they work on their assignments. The same is not true for the U.S. students in our sample. Only seven U.S. students (7.1%) preferred to share a computer. This finding does not support the first hypothesis.

Only eight Chinese and seven Ghanaians students use computers at work. In contrast, 43 U.S. students use computers at work. This is not surprising since more U.S. than Chinese and Ghanaians students work while attending the university and virtually all U.S. businesses use computers.

Sixty-five U.S. and thirty-nine Ghanaians students used Windows. Seventy-six Chinese students used DOS without Windows. Fifty of the Ghanaians students did not know what operating system they had been using.

U.S. students spend more time using computers (15.28 hours per week) than the Chinese students (4.73 hours per week) or the Ghanaians students (1.77 hours). Concomitant with this difference in usage is a difference in self-reported computer competency. The Chinese and Ghanaians reported feeling less competent in their use of computers than did the U.S. students. Hence more U.S. students than Chinese and Ghanaians feel that computers are significant in their ability to conduct their work.

Conclusions and Implications

The differences in computer ownership among Chinese, Ghanaians and U.S. students reflect economic realities. In our personal experience, the few Chinese and Ghanaians students who own a computer are likely to live at home and be the children of university professors. Because much of the hardware and software is produced and sold by more affluent nations, the expense of importation makes the acquisition and maintenance of computers prohibitive for many people in developing countries.

Similarly, the willingness of Chinese and Ghanaians students to share a computer during work has economic and cultural roots. The limited number of computers among Chinese and Ghanaians students dictates that they share computers. Since the survey asked students if they "preferred" to share computers, the Chinese and Ghanaians students could have answered "no" if they preferred working alone. The fact that they indicated a preference for sharing computers is, therefore, indicative of a cultural valuing of collaboration and sharing. The willingness to share the computer fits within the larger cultural context of collaboration and establishing close relationships.

The use of DOS versus Windows indicates that the power and relative state-of-the-art of the Chinese computers is significantly lower than in the United States. The fact that 57.7% of the Ghanaians sample either did not know or did not indicate a platform is intriguing. This response may indicate a general lack of computer knowledge or a lack of knowledge about the specific computers used. Given Darkwa's (1966) statement regarding the need for increased computer skills among Ghanaians, it is likely that a lack of computer competence underlies this finding.

The authors find the attitudinal differences interesting and informative. The Chinese and Ghanaians feel as positive towards computers as U.S. students do, though they have less access to computers. At the same time, they report feeling less competent in their use of computers than do the U.S. students. Because of the perceived inherent benefits of the computer and the general lack of access to it, the computer has become an object of positive desire. In the U.S., the every-day presence and abundant supply of computers have made computers accessible to students. American's fascination with progress and technology leads to positive attitudes toward computers.

At the same time, social and political forces equate computers with economic progress and national well being. Indeed, the political and social push toward technology may have a positive influence on attitudes towards computers.

Diversity — 197
Even those with few opportunities to use a computer believe that it is important for economic growth. The government in the People’s Republic places heavy pressure on Chinese students to support two major educational goals: to master English and to learn to use computers. Hence their attitudes and feelings towards computers are very positive.

Our findings suggest that access and competency are closely linked; those who have the most access also tend to rate themselves as more computer competent. This finding is consistent with previous research and with the need for extended hands-on practice before individuals feel computer competent.

Our findings suggest that students arriving at our institutions of higher learning from Ghana and mainland China will have positive attitudes towards computers, but are likely to have little experience and competence in using them. Given the increasing incorporation of technology in higher education, these students will be at a distinct disadvantage in classes where instructors require word-processed papers, internet searches for information, or even asynchronous learning activities. By the same token, American businesses in these countries will need to invest in employee computer training.

Our findings also suggest that attitudes and competence may not be directly related. Students with positive attitudes towards computers may still lack necessary computer skills. Societal and political valuing of computers seem to play a strong role in the development of computer attitudes.

In addition, our data suggest that cultural values and socio-economic factors influence how people prefer to work with the computer. Where collaboration is valued, individualized computer use may not be valued. Further research on culture and technology will increase our understanding of diverse learners’ needs and expectations.

USING LIVE TELECONFERENCES TO PROMOTE DIVERSE PERSPECTIVES

Cynthia Anast Seguin
Emporia State University

It is frequently a challenge for educators to help students, whether K-12 or university, gain an authentic understanding of communities and cultures other than their own. This may be an even greater challenge in areas of our country that are rural or isolated. By using technology in creative ways, collaborations of teachers and students can help create greater understanding of diverse perspectives. Teachers in Kansas and Alaska recently collaborated to host a live teleconference to help meet that goal.

Description of the Participants
This collaborative project focused on two middle schools—Burlington Middle School, Burlington, Kansas, and Dzantik'I Heeni Middle School, Juneau, Alaska. The Kansas school is situated in a rural area about an hour’s drive from Topeka. The Juneau school, while situated in the capital city, is geographically isolated—no roads connect to other towns—nestled between high mountain peaks that border Canada and the Inland Passage waterways. Juneau’s population is 31,000; the school district has 5,666 students and the middle school 750. Juneau teacher Devin Jones explains the status of Juneau-Douglas School District technology:

Four years ago the city of Juneau passed the first of two bond measures with the purpose of purchasing technology ($3 million). We went from a smattering of non-networked Apple IIe’s to a fully networked district with a direct 56k connection to the Internet. The second bond ($4 million) was and still is being used to purchase hardware at a ratio of 4 computers per student. Building technology committees identified additional hardware...scanners, projection devices, alpha smarts, digital cameras. Unfortunately, very little of the bond money was set aside to train staff...this is the area the district is trying to address now (D. Jones. email communication, November 18, 1997).

The partner school in Alaska had infused local Native American cultural heritage as well as sophisticated technology in the curriculum and instruction. For example, the Alaska students had researched and developed web sites reflecting local geography and Native American culture. The unique Alaskan perspectives and experiences could be shared with the Kansas students, who, although from a culturally non-diverse rural community, had a rich historical background to share. The web projects of the Juneau middle school may be accessed at http://jsd.k12.ak.us/WWW/AKonline/AKhome.html and at http:/jsd.k12.ak.us/WWW/Schools/dzh/dzh.html.

The partner school in Kansas, Burlington Middle School (USD #244), is located in a small rural community of 3500 population, with a school district enrollment of 1000 and 250 at the middle school. Project participants were teachers Janice McCullough and Jackie Rolf. The Burlington District Curriculum Coordinator, Toni Bowl ing, explained:

Burlington is in the sixth year of aggressive technology implementation. The district has a strong technology integration program throughout its K-12 curriculum. With over 450 networked computers throughout the building, district and to the Internet, teachers and students have access to effective instructional and learning software and hardware. The district has focused its technology efforts on technology literacy, technology integration, administrative technology, and technology education. Much of the success of our technology implementation is due to yearly district-wide staff development priorities. Staff development funding over the past two years has come from a combination of General Fund and the Educational Excellence Grant Program (T. Bowling, email communication, November 19, 1997).

The university partners in this project, Dr. Kirsten Skarstad and the author, are both from Emporia State University. This institution has approximately 6,000 student, and is located in Emporia, a community of 27,000 midway between Kansas City and Wichita. The Teachers College at ESU (http://www.emporia.edu/N/www/sleme/intro.htm) was founded in 1863 and remains the state’s premier teacher-training institution.

Description of the Project
This live teleconference, designed to promote diverse perspectives, began as part of a Goals 2000 grant focused on
alternative assessments. The Burlington Middle School social studies curriculum outcomes required students to research a specific culture and prepare a project for a sixth-grade culture fair to which parents and community members would be invited. The teachers in this project felt that opportunities for the middle school students to connect with individuals from diverse cultures and geographic areas would enhance the social studies curriculum. Thus, the idea for a university campus visit developed into a “Windows to the World” conference that included presentations from college students and community members that focused on a variety of cultures. The live video teleconference with Dzantik’i Heeni Middle School, Juneau, Alaska highlighted the day’s events.

The teleconference was held in one of the media classrooms in The Teachers College. The Burlington Middle School students also used the College computer laboratory with its Internet connections for related cultural research on the day of the teleconference. The Alaskan students used the teleconference facilities at the University of Alaska campus in Juneau.

The teleconference included a student-prepared and student-led presentation about Kansas culture and history that was then matched by a similar presentation from the Alaskan students. Students from Burlington and Juneau exchanged questions ahead of time via fax and email regarding their interests of area and then discussed these questions during the teleconference. Burlington students also had an opportunity to view the web site on Alaska history and geography that the Alaska school had researched and designed and to visit other web sites for resources to use in their Culture Fair projects. The Burlington students also used a diversity web site that the author and students in the Cultural Awareness for Educators course at Emporia State University had developed (http://www.emporia.edu/N/ www/sleme/mcsite.htm).

After the university campus visit and the teleconference with Alaska, the Burlington Middle School students returned to their rural community and completed their cultural projects and presented them to parents and community members at a special evening event, a “Culture Fair,” that was also featured in local newspapers. Many parents helped their children plan their displays, provided cultural family artifacts and ethnic cooking, and even joined their children at the displays.

The Burlington students’ participation and products were assessed using teacher-designed performance rubrics which addressed student use of the technology (the live teleconference and Internet) and the product produced for the Culture Fair. Classroom teaching in both states reflected state and national standards that emphasized what students think and can do as a result of their experiences. These experiences provided opportunities for students to practice written and oral communications skills in a real-life setting. Both school districts’ goals also emphasized high-performance outcomes that relate to civic education in a democratic society; this project helped students work towards this outcome.

Teacher education students at Emporia State University benefited from this project because Burlington Middle School teacher partners visited the campus and spoke to students about their efforts to use alternative assessments. The students were also invited to help with the Windows to the World conference and to observe the teleconference.

**Project Strengths**

A live teleconference adds new dimensions to teaching and learning and, specifically, to promoting knowledge and understanding of diverse perspectives. This technology allows students and educators to have greater connections with other cultures and resources in ways that previous methods could not accomplish. While email projects have become increasingly common, the added dimensions of a large color screen with sound made live interactivity particularly exciting for everyone. Yet, we are just beginning the road to creating a deeper understanding of each other and the power of technology. In this project, the Kansas middle school students learned via technology how the Alaskan students were able to conduct community research and construct a web page to share that knowledge with the world. This is an excellent “students teaching students” type of learning that provides opportunities for students to practice written and oral communications skills in a real-life setting.

Partnerships such as this technology-enhanced cultural project provide a model that could be used for a variety of themes and audiences and become as extensive as time and money would allow. The Alaskan and Kansas school districts and universities were generous with their support of this entire effort. The technology staffs at both universities worked diligently to coordinate the live teleconference and stand ready to troubleshoot if technical difficulties occurred.

**Project Challenges**

Project participants felt that all of the student and teacher activities were successful. Future projects of a similar nature should, however, take into consideration the tremendous amount of time and coordination that was involved with the array of activities that became part of this project. The video teleconference posed the challenge of finding funding and a suitable partner and hoping that the technology at both sites would work perfectly, which it did. The students noted the video teleconference as the project highlight, although the Burlington students were also excited to use the Internet and listen to speakers from diverse cultural backgrounds. Another challenge faced was to work within the schedule of a very busy campus computer lab to allow the Burlington students the use of the computer lab. It would have been better to have more time...
for the students to explore the Internet, as it often takes a while to dig for the best resources. Similarly, it would have been even more rewarding to have developed a closer relationship between the two middle schools before the live teleconference. Unfortunately, the Burlington Middle School did not have Internet connections, which would have made this much easier. One minor challenge involved ‘red tape’ items, such as getting the Permission to Video Tape Release Forms back from the Burlington students and their parents. Some students in the end were not able to attend because they did not have these permission slips returned.

Implications for the Future

If we are educating for a democratic society, collaborative efforts that promote understanding and acceptance of diversity become increasingly more important in our communities and indeed globally. This project provided a viable model for schools with limited resources situated in geographic areas limited in diversity who would like to deliver multicultural education more effectively and authentically. The need to make these connections and continue them at deeper, long-term levels provides important future opportunities for diversity education. This author recommends that projects of a similar nature also allow for student assessment in diverse ways, such as the use of rubrics and written student reactions/journal entries.

The Windows to the World collaboration helped middle school students, faculty, and prospective teachers enhance their beliefs and understandings about learning by creating an environment that reaches outside the windows of the classroom to promote global understanding. Planners of this teleconference hope that the middle school students will begin to view the world differently because of their greater understanding of diverse cultures and geographies gained from their own active learning.

The author encourages readers to contact her if they would like to become a partner in a similar project.

Values education is one of the most controversial issues in the United States. Hardly any teacher or administrator in American public schools likes the term values education, or its alternative terms: moral education, character development, and ethics education (SSHE, 1991). Compared with this American phenomenon, values education in the Chinese elementary curriculum is less controversial due to the Outline for Values Education in Elementary Schools stipulated by the Chinese State Educational Commission in 1988. No matter how controversial the issue of values education appears, all elementary curricula in Chinese and American schools include a large amount of time teaching values, though the definitions and content of values taught may differ significantly.

According to the Hastings Center’s report (1991) on the teaching of ethics, values are generally used to denote the “normative, valuational, and subjective side of human life,” and ethics more often refer to ethical theories and the “application of principles and norms to moral problems”. The American Heritage Dictionary (1991) defines value as “a principle, standard, or quality considered worthwhile or desirable”. Values education, as used in this article, includes both normative values and their application principles for students.

Although values education in the elementary curriculum helps students develop normative values and application principles in ethical issues, the means by which it is accomplished in Chinese and American elementary curricula are substantially different. These differences are reflected in teaching objectives, instructional content and teaching methods.

The first part of this paper examines what values are advocated in the elementary textbooks of Chinese and American schools and analyzes these differences in the context of their social and cultural backgrounds. The second part describes how the researcher uses the Asymmetric ToolBook and the Microsoft Power Point to present the research in a multimedia environment.

How Values Education Is Taught in Chinese and American Elementary Schools

In 1988 the Chinese State Education Commission promulgated the Outline for Values Education in Elementary Schools. It set the aims, content, basic requirements, principles and implementation methods for values education in the elementary schools. The goal of the Outline was to teach students good behavior through cultivating the Five Loves (i.e., love for the country, love for the people, love of work, love for science and love for socialism/leaders). These goals were to be achieved through moral education classes, values education in other subjects, extracurricular activities, after school activities organized by the Young Pioneers and student associations, and through support of families and the society as a whole (CSEC, 1994).

Because Chinese elementary students only have an hour of moral education every week—an elementary total of 170 to 240 hours depending on 5-year or 6-year schooling, many values education goals have to be achieved through subject classes. Thus the Chinese language arts class has an average of 10 hours every week and a total of 1666 to 1734 hours depending on years elementary schooling (CSEC, 1994). In addition to the content of the Language Arts, the Chinese language arts class also includes much of the values education content of Social Studies found in American elementary schools.

On the other hand, setting aside a class called Moral Education in American public schools is virtually impossible. Few educators and parents will endorse it. As Wagner (1996) put it, “Efforts to impose forms of character education with a predetermined set of values onto students and communities often provoke bitter and divisive debate between many liberals and conservatives” (p.36). Therefore, there is no separate subject labeled Values Education in American schools. Most of the teaching objectives related to values education are to be fulfilled in the social studies class. Consequently, the writer selected the Chinese language arts textbooks and the American social studies textbooks to compare the values orientation of their elementary curricula.
The Chinese language arts textbooks selected for the research were the 3rd to 8th volumes of the Elementary Chinese Textbooks for the Six-Year Elementary System. The 1st and 2nd volumes were basically Chinese character recognition; beyond the 9th volume, there was mostly literature. Therefore, the writer used the 2nd through 4th grade textbooks (i.e., 3rd to 8th volumes) to examine the major content and values orientation. The American textbooks selected were the Houghton Mifflin Social Studies Series (1994). It was one of the popular social studies textbook series for American elementary schools.

Values Emphasized in American Elementary Textbooks

John Jarolimek (1990), Chair of the Task Force on Scope and Sequence of the National Council of Social Studies, summed up the democratic beliefs and values that should be taught in the social studies class of public schools as: rights of the individual, freedoms of the individual, responsibilities of the individual, and beliefs concerning societal conditions and governmental responsibilities. The Houghton Mifflin series emphasized: (a) National Identity, which includes pluralism, democracy, American symbols, and reaffirmation of American ideals; (b) Constitutional Heritage, which consists of balance of power, origins of constitution, and reinterpretation of ideals; and (c) Citizenship, which covers individual and state, democratic behaviors, selection of leaders, human rights, settlement of disputes, and strategies for pluralism.

Based on Jarolimek's recommendations (Jarolimek, 1990), the Scope and Sequence of the Houghton Mifflin series (Houghton Mifflin, 1994), and David Saxe's analysis in Social Studies for the Elementary Teacher (Saxe, 1994), the values highlighted in the American elementary social studies textbooks may be summed up as individual rights, personal freedom and responsibilities, constitutional heritage, and national/personal identities. Table 1 illustrates the values in the American social studies textbooks:

Values Highlighted in the Chinese Elementary Textbooks

Because there was no detailed outline of values education in the Chinese textbooks selected, the writer used a self-designed instrument. To examine the major value messages advocated in the Chinese Language Arts textbooks, the writer combined the major values Chinese education goals of Five-Loves with one of the most important values in American textbooks, i.e., individual rights. These categories are: (a) Love for Science (including natural facts and stories of scientists), (b) Love for Political Leaders and Social System, (c) Appreciation of Cultural Heritage, (d) Affirmation of Individual Rights, and (e) Other Values.

Procedure

Based on these five categories, the writer counted and clustered the major themes/moral messages delivered in each textbook to examine their values orientation. For example, a story about the late Premier Zhou Enlai and his caring for people was grouped under Love for Political Leaders, and "The Story of Isaac Newton" was clustered under Love for Science. By using the lesson as a unit, the writer counted a total of 190 lessons in the 8 volumes of the textbooks. If the researcher discerned multiple value messages, the lesson went to the category which highlighted its most prominent moral message. To test the validity of the instrument, a pilot study was conducted. The researcher shared her counting and content analysis of 5 lessons with the students and teachers of the Hope Chinese School in Maryland and revised her instrument accordingly. The results of the research are presented in Table 2.

If one examines Table 2 in light of the Five-Loves advocated by the Chinese State Education Commission, four of the Loves are sufficiently covered. Indeed, the Love for Science category takes up about half of the content. The 5th category, Love for Work, though not indicated in a separate category, is well represented in many lessons. It is Affirming Individual Rights, one of the most important values in American culture, that is hardly mentioned in any of the Chinese elementary Language Arts textbooks. Figure 1 illustrates the cluster and percentages of core values in 190 Chinese lessons.

Attitude Differences
The first difference between American and Chinese elementary schools lies in the different attitudes toward values education. In China, values education is generally regarded as a positive term. Moral education is advocated and built into the formal curricula of elementary schools. In contrast to this Chinese attitude, most American teachers and parents view values education as problematic. Many parents and church groups challenge the values taught in public schools and demand parental control in shaping their children’s value system.

Content Differences
As shown in the two tables above, the values taught and emphasized in these two countries are very different. The American values system emphasizes rights, freedom, identity and constitutional heritage. Love for others is not a priority value in mainstream American culture. On the other hand, the Chinese system emphasizes the Five Loves and personal responsibilities. The concept of individual rights and freedom, a primary value in American society, is hardly encouraged in Chinese elementary textbooks. Just as American schools emphasize individual rights, Chinese schools place great emphasis on individual responsibilities. From children’s classroom responsibilities to the roles of a citizen, the concept of personal responsibilities is well specified in the Chinese textbooks.

Method Differences
Compared with the traditional teaching methods in Chinese classrooms which involve much written work and rote learning, the American elementary classroom provides far more participatory and hands-on approaches. From acting out the role of a citizen to designing a classroom constitution, American students are asked, from a very early age, to participate in the democratic process. During instruction, numerous teaching aids are employed to teach...
values, such as making a Flag Cake to teach American symbols and ideals. Fun and hands-on exploration are highly emphasized throughout the learning process.

**Outcome Differences.**

To observe the impact of values education on American young adults and determine their perceptions of values, the writer conducted a study among 70 Education seniors at Shippensburg University. The writer designed a questionnaire by mixing the Five Loves recommended by the Chinese State Educational Commission with the five values highlighted by Jarolimek and the Houghton Mifflin Social Studies Series. The writer asked the students to rearrange them in the order of their importance to them.

Of the 70 students that completed the questionnaire, 34 people (49%) ranked Freedom of the Individual as the most important value for them and 26 (37%) ranked the Rights of the Individual highest. The combined rate of ranking the Freedom of the Individual and Rights of the Individual as most important totaled 60 people, 86% of the participants. Ranked as least important values were Love for Science and Love for My System. Though the writer changed the political phrase of Love for Socialism into Love for my Social System, fifty-two students (74%) ranked it as the least important. Figure 2 illustrates the percentages of the most important values.

![Figure 2. Most Important Values for 70 American College Students](image)

**Summary and Discussions**

A comparison of Chinese and American elementary textbooks indicates a substantial difference in values education in the two countries. The American textbooks tend to emphasize personal rights, freedom, identity and the constitutional heritage, while the Chinese educational system uses the Five-Love principles to teach their children.

The different values orientation in school textbooks reflect the different social and cultural traditions of the two countries. The American schools are created in the spirit of the Declaration of Independence and guided by the Constitution of the United States. Both documents are largely born out of a philosophy that has its roots in the Magna Carter and in Social Contract theory. The macroculture of American society subscribes to a values system that has freedom, rights and individualism at its heart. The American macroculture maximizes individual gains within a legal framework. Working for the interest of others is a secondary orientation in American society. This is why when the late President John F. Kennedy (1961) said, “Ask not what your country can do for you, ask what you can do for your country,” it became a pacesetting message for the nation.

On the other hand, the same famous quote could have been said ideologically by thousands of Chinese political instructors because it is a dominant value in Chinese society. The guidelines of values education for Chinese schools are largely based on Confucius’ philosophy which emphasizes individual responsibility and service to the family, community and the country. The values education curricula of both countries are invariably rooted in their historical and cultural backgrounds.

Grounded in different cultural heritage and nurtured by prevailing social philosophies, the values education curriculum is, first of all, a product of a society. It then adds to that society by helping prepare ideal citizens who perpetuate and improve the existing system. The experience of comparing values education in Chinese and American elementary textbooks illustrated this very phenomenon.

**Multimedia Presentation of Research**

The multimedia presentation of this research was originally created by Asymmetric ToolBook II 5.0, a software construction set that teachers can use to develop their teaching projects. It has all the features of Windows applications, such as graphical user interface, event-driven programming and ability to interact with other Windows applications. The researcher used its graphics, buttons, sound, animation and Openscript features to create a multimedia presentation of the above research. For the sake of software compatibility and presentation convenience at the 9th SITE Conference, the researcher converted it into a Power Point presentation. The finished product contains 40 screens consisting of twenty digital pictures, 3 movie clips, 3 figures, some music and many hypertext pages. Though some of the animations are lost in the transition, their design principles and major features are quite similar. Some of the designer’s experiences follow.

**OverAll Design of the Presentation**

The overall design of a multimedia presentation is critical. The designer not only has to consider what she
wants to present, but also what messages the audience will get from viewing the hypertext screens. Very often the audience is drawn toward the dazzling electronic bells and whistles. The designer needs to spend much time at the beginning of the project selecting the most effective communication approaches.

Readability of the Screen

Readability of the screen is very important because the bulk of the information will be obtained from the screen. Select an appropriate font size, use content words and limit the number of headings. The font for the opening page may be set at about 40 points with each page containing no more than 6 lines. It is unnecessary to write detailed information on the screen; when the presenter reads the 5 to 6 essential words in a line, the readers will be able to fill in the rest of the information. For general purposes, using templates is often a convenient shortcut.

Import Digital Images

The Asymmetric ToolBook and Power Point employ different ways to import graphs, charts, pictures, and videos, but the methods are more or less the same, namely, cut and paste, insert or import. Spending some time on the software, one will get used to them quickly. It is the creativity and depth of the project and selection of images that will take the bulk of one’s time.

Avoid Screen Clutter

Because multimedia software enables the author to use fancy tools with great ease, it is important not to distract the readers by using too many dazzling digital images or music. Sometimes, excessive use of transitions and special effects may make your presentation too cute. Consequently, the ultimate purpose of the presentation is compromised.

Logical Reasoning vs. Non-linear Nature of Multimedia Presentation

Multimedia is any combination of data, digital movies, animations, graphics, text, and sound delivered on a computer. It is a highly non-linear environment. Therefore, the designer needs to balance the logical and sequential presentation of main content pages with the temptation of using overwhelming effects.

Navigation Control

It is important that the presenter design the demonstration in a way that allows her to navigate the demonstration with ease and to change the length and direction of each screen at will.

Selecting and designing a multimedia presentation is a never-ending learning process. In this project, the researcher tried Macromedia Director, Authorware, Asymmetric ToolBook II, and, finally, Microsoft Power Point. She might have just scratched the surface of the capacities of these multimedia software programs, but one thing is clear—a multimedia environment has certainly made her presentation more effective and, therefore, made her research more accessible to more students and colleagues.

Although written in 1994, the lyrics of Neil Young’s “Driveby” clearly foreshadow what has become an even more common occurrence in 1997. From his concerns about driveby shootings, we have moved to frequent reports of in-school muggings and abandonment of newborns in dumpsters and toilets. Consequently, these events have prompted many parents and educators to demand increased attention to our children’s moral education. Under such pressure, many educators have turned again to programs using values clarification and/or moral reasoning. Critics, however, claim that such programs lack the moral content to provide learners with a true moral compass to guide their actions (Sommers, 1984). Others respond that the diversity of values among the burgeoning public school communities render a consensus on moral education almost impossible. We intend to give a brief synopsis of recent trends in moral education and suggest ways in which a blending of idea and product technologies can promote the development of four specific moral sentiments.

Background: Grounding Our Moral Circuitry

Moral education has, in various forms, been a consistent component of American education since colonial times; however, dramatic changes in recent American culture have rendered efforts at engaging moral education in the public school classroom increasingly controversial. Commenting on this reality, McClellan (1992) explained that during the 1960’s and 1970’s:

The forces that made moral education so problematic for public schools were the products of a number of social and cultural upheavals. The effort to end racial discrimination, the waging of an unpopular war, a deepening cultural pluralism, and a growing willingness to expand the range of acceptable personal conduct all worked to weaken the commitment of schools to moral education. . . . With deep suspicions now sharpening racial, ethnic, and class divisions, Americans lost faith in their ability to find common ground. Increasingly they sought to preserve a fragile peace by accepting differences and encouraging tolerance. In the process, they elevated relativism into a primary social value. (p.84)

In many communities, such relativism became increasingly antagonistic to the “content” of character education programs that prescribed specific virtues and conduct. Consequently, school districts frequently turned to Simon’s Values Clarification Program and/or to Kohlberg’s Moral Reasoning Approach since each model encouraged, in different ways, the development of a student’s personal value and belief system and minimized the cultivation of specific character traits (McClellan, 1992). In various configurations, these two approaches continue to be the scaffolding of numerous moral education programs throughout the country today, although many public schools are returning to “repackaged” character education programs, which ironically often employ elements of values clarification or moral reasoning (Lickona, 1988).

The Moral Sense

Simon’s and Kohlberg’s respective models, and even contemporary hybrid models of earlier character education programs, focus centrally on the cognitive dimensions of moral conduct—what are the moral issues or dilemmas and how should one address and act on them? Recent research on moral development, however, has identified core moral sentiments or “feeling states” that contribute significantly to
the development of moral awareness and moral behavior. Damon (1988) contends that most scholars believe that emotions are a natural component of a child's social repertoire, and that the potential for moral-emotional reactions is present at birth. Some have gone even further in claiming that moral emotions constitute the one feature that unites humans from all the world's diverse cultures.

While various developmental psychologists and moral educators have been researching these moral sentiments (Damon, 1988, 1994; Kagan, 1984), Wilson's (1993) analysis is especially clear and convincing. He has identified four moral sentiments that, he claims, are innate and that comprise the bedrock of human moral behavior: sympathy, duty, fairness, and self-control. These sentiments are not themselves the "content" of moral action, but rather the predisposition for moral action. Each culture defines how these sentiments are operationalized or put into action (Damon, 1988).

**Moral Sentiments: Plugging-In**

In the context of Wilson's research, it is clear to us that teacher educators have an obligation to address issues of moral education intentionally by providing preservice and in-service teachers fruitful strategies that foster the cultivation of moral sentiments. Furthermore, we contend that educational technology is an especially effective tool in engendering the development of sympathy, duty, fairness, and self-control in the classroom. With these assertions in mind, we intend that this paper serve as a point of departure for teacher educators—especially for those who teach technology utilization courses. We showcase here four foundational moral sentiments that may be incorporated with educational technology, basically a blending of product and idea technologies (Sweeder, Bednar, & Ryan, in press; Hooper & Reiber, 1995). Four integrated strategies that we believe pre- and in-service teachers can use to "plug into" those moral sentiments include virtual gatherings, social action projects, problem-solving computer courseware, and video production projects. It is our hope that by introducing our pre and in-service teachers to these strategies that they will, in turn, share them with their present and/or future students in order to heighten their moral sensibilities.

**Virtual Gatherings: Sympathy**

A virtual gathering (Harris, 1995) is a form of telecommunications activity which is meant to "bring together participants from different geographic locations and time zones in real-time to either participate virtually 'in person,' in a computer-mediated meeting, or simultaneously 'in spirit,' without direct electronic contact, in similar activities at different project sites" (p.61). Virtual gatherings appear to be an ideal way for teachers to develop the moral sentiment of sympathy. For example, after defining what virtual gatherings are and discussing examples of how they have been used in basic education, teacher educators can have their pre and in-service teachers invent their own virtual gathering projects. For example, one might have pre and in-service teachers participate in a combination of outreach activities similar to one identified by Harris as "A Day Without Art," which took place in Florida across all sixty-seven school districts in observance of the Eighth Annual World AIDS Day (1995). Using a combination of Internet Relay Chats, and a preorganized symbolic action targeting the removal of blindfolds from museum statuary, "A Day Without Art" helped not only to develop AIDS awareness, but also to engender sympathy for the welfare of those afflicted with that life-threatening disease.

Harris' virtual gathering project might serve as a template for other ways in which we could develop student awareness for the moral sentiment of sympathy: Why not "A Day Without TV," in order to spend some time visiting or talking to the elderly or infirm, or "A Day Without Dessert" in order to devote time collecting food for the homeless both at home and abroad? Using curriculum-specific topics as springboards, science, literature, or mathematics teachers could concurrently address content and/or community-based concerns, technology use, and emotional pre-dispositions.

**The Social Action Project: Duty**

Teacher educators can also use the Internet to help their pre- and in-service teachers tap into a variety of real world contexts for humanitarian, action-oriented telecommunications activities which involve children. "Social action projects" range from helping raise money in aiding the homeless, to organizing, scheduling, and conducting worldwide beach sweeps in order to "Save the Earth's Beaches." Again, technology-infused projects of this nature address not only traditional curricular concerns but also heighten students' moral consciousness and develop their communal, if not universal, sense of duty or responsibility to humanity.

**Decisions, Decisions: Fairness**

An effective way teacher educators might help pre- and in-service teachers recognize how to incorporate the moral sentiment of fairness would be through the careful selection and re-purposing of computer courseware. For example, Tom Snyder's Decisions, Decisions: The Environment (Dockterman, 1990) and its accompanying teacher's guide (Dockterman, 1988) are primarily intended to improve student decision-making and critical thinking skills. However, with a modicum of creativity, classroom teachers can readily adapt this technology to develop their students' moral sense of fairness. In Decisions, Decisions: The Environment, students are encouraged via small and/or large group collaboration, multiple perspective-taking, and role-playing simulations to analyze and solve a "real-life situation"—namely, What is causing fish to die in the local pond? Playing the role of the mayor of Alpine, students are asked not only to solve this multifaceted problem, but also
take into consideration the advice of four mayoral advisors: an independent scientist, an economist, a campaign manager, and a representative of an environmental council.

In addition, the mayor has to weigh and balance a number of other complicating circumstances, such as preserving the valuable jobs which are at stake at the local mining company, a company which may be the possible source of the pond’s pollution problem. All of this, by the way, takes place during a crucial election year!

**Video Production: Self-Control**

Teacher educators can explore the moral sentiment of self-control with their pre- and in-service students through video production projects. For instance, by experiencing the three-stage, videographic process—pre-production, the ‘shoot’ itself, and post-production—students also learn about the four basic elements of cooperative learning (Kindsvatter, Wilen, & Ishler, 1992), which collectively deal with the establishment, maintenance, and promotion of interpersonal relationships. An important aspect of any challenging, collaborative endeavor such as the creation of a coherent “movie story” (Sherman, 1991) necessitates self-control and the ability to compromise, especially at a video project’s outset, the pre-production phase, when themes, plots, characters, dialog, responsibilities, and so on are being invented and determined collectively. Compromise, by definition, involves the settlement of individual differences, at least in the short run, in order to permit a project to move forward, prosper, and meet the longer-range goals of the group: a completed, creative, and coherent video.

**Time to Re-Wire**

Moral theorists will undoubtedly continue to debate the content and process of moral education, but a cursory review of local newspapers, talkshows, and popular musical lyrics suggests that there is an immediate need for intervention. We believe now is the time to re-wire moral education—not through separate courses or specialized programs, but rather through a creative, integrated circuitry of educational technology soldered to four universal moral sentiments. Since classroom teachers are always on the front lines, teacher educators must provide their pre- and in-service teachers with a range of proactive strategies to use when working with learners.

In a 1995 comprehensive nationwide assessment, the U.S. Congress Office of Technology Assessment (OTA) indicated that, in the process of acquiring hardware and software for students to use, teachers who are perhaps the most valuable part of the education equation are often overlooked. The CEO Forum (1997), for example, reported that of the total dollars spent for technology in schools only 6 percent of those dollars were spent on teacher education. In New Mexico, only 4 percent of technology monies have been slated for professional development (Bingaman, 1997) despite the OTA's recommendation of 30 percent. Seeking assistance to address teacher education needs, Belen Public Schools in Belen, New Mexico submitted a Goals 2000 grant proposal to secure funding for teacher education and technology integration. The grant was awarded for the 1996-97 school year. This paper presents a description of the Belen Goals 2000 Professional Development Project and evaluation data relevant to that project.

A Framework for Professional Development

Designing professional development for an information age means moving away from the traditional model of one size fits all, inadequate opportunity to practice new skills, and little ongoing support (Fulton, 1996; Grant, 1996). Research on professional development suggests that teachers learn best and are more likely to incorporate new approaches into their teaching when they can experiment and reflect in a safe setting. Teachers must have ample opportunity to discuss and collaborate with their peers and instructors (Fulton, 1996; Grant, 1996; Yocam, 1996). Professional development must help teachers "move beyond 'mechanical use' of curriculum and technology to become facilitators of inquiry" (Grant, 1996, p. 1).

Research says that professional development has to be directly connected to daily work with students, related to content areas, organized around real problems of practice instead of abstractions, continuous and ongoing, and able to provide teachers with access to outside resources and expertise . . . Teachers have to practice change and continually work with others on debugging the problems they encounter (Darling-Hammond, 1997, p. 5).

In an effort to support teachers new to technology integration, a number of schools have paired novice and experienced teachers in an approach referred to as mentoring. Key features of the mentoring approach are that assistance is provided within the context of a personal relationship and focused on the needs of the novice user (MacArthur, et. al., 1993). Since teacher/presenters understand classroom culture and the demands of teaching, their guidance is often more relevant and credible to other teachers. Familiar with the regular work in classrooms, these teacher/presenters can help teacher/participants see how technologies can enrich and support learning (Grant, 1996). Teacher/presenters can also play an invaluable role in generating ideas and problem solving with their peers.

Implementing the Project

The Belen Goals 2000 professional development project established workshops designed to facilitate teachers supporting teachers to integrate technology. The workshops were designed to provide opportunities for 48 Belen teachers (a) to experience excellent models of technology integration and (b) to think systematically about the translation of those models into their own classrooms.

Upon notification of the award of the Goals 2000 grant, the original grant writing committee selected Dr. Priscilla Norton as outside facilitator. In addition to the outside facilitator, the grant made provisions for a district-wide inservice program for 48 of the districts 250 teachers, providing money for substitute teachers and stipends. Once a district teacher-training lab with 12 Internet-linked computers existed, the committee met with Dr. Norton to discuss the process of implementing the professional development component of the project.

The committee agreed that a teachers-teaching-teachers model would be implemented. Dr. Norton would design two
three-day workshops; the first workshop would focus on using an integrated software package and the second workshop would focus on using email and the Internet. The committee also agreed to invite all district teachers to participate in the Goals 2000 project, and that 12 facilitators and 36 participants would be selected from those who applied. The teachers selected to participate would be divided into four groups of twelve. One group of twelve would comprise those whose application reflected their desire to participate and their willingness to teach others what they had learned; three groups of twelve each would be designated as participants. The committee decided that the first series of workshops would be presented during February using substitute teachers, and the second series of workshops during the last two weeks of July and the first week of August with stipends given to all attendees. Dr. Norton would conduct each workshop with the facilitators and then selected facilitators would replicate the workshop with the remaining three groups of twelve participants.

The twelve facilitators ranged in age from 26 to 55 years and the majority (90%) was female. Fifty percent were elementary level teachers and the remaining secondary group taught history, Title 1, math, and English. They had an average of 14.8 years of experience. The thirty-six participants ranged in age from 26 to 55 years of age, and the majority (85%) was female. Fifty-eight percent were elementary level teachers and remaining secondary group (42%) taught social studies, Title 1, science, math, special education, and Language Arts. They had an average of 11.4 years of experience.

Workshops de-emphasized the mechanics of technology and focused on integrating technology with the curriculum. They were structured to engage attendees in model lessons, with attendees becoming content-area learners while also learning about integrating technology. Ample opportunities were built into the structure of each workshop for drawing lessons from their own experiences that might be generalized to their own practice. Each workshop ended with attendees designing a lesson they could use in their own practice.

The February workshop asked attendees to become political activists and prepare a proposal and presentation that would help the workshop leader identify the perfect presidential candidate for educators. Attendees were given a model to use in the preparation of their proposal. Their final proposal had to include a logo and name for their consulting firm. It needed to include the construction, administration, and analysis of a survey. Attendees were assisted in using a word processor to prepare their survey, a spreadsheet for analyzing the results, and a word processor and graphs constructed with the spreadsheet to present a political platform for their candidate. Attendees used a presidential database to identify six historic attributes of an electable president (i.e. the average president is between 50 and 60 years of age). They were asked to create a potential classified advertisement to locate the perfect candidate using these attributes. They were asked to create a slogan for their perfect candidate and prepare either a bumper sticker or poster using the graphics program. Final proposals were spiral bound and presented to the class. The afternoon of the third day was reserved for participants to divide into grade level groups and create a lesson plan modeled on their workshop experience.

The summer workshop introduced attendees to the district’s email system and the Internet. Using email accounts established prior to the workshops, the workshop leader made a short presentation on using Pine and then introduced an email version of the game of Clue. Next, in small groups, attendees used a list of six URL’s to construct a rubric for judging the validity and reliability of an Internet site. Rubrics were shared with the large group. Third, attendees were asked to write down three things about which they would like to learn more. Internet search engines were introduced, and attendees located sites related to their list. On the second day, attendees completed a short WebQuest (Dodge, 1995) using the Internet to research a trip to a Spanish speaking country of their choice and write a letter to their rich uncle. Once again, students divided into grade level groups and created a WebQuest for their own students.

**Assessing the Project**

**Teacher Concerns about Technology**

In order to assess the level of teacher concerns related to the integration of technology as a change or innovation, the Stages of Concern About the Innovation Questionnaire (SoCQ) was administered. The SoCQ sought to identify changes in teacher concerns about technology and was administered just before the first workshop and just after the last workshop. The instrument is based on a seven stage developmental model: (0) awareness; (1) information; (2) personal; (3) management; (4) consequence; (5) collaboration; and (6) refocusing (Hall, George, and Rutherford, 1979). The SoCQ consists of thirty-five questions each designed to reflect concerns relevant to one of the seven stages of the model. Respondents rate the degree to which each item reflects their feelings using an eight point Likert Scale that ranges from “not true of me now” (0) to “very true of me now” (7).

The 35 statements were collapsed into the seven stages identified by the manual. A paired t-test was performed for each stage, using an alpha of .01. Results of the analysis are presented in Table 1. For facilitators, t-tests revealed a significant decrease in reported concerns related to Stage 1 – Information, reflecting declining concerns as the mean rating moved toward “not true of me now” for such items as “I have a very limited knowledge about technology.” For participants, t-tests revealed significant decreases in reported concerns related to Stages 0 and 3. This reflects
declining concerns as the mean rating moved toward “not true of me now” for such items as “I don’t even know what technology is” (Stage 0) and “I am concerned about my inability to manage all that technology requires” (Stage 3).

* p<.01

Although there were no other significant changes in levels of concern, Figures 1 and 2 show that while concerns related to Stages 0 through 4 decreased during the project concerns for Stage 5 – Collaboration and Stage 6 – Refocusing increased. This suggests that both facilitators and participants were shifting from an exclusive focus on the impacts of technology itself and toward concerns about maximizing technology’s effects (Stage 5) and modifying the use of technology based on the experiences of students (Stage 6).

### Teachers’ Use of Technology

In order to determine if teacher use of technology changed as a result of participation in the Goals 2000 project, a survey was administered with the SoCQ.

Attendees’ responses suggest subtle but important shifts toward more use of technology with 70% of the facilitators reporting daily use of technology and nearly half (46.2%) of the participants reporting daily use of technology. When asked which software applications they used, facilitators shifted from 70% reporting never using databases to 60% reporting occasional use. Thirty percent of the facilitators reported never using the Internet with students at the start of the project while 60% reported using it often at the end of the project. For participants, there were important shifts in the use of word processors (42.3% reporting often) and the Internet (from 57% reporting never at the beginning to 26.9% reporting occasional use). When queried about their interactions with their peers related to technology, the participants made few changes. Conversely, for the facilitators, there were changes particularly in the category of “never.” Seventy percent of the facilitators reported never working with other teachers to design technology using curriculum before the workshops but only 10% reported never at the end of the project. Fifty percent said they never worked on technical problems related to software with others at the project’s beginning while only 10% said never at its conclusion. For the facilitators in particular, these shifts seem consistent with the increased desire to work collaboratively with others expressed above.

At the completion of the final workshop, an open-ended questionnaire was distributed with the posttest SoCQ and the survey of technology use. The questionnaire asked four questions. The first question asked facilitators and participants what they had learned about technology. Eighty-six percent of the combined group mentioned learning about a variety of software applications, 27% stated that doing/using is knowing, 21% wrote they were less fearful or that technology was less mysterious, 13% mentioned that using technology was fun, and 10% wrote that using trial-and-error and taking chances with technology was important.

The second question asked facilitators and participants what generalizations they could make about teaching and learning with technology based on their experiences during the workshops. Forty-four percent wrote that learning-by-
doing and exploring instead of lecture and presentation was important. Combining responses for the two groups resulted in forty-two percent stating they now believed that the focus should be on content not on technology and that project-based or problem-based learning was best. Thirty-three percent mentioned the importance of hands-on learning, and 25% wrote about the value of collaboration and learning with a partner. Twenty-three percent defined the role of the teacher as facilitator rather than director. Thirteen percent mentioned that the models used during the workshops could be adapted to their own classroom.

The third question asked facilitators and participants to suggest any changes in the workshop structure they would recommend. Three respondents mentioned providing free lunches, improving the air conditioning, and doing fewer surveys respectively. All of the remaining 45 workshop attendees stated the need for more technology learning workshops. They recommended extending the model to include more teachers and asked for more opportunities for themselves. In addition, thirty-five percent of respondents stated the need for more technology access in their own teaching contexts.

The fourth question asked facilitators and participants what activities they had engaged in with other colleagues. All the participants either left the question blank or wrote “nothing yet.” The 60% of the facilitators, on the other hand, stated they had shared ideas with other teachers, and 40% reported they had either presented other workshops or collaboratively designed lessons with colleagues in their own building.

Conclusions

Can six workshop days make a difference in teacher attitudes and uses of technology? The answer is mixed. Looking at the data, it is possible to conclude that the Goals 2000 workshops changed teachers in subtle and emerging ways. The workshops decreased the information concerns of facilitators and the awareness and management concerns of participants. Data suggest that attendees use of technology to support the learning increased. Facilitators, who were placed in the role of teachers of teachers generalized that role and worked with colleagues outside the structure of the Goals 2000 project. Yet, this data points only in the direction of change, not toward substantial or deep changes in educational practices. As the teachers themselves recognized, more is needed – more technology education for teachers and more technology for student use. This project set a process in motion. It demonstrated that a little can go a long way. To fully realize the beginnings of change set in motion by the Goals 2000 project, however, it will take more before hopes for district-wide technology integration become reality.

Introducing technology into schools is a significant challenge because it requires change in curriculum and teacher practice. The Office of Technology Assessment (1995) concludes that for computer technology to become an integrated part of schools a high-quality preparation of staff is needed. Rutherford and Grana (1995) suggest that resistance to change is caused by an array of faculty fears. Included in these are “fear of change, fear of time commitment, fear of appearing incompetent, fear of techno lingo, fear of techno failure, fear of not knowing where to start, fear of being married to bad choices, fear of having to move backward to go forward, fear of rejection or reprisals” (p. 512). Several studies (Strudler, Quinn, McKinney, & Jones, 1995; Willis, Willis, Austin, & Colón, 1995; Roberts & Ferris, 1994) show that one of the problems with integrating technology into any curricula is the teacher in the classroom. There are a number of reasons for this, such as computer illiteracy, computer phobia, disinterest, lack of equipment, and lack of support personnel. Rapid technology changes make it difficult for faculty to stay current and using technology is frustrating. In addition, using technology is risky and faculty find it hard to take risks.

Teacher inservice can help teachers overcome computer illiteracy and phobia, but may not always help teachers integrate computers into their curriculum. Inservice programs that include full-time, site-based training that focuses on the individual needs of the teachers have a better chance of achieving the desired change of technology and curriculum integration (Pappillion & Cellitti, 1996). The changes teachers must make take time and must reflect the concerns teachers have about technology and the curriculum.

This paper reports on a collaborative effort between a university teacher education program and a public junior high school in a program to integrate technology into the school curriculum. The focus is to document how this collaborative effort reflects Michael Fullan’s (1993) eight basic elements of change in the schools. In his study of educational change, Michael Fullan (1993) concludes that “change is a journey of unknown destination, where problems are our friends, where seeking assistance is a sign of strength, where simultaneous top-down and bottom-up initiative merge, where collegiality and individualism co-exist in productive tension.” (p. viii). He describes change as a move of educational systems toward learning environments where change is a part of daily work, not the latest policy decision:

- Problems are our friends or conflict is essential. Problems are inevitable and you can’t learn without them.
- Vision and strategic planning come later. Premature visions and planning blind.
- Individualism and collectivism must have equal power. There are no one-sided solutions to isolation and groupthink.
- Neither centralization nor decentralization works. Both top-down and bottom-up strategies are necessary.
- Connection with the wider environment is critical for success. The best organizations learn externally as well as internally.
- Every person is a change agent. Change is too important to leave to the expert, personal mind set and mastery is the ultimate protection. (p. 21-22)

Research Design

The focus of this research project was to investigate an inservice program aimed at developing curriculum that integrates technology into instruction that includes the problem-solving process. The university-public school partnership had defined inquiry and professional development as two of its primary functions. The two partners were jointly committed to helping teachers develop new curriculum that integrated technology (O’Neil, 1992; Broughy, 1992). Participants had discussed the importance of defining problems for students to solve as a part of the inquiry process and that the problems needed to be authentic and real-world in nature. Learning had been
discussed as an on-going process of construction, generation, and creation of meaning enhanced by interaction with other learners in cooperative and interdependent efforts. The design was based on one similar to that reported by Solís (1997).

An earlier project began in a school with only one teacher being mentored by a university professor. The professor spent time helping a classroom teacher learn to use computer programs that were available at the school. The teachers and students were introduced to a spreadsheet program as a tool in data collection and analysis problems. The students were then placed in groups of four and asked to design and complete a problem that would require the collection and analysis of data. The professor worked with both the students and the teacher to select the problem and analyze the data (Wentworth, 1996).

As the program expanded to the whole school, teachers began to think about curriculum that could be enhanced with technology. Participants worked with software that enabled them to integrate technology into their curriculum with minimal acquisition of new skills. Initial work began in group sessions with teachers from one or two disciplines and moved to the classroom when the teachers had planned instruction that needed technology support. The teachers were encouraged to move at their own pace as they used the technology in their classrooms. Reflection and evaluation was an on-going process to keep the project on course, given the increased numbers of persons involved. The approach was similar to the one proposed by Resnick (1996) in his proposal of distributed constructionism. Their worked was shared with others in the group and with their students. In the process of sharing and teaching, participants rethought their work and learned from each other.

The professor, as part of a larger program of teacher education, was also involved in the supervision of student teachers in this particular school. The teacher education program was changing this same year to include university course work for the student teachers to be done at the school. The professor spent at least two full days a week in the school working with student teachers and with classroom teachers on the development of their integrated curriculum. Having the student teachers in some of the classrooms allowed some teachers freedom to develop lesson ideas and help in the computer lab with other teachers who did not have student teachers in their classrooms. Along with the integration of technology in the classroom, the teachers were placed in teams to integrate across subject areas. As teachers produced lessons that integrated in this way, they provided them to the district.

Several lesson plans were created and implemented by the teachers. Two examples are listed here:

1. You were very interested in the weight lifting at the Atlanta Olympics. You thought about the size and weight of the participants and the amount of weight they lifted. How would you determine which weight class lifted the highest weight as compared with their body size? Which person would you declare as the “strongest man on earth” based on this?

2. You are interested in how the Olympic games will effect the area of Salt Lake City in the year 2002. What areas of change do you expect to find? What data will you collect before the games? What data will you collect after the games? What predictions will you make based on the information you can collect about the Olympic games in Atlanta?

Question 1 integrates both mathematics and physical education. Question 2 integrates social studies and mathematics. Teachers collected data on these questions and then began to define questions for their students as examples. As the teachers implemented these in their classrooms, the students began to ask their own questions. The teachers were excited to see students engaging in inquiry in this way.

The researcher, the teachers, and students kept research logs of the projects from conception through final report. The researcher kept an account of the types of problems designed by the teachers, the discussion about the data required to answer the question, the use of technology to solve the problem, and the final analysis and representation of the data. Throughout the project, the researcher interviewed the teacher and students about their work, asking questions to get at their problem solving and their views about the use of technology as part of the problem-solving process: how did they select the data to collect, how did the technology aid in the analysis of the data, what conclusions were drawn from the results. The researcher also kept a journal of frustrations and successes experienced by the teachers and students.

Results

The data collection and data reduction techniques were based on methods perhaps most specifically discussed by Miles and Huberman (1984). The transcribed interviews, journals, and logs were coded as to their connection to Fullan’s eight elements of change.

You Can’t Mandate What Matters

Some teachers were unwilling to participate in the project because it was not required by the district or principal. However, once the initial inservice took place most teachers were excited to begin designing curriculum that would include the technology they had seen. Eighty-seven percent of the teachers in the school participated in the inservice group sessions; 95% of those teachers designed curriculum that integrated technology. Only 38% of...
those teachers actually implemented the lesson with students. Many of the others said they planned to try it the next year when they could plan for it more easily.

**Change is a Journey not a Blueprint**

The university professor and the school teacher had learned from their experience of the first year that defining the problem presented to the students was a key element to successful integration projects. They did not impose their experience on teachers but encouraged them to think of specific questions to ask their students. The method for using technology was not dictated but suggested to the teachers.

**Problems are Our Friends**

Four months into the school year, the software was still not available, and the school learned that it was not to be donated, but would need to be purchased. Software was not licensed on all machines initially so work could not begin as early as had been hoped. The new computer lab was not wired on schedule, which also delayed the inservice. The only good that came from this is that there was time to become familiar with teachers in their classroom, what their expectations were for technology, and to problem solve. However, the fact that many teachers did not have time to implement their lessons was a direct result of this problem. Many of the teachers did implement technology the next year with perhaps more help from each other and less from the university specialist. The benefit here was that teachers learned to share ideas and expertise and not depend on an outsider for help.

**Vision and Strategic Planning Come Later**

Curriculum that includes technology was seen as an ongoing process that would develop over time. It was felt that more complete integration would come after teachers had become familiar with the software and exposure to inquiry learning. After the work with one teacher, then with one faculty, a vision for this type of inservice began to develop. The university professor and the teachers worked to think through the vision.

**Individualism and Collectivism must have Equal power**

“One of the things I’ve liked about this is that [the university professor] has not told us everything to do,” said one participant. “I was able to plan things for my classroom the way I wanted them and then she tried to help me make them work for what she was doing.” Teachers were learning from each other things they planned for their classrooms. The collective concern was that technology become a part of curriculum. The individual concern was that teachers be allowed to select lessons that were appropriate and interesting to them, not some larger agenda. These two concerns were given equal weight throughout the project.

**Neither Centralization nor Decentralization Works**

The school and the university shared in many discussions about design, implementation, and analysis of this project. No one group took away from the other. The university-public school partnership had been on going for several years and trust had been established between both organizations. Relationships had been built over a long period of time. Having a teacher at the school who had been through the process was a great benefit as well. She was able to help teachers when the professor was not at the school. She supported their ideas, and helped them prepare work that integrated content areas.

**Connection with the Wider Environment is Critical for Success**

Both the nature of collaboration among school departments, and the type of lessons designed by teachers indicate connections to the wider environment. The inservice was done with groups of teachers by departments that would naturally have similar content. Two examples of questions to ask students to begin the projects were about the Atlanta Olympics and the Olympics coming to the local community in 2002. Integration of content areas and local issues support the value of connecting to the wider environment.

**Every Person is a Change Agent**

“I can’t believe how much help we’ve been to each other,” commented one teacher. “Having us learn this, then help each other integrate it into the classroom has been great.” When teachers take on the role of change agent, they share in the creation of the vision. They begin to believe that they are experts. They lose their fear of change.

**Conclusions**

By making technology a construction tool in curriculum development, teachers were able to see quick results and impact in their classrooms. This inservice program designed as a partnership between a public school teacher and a university instructor seemed to support Fullan’s eight lessons of change. Very few comments and events were given just one code. “Problems are our friends” linked to the lesson that “change is a journey not a blueprint” the most often. Many problems occurred, but most of them were not considered “friends” by the participants, even when they did lead to additional inquiry and new understanding. “You can’t mandate what matters” stood alone more often than other lessons. When it was linked to other lessons, the most common was “vision and strategic planning come later.” “Individualism and collectivism must have equal power” and “neither centralization nor decentralization works” seemed to occur together. They were often linked to “connection with the wider environment is critical for success.” “Every person is a change agent” paired with every other lesson to some extent. This lesson seemed to be central to the inquiry process.
Teachers worked on the same software and began together, so they supported each other in the learning curve. Teachers were able to consider integration of content area as they included technology in their curriculum. Having a university professor at the school helped the teachers initially try the technology. They worked together with the students to learn the software, and then determine how it could enhance the curriculum. As the year progressed, the professor spent less time teaching how to use the technology and began to help teachers rethink instruction and content. New types of problems were considered because the technology could help the student investigate and seek out answers.

Both students and teachers enjoyed experimenting with the technology. They worked together to define questions that had significance for the content of the curriculum. The questions were complex and interesting, requiring many days to complete. Teachers and students worked several days defining the problem and deciding on the data required to answer the question defined by the problem. Teachers and students felt like co-investigators and learners. The teachers began to feel confident in their abilities to use the technology. They began to trust the students to learn specific content as they defined their own problems.

As the program progressed, conversations moved from the mechanics of designing and implementing technology into the classroom to more substantive issues of learning and teaching, school renewal and professional development. Teacher renewal (inservice) was a natural outgrowth of teaming and could lead to a new way of looking at professional development as a natural part of teaching and teacher education. This pilot has implications for a new way of thinking about professional development. It becomes an ongoing learning model instead of an inservice course taken after school, on Saturday, or during the summer months. The collaborative nature of the program can provide a road map as future programs continue to explore professional development through inquiry.

As new inservice programs at additional sights are begun, participants must remember Fullan’s eight lessons of change. Visions and strategic planning must come from all the participants. New participants will have their personal concerns about what matters. Individual concerns must not be lost to collectivism. The participants will need to come together to negotiate their program, just as the participants in this program did. This pilot should not be used as a strict blueprint, but only as a road map to guide the journey. The university-public school partnership should continue to provide the necessary opportunities of such work to take place. The partnership should continue to evaluate the importance of collaborative learning through inquiry as a bases for school renewal and professional development.

There are many changes underway in the educational computing class and all of the papers this year reflect the changes in some way. The recent NCATE report, Technology and the New Professional Teacher: Preparing for the 21st Century (available on-line at www.ncate.org) states that “recent research indicates that most teacher education programs have a long way to go” (p. 4) and that “the nation’s teacher education institutions must close the teaching and learning technology gap between where we are now and where we need to be” (p. 3). They also say that teachers need to be aware of the new technologies, the new role of the teacher, and how these will interact in the classrooms of the future.

Another important point made by the NCATE report that directly impacts the educational computing class is that the teachers who teach teachers today need to be modeling technology use and encouraging the future teachers to be risk takers and lifelong learners. We should be encouraging our students to embrace the new technologies and the new challenges they present. This requires change in several ways. The NCATE report explains it this way—“What is required is a transformation of the culture of teacher education, one in which technology is seen as changing relationships between students and teachers and between learners and knowledge” (p. 8).

The first paper in this section Design of a Computer Literacy Course in Teacher Education by Leh looks at the design of the introductory computer courses. The design includes structure, content, and whether it is a required course or not. The next three papers discuss attitudes and learning in the educational computing course. Teaching Pre-Service Teachers Technology: An Innovative Approach by Gunter, Gunter, and Wiens describes research done to restructure the educational computing course in order to make a difference in students’ attitudes. Action Research in the Educational Computing Class by Bump defines action research and describes the research done in the educational computing class to gather feedback and reflection from the students in order to enhance and improve the course. Learning about Learning in an Introductory Educational Computing Course by Niederhauser, Salmen, and Fields examines how this course can provide future teachers with an opportunity to examine learning theory in the context of the class and apply it when they become teachers.

The last three papers describe actual projects and products that have been completed by students in the educational computing class and how these impact their training as a professional educator. Instructional Strategies for Integrating Technology: Electronic Journals and Technology Portfolios as Facilitators for Self-Efficacy and Reflection in Preservice Teachers by Kovalchick, Milman, and Elizabeth describes the use of electronic journals and technology portfolios as an instructional strategy in a reflexive approach to learning. Anchored Instruction in Preservice Educational Technology Classes: A Research Project by Bauer tells of the need for empirical research supporting the claim that anchored instruction is an effective approach to use to prepare teachers for integrating technology in the classroom. Teaching “How to” Technologies in Context by Leigh demonstrates the use of situated learning and constructivist strategies in the educational computing class.

NCATE will publish another report in the year 2000 which will “introduce its latest set of accreditation standards which will undoubtedly raise the bar for the use of technology in teaching and learning in schools of education” (p. 3). As teacher educators we should be proactive and fearless in our approach to teaching the teachers that hold the key to the development of their students into lifelong learners. The papers in this section suggest several ways in which this process can be started.

Wren Bump is an assistant professor in the department of Curriculum and Instruction in the College of Education at Texas Southern University. She is also the instructional technologist for the College of Education and does faculty and staff development as well as student teacher training. She has been teaching introductory educational computing classes for the past nine years in a variety of situations. She can be reached at wren@tenet.edu or (713) 313-1832.
Design of a Computer Literacy Course in Teacher Education

Amy S.C. Leh
Oklahoma State University

Technologies of the 20th century have changed how we live, how we conduct business, and how we communicate with each other. Of course, they also affect the way we teach and the way we learn. The business world demands schools to prepare students for effective use of technology in their future work places. The president and vice president of the United States expect every child in our nation to feel comfortable on the Information Superhighway. In addition, computer-to-student ratios have dropped consistently from 1:50 in 1985 to 1:20 in 1990 to an estimated 1:9 in 1997 (National Council for Accreditation of Teacher Education [NCATE], 1997).

All of these facts indicate that new technology is affecting our classroom practice and also the culture of the schools. This technological influence is challenging our teachers and will challenge the two million new teachers who will be hired over the next decade. The new teachers should feel comfortable with the new culture of the schools and be ready for the requirements of teaching in the “Information Age.” Are our teacher education programs preparing the two million new teachers to face the challenges? Unfortunately, most programs “have a long way to go” (NCATE, 1997, p.1).

The NCATE task force assists colleges of education by summarizing the technology skills and knowledge which a new professional teacher needs to acquire during the preservice training: new understandings, new approaches, new roles, and new attitudes (NCATE, 1997). The teachers need to understand the deep impact of technology on the nature of work, on communication, and on the development of knowledge. They must use a wide range of technological tools and software as part of their own instruction. They must help students in the use of technology to gain information which goes beyond textbooks and teachers. In addition, they should be fearless in the use of technology and be life-long learners.

To respond to the professional call, several teacher education programs have been offering computer courses to help the future teachers. The following research focused on one of the computer courses, an introductory computer literacy course, which is commonly offered at colleges of education. The study reports how the course is taught and what is taught in the course at different universities.

The Research Study

The study was designed to investigate the structure and content of the introductory computer literacy course at colleges of education at universities in the United States. The structure and content of the course were examined.

Research Problem

Due to the need for the new professional teachers, colleges across the nation are being equipped with technological tools. Programs preparing teachers to utilize these devices for enhanced learning still need to be developed and adjusted. Many universities help their students take advantage of these new tools by offering introductory computer literacy courses. Unfortunately, there has been little discussion on what skills and knowledge teachers must have to take advantage of the new technological tools (Old Dominion University, 1997).

Research Questions

1. What structure is used for the course?
2. What skills are students required to master in the course?
3. What knowledge do students need to acquire in the course?

Procedures and Methods

Nine universities were selected for the study: Arizona State University, Florida State University, Harvard University, Indiana University, Massachusetts Institute of Technology, Pennsylvania State University, Stanford University, University of Virginia, and Yale University. These universities either are considered to be prestigious universities or have the reputation of offering an outstanding educational technology program.

First, phone calls were made to each university to find a course which prepares undergraduate education students
depending on the interest of the individual student. Similar
PSU can be a one-credit, two-credit, or three-credit course
other courses are also available. In addition, the course at
is not necessary to require this specific course because
the course. According to the professor who was interviewed, it
At PSU, several computer courses are offered to under-
and content of the courses still vary from one university to
research are similar to each other. However, the structure
of computer courses; instead they integrate technology into
other education courses, such as method or foundation
technology courses; instead they integrate technology into
other universities do not offer independent education
technology courses; instead they integrate technology into
other education courses, such as method or foundation
courses. Yale University is an example of these universities.
Therefore, the research focused on four of the universi-
ties which offer a similar introductory computer course:
Arizona State University (ASU), Indiana University (IU),
Pennsylvania State University (PSU), and University of
Virginia (UV). EMC 321: Computer Literacy (Arizona State
University, 1997) offered at ASU, W200: Microcomputers in
Education (Indiana University, 1997) offered at IU, INSYS
400: Introduction to Instructional Technology for Educators
(Pennsylvania State University, 1997) offered at PSU, and
EDLF 345: Introduction to Computers & Media in Teaching
(University of Virginia, 1997) offered at UV were selected for
the research. Phone call interviews were conducted to
obtain detailed information on the specific course at each
university and the course webpages were downloaded for
analysis.

The data collection and analysis focused on structure
and content of the courses. How the course is taught and
what is taught at each university were categorized and
analyzed.

Results
The four introductory computer courses selected for the
research are similar to each other. However, the structure
and content of the courses still vary from one university to
another.

Structure: The introductory computer course is a
required course for students at the College of Education at
ASU and IU, but is not required for students at PSU and UV.
At PSU, several computer courses are offered to under-
graduate education students, and they may choose any
course. According to the professor who was interviewed, it
is not necessary to require this specific course because
other courses are also available. In addition, the course at
PSU can be a one-credit, two-credit, or three-credit course
depending on the interest of the individual student. Similar
to PSU, several computer courses are offered to undergra-
duate education students at ASU. In contrast to PSU, the
course is required at ASU.

At ASU, the course contains lecture and lab. The
lecture is conducted in a big lecture hall which can accom-
modate more than 150 students. Students learn the con-
cepts with approximately 100 other students in the big
lecture hall. The lab is conducted in small groups in a
computer lab with approximately 25 computers. Students
have hands-on experience in the computer lab. Students
have two instructors, one for the lecture and one for the lab.
The lecture syllabus and the lab syllabus match each other.
The course instructors use identical syllabi and conduct
weekly meetings to maintain consistency of the course.
Students take identical mid-term and final examinations.
With two or three lectures, this structure allows the same
course content to be taught to more than 300 students
simultaneously.

At IU, the course is structured differently. There is no
separation into lecture and lab sections. The course is
conducted in a computer lab where the instructors teach
both computer concepts and skills. The course instructors
use similar syllabi. However, since many instructors are
teaching the class and since about 500 students are taking
the course, an instructor of the course, addressed in a phone
interview, said that the course content might vary slightly
because each individual instructor might emphasize different
concepts or skills.

Content: The course contains concepts and skills at all
four of the universities. Concepts include knowledge of
computer technology and design, such as basics of
hardware and presentation design. The students are
expected to master skills such as word processing, spread-
sheet, and database. ClarisWorks and MSWorks are
commonly used for word processing, spreadsheet, and
database. PowerPoint is frequently employed for presenta-
tion and HyperStudio for multimedia. Word, Excel, and
FileMaker Pro are used by IU.

Students at all four universities learn concepts and skills
of word processing, spreadsheet, database, e-mail, and
webpage development. In addition to these skills, students
at IU, PSU, and UV learn multimedia and presentation
applications. Instructors at PSU help students integrate
technology into instruction by teaching them how to write a
lesson plan. Instructors at UV encourage students to
participate in outside activities by giving them field assign-
ments.

Compared to students at IU, PSU, and UV, students at
ASU lean fewer applications in the course but spend more
time on each application. Their course only emphasizes
word processing, spreadsheet, database, and webpage
development. Since other computer courses are available at
the College of Education at ASU, the students are encour-
Table 1 lists main concepts and skills the course involves in each university. As mentioned earlier, an instructor at IU might focus on some skills that might not be emphasized by another instructor who teaches the same course. The course at PSU can be a one-credit, two-credit, or three-credit course. A student, who takes the course as a one-credit course, spends less time and learns fewer computer applications than a student, who takes it as a three-credit course. For example, multimedia and HyperStudio are not taught to the former students, but only to the latter students. Therefore, a student might not learn all concepts and skills listed on the following table depending on his/her university structure and instructor.

Implications
Preparing education students (future teachers) to teach in the Information Age is necessary. The students must understand their new roles, use new approaches, and have new attitudes. Being able to use technology, especially computers, and to integrate them into instruction is essential. Every teacher education program has to prepare our students for the technological change in the society and in schools.
Conclusions

Technology development is affecting our schools. Teacher education programs are required to prepare students to understand their new roles, use new approaches, and have new attitudes for teaching in the Information Age. An introductory computer course similar to the courses offered at the four universities of this research study is strongly suggested to be offered to students at each college of education. Different structures are employed at the universities. An institute should choose a structure that fits the institute and keeps the course consistent. Surely, the course content may be affected by the course structure and institutional characteristics. The course content at the four universities provides the education students with the computer concepts and skills which they are expected to know for their future teaching: word processing, spreadsheet, database, multimedia, presentation, e-mail, Netsearch, and integrating technology into instruction. An education student with these computer skills and knowledge will become a qualified teacher who can prepare the children in our nation to face the challenges of the modern world.

TEACHING PRE-SERVICE TEACHERS TECHNOLOGY: AN
INNOVATIVE APPROACH

Glenda A. Gunter
University of Central Florida

Randolph E. Gunter
University of Central Florida

Gregory A. Wiens
University of Central Florida

As technology has quickly been changing and revolutionizing the computer industry, education and educators have continued to have difficulty embracing the technology with open arms. Along with the availability and expanded capabilities of the computer and related technologies in the classroom, student attitudes toward computers remain a barrier in the learning process of technology (Clawson, 1996; Gunter, 1994; Gunter & Murphy, 1995).

Research has shown that a pre-service teacher’s initial attitude toward technology may either positively or negatively impact their future use of educational technology in the classroom (Reznich, 1996). Faculty should be knowledgeable of the factors that could cause students to exhibit behavioral characteristics such as: computer anxiety, computer confidence, computer liking, and computer usefulness.

Faculty must understand that one of the strongest impacts on the educational process is that students’ attitudes affect their process of learning. Educators must reevaluate their educational focus, thus leaning toward the use of technology with positive experiences for pre-service teachers (Clawson, 1996). Every effort to assure pre-service teachers’ initial exposure to educational technology is positive and motivational should be made. Educators need to strive to light a fire and motivate pre-service teachers to understand the influence educational technology can have in their lives and classrooms.

A report published in 1997 by the National Council for Accreditation of Teacher Education (NCATE) titled Technology and the New Professional Teacher - Preparing for the 21st Century Classroom, stated “The nation’s teacher education institutions must close the teaching and learning technology gap between where we are and where we need to be. Teacher education institutions must prepare their students to teach in tomorrow’s classrooms (p 1).”

The majority of pre-service teachers continue to enter institutions of higher learning lacking the positive attitudes, proper skills, and knowledge in the use of computers. All pre-service teachers should be competent in computer related skills. Students should be provided with the skills that will enhance their abilities to not only compete in a global economy, but survive well into the 21st century. To date, many institutions of higher education have failed to properly prepare pre-service teachers with positive experiences while learning the required technological skills.

Furthermore, students have not been provided with insight into the potential educational technology can have on public education. The federal government is investing $2.25 billion a year to provide high speed Internet access in all K-12 classrooms. By 2000, many K-12 classrooms will have access to the Internet. It is essential that Colleges and Schools of Education instruct pre-service teachers how to integrate the vast resources of the World Wide Web and related technologies into their classroom curricula. In addition, teachers need to understand the teaching processes that can be enhanced by using the computer and acquire evaluation skills for determining when to use the computer. Pre-service teachers need to learn how to assess the effectiveness of the computer when it is used in the instructional scheme. Institutions of higher education must develop motivational strategies to provide pre-service teachers with these evaluation skills.

Purpose of the Study
The purpose of this pilot study was to examine variables that could possibly influence attitudes toward learning and working with computers of College of Education pre-service teachers at the beginning and end of an introduction to educational technology computer course taught at the University of Central Florida during Summer 1997. The course used for this research was EME 1040, Technology for Educators. The variables examined in this study were computer attitudes and student perceptions. For purposes of this study, computer attitudes are identified as computer anxiety, computer confidence, computer liking, and computer usefulness (Gunter, 1994; Henderson, Deane, Barrelle, & Mahar, 1995; Loyd & Gressard, 1984).
The introduction to educational technology course was redesigned to incorporate innovative strategies for teaching pre-service teachers to use technology, teach with the technology, and find creative ways to help pre-service teachers to integrate technology into the curricula of their future classrooms. The researcher wanted to determine if these strategies could make a difference in pre-service teachers’ attitudes towards technology after completion of the course.

Methodology and Instrumentation

The research design for this study was causal-comparative. Due to the nature of classrooms with intact groups, the causal-comparative method was used. Causes are studied after they have already exerted their effect on a variable. Otherwise known as ex post facto research, the causal-comparative method was utilized to explore the relationships among variables. Statistical tests used were t-tests and they were considered significant at the .05 level.

The instrument used for this pilot study was the Computer Attitude Scale (CAS) developed by Gressard and Loyd (1985). The CAS is a 40-item instrument that is divided into four, 10-item subscales: Computer Anxiety, Computer Confidence, Computer Liking, and Computer Usefulness.

The CAS has been successfully used with 7th-12th grade students, college students, teachers, and administrators. To explore functional use of the CAS, Loyd and Gressard (1985) and Loyd and Loyd (1985) ran a study that indicated the CAS is reliable and valid for measuring attitudes. The coefficient alpha reliabilities were .89, .89, .89, and .95 for Computer Anxiety, Computer Liking, Computer Confidence, and the Computer Usefulness Subscales, respectively. A factor analysis revealed the subscales were sufficiently stable and the instrument could be used confidently and effectively in research and program assessment. The CAS has been tested through many studies to determine the stability of the CAS and subscales to determine their effectiveness in reflecting change in computer attitudes as a result of computer instruction and experience. The CAS was found to be sensitive to attitude changes resulting from computer instruction and experience.

Description of Sample

The sample for this pilot study were students enrolled in an introduction to educational technology course, EME 1040 Technology for Educators taught in the College of Education at the University of Central Florida during summer 1997. The sample utilized in this study were those students who completed both the CAS pretest and posttest. Twenty-nine students completed the pretest with posttest being completed by 26 students. After completion of the posttest, 26 students were matched by pretest to posttest. Therefore, the sample of students for this pilot study was 26. The sample consisted of 21 females and 5 male students of ages ranged from 19 to 46 with 76% being 26 years or younger. Twenty of the students in the pilot sample had attended a community college prior to entering the University of Central Florida. Eighty-nine percent of the students stated they had primarily learned technology on their own. Sixty-one percent had access to a home computer.

Description of the Course

Knowing that students enter the classroom with predetermined attitudes toward technology, faculty created innovative teaching techniques that were demanding but not threatening. Techniques and strategies were developed that created an environment for students that made learning technology not only relevant to the real world, but also fun.

 Learners need to learn to use technology in a non-threatening environment. In order for students to embrace technology, they need authentic hands-on exercises, time, access, support, and resources to acquire ability through experience. Therefore, a major focus of the course was to provide opportunities for students to not only learn to use the technology but also learn to teach with technology.

The following is a summary of the basic curriculum and course issues that were considered fundamental to the overall success of the course.

Curriculum Issues. The course curriculum was completely redesigned prior to the start of the semester and was based upon state requirements, instructor experience, and formal inputs from regional K-12 teachers, K-12 technology coordinators, K-12 administrators, and College of Education faculty. During the first class session, each student was required to complete a detailed computer skills questionnaire that covered over 35 specific computer and educational technology skills. The course curriculum was modified after the first class session based upon the identified students’ skill levels. The curriculum was also continually updated as the semester progressed based upon student performance, student comprehension, and new educational technologies. Traditional software tutorials were not used. Whenever possible, introduction and practice of software programs were immediately followed by practical application of the software in an educational setting. Integration of technology into K-12 classroom curricula was emphasized throughout the course.

High Impact and Low Threat. The course was considered by faculty to be a high impact class because hundreds of different specific educational technology and basic computing topics were covered. In addition, students were introduced to dozens of different software programs and the educational resources of the World Wide Web. All course activities and requirements were designed to be motivational and to empower pre-service teachers to use technology while at the same time creating positive experiences for all students. Traditional testing was not used. Instead, on-time and mandatory class attendance, hands-on exercises, out-of-class education related projects,
students' attitudes from the pretest to the completion of the course students had less anxiety toward the four subscales. The findings indicate that after the posttest score to formulate the Computer Anxiety Subscale Gain, Computer Confidence Subscale Gain, Computer Usefulness Subscale Gain, and Computer Liking Subscale Gain, Computer Usefulness Subscale Gain. The results of the t-tests revealed statistically significant differences between the pretest and posttest means on each of the four subscales. The findings indicate that after completion of the course students had less anxiety toward technology. Students’ attitudes from the pretest to the posttest revealed statistical significant differences that occurred over the duration of the semester. Students in the College of Education were found to have a more positive attitude toward learning and working with computers after completion of the introduction to educational technology course. College of Education pre-service teachers had lower anxiety, more confidence, and found computers more useful at the end of the semester. An introduction to educational technology course made a difference in these students' attitudes toward computer technology.

N=28  \( p < .05 \)

Students were also asked to reflect on their experiences in the class through quantitative open-ended questions. Students expressed their feelings and perceptions of their experiences during the semester. Each of the following are direct quotes from several student responses, “Before this class I only knew the basics, word processing, and now I am confident I could build a database, spreadsheet, and Hyperstudio project”; “This class has built my confidence with computers!”, “I found myself wanting more and more to use technology in the classroom as a learning tool.”; “I learned so much. I can not explain how important this class was for me and how it influenced me.”

### Conclusions and Recommendations

Analysis revealed a statistically significant change in computer attitudes of students over the semester. The research indicated that the introductory course was successful in significantly reducing the incidence of computer anxiety.

The introductory computer course is fundamental to a student’s success with computer technology. Students in many education degree programs are not required to take any computer-related courses. Universities need to require at least one computer literacy course regardless of the student’s program of study. Computers have infiltrated every aspect of our lives; therefore, all students should be prepared to enter the work force with adequate computer skills.

Therefore, the researchers concluded that computer anxious students could be taught in a way that could reduce computer anxiety. Thus, the more knowledge students gain...
coupled with a positive experience in the classroom the lower their anxiety levels and the more positive their attitudes toward computers.

The researchers suggest the need for further research on computer attitudes in order to prepare students to possess information technology skills required to enter the work force. Whether in education, business, engineer or history, all degree programs need to emphasize the necessity of students possessing high-tech skills to compete in a world class global society. The changing of students' attitude involves persuasion and an understanding of the influences that determine a student's attitude. This study revealed that students continue to enter the university system with low skill levels and high levels of anxiety. From this pilot study, results confirm that how a course is taught can change students attitudes and perceptions of technology. Faculty must address these pre-existing attitudes and encourage and challenge pre-service teachers to not only learn how to use technology but how to integrate technology into their own classroom curriculums.

Educational Computing Course — 227
The educational computing course has been part of the required courses for teacher certification for several years and has changed and evolved as a result of new practices and mandates through the years. I have taught this course at both the graduate and undergraduate levels for the past nine years and I have noticed an ever-increasing amount of competencies that are required of the education students. Not only are the students required to master the basic technologies, they are expected (in the same semester) to apply these technologies to lessons or classrooms situations. (This burden is being alleviated somewhat as other education classes begin to require technology use in the completion of assignments.) The students in these classes, when presented with the full to overflowing syllabus, express dismay, confusion, and despair, and compare their projected semester experience with trying to climb an impossibly high mountain with very little preparation and even less supplies.

Each semester I have tried to provide better and more detailed "maps" of the "mountains" with more "signs" and "guideposts" along the way. My training is in special education and I know how to break a job down into manageable and attainable pieces so the student will be successful. Also each semester I get feedback in an informal way and apply it in the next activity or the next semester's class. Each semester I find that some students have no problem "climbing the mountain and seeing the whole view from the mountaintop" (or, in other words, catch on quickly and have no problems with the activities and the course); whereas, other students have problems with each day of "climbing," or with the "path," or with their "supplies" for the "climb," or even with seeing where the "path" is leading them.

This led me to ask: "How could I formalize this process of action, reflection, and feedback?" and "Do certain types of learners do better with certain types of activities and certain structures for activities?". This paper defines action research, describes the action research done in the educational computing course for the Fall 1997 semester, and finally, discusses what was found and what action will be taken to improve the course.

What is Action Research?

Action research is a type of methodology that includes both action and research. The action refers to the change that will occur as a result of the research. The research refers to a "systematic effort to generate knowledge" (Deshler & Ewert, 1995). Dick (1997c, p 2) asserts that action research "allows you to develop knowledge or understanding as part of practice" and "allows research to be done in situations where other research methods may be difficult to use." Dick (1997c) suggests using action research if the researcher needs flexibility, or wishes to involve the participants, or desires to bring about change at the same time the research is being done. Action research "allows for systematic understanding to arise from activities which are oriented towards change. It has a capacity to respond to the demands of the informants and the situation in a way which most other paradigms cannot" (Dick, 1997c, p. 4). Reason and Heron's (1997) "collaborative inquiry" (another term for action research) is described as "a way of working with other people who have similar concerns and interests to yourself, in order to understand your world, make sense of your life and develop new and creative ways of looking at things. You also learn how to act to change things you may want to change and find out how to do things better" (p. 1).

In A Beginner's Guide to Action Research Dick (1997a) and his colleagues outline and discuss the major characteristics of action research:
- It is cyclic – similar steps tend to recur, in a similar sequence;
- It is participative – the clients and informants are involved as active participants in the research process;
- It is qualitative – it deals more often with language than with numbers; and
- It is reflective – critical reflection upon the process and outcomes are important parts of each cycle.

Action Research Procedures in the Educational Computing Class

Description of the Class

The educational computing class, CUIN 6320 Computers in the Classroom, at the University of Houston is a required course for teacher certification. Students must master
several technologies and learn to integrate them into the curriculum they will be teaching. All grade levels and subject areas are represented in the fifty students enrolled in CUIN 6320. Also all levels of computer expertise from novice to expert are present in the class, so the semester begins with basic information and activities used to introduce both operating systems, Macintosh and Windows 95. Several required activities are included in the curriculum that introduce students to word processing, draw, paint, desktop publishing, email, the world wide web, web page development, presentation software, and multimedia. Students are then required to do four projects that expand their knowledge about four of the technologies. The last requirement is a teaching unit in which at least three of the technologies have been integrated.

Methodology and Instrumentation
As part of the midterm the students were given two surveys and a series of questions. Preceding this were discussions about learning styles, learning preferences, and action research. The students were told that their answers would be compiled, analyzed, and utilized to improve the course. They were encouraged to be thoughtful and truthful in their answers and that full credit would be given for the completed assignment. The two surveys that were given were the Gregorc Style Delineator (Gregorc, 1985) and the Productivity Environmental Preference Survey (Dunn, Dunn, & Price, 1996). The Style Delineator is based on four quadrants that represent how a person perceives the world (abstract or concrete) and orders that information (sequential or random). A person’s learning style will be dominant in one of the four quadrants with the results being Abstract Sequential (AS), Abstract Random (AR), Concrete Sequential (CS), or Concrete Random (CR). Research shows that there is significantly greater chance that graduate students will be Abstract Sequential (Cromwell, 1996) and that they like to dig into assignments, work alone, and organize work in large chunks to see the total picture (Andrews & Wheeler, 1994). Andrews and Wheeler (1994) also found that Concrete Sequential students tended to prefer traditional methods of instruction with deadlines and preselected assignments; that Abstract Randoms liked working in groups, creative scheduling, and less specific assignments; and that Concrete Randoms preferred to choose their products, methods, and due dates in a flexible framework.

The learning preferences survey shows preferences such as environmental (noise, light, temperature), emotional (motivation, persistence, responsibility), sociological (individual or team), and psychological (perception, intake, time) (O’Connor, 1997). Using a preference survey is a “useful first step toward analyzing the conditions under which an adult is most likely to produce, achieve, create, solve problems, make decisions, or learn” (Price, 1996).

The third part of the midterm consisted of several questions that the students were to thoughtfully answer. For the sake of space the questions will be listed in the results section.

After the midterm was collected and analyzed, the information gained was used to adapt and modify the upcoming assignments and class time. The students then had more time for reflection and feedback as we progressed through the class.

Results and Findings
Out of the 50 students that were surveyed, 38% were Abstract Sequential, 28% were Abstract Random, 20% were Concrete Sequential, and 14% were Concrete Random. Table 1 shows the percentage of each of the four learning styles and their preferences on a sampling of the questions from the Productivity Environmental Preference Survey.

Reflective Questions. The following questions were analyzed by the four learning styles groups.

• What was your most successful previous learning experience? (not in this class) Why? The AS group described experiences in which new techniques and creative methods were introduced and used; active learning at their own pace was allowed; teachers treated students as individuals and were accessible to students; and there was much group work. The CR group described experiences that were boring, negative attitudes, extensive reading, holistic learning, no guidance or assistance, and no opportunity to manipulate the concepts to get the required results. The AR group described experiences that were structured informally and had lots of choices and hands-on activities that related to the real world and to their experiences. The CS group described experiences that included challenging classes, in-depth reading, concrete demonstrations, thought-provoking discussions, and direct and immediate application of the lecture concepts. The AR group described experiences in which they were totally immersed in a Spanish-speaking environment; experiences where they had to learn everything by themselves; experiences in which they observed and learned from others; and experiences that utilized higher-order thinking and had lots of structure and strict deadlines.

• What was your least successful previous learning experience? (not in this class) Why? The AS group described experiences in which there was no interaction; there were lots of facts to be memorized; there were vague directions; and individual ideas were rejected. The CR group described experiences that were boring, vague, and consisted of lectures and notetaking. The CS group described experiences that included teachers with negative attitudes, extensive reading, holistic learning, no guidance or assistance, and no opportunity to manipulate the concepts to get the required results. The AR group described experiences in which they learned something that they could not apply or practice; they also described boring lectures and large classes.

</table>

- What do you consider to be your major blockages to learning? The AS group said distractions, time, anxiety, lecture classes with no opportunity to practice, comprehension of written material, lack of desire, inadequate background, getting started, disorganization, boredom, and procrastination. The CR group said lack of interest, no hands-on training, low concentration, and not being able to relate the material. The CS group said low self-confidence, vocabulary, small attention span, difficult time understanding directions, procrastination, perfectionism, not writing something down, attitude, irrelevance, and no purpose for the assignment. The AR group said time, stress, things that interest me, a large amount of reading, boredom, irrelevant or boring material, too much information presented at one time, and fear.
- Reflective thinking means watching yourself as you learn something and observing what you do, how you do it, and how you feel about it as you do it. Reflect back on one of your learning sessions in this class and describe what techniques or patterns of behavior you might be using to learn. Were you guessing? Were you asking for help? If you did not ask for help, why not? Were you using trial and error? Were you embarrassed? Lost? Frustrated? Excited? Satisfied? Did you gain energy or were you worn out? Did you keep bashing your head against the wall? Were you flexible or rigid? Did you learn better with others or by yourself? (This last question was from Algonquin College of Applied Arts and Technology, 1996)

The AS group did not mind asking for help from others and liked working in groups although they were hesitant at first; they used trial and error much of the time; they were worn out by the end of the class time. The CR group was flexible in their learning and would guess much of the time; they found it hard and tedious to follow the step-by-step instructions of the activities; they like to figure things out in their own creative way; they were energized by the learning and the class work. The CS group concentrated on the steps and "getting it right"; they were anxious and rigid as they completed their activities; they wanted more organization and direction on the student-choice projects; they did not mind asking question after question because it kept them from becoming completely frustrated; they also wanted as much material and information as they could get before attempting any of the activities. The AR group liked to practice things on their own and try to figure things out for themselves and explore their other options; they were flexible and even changed ideas and strategies in the middle of a lesson; they were motivated to do more and felt energized by the work; and they were frustrated by others always asking them questions.

**Conclusion**

In answering the first question, "How could I formalize this process of action, reflection, and feedback?", the use of the midterm as this assignment provided the answer. The students were motivated to give thoughtful answers in order to receive full credit and they were able to analyze their own
feelings more accurately and use them in a more positive way. They found that they were not alone in their experiences and feelings and that the experiences were a normal and acceptable part of the learning process.

In future classes the reflection will be a weekly activity so that it is not an overwhelming exercise and the students can profit from these reflections. Also the teacher will spend more time with small groups each class period so that students feel like they are getting as much help and encouragement as they need.

In answering the second question, “Do certain types of learners do better with certain types of activities and certain structures for activities?”, there were similarities found within each of the four learning style groups. The students were anxious to see the results of the two surveys and to get feedback on what the results meant. They liked doing the self-study and finding out more about themselves as learners. This information helped them as they approached the new experiences in subsequent classes. These surveys also helped them to see that they were not alone and that some experiences would be more positive than others would, and that it was all right to have particular preferences.

In future classes these surveys will be done immediately so that the students can use them as a learning experience and a foundation for the whole class. This experience will make them better, more thoughtful practitioners in their professional lives and will allow them to see things through the eye of the learner. It should also help them evaluate their experiences more thoroughly and grow as lifelong learners.

Current trends in education reflect a shift from traditional didactic pedagogy toward student-centered constructivist instructional practices. These trends are evident in increased attention to constructivist learning theory and teaching methods in preservice teacher education courses (Howey, 1996), and in recent curricular reform reports (National Association for Secondary School Principals, 1995; National Council of Teachers of Mathematics, 1991; National Research Council, 1995; National Science Teachers Association, 1990). Although preservice teachers have been exposed to constructivist theory in their coursework, teachers rarely draw on the learning theories they have studied to guide their practice (Pinegar & Carter, 1990).

Teachers tend to base their pedagogy on their experiences as learners in didactic K-12 classrooms (Knowles & Holt-Reynolds, 1991, Lortie, 1975), rather than relying on formal theories of learning. They often interpret constructivist reforms in light of their previous school experiences and implement constructivist practices in idiosyncratic ways. For example, a constructivist use of manipulatives might entail allowing students to use hands-on materials to develop a concrete representation of an abstract mathematical concept. This process helps students construct more complex understandings and their own problem solutions. However, some teachers integrate manipulatives with their didactic practice by demonstrating the correct way for students to use the materials to solve a problem. Thus, teachers can transform constructivist uses of manipulatives to fit with their existing practice.

Helping teachers change their pedagogy to reflect a more constructivist orientation is a difficult and challenging process. Educational psychology-based courses on learning often present models of learning as complex and abstract theories that are divorced from preservice teachers' personal learning experiences. On the other hand, methods courses typically focus on constructivist instructional strategies (i.e. cooperative learning, reciprocal teaching, discovery learning), helping preservice teachers understand how to teach in constructivist ways, but without providing explicit links to the theory-based assumptions that underlie constructivist practice. Preservice teachers need to experience constructivist learning activities from a student perspective if they are to be effective constructivist teachers (Stofflett & Stoddart, 1994). Helping preservice teachers reflect on their experiences as a constructivist learner can help them make important connections between learning theory and related instructional practices.

Most stand-alone technology courses focus on helping preservice teachers learn to use various hardware and software applications (i.e. Downs, 1992; McKenzie, 1994; Niess, 1991; Raiford & Braulick, 1995), and current standards focus on ensuring preservice teachers develop specific technology competencies (Wiebe & Taylor, 1997). Although developing technology related skills is an important goal for teacher education programs, the preservice technology course can also provide a unique context for future teachers to explore their own learning. Unlike methods courses, in which preservice teachers often know the content and focus on learning to teach it, preservice teachers expect to learn new concepts and skills in the technology course. Many preservice teachers enter the class with word processing experience, but little exposure to other productivity applications (Sheffield, 1996). They often have minimal experience with e-mail or Internet browsers and it is rare to find a preservice teacher who has considered instructional uses of technology beyond drill-and-practice activities. Thus, most preservice teachers bring limited skills and understandings needed to integrate technology with their instruction. The technology course provides a forum for them to develop technological competency as they reflect on their own learning processes, develop a deeper understanding of learning theory, examine the relationship between theory and practice, critique the nature of school-based learning experiences, and analyze assumptions underlying instructional methods.

To accomplish these goals, two instructional activities were designed to provide preservice teachers with a common learning experience that exemplified contrasting
approaches to instruction. One activity was a highly structured, teacher directed lesson based on a didactic instructional model. The second activity required preservice teachers to assume primary responsibility for planning and implementing the project as they worked cooperatively to support each other as a community of learners. This activity was based on a constructivist instructional model. Preservice teachers completed these activities during the first quarter of the class and used them as a referent for understanding the discussions and activities that followed.

**Didactic Activity**

The initial computer activity involved developing a home page using HyperText Markup Language (HTML). Preservice teachers completed the activity by working individually at a computer with little peer interaction. The activity was highly structured as preservice teachers were given a handout that included all of the information they would need to complete the project. The handout provided precise directions that stated exactly what needed to be typed into the text editor (in boldface type), and a detailed explanation of what each line of the program did. Many preservice teachers quickly realized that they could simply type in the boldface lines without reading the detailed explanations and complete the assignment. Their focus was on completing the task rather than developing an understanding of what they were doing. The instructor moved around the lab encouraging the preservice teachers to follow directions exactly, praising their efforts, pointing out typos, and providing technical assistance when necessary. Before long, completed home pages began to appear on monitors. Following the directions exactly provided preservice teachers with identical projects—if they had typed the information correctly, they got it right. The underlying assumption was that since they have produced the correct product, they had learned the important concepts through the process.

A brief multiple-choice test was administered at the beginning of the next class period as a traditional assessment of what had been learned. Test items were taken directly from the detailed explanations on the worksheet (which few students had even read). A review of the right answers followed with considerable praise as a reinforcer for those who had managed to choose correct responses. At this point, a fairly large group of preservice teachers felt frustrated and angry. They had accomplished the task and produced an acceptable product, but the quiz forced them to reflect on how little they had learned. Interestingly, preservice teachers criticized the nature of the instruction and their perception of what the instructor should have done, and refused to accept responsibility for their own learning.

The class discussion that followed focused on tying the activity to behavioral learning theory—expert designed outcomes, focus on product, detailed sequential instructions, ongoing praise and feedback, and tests of factual information in which the teacher determines what is important and what counts as a right answer. The instructors explained how didactic instructional principals had been used to design, teach and evaluate the lesson, and many preservice teachers acknowledged that this activity was fairly representative of their previous school-based learning experiences. The heart of the discussion, however, centered on learning.

Preservice teachers felt satisfaction from completing the home page but questioned whether they had learned anything meaningful from the activity. Some preservice teachers had experience with HTML and did not believe the activity had added to their knowledge. Others had no experience with HTML and, although they had produced a home page, did not believe they had learned the skills and understandings necessary to independently create a home page, much less teach their future students to do it. Most preservice teachers confessed to having adopted a “get it done” strategy with little concern for developing an understanding of the HTML code. They were unwilling to spend time outside of class to work on the assignment, nor had they reviewed the handout to try and make sense of what they had done. All admitted that, although the activity was fun, and seeing the finished product was rewarding, they had not really learned much that would be useful in the long term.

Further discussion addressed the appropriateness of the activity for the desired outcomes. If the goal for the activity was to help preservice teachers develop an understanding of how to develop a homepage using HTML, the instructional method was inappropriate and preservice teachers’ approaches to learning were ineffective. However, our goal as instructors for the course was met. Preservice teachers were forced to critically examine both the fairly traditional instructional methods used for the lesson and their role as a learner.

**Constructivist Activity**

The second activity involved creating a home page through a more active constructivist approach. The assignment involved developing a home page around an academic theme. Preservice teachers had a good deal of flexibility in planning and implementing the project. They learned to search the web for relevant information and sites, read source code from other pages to get ideas for features for their own page, and learn from and teach each other. Preservice teachers were encouraged to be creative, to share their work and expertise with their classmates, and provide suggestions and help for each other. The assignment helped the group develop into a community of learners and they continued to help and support each other through the remainder of the course. The activity was spread over several weeks so that students would have ample time to develop deep and connected understandings of the process.
The preservice teachers initially experienced a good deal of frustration and anxiety working on the project. As the project progressed, they recognized the considerable time and effort needed to engage in meaningful learning. The instructor was available as a resource, guiding preservice teachers in potentially fruitful directions and asking questions to challenge thinking rather than providing information and giving directions.

A group evaluation session allowed each preservice teacher to present their work, explain some of the features they had incorporated, and address questions from their peers. Preservice teachers shared their ideas, criticisms, and suggestions freely. All participants benefited from the information shared during the formative evaluation session. In the ensuing discussion, the class explored the components of a constructivist learning orientation that were apparent in this activity—student agency in designing the activity; actively seeking, organizing, and producing knowledge, cooperation with peers, and holistic evaluation of the project.

Preservice teachers stated that the project had been an excellent learning experience, although it had been extremely time consuming and frustrating. They reported that the project took on personal significance as they worked through their difficulties and many went beyond what was required because of their high level of interest and engagement. The discussion was structured to encourage preservice teachers to reflect on the nature of meaningful learning, roles of the learner, and roles of the teacher. Taken together, the didactic and constructivist learning activities provided an experiential referent that the preservice teachers could draw on as they considered the role of educational technology in the learning process.

Building on the Foundation

These learning activities met several of the course goals. First, class discussions prompted reflection. The preservice teachers were encouraged to think about the strategies they employed to complete the activities, how their motivation and goals differed relative to the projects, and the differences in their levels of understanding of HTML relative to the two activities. The activities also provided a common experience-based referent for reflecting on two important theoretical orientations toward learning—behaviorism and cognitive constructivism. Readings and class discussions about learning theory that occurred concurrently with the activities were greatly enhanced because preservice teachers were able to relate the theory to their own personal learning experiences. These experiences enabled them to examine the relationship between the assumptions underlying the theory and the instructional methods used in the class. Other course activities built on this foundation.

Software Evaluation

Software evaluation focused on the underlying theoretical assumptions about learning that guided its design (e.g., behavioral principles in drill-and-practice and tutorial software, and constructivist components in programs like SimLife and the Geometer's Sketchpad). Class discussion of software evaluation focused on how the same piece of software could be used to support more traditional didactic instruction (e.g., teacher PowerPoint presentations) or a more constructivist orientation (e.g., student PowerPoint presentations). Potential learning objectives were examined relative to how various types of software supported different learning goals (e.g., memorizing, problem-solving, exploration, etc.). Thus, preservice teachers used their own learning experiences as a referent for analyzing assumptions about learning inherent in instructional uses of technology.

Field Experience

Preservice teachers were required to conduct observations and interviews with teachers during a two-week field experience. They examined the types of software teachers used, how teachers used the software, and teachers beliefs about the role of technology in education. Learning theory provided a framework for the preservice teachers to critique and understand classroom applications of technology. This activity addressed the goal of helping preservice teachers explore and critique the nature of school-based learning experiences and analyze the assumptions underlying various instructional methods.

Student Outcomes

Student feedback revealed a range of opinions concerning the value of the course. Most students reported increased motivation and a better understanding of material learned through constructivist methods; however, some students failed to see the relevance of connecting theory to practice. Thus, although they claimed to enjoy constructivist learning activities, students questioned the need to understand learning theory. Excerpts from course evaluations reflect their thinking: "[You] might want to back off from all the psychology and philosophy material. I felt we spent too long on this subject. In fact, very long with respect to this being a computer introduction class." And "I do not feel that this course will help me as a teacher in the area of technology. I believe the behaviorist/constructivist [information] could have been taught in the first couple of weeks, then we could have studied more useful things."

Other students, however, embraced the importance of the learning theory component of the class: "This was a great class. It was difficult and challenging which really made me think and examine my own motivations and knowledge." And "The information we learned... was useful to me and helped me understand new concepts. I think I understood the differences between behaviorist and constructivist approaches better than in any other classes.
where we’ve talked about these things.” Learner variables, such as whether preservice teachers were willing and able to be active learners and reflect on their own learning processes, influenced what students gained from the course activities. Making connections between the readings and discussions about learning theory, their personal learning experiences, and the instructional practices they observed required effort on the part of the student.

Conclusion

The actual activities (learning to write HTML code) is not critical to the value of the course. We chose this topic because it was unfamiliar to most of our students. Any novel and complex learning activity could be framed to contrast the differences between didactic and constructivist instructional methods.

Preservice teachers developed increased confidence and competence in their ability to use computers by the end of the course. Skills were learned in a highly motivating “project-based learning” context (see Blumenfeld, Soloway, Marx, Krajcik, Guzdial & Palincsar, 1991), in which students take responsibility for determining what they need to know and how to go about learning it. Support was available, including peers, instructors, and lab technicians, and students decided how to best use these resources. Students had developed many skills for using technology as they completed the course. They had also learned strategies for getting new skills when they were needed.

However, students in the course learned more than just competencies for using computers in the classroom. The learning theory backbone of the class enables them to make decisions about how different types of computer programs can support different learning goals, how to select software that meets learner needs, and how to evaluate new educational technologies from a student learning perspective. The connections they make between learning theories, their own learning, and educational technology provide a solid experiential base that will serve them well in the teaching profession. Students developed a theoretical orientation to learning that guides decision making about how to use technology in their instruction, rather than specific ways to use computers that will soon become outdated.

INSTRUCTIONAL STRATEGIES FOR INTEGRATING TECHNOLOGY: ELECTRONIC JOURNALS AND TECHNOLOGY PORTFOLIOS AS FACILITATORS FOR SELF-EFFICACY AND REFLECTION IN PRESERVICE TEACHERS

Ann Kovalchick

M. Elizabeth  
University of Virginia

For most undergraduate teacher education students, technology skills begin and end at the basic survival skills of paper writing using a word processor and, perhaps, sending e-mail. Frequently, these students approach a required technology course feeling some fear or anxiety related to the more sophisticated use of computers. They often perceive themselves as novice technology users, discounting their own level of experience with word processing software and e-mail as a useful foundation for further skill development. Factors contributing to this are the preservice teachers' insufficient experience with computers, their lack of understanding of how interactive technologies can easily be integrated into the curriculum, and little confidence in their abilities to acquire computer instruction (Hunt and Bohlin, 1991; Zelman, 1986). In addition, the enormous marketing hype that surrounds technology suggests that anyone less than a power-user is hopelessly unhip, a sensitive claim for most undergraduate students (Kovalchick, 1997).

When students have no training or experience and have no confidence, reluctance to use technology is rooted in computer anxiety or "computerphobia" (Kennewell, 1992). Many preservice teachers are not so much afraid of the machines themselves, as of their own ignorance and lack of understanding. Electronic journals (e-journals) offer students an outlet to share their fears, hopes, and expectations with the instructor about their learning experiences. They also allow the student to communicate with the instructor how they are understanding the content, sequence, and even presentation of the material. Technology portfolios provide students the opportunity to demonstrate their accomplishment and to reflect upon their learning over the course of a semester. This paper describes the use of e-journals and technology portfolios as an instructional strategy in preservice teacher education technology courses.

Description of the Course

Introduction to Media and Computers in Teaching, EDLF 345, is an introductory level, two credit, preservice teacher education course offered every fall at the Curry School of Education at the University of Virginia. The majority of the students are preservice teacher education students—in their third year of college—who are interested in teaching at the elementary, middle, or high school level. A minority are in the Masters of Teaching program; and a few are non-education students. All preservice teacher education students are required to take the course. Those more technologically advanced can substitute a three credit technology course also offered in the Curry School.

E-journals

Journals, widely used as an instructional strategy in the language arts and other subject areas at the K-12 level, are finding their way into teacher education as a way to facilitate the development of reflective thinking. A journal, or learning log, is a compilation of students’ reflections, learning, and feelings about a certain subject or topic. They can be used in a number of ways: for example, teachers can ask students to write in an open-ended manner about the content they have learned, questions they still have, and how the content relates to their own experience. Or, teachers can provide students with prompts for them to write about in their journals.

Journals can provide teachers with a way to assess and monitor student development throughout the learning process, which is not possible through standardized tests or other one time measures. Because they require students to synthesize and reformulate what they have learned, journals and their word processor equivalents, e-journals, serve to
Using E-Journals with Preservice Teacher Education Students

In EDLF 345 the instructors have begun using e-journals as a way to examine the students’ learning throughout the semester and to model a strategy they can later utilize in their own classrooms. After each class, students create an entry in their e-journals using a word processing program. They are encouraged to write about whatever they like related to the class. The following questions provide some guidance for those who do not know what to write about:

- What did you learn today?
- How do you feel about using technology?
- What was the most useful/meaningful thing you learned in today’s class?
- How could you apply the content of today’s class in your personal, academic, or future professional life?
- What did you contribute to today’s lesson/the course?
- What are some of your questions or concerns regarding the class?

Each entry is dated and saved in the same file. They are sent to the instructors via e-mail as an attachment three times during the semester. The journals are intended to provide students a map of where they have been and underline the evolutionary process of their learning as it unfolds. They begin to see that learning is sometimes messy, frustrating, and often announces itself in short spectacular “ahas!”

E-journal Entries

Fall 1997 (E-journal entry)

I was a bit intimidated before making my newsletter and had no idea that I could do as much of it on my own as what I did. I have little experience with computers and the class lesson that day went a little fast for me, I wasn’t quite able to keep up. Thanks for listening.

In many technology classes, students are reluctant to ask questions during class because they are embarrassed or feel that they are the only ones experiencing such problems. E-journals provide a safe way to ask questions, converse with, and offer suggestions to instructors about the class.

A preliminary analysis of student e-journals reveals a pattern in the types of responses included. Their responses generally fall into two categories, “making connections within the classroom” and “making connections outside the classroom.” Below is a table outlining the types of entries in each of these categories.

<table>
<thead>
<tr>
<th>Making Connections within the Classroom:</th>
<th>Making Connections outside the Classroom:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reflective student: These entries are typically written in diary format; they recount what was learned in class and how the student feels about using technology.</td>
<td>Reflective teacher: Students relate how they plan on using technology in their future classrooms as professional technology-using teachers.</td>
</tr>
<tr>
<td>Dialogue with the instructor: Students ask the instructor questions or comment on any aspect of the class (including constructive critiques of how the material was presented).</td>
<td>Other experiences with technology: These responses generally describe students' experiences with technology in different environments, for example, their employment and other classes.</td>
</tr>
</tbody>
</table>

Educational Computing Course — 237
increasing technological world. It is probably not good for a teacher not to have any idea in instructing a student in how to operate different computer programs. I can only imagine how ugly a newsletter would be if I used only a word processor to create it.

Example 2

Fortunately I am not nearly as intimidated by the uses of technology now as I was in the beginning. When I imagined what the instructors of this class would be like I was scared I would get instructors who were unable to deal with people, only computers... I feel very comfortable with both of my instructors and am confident that if I don’t understand something in class, I can get the help needed after class... To say the least my level of anxiety has been significantly reduced since the beginning of the semester.

Early feedback from the introduction of e-journals during the Fall, 1997 semester of EDLF 345 has been highly encouraging. E-journals are providing opportunities for reflection and a means to link what students are learning in the classroom with their future roles as technology-using teachers. They are also allowing students to converse with the instructors and share their meaning-making. Using e-journals as an instructional strategy also benefits the instructor. They help the instructor understand the student better as well as help him/her gauge and modify the class, which can have an impact on current and future students’ needs. In addition, students themselves are more capable of understanding the technological world around them, and how they plan to deal with it.

Technology Portfolios

Whereas e-journals demonstrate learning in its developmental phases, portfolios represent the culmination of a student’s work over a period of time, for instance, a semester. Many definitions exist in the literature regarding portfolios and the types of portfolios that exist. In general, a portfolio is a compilation and reflection of students’ work, efforts, and progress. The different kinds of portfolios are showcase, descriptive, evaluative, and composite portfolios (Halaydna, 1997; Shackelford 1997). Each of these has unique objectives and methods for assessment. Shackelford (1997) suggests that “As instructional strategies, they promote the application of knowledge, self-assessment, and the development of individual talents, skills, and values” (p. 31). Furthermore, Russell and Butcher (1997) assert:

As a perspective over time during a course or curriculum, portfolios pull together a lot of information and artifacts. These materials lend themselves to formative evaluation and revision. Portfolios have the added advantages of allowing students to organize their knowledge, skills, and materials, to develop an in-depth understanding of the content, and to show peers and professionals what they have learned and can do.

A technology portfolio is similar to a traditional portfolio, but it specifically addresses technology skills and issues. Also, the medium is different since it is organized using a combination of electronic media such as hypermedia programs, database, spreadsheet, and word processing software, as well as CD-ROMs and the World Wide Web. Technology portfolios can be print-based, saved on a computer disk, compiled on a CD-ROM or HomePage, or a combination of the above. How it is published depends on the resources available in addition to the teacher’s objectives. Tuttle (1997) contends that digital portfolios should be used because they demonstrate wider dimensions of learning, their parts can be interconnected, and they save space.

Levin (1996) explains that technology portfolios can be used to meet ISTE/NCATE guidelines. One challenge to meeting these guidelines is that cheaper, easier to use multiple choice tests do not accurately measure students’ competence in technology. Technology portfolios are the answer to the dilemma as they serve as performance-based measures. Performance-based assessment has become increasingly accepted in education, especially by some major teacher education organizations, for instance, the Interstate New Teacher and Support Consortium (INTASC).

The items in a technology portfolio will depend on the context of the technology training, the resources available, and the amount of time (e.g., stand alone semester course or methods class that integrates technology). Levin (1991) and Petrakis (1996) describe the components for technology portfolios—specific to their objectives—which they have used with preservice teacher education students. The following items can be included:

1. Educational technology philosophy statement (Why technology is important for instructional purposes.)
2. Hands-on competencies/projects completed in the course
3. Weekly E-journal entries
4. Samples of work created outside of the requirements of the course
5. Self-evaluation of the items included in the portfolio

In EDLF 345, students collect examples of their work over the course of the semester for inclusion in their technology portfolios. These portfolios are intended to allow students to make a personal statement, which reflects their growth, change, and competence in the use of technology. As such, the cornerstone of the Technology Portfolio is a self-evaluation. Students are asked to provide an analysis of each piece of work that they choose to include in their technology portfolio. This self-evaluation must address three issues:

1. Students must comment on the quality of the work
2. Students must provide a rationale for each item’s inclusion in the portfolio
3. Students must describe how - as a teacher - they might use the technology represented by the work toward an instructional goal

238 — Technology and Teacher Education Annual — 1998
Students are encouraged to consider a broad definition of how success can be demonstrated. In this way, technology portfolios function as an instructional strategy that emphasizes problem-solving and the development of a conceptual understanding of software applications rather than simply the performance of various keystrokes, commands and menu selections. Instead, they are encouraged to consider patterns in the design of interface metaphors that serve or hinder user-friendliness and to critically evaluate much of the "hype" that surrounds technology promotion. Training preservice teachers to use technology requires that they be prepared to advocate for technology that supports their instructional goals and those of their students. It's likely that they will need to function as change agents in a system constantly under pressure to reform. For this reason technology use is not presented as merely a series of technical competencies, but also as having psychological, social, and economic aspects.

Self-efficacy and a reflexive approach

As defined by Bandura (1993), self-efficacy relates to an individual's perceptions about his or her own ability to perform a specific function. As such, it is a good predictor of behavior. People with low self-efficacy tend to shy away from those situations where they feel they have little control or ability to handle a task. Consequently, those with low self-efficacy toward technological innovation are likely to feel high levels of anxiety, and as a result, resist learning to use computers. Those same feelings of inadequacy about technology regulate the degree of commitment and perseverance an individual is willing to put forth to the learning situation (Olivier & Shapiro, 1993). Mager (1992) suggests that performance mastery is the principal way to help build self-efficacy. Technology portfolios offer a means to document performance mastery as a personally relevant process, and e-journals help students reflect about the whole process.

The role of reflexive thought in preservice technology training is central to students' growth beyond a basic level of skill and operational facility in using technology and media for education. The use of technology portfolios and e-journals places an explicit focus on the relationship between technology applications and instructional methods. This reflexive approach to technology training encourages students to consider technology as both a user/learner and a user/teacher. In this way, students articulate their awareness of the effectiveness of instructional methods supported by technology and can develop skills to become thoughtful decision-makers regarding its uses. For example, by fostering opportunities for metacognitive development, a reflexive approach helps students gain accurate perceptions of how their behaviors may support or impede learning, as one student concluded in his portfolio:

Fall 1996 (Portfolio self-evaluation)

On September 3, 1996 I began a class on computer technology that I was sure would be a waste of my time. There was nothing I could learn that would enhance my teaching ability; I was positive. I guess it just goes to show that I shouldn't listen to my pride. We can all learn from the knowledge of others, so I have dedicated my portfolio a "Portfolio of learning" because this semester I learned that I am never too old to learn something that will benefit my students, and I should never let pride or fear of weakness stand in my way.

Specific competencies, such as those that require students to evaluate software, CD ROM's and websites can also nurture self-confidence and self-reflexive awareness. Focusing student attention on evaluation processes helps them to realize that as users rather than as programmers or technical specialists, they possess sufficient knowledge to judge technology's instructional utility.

Conclusion

Too often novice technology users discount their own level of experience with word processing software as a useful foundation for further skill development. E-journals and portfolios shift the emphasis from one of achievement to one of effort. They help to make students' technology training a sense-making process that is constructed at their own pace and is driven by their individual needs and interests. As one student wrote in her Technology Portfolio:

Fall 1996 (Portfolio self-evaluation)

I was very nervous about this class when I first registered for it. The only computer skill I possessed was word processing, and I had previously been frustrated with computers when I did not know how to operate them. I looked forward to learning about computers so that I could put aside some of my frustrations, yet I was worried that I would not be able to understand the material. Now I feel quite comfortable with computers. I may not be able to answer all the questions about computers or do some applications really fast, but I have enough knowledge about computers that I could probably figure out most problems.

A reflexive approach to technology training may employ performance-based approaches, such as the weekly skill-based competencies. However, a reflexive approach is constructivist in design as well because students actively participate in making their own meaning. Technology portfolios support students' learning by requiring them to make deliberate choices about what to include in their portfolios and to link their present skill level to a skill level at an earlier point in time. Technology training can be a thoughtful experience when it encourages students to comment on their learning through the use of e-journals and technology portfolios, to work collaboratively in both learner and instructor roles, and to critique technology's educational function. Finally, e-journals and technology portfolios
can be used as a means of meeting and demonstrating ISTE/NCATE guidelines as well as many states’ licensure requirements for teachers.

Many professional teacher education programs require students to take courses that prepare them to integrate the use of various technologies in their daily teaching activities. One approach to the design of such courses involves using a theme or anchor around which various learning activities take place. This approach has been referred to as “anchored instruction” (Bransford, Sherwood, Hasselbring, Kinzer, & Williams, 1990).

While researchers have claimed that anchored instruction is an effective approach in preparing preservice teachers to integrate technology (Bauer, Ellefsen & Hall, 1994; Bauer & Summerville, 1996), very little empirical data exist to support these claims. In this study, the researcher designed, tested, and employed an instrument in order to answer the following research questions:

1. will students feel that they learned basic technology skills?
2. will students understand why the instructor used an anchored instruction approach?
3. will students feel that they can apply anchored instruction as a technique for technology integration in their own teaching?
4. will students have enjoyed participating in the class?

Forty-eight students enrolled in three sections of a one-semester-hour preservice educational technology class during the summer, 1997, participated in this study. Table 1 summarizes the characteristics of the subjects involved in the study.

Limitations of the Study

The reader is cautioned that there are three limitations to this study that may threaten its generalizability. First, the researcher also acted as the instructor for these preservice educational technology classes. This individual has had nearly twenty years of classroom experience and has won awards for excellence in teaching. It is possible that other approaches could have yielded similar results in terms of student satisfaction.

Second, this study utilized intact groups with a single treatment-posttest design. No control group was used, and there were no attempts to randomly select subjects for this study.

Finally, at the time of the writing of this article, internal reliability statistics have not been calculated for the instrument used. Also, a significant amount of qualitative data including field notes and open-ended responses designed to triangulate the Likert questionnaire was collected. Analysis of this data is ongoing.

Using MECC’s Oregon Trail as an Anchor

The instructor began by explaining the basic concepts of anchored instruction to the class, and then employed the principles of anchored instruction in teaching the class for its entire six-week duration. During the last session, students were given a fifteen-item questionnaire that focused on the four research questions mentioned previously.

Oregon Trail, MECC’s popular computer simulation program, was selected as the anchor for the course. This program fit the requirements of a good anchor by providing a rich learning environment upon which many learning activities could be built (McLarty, Goodman, Risko, Kinzer, Vye, Rowe, & Carson, 1990). All of the activities involved the integration of appropriate technologies, including word processing, spreadsheets, presentation software, drawing and painting programs, hypermedia, Worldwide Web exploration, and audio/video processing.

The researcher borrowed five key decision points for using anchored instruction from McLarty et al., (1990) and added one additional item. They were as follows:

- Choosing an appropriate anchor (McLarty et al., 1990)
- Developing shared expertise around the anchor (McLarty et al., 1990)
- Expanding the anchor (McLarty et al., 1990)
- Teaching with the anchor (McLarty et al., 1990)
- Allowing student exploration (McLarty et al., 1990)
- Sharing what was learned from the anchored instruction (Bauer, Ellefsen & Hall, 1994)
Students first explored MECC’s Oregon Trail simulation program in order to develop a shared expertise around the anchor. They collected data as they ran through the simulation and organized it using a spreadsheet program. The resulting product looked like the sample shown in Figure 2.

This activity accomplished at least two objectives. First, students learned how to collect and organize data electronically. Second, students learned basic spreadsheet operations such as data entry and creating formulas to automatically calculate values (miles traveled between landmarks, miles traveled per day, etc.). Students then formulated and tested hypotheses based on the data that they collected. For example, they hypothesized that the number of miles traveled per day would decrease as the wagon train crossed the mountainous regions of Wyoming, and that travel would be slower during rainy or snowy months than it would be during dry months. Again, students used the data that they collected to affirm or contradict their hypotheses.

Another type of data that is easily accessible is the trail log or diary (depending on which version of the Oregon Trail software is used). Both the trail log and the diary keep track of daily events during the simulation. Students exported these files to a word processor and used them as a basis for a creative writing activity where they wrote fictional letters home from the trail. Students were encouraged to embellish the details of their vicarious adventures along the Oregon Trail.

The next activity involved exploring the Worldwide Web to see what information students could find related to the Oregon Trail. This activity was designed to follow McClarty et al.'s third and fifth decision points—expanding the anchor and allowing student exploration. Students were organized into small groups. Each group selected a site along the Oregon Trail to explore. Several excellent Worldwide Web sites were identified including the following:

- http://pbs.org/opb/oregontrail (This website includes sections on facts, myths, and trivia along with a teacher’s guide for using the PBS video series)
- http://www.teleport.com/~otic/stories ("The Road to Oregon: Articles About the Oregon Trail")
- http://www.isu.edu/~trinmich/facts.html (Idaho State University’s “Fantastic Facts About the Oregon Trail")
- http://www.ukans.edu/kansas/seneca/oregon/mainpage.html (University of Kansas “Oregon Trail: The Trail West")
- http://www.ohwy.com/or/or/oregontr.htm (Oregon Online Highways)
- http://www.mecc.com/ies/oto/oto.html (MECC’s online version of the Oregon Trail computer simulation)

Once the information was gathered and processed, Powerpoint presentations were developed. These presentations included scanned pictures, images downloaded from the Worldwide Web, Quicktime movies, and text. Students used a computer projector to share their projects.

Students expanded the anchor even further by developing individual Oregon Trail Hyperstudio stacks related to their areas of interest or academic major. One earth sciences student, for example, developed a stack that explored various geomorphic features along the trail. A music major developed a stack that explored composers of the 1840’s.

**Anchored Instruction Questionnaire:**

**Summary of the Data**

At the conclusion of the course, students completed a fifteen-item Likert questionnaire in order to answer the research questions. There were between three and five items

for each of the four research questions. The data summarized below include (a) the research questions, (b) the individual items from the questionnaire related to each research question (not in the same order in which they appeared on the original questionnaire), and (c) tables containing percentage data for each item from the questionnaire.

Research Question 1. Will students feel that they learned basic technology skills?
   Item 1. I am satisfied with the amount of information that I learned in this class
   Item 2. I learned very little about educational technology in this class.
   Item 3. I learned a lot about educational technology in this class.
   Item 4. The projects in this class were a waste of time.

Research Question 2. Will students understand why the instructor used an anchored instruction approach?
   Item 5. I understand why the instructor used the Oregon Trail simulation as a theme or anchor for this class.
   Item 6. I have no idea what anchored instruction is.
   Item 7. The instructor should continue to use anchored instruction as a basis for teaching this class.

Research Question 3. Will students feel that they can apply Anchored Instruction as a technique for technology integration in their own teaching?
   Item 8. Using the Oregon Trail simulation as the anchor in this class helped me understand how to integrate technology into my own teaching.
   Item 9. I understand how I can use Anchored instruction in my own teaching.
   Item 10. Using the Oregon Trail simulation as the anchor in this class confused me about how to integrate technology into my own teaching.

Research Question 4. Will students enjoy participating in the class?
   Item 11. I looked forward to coming to this class.
   Item 12. I dreaded coming to this class.
   Item 13. I enjoyed using the Oregon Trail simulation as a basis for the projects in this class.
   Item 14. I would have preferred another approach - rather than anchored instruction - in this class.
   Item 15. Using the Oregon Trail simulation as a basis for the projects in this class was a bad idea.

Discussion and Conclusions

The data indicate that the anchored instruction approach worked well for the preservice educational technology course. Students reported:
- they did learn technology skills that they could use in their teaching;
- they understood why the instructor used anchored instruction;
- they could apply the approach in order to integrate technology into their own teaching; and
- they enjoyed participating in the class.

Technology integration is an important skill for preservice teachers to develop if they are to be innovative and successful professional educators. It is a topic that is discussed in most preservice educational technology courses and in textbooks. Rarely, however, do instructors model technology integration using techniques that preservice teachers can easily apply in their own teaching. Anchored instruction is one model that can be used to show preservice teachers how to integrate appropriate technologies in their teaching regardless of the grade level or content area. The data presented in this study clearly indicate that students responded positively to this approach and learned essential technology skills in the process. There are, perhaps, other models and approaches that may be as effective in preparing the current generation of teacher candidates. Individuals in charge of preservice teacher technology preparation should actively seek out these models and approaches and conduct further research to determine their effectiveness.

For an update to this article, plus other information related to anchored instruction in preservice educational technology courses, check the following URL: http://

TEACHING ‘HOW TO’ TECHNOLOGIES IN CONTEXT

Patricia Randolph Leigh
Iowa State University

Many educators contend that learners learn best when they are active and engaged in activities that are linked to real-life experiences (Bednar, Cunningham, Duffy & Perry, 1992). The concept of having new learning related to personal experiences or prior knowledge is key to situated learning theory and also central to the constructivist paradigm (Fosnot, 1992). Such activities are thought to be both motivating, causing the learner to better attend, and a trigger to prior knowledge. Situated learning is concerned with the learning activities as well as the learning environment. In clarifying the challenges, Harley (1993) states, “for the classroom teacher the challenge of situated learning theory becomes one of developing methodologies and course content that support cooperative activity, and reflect the complex interaction between what individuals already know and what they are expected to learn, recognizing that ultimately meaning can only be established by and not for the learner” (p. 47). The students also face challenges in that “the role of learners within authentic, situated learning activity is one whereby they are encouraged to recognize that they themselves are intentional agents creating their situate experience within a culture of activity, as opposed to being simply external observers or incidental actors” (p. 49).

Reformers, futurists and educational technologists agree that advanced technologies can go far in creating and supporting complex and rich learning environments (e.g., Dede, 1996; Means, 1994; Cognition and Technology Group at Vanderbilt University, 1993). The classroom teacher is thus encouraged to learn the techniques for creating authentic learning environments as well as become familiar with the technologies that support them. In fact, the encouragement to use technology in the classroom in compelling ways has found itself in the formalized guidelines and standards written by the International Society for Technology in Education (ISTE) and the National Council for Accreditation of Teacher Education (NCATE, 1995). Consequently, the faculty in teacher preparation programs are not immune to these challenges. In preparing teachers that will likely create rich learning environments in the classrooms of the future and use technology in meaningful ways, faculty are encouraged to model such practices throughout the preservice curriculum (Thompson, Schmidt and Hadjiyianni, 1995). In order to use or create technology supported environments or incorporate technologies into daily curricula, classroom teachers need at least a basic knowledge of the operation of the technologies. To meet this need, technology courses in curriculum and instruction departments naturally contain ‘how to’ components. In introductory undergraduate and graduate level instructional technology courses at Iowa State University, students are taught how to use photography and video technologies as well as computer-based tools. In these beginning courses, the emphasis is on ‘how to’ operate the technology, although effectively integrating the technology or the technology products created by the students into learning environments is discussed throughout these courses. The problem becomes how to model the use of situated learning in the teaching of these ‘how to’ technologies. One could possibly use computer simulations to teach the complex nature of certain technologies. Such a strategy was described by Valde, Bower and Thomas (1996) in teaching the workings of the computer memory as students strive to learn computer programming and the basics of how a computer works. However, the instructor of the graduate introductory instructional technology course described in this paper chose to create a situated learning environment using low-technology everyday surroundings to teach the fundamentals of photographic and video production. It should be pointed out that throughout the course, students were encouraged to use the learned techniques to enhance their classrooms or to create video-based learning environments.

The introductory instructional technology course is a survey course covering various technologies. The instructor decided to link the photography, audio, and video laboratory exercises together into a cohesive laboratory project anchored in the campus environment. Small groups of students worked together learning to operate 35mm single lens cameras, video recorders, video presentation equipment (Elmos), video editing stations, video dubbing equipment and audio equipment. In addition, the product from one laboratory exercise fed into subsequent exercises. This idea of connecting the assignments is somewhat different than what is done in survey courses where each laboratory
exercise is independent of another. In such cases where the assignments or exercises are independent, a group’s performance on a photography assignment does not influence their performance on the video editing exercise or a final laboratory product. By linking the exercises together, the instructor hoped to more accurately reflect real-life video production. Thus, each student group learned the various steps of video production by performing the laboratory exercises. The instructor specified a video tour of the Iowa State University campus as the final laboratory project thus providing a real-life environment in which the students could relate and have shared experiences.

This paper outlines the organization of the laboratory exercises and relates how learning in context aided student groups that were expected to use the knowledge attained in the laboratory classroom to produce a graded video project outside the laboratory classroom. The graded video project would contain many or all of the components of the laboratory project yet focus on a social issue of their choosing.

Methodology

During one of the first laboratory exercises, the students were instructed in the use of the video presenter (Elmo) machine to transfer prints to video and were given brief demonstrations on the use of the video editing stations and audio equipment. The photography laboratory was the first laboratory involving in-depth exposure to the technologies. Since photography was not in the area of expertise of the instructor, a senior graduate student delivered a twenty-minute session including direct instruction on the parts of the camera, emphasizing the use of aperture and shutter speed settings to achieve equivalent exposures and to alter the depth of field. During this session each student had a single lens camera to handle. Afterwards, the students were asked to form groups to carry out the laboratory assignment.

Photography assignment

The instructor had sketched various buildings or points of interest around the Iowa State Campus. These roughly drawn sketches were then transposed onto laminated storyboard cards created in PowerPoint (Figure 1). An effort was made to include long, medium, and close range shots. The students divided into three groups and each group was given one camera, one roll of 24 exposure color print film, and an exposure recording sheet (Figure 2). The film was loaded into the cameras prior to leaving the classroom. Because one group failed to load the film properly and no extra rolls of film were available, the class was divided into two groups rather than three. The two groups of students were each given six of the twelve storyboards and were instructed to photograph the points of interest sketched on the cards. They were further instructed to allow each member of the group hands-on experience with the camera and to experiment with various exposures (aperture and shutter speed) for each storyboard card. For each film exposure, the students were to record the storyboard card number, aperture, shutter speed and ASA setting.

Figure 1. Storyboard card

Figure 2. Excerpt of recording sheet entries

The student groups returned the two rolls of film and the recording sheets to the instructor. They discussed the exercise and pointed out that some of the storyboard shots were impossible to obtain without special lenses. They emphasized the importance of the photographer being given that information or being able to anticipate the need. Once the film was processed, the storyboard cards were displayed along with the corresponding prints of various exposures and small graphics depicting the aperture and shutter speed settings that were indicated on the recording sheets (all exposures used the same ASA settings). The students examined the prints and commented on the effects that aperture and shutter speed settings had on exposure and depth of field (figure 3). Because of time constraints during the summer session, the prints were transferred to video tape by the instructor rather than the students, and put aside for a later laboratory assignment. The students had observed the techniques for placing photographs to video and would use this technique for a photo essay assignment and later for the graded video assignment. At this point the instructor focused on how still photographs are used in the context of creating a video and did not want to consume undue laboratory time repeatedly carrying out the technique of transferring the many photos needed for the laboratory video.

Educational Computing Course — 247
Video assignment

Prior to performing the video assignment, each student was given a video recorder and practice tape to handle. The instructor reviewed the operation of the recorder and the techniques covered in the assigned readings as the students followed along. For the actual assignment, pairs of students were given one video camcorder and video tape and instructed to take video footage of the structures and grounds comprising the College of Education. They were made aware that this footage should fit into a video tour of the campus along with the still photographs taken earlier. Suggested areas for recording were the terrace garden area and the college grounds where students sit and read or relax. Each pair of students was also instructed to interview a faculty member or a student about Iowa State. They were reminded of the video techniques covered in the assigned readings.

Upon returning to the classroom, some students realized that they overestimated their skill in the use of this technology that has become somewhat of a household item. One group inadvertently turned the recorder off each time they attempted to record the landscape or an interview yet video recorded their feet and captured their personal conversations as they walked along. Other groups experimented with in-camera editing by incorporating cutaways or motivated cuts in their footage. Viewing the exercise footage was both instructive and entertaining for the instructor and students.

Video editing assignment

Working from the photography storyboards, the instructor developed a script and then used the audio sound room equipment to narrate the script and background music onto a video tape (Figure 4). Three copies of this tape were made to serve as master tapes in the video editing assignment. The student groups worked together at the three video editing stations inserting footage from the tapes created from the photography and video assignment onto the master tape (with sound track only). Because of limited laboratory time, no one group attempted to insert all the graphics indicated on the script but instead began the assignment at staggered points in the script. Each group member had the opportunity to perform at least one video insert. The exercise was extremely challenging because the points for appropriate inserts were cued by the narrated script, yet the instructor’s voice was barely audible when using the editing stations. Though this was unfortunate, the frustration alerted the students to the need to select a narrator with the desirable voice quality and adequate recording volume when creating their graded video project assignments.

As we leave the Union’s front entrance we have a nice view of the Campanile. This memorial was rededicated by the current university president and chimes out various musical renditions usually over the noon hour. You can also set your
watch by the campanile clocks for they ring on the quarter hour.

Figure 4. Excerpt from video script.

Audio and Dubbing Assignment

Though the audio sound room was demonstrated, the students did not have significant hands-on experience with the equipment up to this point. As pointed out earlier, the instructor produced the sound track for the video editing assignment in order to conserve time and model audio production techniques by giving them a product to work with that incorporated the various techniques (i.e. fade ins). Student groups would need to produce such a sound track for their graded video projects, therefore they were given laboratory time to practice the use of audio production techniques. The three groups of students rotated with one group in the audio room while the other two groups worked at the video dubbing stations. Each group of students laid a different portion of the sound track using the script that the instructor created. This exercise was for practice only and did not affect the final laboratory videotape.

During this same time period, one group of students at the dubbing station copied their portion of the video editing assignment onto the tape that would be the final video laboratory product. The second group simply watched and facilitated the copying process. The rotation schedule for audio and dubbing stations follows:

First 10 minutes
- group 1 — copy your video assignment to the master video tape
  (group 3 watches and facilitates)
- group 2 — lay your portion of the practice sound track

Second 10 minutes
- group 2 — copy your video assignment to the master video tape
  (group 1 watches and facilitates)
- group 3 — lay your portion of the practice sound track

Third 10 minutes
- group 3 — copy your video assignment to the master video tape
  (group 1 watches and facilitates)
- group 1 — lay your portion of the practice sound track

Once the three groups had rotated through the dubbing station, the three video editing assignments had been transferred to one video tape - the final video laboratory product. The students and instructor returned to the laboratory classroom to view and critique the final video.

Conclusions

From the instructor’s perspective, the success of this approach, teaching various technologies in context, was determined by how well the students adapted the photographic and video techniques used in the laboratory assignments to create their graded video projects. By the end of the second week of this four week course, the students had divided themselves into three groups and had chosen the topics for the video projects on which they were to collaborate. The only parameter supplied by the instructor was that the topics of the videos focus on social issues. After a lively whole class discussion in which the instructor offered no input, the students decided upon ‘staying in school’, ‘recycling’ and ‘elder care’ as video project topics and the individuals grouped themselves according to shared interests in the three topics. The three groups had to work on the projects outside of class or laboratory time. The video project consisted of a script and videotape that used a continuous sound track onto which still pictures or video footage were inserted.

The instructor evaluated the three projects very highly in that the video scripts and tapes met or exceeded expectations. During the production process, the student groups exhibited a high level of enthusiasm for and commitment to the projects. This seemed to result from being involved in projects in which the group members had an interest or personal involvement. For example, the group working on the topic of elder care expressed a desire to produce a high quality videotape that could be used by a care provider in the area. A second group became interested in having their video about Iowa State’s efforts at recycling shown on the campus television station. Teaching the ‘how to’ technologies in a context in which the students could relate and subsequently allowing them to apply the new knowledge in contexts that were of personal interest or linked to personal experiences seemed to contribute to the success of the photography and video unit. Furthermore, success also appears related to the fact that the students were able to see how the techniques taught in the laboratory actually fit into producing the laboratory product and were later able to draw upon the laboratory experiences when involved in similar projects such as the graded videos.

Patricia Randolph Leigh, Ph.D. is an Assistant Professor, Curriculum and Instruction, Iowa State University, Center for Technology in Learning and Teaching, College of Education; N108 Lagomarcino Hall, Ames, Iowa 50011-3192; (515) 294-3748—office; (515) 294-6206—fax; pleigh@iastate.edu
This section on Educational Leadership discusses a variety of salient issues regarding leadership. Leadership comes from many sources. The reader will see in the articles traditional leaders, principals, and what we may consider non-traditional leaders in education, students. The articles seek to solve issues that challenge and force changes in our educational environment. Change occurs when the climate is conducive to efforts brought on by the leader.

In this section the authors have viewed leadership through multiple lenses. These lenses include leadership and technology and educational reform. Technology is a hot item with the increased funding from public and private funds. With the increased funding, traditional leaders are trying to implement technology without the knowledge or the support to do so. Policymaking is another area that needs to be addressed as educational reform is debated.

The following is a brief synopsis of the papers included in this section:

- Aguilera and Mims and McKenzie’s papers describe how practicing administrators lack essential knowledge and skills in the area of technology. Administrators can improve the use of technology in their schools by becoming familiar with it themselves.

- Carlson discusses the systematic policy formation as it contributes to the strategic planning process for school technology.

- Cathey, Chaffee, and Sharp’s paper describes in detail the SWAT team approach to integrating technology into the curriculum revolves around the creation and development of a core group of teachers from different disciplines who act as a catalyst for change within their curricular area. SWAT stands for Savvy With All Technology.

- Facciola and Roberts shows how many administrative hurdles need to be removed in order to enhance the benefits students receive from using computers. These hurdles include budget, training, support, staffing, changing roles, usage policies, and community access.

- Hamilton, Eagleton, and Corkill discuss the lure of bells-and-whistle technology that leads districts in making hasty decisions when purchasing. Without a clear vision of how to successfully implement technology will lead spending huge amount of public money or relying on repeated bond issues. Levine also looks at making appropriate strategies in realizing the maximum benefits of using technology.

- Heflich looks at the impact of technology on changes in teacher practices and student learning. This paper attempts to clarify relationship between school culture and technology and how this understanding is needed in the face of school reform.

- Kauffman and Hamza discusses ten fundamental ideas to change our educational systems function within an Industrial Age economy to an Information Age economy.

- Kirby focuses on the realm of variables that influence distance education in terms of student performance. This article compares distance education classroom to a traditional classroom.

- MacNeil and Delafield’s paper shows how technology has the potential of reforming education. The key person in this is the principal. It asks principals to rate the importance of technology implementation and professional development.

- MacNeil and Harmon discusses how technology can enhance human contact and facilitate interpersonal communications.

- Queitzsch shows how a neutral organization, Northwest Educational Technology Consortium, can be used to facilitate outcomes in using technology in a pre-service education program.

- Riedl, Smith, Ware, Wark, and Yount explores attitudes, skills, and knowledge needed to support a technology-rich environment. Deminico also looks at the attitudes of educational decision-makers about technology use.

- Schulz-Hamsa discusses the forging alliance between inclusion and technology.
Stockebrand and Altoff looks at the seven core values which U.S. citizens agree should be taught in school. Phi Delta Kappa has developed the League of Values-Driven Schools and discusses how this will lead education into the twenty-first century.

Sullivan and Keating administered a survey to determine computer literacy amongst principals and also the training needs.

The Early Adopters discuss an option of providing leadership in the implementation of technology. Students may provide an option to complement administrators' role as a leader.

Wark, Beasley, Erwin, and Zimmerman's paper explores a proposed model to provide administrators with a workable method to connect assessment, School-to-Work initiatives, technology, and students.

Zimmerman and Wark look at the development of teachers' technology skills and the integration of these skills into their content area classrooms.

Educational leaders have many issues to explore as we near the twenty-first century. The articles in this section provide insight in the use of technology, educational reform, policy making, and fundamentally who are the faces of our leaders.

The Early Adopters: Rhea Walker, Polly Mumma, Debra Kurth, Stacey Long, and Stephanie Sasser; Center for Technology in Learning and Teaching, N108 Lagomarcino Hall, Iowa State University, Ames, Iowa 50011, Email: tea@iastate.edu, Web Page: http://www.educ.iastate.edu/cilt/tea/homepage.html
Picciano states, “While the effectiveness of computers in instruction continues to be debated, the effectiveness of computers to provide information, manage budgets, and improve operations has been accepted (1998).” Administrator’s can help improve the use of technology in their schools by becoming familiar with a few basic computer software tools. The Association for Supervision and Curriculum Development (1997) discusses various uses of current technology in our schools today. Cornett (1983) stated that the person most responsible for the success or failure of a public school was the principal. Most university preparation programs meet their state’s administrator certification requirements by offering a series of courses, focusing on knowledge, not on skill development. “Few critics propose solutions or even clear directions for improvement,” (Witters-Churchill, L. W., & Erlandson, D. A. (1990). Most students in the author’s administrator preparation classes, both at the principal and superintendent levels, indicate that they know very little in the area of technology. The knowledge level of practicing administrators is also very poor. As a former superintendent of schools, the author also found that practicing administrators lacked essential knowledge and skills in the area of technology. With university preparation programs for principals viewed as less than adequate (Finn, 1986; Gorton & McIntyre, 1978; Hills, 1983; Kelley, 1986), it is imperative that present and future administrators learn these tools very quickly and effectively.

Browsing and Using the Internet

The Internet gives administrators the ability to communicate with other people and computers worldwide (Ryder & Hughes 1997). It is also a communication tool for gathering information available instantly from around the world. Rather then learn the history or detail about the Internet, the author suggests using the Internet for short periods of time over a semester. The following are suggested steps for learning the Internet:

**Step 1.** Use a computer with the capability to read Microsoft word files and which is connected to the Internet or Web. This is necessary for using this document to its maximum potential.

**Step 2.** Your first task is to become familiar with the Internet by accessing the author’s activities from the Internet. This can be accomplished by using the following address (or by clicking on the following Web locator if this manuscript is read on a computer): http://www.csbs.utsa.edu/users/raguiler/fin1.htm. More structure and information on using the Internet is available on the Internet by accessing the Internet Handbook at http://home.netscape.com/eng/mozilla/2.01/handbook/. Complete all the activities on this particular Web page. The objectives for this assignment are: a) A student will become familiar with and use the Internet. b) A student will become familiar with icons used on the Internet. c) A student will be able to conduct a “search” on the Internet. Once the first assignment is completed, advance to the bottom of the assignment and click on Assignment 2: http://www.csbs.utsa.edu/raguiler/fin2.htm. Once the two assignments are completed, a student’s knowledge level about the Internet should increase greatly providing the foundation for more in-depth and personal Internet searches.

Organizing Your Favorite Web-Sites

As you learn to navigate the Internet, you will find Web pages of interest and may want to use them again at a later time. The Favorites Icon allows you to save and list all the Web pages that you would like to use at a later date.

**Step 1:** Find a Web page on the Internet that you would like to use in the future.

**Step 2:** Click on the Favorites Icon

**Step 3:** Click on the Add to Favorites Icon

**Step 4:** Repeat steps 1-3 as you find other Web pages of interest to you.

Once you have completed Steps 1-4, you can view the list of bookmarks that you have added to the computer. By
Organizing Your Bookmarks

As the list of favorite sites increases, the listing should be organized in a meaningful way by creating "folders" for each main category of bookmarks. For example, by creating a folder entitled "Personnel," you would "click and drag" any bookmark from your list into the "Personnel" folder. You simply review your listing of favorite Web pages and determine the major categories for each folder to be developed.

Step 1: Click on the Favorites Icon
Step 2: Click on the third yellow briefcase icon to create your new folder.
Step 3: Type the name of your new folder (i.e. Personnel).
Step 4: Click on the "OK" icon.
Step 5: Click on the "Add" icon. You have now successfully added a folder entitled "Personnel" into your favorites listing.
Step 6: Repeat Steps 1-5 for adding additional Folders to your list of favorites.
Step 7: Once you have completed creating the major Folders, click on the "Favorites" Icon, click on the "Open Favorites" Icon to get to your list of Web page, and "click and drag" each Web page into its particular folder. Other folders that may be useful to an administrator are Legal Issues, Classroom Support, Grants and Resources, Student Sites, and Schools on the Web. You may create a "Miscellaneous" folder to handle those Web-pages that do not fit into the categories that you have created and place the remaining Web pages into this new file.

Other Interesting Web-Sites for Administrators

Job Searches. If an administrator is interested in searching the Internet for employment opportunities, the following Web-sites provide a good start:
- Texas Association of School Administrators’ Job Bulletin: http://www.TASAnet.org/cgi-bin/jobs

Legal Sites. The Internet also serves as a good source for information on legal issues. The following sites provide the springboard for legal information:
- Law by Country: http://www.law.emory.edu/LAW/refdesk/country/foreign/
- Legal Material by Topic: http://www.law.cornell/topical.html
- Legal Research Jumpstation: http://www.paralegals.org/LegalResources/home.html

Professional Organizations. Information on many professional organizations is now available on the Internet. Other organizations are generally available through these sites:
- Association for Supervision and Curriculum Development: http://www.ascd.org/
- American Association of School Administrators: http://www.aasa.org/
- Texas Association of School Administrators: http://www.TASAnet.org/
- Other Organizations: http://www.yahoo.com/Education/Organizations/Professional/

Using an Electronic Spreadsheet (Microsoft Excel)

An electronic spreadsheet can be used to assist an administrator in organizing and/or calculating data in a very quick and efficient manner. The limitations in the use of the electronic spreadsheet are generally limited to the level of expertise of the user. The following news address: news://csbs.utsa.edu/utsa.csbs.ed15103 will allow you to experience an electronic spreadsheet that has already been developed for some school activities. Once you have accessed the spreadsheet program through the Internet, simply follow the directions on each worksheet to complete this learning module.

Lesson 1: Using the Student Enrollment Projection

This module is designed to assist you in projecting student enrollment changes in your school or school district. It is based on a Trend Analysis Statistical Model and will require student enrollment data over a five year period. Projections are then made for an additional five years.
- Open the Excel Spreadsheet program
- From the File menu, open file in Drive A
- Once in Drive A, open "Aguilera"
- (If you performed these steps correctly, you should now be on page one of the Electronic Spreadsheet Program for Administrators (ESP) which is labeled CONTENTS

Move your cursor around the spreadsheet and change the information in any of the cells with words in them. What did you discover?
- Now move the cursor to the various "red dots" found throughout the first page of this Electronic Program. Again, summarize what you see at every point having a red dot.

Lesson 2: Using the Salary Schedule

For your second operation, move to the next worksheet in the ESP Workbook: SALARYSCHEDULE. Explore the Salary Schedule as you did previously by placing the cursor...
at the “red dots” throughout this worksheet. After reading the “notes” found in the worksheet, write down what you have analyzed about this worksheet. In other words, what will it do and how do you get the information.

Lesson 3: Using the Scattergram
The Salary Placement Scattergram is your next activity. Again, scan the worksheet with your cursor and describe the purpose of this module.

Lesson 4: Using the Salary Cost Module
The last module in this ESP workbook, is the SALARY COST module. What is the purpose of this module and what information can you hope to gain from the worksheet?

Lesson 5: Modifying the Enrollment Projection
This lesson is designed to allow you to actually use each of the modules by inputting your own information into some of the ESP Modules. The reason you have been unable to change any of the modules or input information into them is that each of the worksheets have been protected. You will learn how to change the protection status of a worksheet by changing it to an unprotected worksheet. Once you accomplish this, the worksheet module will allow you to input information as required.

Step 1: Go to the Enrollment Projection Module
Step 2: Click on the Tools Icon on the top Toolbar
Step 3: Click on the Protect command
Step 4: Click on the Unprotect Worksheet command
Step 5: You are now ready to input information into this module, but you must be very careful. Do not type any information into the red section of the worksheet. If you do, you will lose the formulas built into the spreadsheet and the calculations will not be accurate. Type in the following numbers (do not type in any words):

- Student Enrollment Five Years Ago: 40,000
- Student Enrollment Four Years Ago: 41,000
- Student Enrollment Three Years Ago: 41,500
- Student Enrollment Two Years Ago: 42,200
- Student Enrollment This Year: 43,000

What is the projected student enrollment for next year? What is the projected student enrollment in three years? What is the projected student enrollment in five years? What is the purpose of the chart and why would you want to utilize a Trend Analysis in the first place?

Lesson 6: Modifying and Using the Salary Schedule
Step 1: Use the same process that you used in the previous activity for Unprotecting the Salary Schedule Module.
Step 2: Develop a salary schedule that is increased by 5% horizontally (across) and 4% vertically (down) with a starting salary of $23,500. What is the salary for a teacher at Step 2 with an M.A.? What is the salary for a teacher at Step 10 with an Ed.D.? What is the salary for a teacher at Step 5 with a B.A.?

Powerful Presentations
An electronic presentation is another approach an administrator should utilize for becoming familiar and confident with technology. Microsoft Office PowerPoint Presentation will be the software program described in this section. By following this module, you will be able to create a presentation with a title page, a bulleted page, and a bulleted page with clip art.

Choosing a Background for Your Presentation
Step 1: Click on the PowerPoint Icon
Step 2: Click on “Template” and click the “OK” button to allow the selection of a background for your presentation.
Step 3: For the purpose of this lesson, move your cursor to the “Portrait Notebook” icon and click “OK.”

Creating a Title Page for Your Presentation
Now you are ready to create your first slide. This step allows you to select the type of slide you will use from a variety of templates or Auto Layouts.

Step 1: Place the cursor on the first Auto Layout and click “OK.” You are now ready to create your Title Page.
Step 2: Place your cursor on the section of the slide, which reads “Click to add title,” and follow the instructions. Type in the title and subtitle of your presentation.

Creating A New Slide
Step 1: To create a second slide, place your cursor on the “Insert” menu found on the toolbar at the top of the screen and click your mouse once.
Step 2: Click your mouse once on “New Slide.” This action will take you to the Auto Layout section once again.
Step 3: Place your cursor on the second Auto Layout, which is a bulleted list, and click “OK.”

Step 4: Follow the instructions on the Auto Layout for placing the title of this slide.
Step 5: Add the supporting information or “bullets” on the section “Click to add text.” After each line of information or bullet is added, hit the “Enter” key on your keyboard to create another bullet. Continue until 3-5 bullets are entered on this slide.

Creating Additional Slides
Step 1: You will now create a third slide by repeating step 1 in the previous section.
Step 2: Place your cursor on the ninth Auto Layout, which will create a slide with text and clip art. Click the “OK” button.
Step 3: Add the title of this slide.
Step 4: Add 3-5 bullets on this slide as instructed by the Auto Layout.
Step 5: Double click your mouse on the drawing to add clip art. This action will engage Microsoft Clip Art Gallery that contains several categories or types of clip art.

Educational Leadership — 255
art. Experiment with the clip art by placing and clicking your mouse once on the category you would like to see. For example, if you place the cursor on the "Animals" category, you will see several pictures of animals. For this activity, place your cursor on the polar bear and hit the "Insert" button. Congratulations! You have now created your third slide with clip art.

Saving Your Presentation

Step 1: Click once on "File" on the toolbar at the top of the screen.

Step 2: Click once on the "Save As" sub menu item.

Step 3: Type the name of your presentation: Sample Presentation

Step 4: Click on the "Save" button to save your presentation.

You now have the basic information to develop powerful electronic presentations. Your challenge is to continue playing with PowerPoint over the next year and learn to apply additional features found in this program. Try to make a presentation using PowerPoint within the next couple of weeks.

Summary of Your Lessons

Now that you have completed the Internet activities, the Electronic Spreadsheet activities, and Electronic Presentation activities, you should be more familiar with each of the applications that can be used immediately for improving your present position. The challenge you are now faced is to continue your personal development with these administrator tools and to begin experimenting with other technology programs.

Creating Technology Policy: A Systematic Model

Randal D. Carlson
Georgia Southern University

Policy making involves guiding decision making over long time periods and wide areas of interest for leaders and resource managers. First (1992) ascribes three focused characteristics to policy making: functioning from a strategic perspective, providing developmental guidance and clarification for major objectives, and furnishing priorities for resource allocation.

Policy, then, provides the steering mechanism that enables planning to take place. It is a first step in the planning process that enables the establishment, clarification, and prioritization of strategic goals and objectives. The tests of successful policy are an examination of the program accomplishments to determine whether the intended beneficiaries are truly profiting from the initiative and a judgment about the fairness of the policy to all constituencies. This paper will examine systematic policy formulation as it contributes to the strategic planning process for school technology.

Levels of School Technology Policy

Policy affecting school technology exists at three distinct levels that correspond with the three general governmental levels: federal, state, and local. It is not by accident that these levels exist. These levels represent the three hierarchical units that exhibit fiscal control over the schools, since one of the primary characteristics that determines policy is resource allocation. The entity controlling the resources frequently sets policies concerning use of the funds.

Federal policies that affect local technology policies are typically global in scope and funded above local levels, if they are funded at all. They are frequently promulgated by public laws or the resulting interpretation and implementation of these laws. A current example of this is the challenge for this nation “to connect every classroom in America to the information superhighway with computers and good software and well-trained teachers” (State of the Union Message, Jan 23, 1996). The President and Congress provided further policy guidance in this area with the passage of the Telecommunications Act of 1996 (McDonald, 1996).

State policies tend to be more focused on practical and specific issues. Legislatures play a major role at this level, although governors may wield some influence, as has been the case with Governor Zell Miller in Georgia. His policy on the use of lottery proceeds to fund instructional technology throughout the state has been uniquely applied because it must be used to fund “new” programs (Tucker, 1992). Of the thirty-six states and the District of Columbia that have established lotteries as a means of raising funds (Keating, 1996), Georgia’s policy stands out as the one that has not offset funds in the general revenue stream (Allen, 1991; Jones, 1994; Jones & Amalfitano, 1994). These funds have provided a realistically funded mandate to local policy planners.

Local policies reflect the cumulative effect of federal and state policies, but have a unique local flavor added to this level. That is because policy reflects the community values and needs and each community makeup is different. Technology policy in the Silicon Valley of California is much different than that of rural southeast Georgia. Employers require different skills and competencies and the general community expectation is different. School technology policy, then, is framed by these three very different influences. Given the competing nature of the policy influences and the fact that budgeting is usually a zero sum game, how does one form a rational technology policy?

A Systematic Approach To Policy Formulation

Policy does not appear. It must be formed and nurtured past many gray areas and hidden obstacles before a policy can be implemented. A systematic approach to policy formulation will enable policymakers to establish realistic policies in reasonable time frames. The Policy Formulation Model in Figure 1 is a process that can be used to guide policy formulation. Central to the process is the goal. The goal is the guiding force — the focus of the entire process. Circumscribing the entire process is evaluation. The evaluation element enables the process to continually be checked for adherence to the stated goals and objectives, which should reflect law at all three levels. In addition, the goals and objectives are continually subjected to the scrutiny of objective reality. This provides realism for the process.

Identify Resource

Collect Data

Develop Policy

Prioritize Options

Articulate Policy

Goals

Determine Guidance

Evaluation

Figure 1. The Policy Formulation Model.

The six elements that ring the goals may be accomplished in any order. This nonlinear approach allows accomplishment of these elements to be determined by the application context or the particular local situation. It should be recognized that very frequently, these elements are accomplished in more-or-less sequential fashion, beginning with either "Collect Data" or "Articulate Policy."

Beginning at "Articulate Policy" recognizes that policy formulation is a never-ending, circular process. Policy formulation may begin after a pseudo-policy is formed. Data are then collected and the rest of the systematic elements performed in order to verify the original policy formulation idea. Alternately, an existing policy may be examined to confirm that it continues to meet the tests of a successful policy. Current policy can be subject to the scrutiny that the systematic policy formulation process brings. In this manner, the process can be thought of as an evaluation process, either formative or summative.

Beginning at "Collect Data" recognizes that as one begins to formulate policy, one must gather as much data as possible about a circumstance prior to looking at policy alternatives. In this form, there are far fewer preconceptions about what the policy should be, therefore fewer alternatives to discount.

Goals

The goal of the policy can be determined from sources both internal and external to the system. External sources may be superordinate legislative or administrative bodies, state or federal governments or agencies, certifying bodies or professional organizations, or community associations. Goals can be specific or philosophical, for example, "Students will take 2 years of a foreign language in order to graduate with a college preparatory diploma," or "Students will graduate prepared to meet the challenges of the 21st Century." Internal sources are likely to be the stakeholders — the administration, teachers, and students. These stakeholders may raise an issue that they feel should be focused on, such as "Students should graduate from secondary school with better research skills." These goals are set up as a "strawman" to be verified, better articulated, and enhanced, or through the policymaking process, they will be modified or discarded.

Collecting Data

One must first of all decide upon the kind of data that must be collected and the motivation behind the data collection effort. Data are collected for two general reasons. The first is to articulate or validate the goals that drive the entire process. These data could be "hard" or factual, but are more likely to be opinions. The difference is an important one for policymakers to recognize. Factual data can be verified by sources independent of one individual or group. For instance, the statement, "The students at Wayland Elementary School do not have enough access to technology," may or may not be supported by the fact that in each classroom there are 5 multimedia computers hooked up to the internet, a TV with satellite feed, a videodisc, and a VCR, with access to 125 different software titles and 100 videotapes in the media center.

The second general reason for data collection is to specify the target state and the current state. The target state attempts to identify the situation that must be attained while the current state represents the existing situation. These states are sometimes called "what should be" and "what is." This type of data is more likely to be factual than the preceding type. Using the technology example again, one may collect data on required technology and also existing technology.

Data collection of factual information may be accomplished through existing (sometimes called archival) records, observations (depending on the characteristic observed), and tests; opinions may be accomplished through interviews, focus groups, questionnaires (surveys), or community forums. Factual information is most likely to be collected using quantitative data collection techniques, while opinions are most likely to be acquired through qualitative data collection techniques. Numerous books are written about data collection. For this discussion, it is sufficient to say that after data are collected, the goals can be verified and refined providing the policymaker with a stronger basis for understanding what the target state should be and the current state is.

Supporting the general goal of "schoolwide technological literacy," the policymakers may collect data on the target state. They may research existing law and higher level policy to discover current guidance. They may send out questionnaires to similar schools throughout the state, region, and nation to find out what motivated the existing policies and
the strength of the feelings for those policies. They may conduct interviews with specific individuals who have special expertise in the area or whose opinion would be particularly helpful in the situation. They may conduct focus group studies to find out opinions of teachers, students, or other affected groups. They may conduct community forums to find the community feelings.

Determining the current state is frequently easier, because one is trying to find "what is" instead of "what ought to be." To do this, one must simply go on a fact-finding trip — in fact, much of the data can be collected concurrently with the target state data. This data is dominated by factual data. Examples of the data and collection techniques may be:

- research of existing measures of accomplishment, such as standardized test scores, attendance, or discipline incidents.
- surveys of the stakeholders (teachers, students) to determine current level of accomplishment or they may conduct a focus group to try to get the same type of information.
- interviews of other stakeholders (principals, curriculum specialists, media specialists) to determine their perceptions.
- observations of the use of technology in the educational process.
- looking at existing records, such as equipment and facilities' records.

**Determine Guidance Needed**

Once the data have been collected, the policymaker must then compare the data concerning the current state to that of the target state. This may be a straightforward, simple task as may occur when a new goal has been added to an organization’s mission. It also may be complex, with many interacting components. The policymaker in this instance must organize the data in such a way that the differences between the current and target states are identifiable.

One aid in the accomplishment of that complex task is to build a table (Table 1). List in the columns the state and in the rows the characteristic. A helpful tool to use for determining the characteristics is the concept map (Figure 2). The policymaker must list and relate the essential characteristics of the goal. Once the characteristics have been described concerning current and target state, the gap should become apparent and the policy need established.

**Identify Resources**

Resources and the correlated constraints should have already been identified during the data collection phase. It is helpful to list these as we begin to solve the problem being researched. In that way, it is easier to realize where our strengths and weaknesses are. It is helpful to look at these from a positive aspect — “What can I do to maximize the potential strengths?” One must avoid the tendency to dwell on the constraints. However, these constraints may point to the need for a policy. Examples of resources may include time, funds, personnel, equipment, facilities, space, materials, group identification, philosophy, and organization. From this list, one can identify areas where solutions may evolve and areas that may be in need of further research and problem solving.

| Table 1. Needs Resolution Format. |
|---|---|
| **Target State** | **Current State** |
| Budget | Resources |
| Training | Access |
| Support | |

**Prioritize Options**

It is not unusual for the policymaker, especially when working with many goals, to identify the need for several policies in numerous areas. The process for arriving at the needed policy is one of brainstorming solutions and prioritizing the possibilities. Brainstorming solutions is a technique familiar to many planners (Jonassen, Hannum, & Tessemer, 1989). It involves systematically generating lists of possible solutions. These possible solutions are not initially judged on their merit. Their value is to provide an exhaustive list of possibilities and to generate other solutions. The method for building the list is not important. It may be generated on butcher paper in a community forum or through the electronic equivalent, a user group.

Once the list of alternatives is generated, then the list must be prioritized according to some criteria. Frequently the criteria are established when the goals are generated. If not, the criteria must be established before the prioritization can occur. Criteria may include:

- **Size** — biggest gaps or the largest policy needs
- **Importance** — the most critical gaps or policy needs

Educational Leadership — 259
Number of persons directly affected — the policy needs of the largest audience
Risk — the policy needs that carry the greatest negative consequences if they are not performed
Feasibility — policy needs that have the highest probability of being successfully accomplished
Cost — the lowest cost policy needs
Political reality — the policy needs of the most powerful or most vocal group

Methodologies for arriving at prioritization include various types of Delphi techniques, card sorts, Q sorts, nominal groups, and storyboarding (Murray-Hicks, 1981; Scott & Deadrick, 1982; Witkin, 1984).

**Develop Policy**

This step is actually selecting from a list of options prioritized according to some criteria and preparing to implement the policy. Solutions to policy needs have been systematically discerned and prioritized according to various criteria. These solutions may be chosen from one or a combination of the criteria. An easy way to combine the various criteria is to construct a matrix (Table 2). That matrix may be filled in with simple numerical data (ranking or rating on criteria 1, criteria 2, etc.) and then the overall ranking determined numerically. There are various other analytical approaches to determining the choice of solution such as the Paired-Weighting Procedure (Wickens, 1980) and Force-Field Analysis (Lewin, 1947).

</tbody>
</table>

Yet, a policy is more than just a prioritized list. It must be workable and it must solve the problem that was identified. Therefore, before any solution is chosen, it should be reexamined in light of those criteria. Workable includes being supportable by the stakeholders that are affected by the policy. Meeting this criterion can be aided by the policymaker’s actions throughout the policy analysis process. If stakeholders are kept informed and their concerns are faithfully considered during the analysis, they are more likely to support the policy. Of course, any solution that does not solve the identified problem should be rejected.

**Evaluation**

Evaluation by its very nature takes on two forms — assessment of how well the policy development process worked and determining if the policy fulfills the goal. Evaluators use the terms formative and summative evaluations for these two processes.

The policy formulation process is by its very nature continuously subject to the formative evaluation process, if properly conceptualized. The circularity of the process requires that each element of the process be examined for consistency and relevance. One may see that if the process depicted in Figure 1 is completed at “Articulate Policy,” it leads back into another cycle of data collection, identification of resources, etc. The reason that the evaluation ring surrounds the entire policy formulation is due to the circularity of the process. It also serves as a reminder for policy formers to continuously evaluate each element in the process. Experts in research design should review data collection. Likewise, each element should be reviewed for adequacy. Experts from within the system are recommended and most usually chosen because the nature of the evaluation subjects the evaluator to low amounts of bias risk (Worthen, Sanders, & Fitzpatrick, 1997).

On the other hand, summative evaluators normally should be chosen from outside the system implementing the policy (Worthen, Sanders, & Fitzpatrick, 1997). Bias risks mount when evaluators from within a system are asked to recommend an adoption or continuance decision. That does not mean that there is no risk of bias from an external evaluator, but that the risk is lessened. This evaluator looks to make a decision based on whether the policy fulfills the policy goals, what are its strengths, what problems were encountered, and what results were unexpected. Ultimately, the summative evaluator must decide if the process would be used again and what changes should be made if it is used.

**Summary**

The policy formulation process model (Figure 2) contains eight elements. The model is focused on the policy goal. Six major policy formulation steps may be accomplished in any order because of the circularity of the process. Evaluation is continuous throughout the process.

THE SWAT TEAM: SUCCESSFULLY INTEGRATING TECHNOLOGY INTO THE CURRICULUM

Marcy E. Cathey
The Madeira School

Madeira had been behind on the advancement technology as compared to many of the competitor schools. In 1995, a major push had started to bring technology to campus. The school funded laptops and desktops to all full-time faculty, and also provided a one week intensive training program by outside technology consultants to bring the faculty up to speed on how to use their computers. The groundwork had been laid for getting technology into the classroom by first giving the faculty the needed equipment and training. Eighteen months later, the faculty only superficial computer users. There had been little follow-up or continued training for faculty to increase their skills and confidence level. Unfortunately, the use was limited to prepare report card comments.

In the Fall of 1996, the cornerstone for the Savvy With All Technology (SWAT) team program was laid. The idea of SWAT was to infiltrate departments with technology specialists and users so that technology would be used across the curriculum in instruction and learning. Dr. Griffith and the administrative team at Madeira approved the Madeira Philosophy Of Technology Use mission statement. This clearly defined how technology would be incorporated and used in the school environment. The statement reads a follows:

We believe that the integration of technology into our community provides us with vital learning and teaching tools, both inside and outside the classroom, and that the technology should serve to support, enhance and expand the educational goals already established by the Madeira community.

This paper will attempt to explain the SWAT program in detail, starting with the program vision, goals, and objectives. Member selection and expectations will be discussed, as well as supporting programs that enabled and facilitated the SWAT program. Two specific projects spearheaded by the SWAT program will be discussed showing the impact of technology application in the classroom through teacher instruction, student-teacher interaction, and student learning. Finally, the next steps for the program will be highlighted as Madeira looks ahead to more integration of technology into all the classrooms.

The SWAT Team Vision

With the mission statement in place, the SWAT team would have direction and purpose in their work. The vision for the SWAT Team was three-fold:

- to create a formal vehicle for integration of technology into the curriculum
- to foster technology leaders in the classroom
- to form a technology support group.

It became obvious that two teams were needed on campus: an academic group and an administrative group. Both had specific concerns, needs, and technology issues, and both could be facilitated through a group forum. Therefore, an academic SWAT team was created to focus on integrating technology into the curriculum and an administrative SWAT team was created to focus on how technology could facilitate work flow and information exchange within and among the different constituents on campus. This paper specifically focuses on the formation, implementation, and successes of the academic SWAT team.

Member Selection

SWAT members were selected using input from several sources. To be a truly representative team, the team needed to be composed of a member from each academic department plus a representative from the library. It was important to select someone who had some prior technology skills or special interest in technology. Each of the department heads were solicited for input about which department member would be their best candidate for the SWAT team. We also encouraged teachers to nominate themselves for review and participation in the SWAT program. After all the information was gathered, the candidate list was reviewed and the team was selected. Confirmation letters with the program goals and member expectations were sent out to the team. The SWAT team was formally recognized at the following faculty meeting as a new and vital part of the community.
SWAT Team Member Goals

The goals for the SWAT team members within each department were straightforward and clear. Within his/her department SWAT team members:

- advocate technology
- provide leadership within his/her department and school-wide
- provide guidance and support to other department members as they incorporate
- technology into their teaching
- identify new software and programs for curricula area
- pilot a project in at least one course within the first year

Swat Team Member Expectations

Additionally, there were performance expectations for each SWAT member. They are as follows:

- each academic department would provide one member to serve on the SWAT team
- each team member would make a three year commitment to the program
- members would attend monthly meetings
- members would provide informal training, support, and/or troubleshooting to his/her department members
- team members would receive a stipend or compensation for participation in the 1998-99 school year

Swat Team Objectives

The first SWAT team meeting focused on setting the objectives for the coming year. It was also an opportunity for everyone to contribute to the establishment of the program's objectives. Creating a shared vision empowers the group and fosters ownership in the program. The successes became everyone's success and it also encouraged the members to work and achieve at higher level. The objectives established at our first meeting were:

- improve information exchange between academic and administrative offices
- integrate technology activities into the curriculum on a scheduled basis
- incorporate two technology activities per quarter
- establish new work habits that include technology (e.g., email)
- SWAT or Department of Technology (DOT) members would assist department faculty and staff in early lessons if needed

Additional Issues

It is also interesting to note that a significant amount of time was spent talking about how technology could help with tedious and repetitious school tasks. It became clear that technology was needed to help facilitate most of the reports that faculty were required to prepare on a regular basis. These reports included: report cards, interim reports, quarterly comments, and daily attendance. The administrative aspects of technology for faculty would be handled by the DOT separately, since they had nothing to do with classroom instruction.

The MEANS

At the beginning of the 1996-97 school year there was not a campus network at Madeira. There were several isolated networks in several of the administrative offices, such as Development and Business Offices, but none of these networks worked together or allowed for any information sharing. The first task was to get all of the offices, both administrative and academic, linked together. Systematically, the network was created using 10-Base T technology, Tut repeaters, and the Internet to establish the Madeira Educational Access Network Service (MEANS). For those offices and buildings that were too far away from the center of campus, a dial-in capability was established. Users from the performing arts building, for example, which is located about a half mile from the network operations control center, had the facility to dial-in to the network for Internet access and mail retrieval. It took about six months to get all eleven buildings on campus connected to the MEANS. Interestingly enough, within a year, the network traffic is so great that Madeira is now considering upgrading the backbone of the MEANS to a fiber optic network.

Implementation of Supporting Technology Initiatives for the SWAT Program

In order for the SWAT program to function, the Department of Technology needed to implement a series of supporting technologies campus-wide. The first of these was the establishment of a wide area network, the Madeira Educational Access Network Service (MEANS). It was crucial to connect all of the academic and administrative offices to the network in an effort establish better communications among all the school's constituents. The next step was the implementation of email for faculty, staff and students. Third, we standardized the campus productivity software to the Microsoft Office, so that everyone could easily exchange information. Fourth, Madeira connected to the World Wide Web through a T-1 connection. Additionally, the DOT provided training for faculty and staff during the school year and during the summer to raise the level of proficiency among the users. Lastly, the DOT provided technology grants to faculty and departments for additional training or equipment so that they could direct and implement the type of technology they wanted within their curricular area. A brief description of each of these initiative follows.

Email For Faculty, Staff And Students

Once the network was growing, the implementation of email campus-wide was the next logical step. In an effort to conserve costs, the DOT decided to use Eudora Lite for its email software. Eudora Lite, and now Eudora Pro, are free to educational institutions. We determined that if this proved...
to be a successful form of communications in our environment, then we could upgrade to a more complex program at a later date. The implementation was done in a phased approach with the progression as follows: the administrative staff, the academic faculty and offices, the international boarding students, the rest of the boarding students, and the day students. Everyone on campus had an email account by the middle of March, 1997, and our daily exchange of messages went from zero to over 3,000 email messages.

**Standardization Of The Campus Productivity Software**

Another obstacle that prevented the most effective communications and information exchanges stemmed from the lack of a standard productivity software for all computer users. The administrative offices were using WordPerfect, both the DOS 5.1 version and the Windows 6.0/6.1 version, while the academic offices were using a similar mix of WordPerfect, Microsoft Works, and ClarisWorks, and the student labs had ClarisWorks. The admissions office had difficulty exchanging information with the development office, because document formatting would get lost in the conversion from one software package to another. The DOT proposed the establishment of a campus standard for computer productivity software so that everyone would be on the same.

The headmistress and the administrative team adopted the DOT’s proposal to standardize the Madeira campus to the Microsoft Office Suite. The Microsoft Office Suite was selected for four reasons:

1. It supported the goal of technology integration into the community because it was a full-feature suite of productivity software that included word processing, spreadsheet, database and presentation tools.
2. It expanded our ability to communicate effectively and exchange information easily.
3. It is a package from an industry leader and stable company.
4. It is available for cross-platform environments where the functionality of the software on the Macintosh or the PC-compatible Windows machine are the same.

**The Internet Connection.** The method the DOT used to create the MEANS was made possible through the school’s connection to the Internet. Netscape Navigator software was added to all the campus equipment in the student computer labs, the administrative and academic offices, and the library. In fact, a separate Internet research lab was established in the library to give students the opportunity to use the Web for research or information gathering anytime the library was open.

**Faculty and Staff Training.** The decision to move to a standard productivity software meant that all the staff and faculty would need training on how to use the new software. The training was comprised of two different tracks: the administrative track, providing six hours of intense Word training and file management, while the academic track consisted of nine hours of training focusing mainly on using Word, but also providing an introduction to PowerPoint and Excel. Training was provided on Windows 3.1, Windows 95, and the Macintosh Operating System. While training was optional, and there was no additional compensation. Approximately 60% of the staff and faculty attended the training sessions offered.

**Technology Grants.** The Board of Directors designated technology grants as a means of helping fund technology projects for the classroom. The DOT had allotted approximately $50,000 the previous year for a variety of department lead activities. For the 1997-98 school year, the DOT increased the amount of technology grant money to $75,000, approximately 50% of the school’s technology budget, to facilitate and support SWAT team efforts departmentally. Major grants were awarded for both equipment and training to the science program, the performing arts program and the foreign language program. Additional grants were given to the librarians, history, and DOT members for specialized training of technology use in the classroom.

**SWAT Projects for the 1997-98 School year**

While all of the disciplines have been working on integrating technology into the classroom, two of the SWAT projects are real standouts. They standout for several reasons, but primarily because of the scope of their impact. The SWAT team projects have had a significant impact on teacher delivery methods, teacher-student interaction, and student learning. A description of each of the projects and the scope of their impact follows this introduction.

**The Science Project**

The science department proposed a full-featured technology grant that included a mix of equipment and training for all three of the science curricula. The biology and environmental science teachers wanted a cluster of four Macintosh computers to run a variety of course content-specific software, as well as enable students to use the Microsoft Office software to write up lab reports, construct data tables using Excel, and create presentations using PowerPoint. They also asked for a presentation system for instruction purposes which was composed of an AV Power Macintosh and 27 inch monitor. The chemistry teachers asked for a PC-compatible presentation system to facilitate lectures and the physics teacher asked for PC-compatible probes to gather data for use in classroom demonstrations and experiments. The entire grant was funded and the results have been astounding.

Daily, one can observe the chemistry teachers lecturing using the presentation system and delivery of the course...
material through PowerPoint. Students are given the basic slides as handouts and use the outline as a guide for taking notes. The teachers felt that the students were able to take better notes since they were able to concentrate on the details of the lecture. The students felt the lectures were better organized, and if the discussion got off track it was easy to get back on track with the notes already in hand. The impact on both teaching and learning, as well as the method of instructional delivery, have all served to improve the educational environment.

The biology cluster and presentation system have been successful as well. The computers loaded with course content-specific software provided students the opportunity to experience the material they learned in a new manner. Students were able to watch mitoses and meiosis on their computer screen. They were also able to replay the events as many times as needed to understand the process. The teacher was free to assist those who need with more individualized attention, while others who grasped the concepts more easily could move ahead to more challenging parts of the same lesson. Personal exchange between student and teacher was dramatically enhanced.

Finally, the physics probes used in combination with the PC-compatibles in the physics lab have greatly facilitated data gathering and measurement. Students experience how professionals would gather similar information in a real lab environment and then use that data to draw conclusions about their subject matter. Here, the physics teacher assumes the role of a facilitator.

- **The Performing Arts Project.** Similar to the science project, the performing arts project has three parts which focus on integration of technology into the curriculum. They are: technology in dance choreography, technology in the theater through set design and desktop publishing, and technology in music. All three facets of the performing arts project have had an impact on learning, instruction methods and the level of satisfaction with the final product.

  The dance instructor has incorporated technology into the dance curriculum by purchasing choreography software to use in the advanced dance courses. Students will be creating their own choreography using the mini-lab of computers housed in the dance studio itself. Once the choreography is complete, the dancers can then have the class perform the dance as written and make adjustments as needed along the way. Students feel empowered to direct the class and the development of valuable leadership skills have been one of the additional benefits to the introduction of technology.

  The theater director has incorporated technology into the theater arts classes through set design and desktop publishing. Plans for the set can be drawn and redrawn easily, and materials needs can be estimated at a tremendous savings. Desktop publishing is taught to create the programs for each production and the final product has dramatically improved since its introduction. The director, the students, and the audience directly benefit from programs that are clean, clear, and easy to read.

  Finally, technology in the music program assists in helping students compose and arrange music. Many of the previous obstacles to musical composition, such as notation, arrangement, and changing the key, has been eliminated with the use of technology. Students can focus on the mood or feeling of the pieces more than the mechanics of which note is flat or sharp. It has encouraged students to compose music who previously would have never tried to do so, and has therefore, enriched their educational experience.

### The Next Steps

The next steps for the SWAT program will be to take the successes experienced in the science and performing arts program and use them as archetypes for the other departments. The challenge of changing instructional styles in the history and English departments will be formidable as the faculty in both these departments are well-established professionals who have achieved a high level of success with the 'tried and true' methods they have used for many years. Additional money for training and an experienced curricular specialist will be one of the avenues to pursue.

### Conclusion

The formation of the SWAT team at Madeira has significantly increased the use of technology in the curriculum as well as across the community at large. There are several key points to consider:

- For technology integration to be successful in our environment, it was essential that the ideas for use come from the ground-up and not from the top-down.
- The SWAT team gives individual members the opportunity to act as a sounding board and troubleshooter for each other as projects developed when problems erupted.
- The school must also dedicate its resources in making the program successful, which means staff development and money. Mission statements alone cannot bring about change. Supporting initiatives, such as network connectivity, and email, can expedite the entire project.
- Most importantly, persistence is the key to any successful program. Evaluate often what’s happening often so that changes can be made for even greater success.

There is no right or wrong with technology application; it is what is most appropriate in a given situation and what will be effective for the desired outcome.

Marcy Cathey is the Director of Technology at the Madeira School, 8328 Georgetown Pike, McLean, Virginia 22102. Voice Office: 703-536-8228; Fax: 703-821-7771; Voice Home: 703-370-8224. Email: mcathey@madeira.org.
The purpose of this pilot study — an original research thesis: “Field-test of a practitioner-made instrument to measure the attitudes of educational decision-makers in New Hampshire on extended integration of technology-based learning strategies facilitated by well-trained and competent teachers” (1997, DeMinico) — was to investigate the attitudes of educational decision-makers about technology’s benefits to education. An inductive questionnaire was developed to determine the answers to many general questions about technology-use. Was technology-use in schools something that decision-makers believed was preceding the future needs of citizens, or another dose of therapy for an ailing educational system that many outside observers considered as having failed? Was a consensus developing among decision-makers about how to manage a learning environment having vast quantities of new data, information, and knowledge? Could increased technology-use abate this phenomenon by encouraging students, teachers, and parents to become life-long learners with well-developed thinking and problem solving skills? Was increased support for staff development of well-trained and technology-competent teachers going to become the cornerstone of successful schools in the electronic age? Was technology-use as a productivity tool becoming a priority in order to better motivate students on learning how to learn so they could lead happy and successful lives as good citizens?

Hypothesis
The literature review suggested that technology-use in the hands of well-trained competent teachers can enhance the engaged learning process with authentic problem-solving and critical thinking activities. Specifically, the works of Jerome Bruner on “process-inquiry and constructivist scaffolding” and William Glasser on “quality schools” where students are workers formed the basis of the research hypothesis to discover answers to the many questions raised in the introduction. [1960, Bruner; 1990, Glasser] Assuming a valid data gathering process, it was hypothesized that a survey taken among administrators, teachers, and governmental decision-makers would reveal their attitudes about, or beliefs in, a relationship among the use of technology, well-trained competent teachers, and enhanced learning.

Instrumentation
The jury-validated questionnaire was framed to ask subjects whether they agreed or disagreed with certain sources of interest, Principles, Opinions, Methods, and Practices, concerning technology-use in schools. Each of the 90 questions on the survey were considered by the researcher to be generally accepted true statements on educational technology-use. All 90 questions on the survey were answered using a Likert scale from one (1) to five (5) with a range of specific determinants from strongly disagree to strongly agree, respectively. Most of the interrogatives used in the survey were gleaned from interpretation of information found on the Internet. The questions were stated in a straightforward manner without any intentional ambiguity or hidden agenda. Each inquiry was crafted by the researcher in a positive way based on widely accepted norms from documented successes in planning and implementing technology integration. An estimated reliability for internal consistency for the questionnaire was computed using Kuder-Richardson formula 21 for rationale equivalence (KR-21). The reliability coefficient was .92, standard deviation was 6.666, with a mean score of 86 out of 90 items on level of agreement versus disagreement. Using Pearson r, all groups within the category of sources were correlated in five comparisons with a mean coefficient of .96 and significant at p < .05.
Procedures
The judgment sample of subjects included all the superintendents from the 69 School Administrative Units (SAU), 10 randomly selected teachers (technology coordinators) from the membership of the New Hampshire Society for Technology in Education, and 21 governmental or non-governmental educational policy decision-makers. None of them were volunteers. The questionnaire was designed with an intent to build upon several accounting-like studies researching numbers and types of technology-use in education by focusing on ratios of equipment to students. However, as a departure from the previous studies and in order to avoid the usual angst over educational funding, the current study was designed to ask decision-makers about extended technology-use in a fiscally unconstrained environment. Questions were presented in a “category of interests” of principles, opinions, methods, and practices in the context of educational objectives and disassociated from funding. All subjects, in three “categories of sources” — Administrators, Teachers and Others — were administered the same questionnaire. The results from jury-validation by experts were used as a control.

Results
The practitioner-made instrument used to investigate factors influencing leadership attitudes of educational decision-makers on extended technology-use learning strategies facilitated by well-trained and competent teachers was determined as reliable and valid. The 90-item questionnaire using Likert-scale scoring sent to a judgment sample of 100 knowledgeable subjects in 3 categories of sources yielded results consistent with expert norms. Descriptive data was analyzed using a chi-square test to compare observed frequency counts of determinants with those expected. At an alpha level of .05, the results were significant, \( p = .000119 \). The null hypothesis was rejected in favor of the declarative, that a relationship existed between technology-use and learning. Group mean score was 96 percent with agreement on 86 of 90 items having a standard deviation of 6.66.

Conclusion
The estimated reliability (KR-21) for internal consistency of the survey instrument was .92 making the instrument appropriate for use with a larger cluster sample of similar populations. Generalizable results from this pilot study, however, were threatened by a small sample size. Nevertheless, the methods and procedures used seemed well-suited for future assessments by educational decision-makers to help them rationalize competing programs that are delaying modernization of American public schools with abundantly sufficient on-line networked computers.

Recommendations
Although there was significant agreement on technology-use being an effective learning tool, subjects felt that change will come about only if teachers are well trained. Therefore, teachers themselves should take the burden of responsibility for their professional development and personal competence in using technology in the classroom.

Teachers should be demanding more exposure to technology during undergraduate and graduate schooling. Certification for having basic skills to operate both a PC and MAC must become mandatory; otherwise, one-day Workshops will go right over teachers’ heads.

Becoming computer literate is not an easy task, but talking the talk is not enough; teachers must walk the walk. They must find time to learn computing on their own time like other professionals, such as physicians and lawyers. Finding time can be facilitated by using computers to ease administrative burdens as well as teaching and learning.

Methods and practices designed for classroom teaching will also work for teachers who wish to learn about computing. The time-value of time spent on authentic tasks is invaluable. Drills, examples and demonstrations are a waste of time after one has achieved a novice knowledge-base.

This study was done to hone the computing skills of the author. Every facet of the project had a particular goal to learn more about a software application or piece of hardware or peripheral, and achieve mastery. The author through his own self-designed learning experience proved that “process-inquiry” works exactly as Jerome Bruner described it, and that a student must be made to work hard as William Glasser suggested. With enough effort in front of a computer screen, competence comes as magically as the day a child learns to read because technology is mathematically logical and follows a pattern of rational thinking.

Introducing computer technology into teacher education programs offers a host of teaching and learning opportunities. Educators argue that computer technology promises everything from enhancing the delivery of instruction, to improving students' learning, to spurring the development of novel models of teaching and learning (Cole, 1990). At South Mountain Community College we sought to reap some of these technological advantages by building a computer laboratory specifically devoted to our Dynamic Learning teacher preparation program. We soon realized, however, that technology did not automatically bring about enhanced learning and educational reform. Instead, the introduction of technology created many challenges for our students, faculty, and administrators. In this paper we explore the challenges our campus faced in order to take advantage of the opportunities computer technology offered us. We examine three issues we believe were critical to our effective use of computer technology: the technology itself, the classroom learning environment in which we use technology, and the administrative changes needed to facilitate our instructional innovations. We emphasize how these factors led faculty and administrators to a dialectical process of discussion and action across campus to meet the needs of our students.

Classroom Technology

The first question raised by the introduction of technology into the classroom concerns the technology itself; "What technology should we use?" The options are vast, ranging from skill specific drill and practice software, through expert-like intelligent tutoring systems, to open-ended tools like word-processors and spreadsheets, Internet exploration, and simulation "games" like Myst and SimCity. The evidence of the effectiveness of the drill and practice programs and the "expert" guidance systems which provide learners much information and usurp most of the thinking is less than encouraging. Often this sort of computer application has minimal, transferable impact on students' learning (Spiro, Feltovich, Jacobson, & Coulson, 1991). It made more sense to introduce our group of prospective teachers to applications which might enhance what they will do as classroom teachers. Therefore, our campus decided to emphasize open-ended computer tools and applications which require learner thought and activity.

Our reliance on open-ended computer tools focused our classroom technology plan on two outcomes we hoped to accrue: effects with technology and effects of technology (Salomon, Perkins, & Globerson, 1991). Effects with computers occur when learner cognitive, affective, or behavioral performance is enhanced during computer usage. For example, if students write more polished essays than they otherwise would while using a word processor that offers grammar and spell checking, they experience an effect with technology. Effects of computers accrue when students grow as a consequence of working with computers. For example, students who compose better essays with only pen and paper after using software which provides composition guidance show an effect of computers. Both effects are prized learning outcomes for our prospective teachers.

Cultivating these two technological outcomes has tremendous benefit for our students. When experiencing effects with computers learners actually form an intellectual partnership with the technology in which students' performances exceed what they do without the technology. When the partnership is well-suited to learning, computers assume repetitive, time-consuming, lower-order tasks, allowing students to focus on more complex, higher-order thinking. For example, many word processing programs allow students to devote time and energy to language choices, organization, argument structures, and theme development by expediting spell checking, formatting, and writing mechanics. The partnership allows students to attempt higher-order, more meaningful tasks that would be difficult to attempt away from the computer. Further, to the extent that students have practiced these new skills, at some point they may be able to employ their new acquisitions absent the technology. Through the use of open-ended computer
tools, technology offers learners the opportunity to develop cognitive and behavioral skills that would be considerably more difficult to develop absent the technology.

While these computer applications offer important learning opportunities for our students, they do not accrue automatically. The value offered by open-ended computer tools presents a bit of a paradox. Most computer applications, especially those suitable for general teacher preparation, teach very little in and of themselves. Rather, it is the thinking in which students engage when using computers that results in learning (Salomon, 1992). Students won’t cultivate the higher-order thinking skills computer applications offer, unless they expend the cognitive effort necessary to focus on them. For example, using a word processor helps students format, spell check, and generally polish their essays, but it does not teach writing skills. However, if students focus on higher-order structures of writing such as theme development, structural organization, argument analysis, voice, and language choices, word processing can help them develop excellent writing skills. Spell checking and formatting are great. But, the learning advantage of word processing comes when students use computers to free themselves from these relatively mundane, tedious, and time-consuming aspects of composition to focus on more challenging aspects like structure, theme development, and issue analysis. Clearly, it is the manner in which students use computer tools which fosters learning. Students must be mindfully engaged to benefit from computer tools (Salomon, Globerson, & Guterman, 1990).

In turn, it is the learning context in which students use computers which influences the quality of their thinking. When students find an activity unexciting or without real consequences, they are unlikely to expend the cognitive effort necessary to cultivate higher-order thinking skills. Thus, the challenge we faced in the Dynamic Learning program was to design a classroom environment in which students were willing to mindfully engage in their learning tasks and take full advantage of the learning opportunities the computer offered them. The key is that the learning environment must lead students to look beyond the surface features of computing and focus on the opportunities for thinking and learning that technology offers. It is the use of technology in the appropriate learning environment which accounts for student learning more so than does the application of technology or novel learning environments alone (Salomon, 1992).

**Classroom Learning Environment**

The Dynamic Learning Program at South Mountain Community College is our attempt to build a classroom learning environment that invites students to mindfully engage in their studies, particularly when using computer technology. Dynamic Learning offers the first two years of a university articulated professional teacher preparation program. A new cohort of students enters the program each year, completing their four semester sequence together as a learning community. The cornerstone of each semester is an integrated block of general studies and education courses taught from a single syllabus. Each block meets about three hours a day for three days each week, and is taught by a team of three faculty members. Due to laboratory course requirements, at least one course each semester is taught outside of the block format. Students also participate in a field experience each semester in local elementary, middle, and high schools, working closely with students, teachers, and administrators from these institutions. This program design allows Dynamic Learning students to study in an environment that is authentic, collaborative, interdisciplinary, and inquiry-based.

Dynamic Learning features authentic learning activities which have impact on students beyond their academic merits. For example, instead of giving public speeches only in the classroom, students earn course credit by speaking in venues outside of class. In particular, students have numerous speaking opportunities in their field experience, working with faculty, administrators, and students at those institutions. Since students choose these speaking engagements themselves, they have personal significance and the event has meaning beyond its course credit. The presentation graphics, outlining, and organizing students do at the computer has significant value to them because they are judged, not only according to classroom standards, but by professional standards by the students and staff at their placement schools as they present lessons, in-service sessions to teachers, and policy proposals to administrators.

The environment is collaborative in many ways. Students work in cooperative teams. They work with students and faculty from the university, high school, and elementary levels. They also work with members of the community on a regular basis as part of their studies. Technology facilitates this collaboration. Since our “classroom” now extends beyond its traditional walls into local schools, universities, government agencies, businesses, and neighborhood charitable organizations, computer-mediated communication is necessary to bring our students in contact with these parties. The planning, organization, writing, and interpersonal skills necessary to such collaboration become the real benefits of computer-mediated communication and the other applications students use in these ventures.

The program is also interdisciplinary in that courses are taught in “blocks” by teams of instructors. Instead of enrolling in a series of separate courses, students meet in a single three to four hour block each school day (9 - 12 credit hours a semester) in which they study several discipline areas simultaneously. Among other benefits, our interdisciplinary focus means we save time by not repeating basic information in different courses (e.g., outlining skills in composition and public speaking courses). As a result, students have time to delve deeper into their course
This focus also encourages students to view educational issues with an integrative perspective. Thus, we spend less time on the basic issues of computer usage, less on the surface applications of technology to an issue (e.g., less on polishing an outline or essay), and more on the deeper applications of technology to real problems (e.g., what sequence of evidence and arguments might be most persuasive to a school board on a certain issue).

This is facilitated through inquiry-based studies in which students explore a theme, issue, or question with the tools of several disciplines concurrently. For example, a typical assignment for freshman Dynamic Learning students is to become agents of change on an educational issue of significance within the community. While students’ projects have various levels of effectiveness, they all employ substantial writing, speaking, and critical thinking skills. In this context, technology becomes an important tool students need to accomplish personally relevant and meaningful goals. Students place a premium on computer time for crafting essays, writing letters, managing deadlines, brainstorming, creating charts and graphs, making presentation outlines and slides, organizing ideas, constructing models, conducting library and Internet searches, exchanging Email, testing ideas, analyzing survey data, and creating and using art, videos, and music. Because students complete these activities to accomplish their own purposes, they do so of their own volition, with attention to detail, and with concern for their results. They are mindfully engaged.

Our implementation of these four principles makes the Dynamic Learning environment substantially different than the traditional college classroom. But, it is our application of computer technology within this innovative classroom learning environment which works to enhance students’ learning. Computer technology affords students the opportunity to focus on higher-order thinking skills by assuming lower-order, repetitive, and mundane chores. The novel Dynamic Learning classroom environment entices students to take advantage of these opportunities technology affords by making their studies personally relevant and meaningful so that they mindfully engage in their work. Thus, heavy reliance on technology in an innovative learning environment has a reciprocal effect: Technology helps create an innovative classroom environment by bringing the community, ideas, disciplines, and people into the classroom. At the same time, our innovative environment makes technology educationally useful by encouraging students to become mindfully engaged in their studies with computers. The result for our students is enhancements in learning that are difficult or impossible without technology applied in an appropriate learning environment.

**Administrative Changes**

The changes we undertook in the Dynamic Learning classroom to support our technology-intensive focus happened neither automatically nor absent challenge. Rather, they posed numerous administrative hurdles for our campus to overcome. With the reliance upon the use of computer technology in the program, there were new capital budget demands and network infrastructure requirements that were negotiated and resolved. Questions of ownership, maintenance, and scheduling for the Dynamic Learning in-class laboratory of 25 computers surfaced. Since all block faculty were not equally skilled with computers, faculty training and support became an issue. Similarly, faculty office computers had to be upgraded and made consistent with lab computers for continuity. Training was needed for students as well as faculty, so that faculty could devote class time to teaching in their areas of expertise, rather than serve as computer tutors. The “real world” focus of the block encouraged students to make real use of technology, in turn, raising issues of student web page and server use policy. Provisions had to be made to bring Dynamic Learning off campus partners access to our technology and integrate our capabilities with theirs. And, our primarily faculty and staff focused Educational Technology Center now had to play a significant role in the classroom usage of technology. Each of these issues had to be addressed in order to support the technological innovations we introduced into the classroom. If any one of these had been ignored, the success of our project would have been greatly curtailed.

The development of learning environment we needed to maximize the educational effectiveness of our technology also posed several administrative puzzles. To start, the collaborative, interdisciplinary format required coordination and adjustments in the student advising process with needs for new advisor training sessions. In addition, this block format necessitated changes in the overall student registration process as students no longer registered for discrete courses but rather for packages of courses. Faculty at South Mountain Community College are contracted to teach a set number of course loads and have an established number of hours of accountability on campus each semester. The established course loading formulas and hours of accountability needed to be modified in order to support the block design of the curriculum developed by the three lead faculty. Broad course schedule coordination also became an administrative project with the need to offer the out of block courses at times which would meet the needs the student cohort. As a result, the program impacted a number of divisions and departments at the college requiring that new allegiances be formed. Faculty and administrators needed to work as a productive team to establish articulation agreements so that students completing the block program at South Mountain Community College could easily enroll in the upper division teacher education program at the local university. All of these challenges were brought about by innovations needed to maximize the instructional effectiveness our technology intensive program. Again, each of
these issues had to be addressed in order for the classroom innovations to succeed.

The Dynamic Learning Program at South Mountain Community College has resulted in a number of instructional innovations which have enhanced student performance, confidence, and persistence. Computer technology has been an important key stone to a number of collaborative and interdisciplinary approaches within this block program. Concurrent with these instructional innovations, a number of administrative processes and procedures had to be modified or developed in order to provide the needed support and structure for this program. Student performance and satisfaction demonstrates the Dynamic Learning program to be instructionally sound and effective. As a result of the success of the program, there has been concomitant campus impact in a number of arenas including policy, budget allocation, student services, schedule development, division to division cooperation, and articulation with other educational systems.

IMPLEMENTING TECHNOLOGY IN FLOWING WELLS SCHOOLS: AN ANALYSIS OF LEADERSHIP

Marc D. Hamilton
Northern Arizona University

Technology is a liability, not an asset. Stories relating the expensive, difficult, and ineffective implementation of new technologies, specifically computers and communication equipment, in our public schools are all too frequent. Quality computers, within five years, go from top-of-the-line, productive, creative tools to forgotten plastic relics collecting dust. The lure of high technology unfortunately leads many districts into snap decisions that sound fiscal leaders can ill afford to make. Spending huge sums of public money or relying upon repeated bond issues without establishing a clear vision of what successful technological implementation should look like is fiscally, politically and socially irresponsible. Beginning with the end in mind; an oft-cited reference to the work of Steven Covey, is prerequisite in bringing about innovative and effective use of technology that promotes student achievement.

Core Values
Flowing Wells, a ten-school district in Tucson, Arizona, turned first to their written core values when beginning to craft their technology implementation plan. A poster in every class outlines the four values all employees are expected to share. First, all decisions will be student-driven, based on what is believed best for the student. Second, every employee will walk their talk and operate with integrity. Third, all work will be quality-focused, modeling the assumption that if something is worth doing it is worth doing well. Finally, the district will respect the decisions everyone must make to maintain balance in their professional and personal lives.

The public expression of these shared values created a framework facilitating the creation, adoption and implementation of the district’s new technology initiative.

Climate for Change
District administrators, through the course of many years, have established communication and trust between themselves and the governing board they are accountable to. Board members and administrators strengthen this communication during annual summer retreats. At the start of fiscal year 1997, all decision-makers in the district were ready and willing to move forward with a new technology initiative. Additionally, a successful salary override recently raised teacher pay comparable to neighboring districts.

The importance of governing board, community and teacher support cannot be overlooked when considering the adoption of expensive new policies. The pacing and timing of major change efforts contribute tremendously towards their success or failure.

Collaboration
The leadership strategies employed by assistant superintendent, Dr. John Pedicone, coupled with the district’s core values, articulated by superintendent, Dr. Phil Corkill, brought together a cadre of teachers, parents and administrators focused on assembling the foundation of the district’s technology initiative. Under Dr. Pedicone’s supervision, ad hoc committees were assembled around the following four themes:

- Curriculum
- Business and Community Partnerships
- Management and Fund Procurement
- Staff Development

Individuals with key interests in each area were selected and asked to staff each respective committee. From the inception of the project there was a high degree of congruency between the skills of the committee members and the tasks that were required of them. Throughout the summer of 1997, the intrinsic motivation inherent in the opportunity to build their own future, fueled the committees’ efforts and ultimately led to the success of the initiative.

Flowing Wells’ Vision for Technology
Guided by articulated core values, the technology team set out first to envision what successful technology implementation should look like. Incorporating the driving themes of each ad hoc committee, the team generated a vision statement that would serve to guide all their future decisions.

Flowing Wells intends to assess, acquire and implement technology designed to enrich instruction and achievement,
and will provide staff and students with the skills and opportunities needed to excel in the 21st century.

Only by clarifying what ultimately is desired can effective task-analysis be undertaken. The committees, as they endeavored to construct their portion of the technology plan, never lost sight of how their work integrated with that of the whole.

**Benchmarks of Success**

Vision and dreams without links to practical, visible measures of success have often derailed otherwise noble efforts at improving instruction, and ultimately, student achievement. To avoid this, the technology team established benchmarks that would truly reveal the extent to which the written vision was being accomplished.

- Every student will have access to appropriate technology at appropriate levels.
- Every student will have access to computers during and outside of school hours.
- All students and staff will have access to the Internet.
- All students and staff will be able to access information according to individual responsibilities from any location within the district.
- All district functions will be tied together through an effective technology network.
- A coordinated and integrated curriculum will be implemented that will prepare students for the world after graduation.
- An effective, applicable staff development program designed to enrich instruction and achievement will be established.

As the summer and the school year progressed, the technology team kept each other apprised of the progress made on each benchmark. This continued, monthly communication strengthened the integration and support between the ad hoc committees.

**Ad Hoc Efforts**

Each ad hoc committee faced, at times, daunting challenges, yet careful task-analysis, thoughtful division of labor, and the already described intrinsic motivation provided the opportunity for each committee to succeed. Intrinsic motivation aside, however, the work of some committees called for additional compensation. Core values must be embraced by all parts of a school district, and providing monetary rewards for exceptional leadership and initiative is only right if initiative and leadership are to be expected. The governing board and district superintendents were well-prepared to meet the compensatory need, having already formulated and executed a five-year budgeting plan.

It is a common occurrence in education to expect leadership, initiative, and exceptional performance from individuals provided neither incentive nor opportunity to. In what other occupation does this logical fallacy hold merit? Flowing Wells’ decision-makers, in addition to walking their talk of high standards and expectations, enacted that other euphemism for integrity: putting their money where their mouths are.

Each committee, engendered with opportunity, inherent desire for success and respectful compensation, set out assessing the needs of their respective realms of concern.

**Curriculum**

The curriculum committee, chaired by principal John Black and comprised otherwise entirely of teachers, built the district’s K-12 technology curriculum around the fundamental paradigm that computers and communications equipment are tools designed to get important tasks accomplished. Technology should not be an end in and of itself, rather the means to whatever end is called for. Basing instructional guidelines on competencies that clearly define what students at each level will be able to do facilitates a streamlined, integrated K-12 curriculum. Instructional autonomy for individual teachers is preserved by basing competencies on actual skills, not assignments.

![Figure 1. K-12 Technology Curricular Outline for Flowing Wells School District](image)

A detailed examination of specific competencies at each level of schooling is beyond the scope of this paper. However, it is important to note that students’ mastery of the software and skills taught is assessed through evaluation of projects done for core-curricular content areas such as language arts, math, science, and social studies. By assessing student applications of content taught, Flowing Wells adheres to its core values and the principle that technology is intended to facilitate accomplishment.

**Business and Community Partnerships**

For five years the technological needs of the district were identified and communicated to the community of Flowing Wells. This continual communication helped secure funding well in advance of the initiative’s implementation. Flowing Wells, however, is not a wealthy district, its
median household income is only $14,580. The majority of families in the district rent, and increases in property taxes due to bond and override efforts are laid squarely on the shoulders of those who do not own the land being taxed.

Typical technology procurements occur in bursts, with huge sums of money being raised and spent every five or ten years. There is no coincidence that procurements tend to follow five or ten year bond cycles. School districts in Arizona, despite the Supreme Court deeming the current capital outlay laws unconstitutional, are forced to rely on increasing the tax burden on the families of the children they serve. The business and community partnerships committee sought to find a more creative solution.

**Leasing.** Instead of purchasing, at enormous expense, hundreds of computers that will be well on their way to obsolescence in five years, the committee investigated the option of leasing technology. Through the local affiliate of Microage, all legal and financial considerations were explored and documented. Though more expensive than purchasing in interim years, leasing avoids having to drop bond issues every five years on communities which cannot afford them. Additionally, the service provided by Dell Computers and Microage ensures the quality of the product and protects the district from the possibility of wide-spread equipment failures (as occurs frequently when districts low-bid for hardware). The lease is up for renewal every three years, allowing the district to upgrade to new technology as it’s made available. The steady fund requirements mandated by leasing facilitate long-term budgeting and expansion planning.

**Management and Fund Procurement.**

Lead by Dr. John Pedicone, the management committee assessed the communication needs of the district in addition to aggressively searching for alternative funding sources such as grants and corporate donations. The committee analyzed the needs of three distinct, yet systemically-tied realms.

With the needs assessments in place for each major sphere of concern, the management committee began structuring future budgeting strategies around the hardware, software, and staff development necessary to achieve the district’s goals. This 1/3, 1/3, 1/3 principle ensures that hardware, software and training capabilities will remain aligned and the district’s spending balanced.

**Connectivity.** Quality communication between all ten sites in the district, as well as the vision to fully incorporate the Internet in instruction, mandated the acquisition and installation of T-1 lines throughout the district. Additionally, through strategic integration of wide and limited area networks, the district intends to connect all classrooms and libraries to communication nexus points, facilitating exchange of information. These connections form the skeletal structure of any effective technology plan. A detailed, two-year plan was outlined to insure success of the connectivity component of the initiative.

Many technology plans develop from the top down, bringing in expensive computers and software before establishing the necessary infrastructure that will maintain and support instructional efforts. Flowing Wells, by installing the hard-wiring first, and ensuring its quality and effectiveness, will establish a healthy foundation in which future technologies can be integrated.

The management committee secured $50,000 through a federal grant. The grant included a proviso that mandated installation of communication lines (which the grant is intended to be used for) by the end of the year. Success in this endeavor will allow the district to pursue $100,000 in additional funds. The E-Rate is a communication-equipment grant drawn from the $2.25 billion telecommunications companies across the country have been required to provide public education. The funds are federally allocated based upon a district’s percentage of students on free or reduced lunches. Districts like Flowing Wells can benefit greatly from the E-Rate, and build a strong foundation further grants can supplement. The E-Rate funding will enable Flowing Wells to realize their connectivity goals by the end of December, 1998.

**Administrative Software.** A district wired together with LAN and WAN networks can greatly increase the effectiveness of its inter-district communication. Attendance, discipline and other records can be maintained, updated and accessed with ease from any location within the district. Streamlining record keeping empowers teachers and administrators to better serve their students by freeing up planning time from administrative and disciplinary paperwork. The committee researched and evaluated a variety of administrative software, deciding upon CIMS and SASSI. CIMS and SASSI are designed to keep records on attendance and provide seamless communication with a variety of state institutions. Incorporation of this software will enable Flowing Wells to have a K-12 integrated attendance system in place for the 1998-1999 school year.
Staff Development

Effective implementation of technology mandates its use and application. Often, however, fancy toys are placed on teacher's desks with the expectation, without any training provided, that the equipment will be utilized effectively. Susie Heintz, staff development coordinator of Flowing Wells, assembled a committee with the articulated goal of guaranteeing quick and effective technology implementation in the classroom. The technology team early on decided upon the purchase of Windows and Microsoft compatible equipment and software. This decision was not made lightly, rather reflecting upon the core values of the district and the prevalence of IBM and Microsoft applications in the work force, it was deemed in the best interests of the students to move away from Macintosh products.

Technology Vanguard. The prior year, with a core group of teachers, some initial training was performed in existing labs. These teachers, known as the Technology Vanguard Team, formed the pool from which the writing and training teams were assembled.

Training Modules. Selected members of the Vanguard Team spent the summer of 1997 writing training modules for Microsoft Windows and Office, specifically Word, PowerPoint and Publisher. Supplanting these core applications, were modules developed for Hyperstudio and Grade Machine +. The modules followed an exacting format and were compiled into a master staff-development handbook. Each module was framed around conceptual elements inherent in each program. These concepts were then broken down into specific objectives, and step-by-step instructions. Each module created the opportunity for participants to make a product for immediate use in their class. Teachers and support personnel walked away from each training seminar with usable material, and as labs were installed month by month across the district, opportunities to continue applying their skills. The modules are of the highest quality, complete with anticipatory sets, guided and individual practice sections, and interactive, step-by-step closures.

Inservices. The modules were structured to cater to a specific level of participant competency. The Windows training, for example, occurred early in the year while the Hyperstudio module was held in February 1998, and required passing a pre-test to attend. The Vanguard trainers attended design review nights held by the staff development coordinator and the writer of the module being examined. The most critical elements of each module were stressed and teaching strategies discussed and refined.

Vanguard members and participants received additional pay for writing, teaching, and attending modules and inservices. Again, this in keeping with the district's core values. The sessions were held in the evenings at a variety of different schools.

Conclusion: An Analysis of Successful Leadership

The Flowing Wells Technology Initiative modeled the Delphi Technique: a leadership strategy that is empowering rather than directive. The district has been aware of the need for improvement in the realm of technology for two years, and this need has been effectively communicated throughout the staff and the community. This legitimacy engendered by open communication, fostered collaboration between district and school administrators, teachers, community leaders, and parents. An appropriate tempo for change was set early on. The big spending push came after a successful override had brought salary comparability to the teachers in the district. Staff development and hardware installation occurred concurrently, well-funded and budgeted early on in the process.

Patience and Problem Solving

Problems were identified, defined and task-analyzed by committees staffed by committed, effective personnel. Realms of concern were identified and systemically examined for inter-relationships and cause-effect scenarios. The team remained focused on the core values of the district and established clear vision and intent allowing success to be measured and tracked.

Continuous Improvement

Intense and continued evaluation of each component of the plan lay ahead for Flowing Wells. Each phase in the change process is examined and refined if found wanting. Serious efforts will be paid to the continued development of curriculum that focuses on application. The curriculum instituted at the Junior High is an example of the competency-based, application-oriented approach to technology and technology training the district is looking for. Over time, as kids grow more fluent in the use of computers, the competencies and the levels at which they are mastered will have to be analyzed and adjusted. Continuous improvement, driven by relevancy, is the lens district administrators are using to ensure student achievement.

Final Take

Thomas Edison, at the turn of the century predicted the radio would make schools obsolete by the 1920s. B.F. Skinner, as the Cold War rolled forward, thought television would do in public education and the need for teachers. Now computer, electronic and distance learning champions are heralding our end as well. Dr. Phil Corkill, superintendent of Flowing Wells, however, notes, “What makes a difference will be a teacher, exquisitely trained, who cares about the kids. Our money should go not only to provide our kids technology, but to our teachers, letting them know they’re our most vital resource.”
Figure 3. Evaluative Realms for Continued Improvement

INCLUSION AND TECHNOLOGY: A MARRIAGE OF CONVENIENCE FOR EDUCATIONAL LEADERS

Irene Schulz-Hamsa
Xavier University of Louisiana

Foreign countries have for years recognized the significance of alliances between nations through a prearranged betrothal. The result: a collective merging of assets serving to fortify the position of each to embark upon further vistas of achievement and to provide a combined force with which to reckon from an invading enemy, if threatened. The forging of an alliance between inclusion and technology represents such a union—a marriage of convenience for educational leaders.

The computer represents the ambassador of public relations—a virtual monolith, designed as a mechanism of cooperation between children with and without special needs. Inclusive education, the elimination of special education as a separate classroom in isolation from the mainstream of the education process, poses a significant challenge to educational leaders of the 21st century. A comprehensive system of education—the total integration of students with special needs in the regular classroom—transverses the mere embracing of the concept of inclusion.

Thinking Differently

Special education was developed over a century ago to meet the unique instructional needs of students considered to be exceptional or special. Since that time, essentially two systems of education have emerged—special and regular education.

A change of thinking in the belief that a dichotomy of practices is mandatory to address the learning needs of students has been slow and arduous. Teaching strategies and practices that enrich the learning environment are advantageous, not only to a few, such as, students with attention deficits or orthopedic impairments, but rather serve to positively impact the collective whole—the entire classroom of students.

Ideally, education has the potential to be the great equalizer. An environment that cultivates solidarity necessitates the incorporation of teaching methodologies in an integrated setting that bridge the regular special educational categories. If schools are to become the cornerstones of progress, then it is imperative for educational leaders to engage teachers in the continued improvement of professional skills regarding the incorporation of technology into the classroom.

Educational leaders must provide all students, including students with special needs, with access to the same opportunities for a quality education. The engagement of the teaching force in activities that promote the continuing acquisition of current knowledge applicable to the next millennium is crucial.

Serving as Catalysts for Change

Leaders of the next generation need to commit teachers to acquiring a repertoire of new teaching practices that weave technology into the curriculum—all within heterogeneous groupings of students. It will no longer suffice for leaders in educational environments of the 21st century to be “guardians of the status quo,” knowledgeable of only the generic, traditional content and process of educational pedagogy and traditional leadership. Rather, the role of the educational leader as a catalyst for change is evolving with the same rapidity as the vision of the teacher as the facilitator of learning.

First and foremost, leaders need to connect diverse collections of students; instructional technology provides the foundation for such an amalgamation. Future leaders must foster the incorporation of technology into the inclusive classroom to maximize the learning process for all students. Administrators need to invest time and energy in activities that range from establishing fundraising partnerships with businesses for the purchase of computers, to encouraging parents to gain new computer skills, to assisting teachers in adapting performance standards in instructional technology.

Identifying Relevant Issues

A prevalent issue that emerges for educational leaders in the use of instructional technology concerns access and equity. Gilster (1997) emphasized that equity within the United States and global equity are of great concern. Although some wealthy suburban areas have high-tech environments, schools located in poverty areas and those...
located in other parts of the world are denied access to computers.

Cost benefit versus cost efficiency in improving educational outcomes is also a consideration for administrators. Some school budgets are delineated to allow for purchases of new computers and the associated technologies—Internet connections and multimedia capabilities. Yet, the fiscal resources necessary for supplying students with high-performance computing and communications technology varies (Coley et al., 1997).

Leaders in educational environments must be cautious not to envision the computer as a panacea for all educational woes for all populations—regular and special education alike. To perpetuate the perception that educational deficits are remedied and gaps in learning circumvented with nothing more than proximity to the computer is erroneous; no truth is less self-evident. A gamma ray-like epiphany does not happen; students do not become transformed by some osmossmotic process that passes from the computer screen to the cerebrum of the student.

Increases in student achievement require the initiation and nurturing of systematic reform. Change requires participation in word and deed of all constituents of the educational process—students, teachers and administrators. Innovations need to embody the enhancement of the focus on professional development, pedagogy, assessment, curriculum and especially leadership.

**Seizing the Opportunity**

The momentum, generated by the clarion call to action for educational reform, must be seized as an opportunity for educational leaders to promote an agenda for change—one that stresses unprecedented spending on computers and associated technologies. Educational leaders must prioritize computer acquisition, installation and replacement as crucial to the success of an educational organization.

Implementing change in educational organizations is particularly difficult and historically slow. Educational leaders must beware of modern Ludites i.e., individuals who abhor technology. One need not look further than the rationale for linear-row seating arrangements in classrooms to truly understand the inertia representative of schools. Beginning with the Industrial Revolution and continuing today, small aliquots of space in singular, designated patterns were designed to mimic the atmosphere of the factory and, most importantly, to prepare students for their jobs as future factory workers.

Many educational leaders are approaching the technology movement with evangelistic-like enthusiasm, proselytizing teachers, parents, school board members and communities into the flock of believers. In creating an environment for a change to a more technologically-focused delivery of educational services, educational leaders should exercise caution in avoiding fallacious thinking where technology is perceived as a "magic potion" in which one dose works well and several doses work even better. Unique applications of technology, implemented by technologically competent teachers, can serve to improve student achievement and prepare all students for employment in the technologically-focused, futuristic world of the next generation.

Educational leaders need to focus on the role of the computer in providing vocational skills and in easing the transition from school to work. Students with special needs are sometimes seen as non-contributing members of our society unable to attain gainful employment. The computer helps all students assess their abilities and talents and establishes a match with potential opportunities.

Today's students are living in electronically-immersed realities in which technology can make learning easier and certainly more fun. School administrators need to: support initiatives that foster innovative uses of technology in the classroom; accept the onus of responsibility as the major change agent of schools; and, provide the resources for the acquisition of the new tools for learning.

**Visualizing for Tomorrow**

A mind set is entrenched: technology is beneficial to improving student outcomes. What is not addressed concerns a value-added dimension: technology is advantageous to students with special needs in a variety of ways, including higher academic performance and increased interaction with peers.

The vision of inclusion is one in which students, regular and those with special needs, interact in a technologically-supportive environment. Significant changes in instructional practices must occur if students with special needs are going to achieve in a regular classroom at levels equal to or higher than when they were in self-contained, special education classes.

Educational leaders must visualize instructional technology as a modem of communication with the potential to serve as a metaphorical olive branch for students with and those without special needs, and for teachers supportive of inclusion and those in favor of exclusion. Students designated as low, average, or high-achieving can benefit from the application of technology in the classroom.

A major critique of inclusion by veteran teachers concerns the perceived deleterious effect an inclusive setting will have on the learning process for regular education students in the traditional classroom. Minimization of negativity concerning the inclusive process stresses the education of pre-service and in-service teachers in strategies that include: the development of an expertise in the learning styles of students and the accompanying technology that promotes the uniqueness of the learning process for each student. Fostering a classroom climate that not only tolerates but appreciates individual difference is imperative.

The classroom of tomorrow will be vastly different from the classroom of the present. Efforts directed at conquering the challenges involved in integrating technology into the
curricula continue to divulge new avenues of learning worthy of exploration by educational leaders. According to (Bruce & Levin, in press) the range of learning experiences for students is dramatically increased and enhanced with interactive, multimedia technology in which text, voice, music, graphics, photos, animation and video provide for active, focused learning.

Innovative projects and resources using a variety of technologies from electronic networks, integrated media, and problem-solving applications support the development of higher-order thinking and provide excellent opportunities for teachers to gain new knowledge and skills. Such programs and projects include: The National Aeronautics and Space Administration On-line Resources for Educators, including The GLOBE Program—Global Learning Observations to Benefit The Environment, NASA Spacelink, NASA Teacher Resource Center Network and NASA's Central Operation of Resources for Educators (CORE).

Leaders of the 21st century must broker the relationship of inclusion and technology as a marriage of convenience. The computer must be personified as a diplomat of public service—a non-threatening purveyor of knowledge that assists educational leaders of the future with the ultimate challenge: the delivery of educational services to academically, behaviorally and culturally diverse students.

Two themes currently receiving considerable attention in discussions of education are technology and reform. Studies are linking the two, some of them with great hope for the future (Sandholtz et al. 1997), and others with a somewhat more concerned view (Means, 1994). The impact of online technology, when used as computer-mediated communication (CMC), on schools will stimulate changes in teaching practice, and in student learning (Heflich, 1996). However, it is well known that schools are social organizations with identifiable and distinct cultures (Sarason, 1991). Cultural change is problematic, depending in large part on factors that are neither fixed, nor linear (Fullan, 1993). This study attempts to clarify the relationship between CMC and school culture, hopefully leading to a better understanding of what will be needed if the promise of technology in educational reform is to be realized.

CMC in education
The presence of CMC in schools is growing rapidly. According to Heaviside, (1996) half of all public schools currently have access to the Internet, and 74% of those not currently connected plan to do so in the future. Even so, only 9% of all instructional rooms now have direct access to the Internet. Among all U.S. public schools, 85% have access to some sort of local or wide area computer network. Public schools have an average 72 computers, however only 14% of all computers in schools have direct access to computer networks (Heaviside, 1996).

Great claims have been made on behalf of the benefits of CMC for teaching and learning. Wilson (1995) reports strong positive effects for the use of technology in the classroom and its impact on teaching methods, teacher attitudes, student achievement, and student attitudes. Students participating in CMC-based learning circles dedicated to student writing demonstrated significant gains in writing ability. (Riel, 1994). A 1995 Office of Technology Assessment (OTA) study distinguishes between teacher-centered instruction and student-centered instruction. Teacher-centered instructors tend to use computer technology in a didactic manner, emphasizing its use to reinforce skills with drill and practice software. Student-centered instructors use computer technology in a more collaborative fashion and are more enthusiastic about its use because it supports their style of teaching (U.S. Congress, Office of Technology Assessment, 1995).

Technology and school culture: The problem of change
Changes in teaching and learning have been subsumed into the general topic of school restructuring. In order for restructuring to succeed, it must address the core cultural relationship between the teacher and the student (Fullan, 1993). Implicit is the idea that schools in much of the country are structurally aligned in ways that inhibit change. The use of time, the requirements of state mandated curricula, and the nature of assessment limit the ability of technology to effect changes in teaching.

Cuban (1986) argues that computers, like other machines before them, are used by teachers in ways that supplement, rather than change, their practice. The fact that the environment limits changes in teacher practice is particularly true when considering the use of technology. Computer technology although relatively inexpensive, is a major investment for schools. Many districts have inadequate access to computers, modems and even telephone lines (Honey & McMillan, 1994). School districts operate...
Barriers to the full adoption of CMC are a significant topic in recent studies. Heaviside (1996) summarizes the problem as a lack of funding and inadequate access to online resources. The OTA report (1995) is more specific. Although schools are investing heavily in hardware and software, they are not exhibiting the same concern with how technology will be used. There is a lack of adequate training for teachers. Furthermore, there is a lack of on-site technical and curricular support for teachers in the use of technology in the classroom. Access is an issue as well. Most online computers are located in offices or laboratories. Teachers need to make special, often difficult arrangements for their classes to use the machines. Finally, the age of computers in schools limits their ability to be of much use in the curriculum. Although the U.S. leads the world in the number of computers in schools, it falls behind in the number of modern computers available (U.S. Congress, Office of Technology Assessment, 1995).

Introducing any educational innovation is a process that needs to confront the culture of school (Sarason, 1991). Fullan (1993) has aptly described the process of educational change as a voyage that is non-linear and full of problems. Educational change will only succeed if the relationship between the teacher and the learner is at the forefront. Fullan (1993) has argued that change needs to involve the effort and support of both teachers and administrators in order to succeed. Furthermore, teachers must recognize and understand the benefits that will accrue to them if they are to abandon their tried and true educational practices for new ones (Sandholz, 1997). The OTA report (1995) advises school districts to invest as heavily in human resources as it does in hardware and software. It advocates a technology plan in which training and support occupy one third of the technology budget.

Summary

Although the real and potential benefits for the classroom use of CMC are evident, its adoption by schools is limited (Heaviside, 1996). One apparent reason for the discrepancy between use and benefit is the fact that CMC is relatively new. In many cases, the discrepancy is a factor of the culture of school and the difficulty of change. A number of studies (Heaviside, 1996; U.S. Congress, Office of Technology Assessment, 1995; Honey & McMillan, 1994; Wilson, 1995) identify funding, access, human resource development, and the implementation process as barriers to change. Fullan (1993) argues that all of these can better be subsumed into the core concept of school culture.

Method

Online interviews conducted as a series of electronic mail exchanges were the primary means of investigation in this study. The asynchronous nature of network communications lends itself to worldwide discourse. Practitioners with access to CMC have the ability to exchange ideas and information almost anywhere in the world.

Sampling was conducted by posting notices on a number of discussion groups concerned with education. The sample was composed of twenty-five educators representing schools in 16 states and 6 countries. Some schools have already adopted CMC, and are experimenting with its use; and others are in the process of adopting CMC. Fifteen of the schools are elementary; ten are secondary or K-12 schools.

An interview protocol was developed for use in e-mail exchange. It allowed for in-depth exploration of the implementation and integration of CMC into the curriculum. It included questions concerning the subject’s teaching practice and the support CMC receives from other members of the school community. Recognition that each school’s experience with CMC is unique favored the use of an unstructured interview rather than an online survey.

Data analysis was conducted according to the guidelines of the Constant Comparative Method (CCM), first described by Glaser and Strauss (1967). The goal of CCM is the emergence of theory from data, derived through repeated review of the data, each time examining it in order to locate common thematic content.

Interpretive validity of the data (Altheide & Johnson, 1994), was established by visiting a number of the sites to develop a visual sense of the school, the people, and the work being done there, and by having subjects review the interview transcripts to determine if they were being correctly represented. The review of transcripts was completed via electronic mail.

Results

Analysis of the interviews led to the construction of themes that represent the ideas, beliefs and practices of the study participants. They include access, a concern for the availability of technology and its ease of use. Themes concerned with school culture are climate, the atmosphere in which the use of CMC transpires, the role of the school administration, and the effect that the implementation of CMC in the school has upon its subsequent use.

Access

The availability of technology in a school has typically been the measure of its use (U.S. Congress, Office of Technology Assessment, 1995). However, the availability of online technology alone does not determine the use to which it is put. A new, broader concept of access is used to distinguish between those schools in which CMC is used effectively, and those in which it is not. Access encom-
passes not only the availability of computers, but also their location and type, the presence of modems and phone lines, as well as any limitations placed on student and teacher use. As such, it addresses a more significant distinction that divides the schools in this sample: the ease with which teachers and students can use CMC.

The schools represented in this study differ in the manner and extent to which CMC pervades the school. High access schools are those in which the use of online computer technology is fully integrated into the curriculum. Local area networks (LAN), with stations in each classroom, offer direct in-school communications capability and access to electronic mail and the World Wide Web (WWW). Teachers in high access schools use online resources with their students. Students have the ability to use CMC and the space needed to work on projects, which originate online. All of this takes place within a school culture that encourages and supports the use of CMC. Low access schools are not connected by a LAN and CMC is available from a single site, which teachers need to schedule in advance. Use of the accessible site may be limited to a few hours a week, or have other limitations such as the absence of good workspace. Student access to CMC is restricted in these schools. A culture of support for the use of online computer resources in the classroom is missing.

The underlying question concerning the classroom-based, curricular use of online computer technology is one of change. The process of change begins with a decision to invest in online technology, leads to the ongoing process of planning, purchasing and installing new equipment, proceeds to training and staff development for the professional staff, and culminates in ongoing technical and curricular support for the use of CMC in the classroom. The most highly accessible schools represented in this study approximate this process. Most others are somewhere in the process, with the least accessible schools just beginning the administrative decision-making process.

**Climate**

A positive school climate is one in which interactions among students, teachers, parents, and administrators are supportive and challenging. Some subjects speak of the respect that underlies all interactions, the level of collaboration and communication among school staff, and the importance of student involvement in their own learning.

Administrators in schools with a positive climate take staff wants and desires into consideration when developing the school schedule or otherwise organizing school activities.

The climate is one in which teachers work together and enjoy spending time with one another, enabling learning to be viewed as something in which individuals become more personally involved.

In contrast, a negative school climate is described as being devoid of support and collaboration. Teachers speak of being isolated from their peers, and lacking coordination and support. Teachers perceive their students as intellectually lazy and the cause of disciplinary problems. Because completion of the curriculum is paramount, innovations are met with suspicion. Although administrators talk of support, they offer little.

Another aspect of climate is the role of parents as part of the larger school community. Most high access schools have an active group of parents, who participate in PTA, serve on school committees, and participate in fund raising activities.

School climate is a significant factor affecting the success of CMC in schools. Schools with a positive climate are characterized as a place where thought is given to the way adults interact with students, and with each other. In contrast, negative school climates are places where relationships among administrators, teachers and students are obstacles to be overcome.

**Administration**

The attitudes, ideas and leadership styles of building and district administrators affect school culture by the level and type of communication they engender, as well as the support felt by individuals. The administrator is a significant actor in all aspects of the process of implementing CMC into the classroom. His/her leadership and active support of the technology plan may make a difference between success and failure.

The importance of the principal in teacher adaptation to the use of technology in the classroom is evident. Effective administrators provide a level of professional leadership that empowers their staff. Good administrators are supportive and flexible, accommodating the needs of their teachers in a number of ways. Administrators can devote the resources needed to replicate successful programs in schools throughout the district. They can develop and support partnerships between schools and universities or corporations to stimulate the use of online computer technology in the classroom.

School administrators are significant in the culture of an individual school. Their leadership and active support of the use of CMC can ensure that it will be uniformly accessible to teachers and students. A lack of administrative leadership and support becomes a barrier to school change that is difficult to overcome. It limits professional growth by teachers and reinforces a hierarchical structure of school.

**Implementation**

Few things foreshadow the success of CMC in the classroom quite as much as the implementation process. Implementation is a complex phenomenon that includes planning and decision-making. It encompasses not only the structural elements of wiring and equipment, but also the socio-cultural elements that support teacher adaptation to change.
The decision to bring CMC into a school typically involves planning by a committee that makes recommendations to the staff and principal. Sometimes the committee has help from an outside agent such as a university or corporation, which can help with finances, equipment and technical assistance. Successful planning efforts become part of the school culture, often stimulated by the district office or the principal.

When planning focuses on equipment and software, the element of professional development may be neglected. The effective use of CMC as a vehicle for enacting the curriculum depends on the adaptation of teachers to the use of technology in the classroom. Teacher appropriation of classroom technology is the result of the individual's ability to change, not simply the act of placing computer technology in the classroom. The OTA Study (1995) finds that extensive staff development is a necessary prerequisite for teachers' successful adaptation to computer technology.

Subjects working in schools which have a high degree of access are uniformly part of a culture in which training and professional development are the norm. Some low access schools severely limit the amount of time teachers have for learning about technology, or adapting it to classroom use. Money for new equipment or training is difficult to find. School district leadership is not supportive, or even anti-technology, and has a difficult time conceptualizing change. Those who advocate for CMC in low access schools often have to confront teachers' fears about changes that may result from its introduction into the school.

The implementation process can significantly affect the rate and quality of the adaptation of the staff to the use of online computer technology in the classroom. Planning and decision-making can help build staff interest in the use of online computer technology in the schools. Finally, the staff's adaptation to the use of CMC and their comfort with the medium is enhanced by an ongoing culture of staff development that focuses on teachers' use of CMC in a curricular context.

Conclusions: The Relationship of Culture to Access

A positive school culture allows a high degree of access to CMC to develop. The aspects of a positive school culture include trust and collaboration among the professional staff, a commitment to professional development, and a respect for students as individual learners and administrative encouragement and support. Together, these factors help make the difficult transition to CMC easier. They also allow the spirit of experimentation and exploration, so necessary for successful online teaching and learning, to develop.

284 — Technology and Teacher Education Annual — 1998
It is the intent of this paper to foster discussion toward new ways of viewing our educational system by effecting change via small, initial adjustments. These initial changes have the potential to change our present, outdated, Industrial Age school system to a modern, Information Age system, where the emphasis is on learning and not teaching.

Since the publication of A Nation at Risk (1983), both educators and non-educators have proposed solutions to the nation’s educational problems. These solutions range from a total rebuilding of our educational system to numerous band-aid approaches. The band-aid approach yields little and tends to perpetuate the status quo. Those in power have nothing to gain from a reformation. It is axiomatic that what bureaucracies do best is to maintain themselves. Thus, for the past one hundred years we have seen little change in an educational system built to sustain an industrial economy.

It can be argued that the only way for systemic change to occur is through a total extirpation of the present, state-centralized model and construction of a new, decentralized system built for an information economy. In fact, there are some convincing arguments for this. (Perelman, 1994; Wilson & Daviss 1994; Gerstner 1995; and Lieberman 1995). Perelman even contends that our educational system will collapse in a few years because of its own internal, bureaucratic, centralized controlled model, in much the same way as the Soviet Union collapsed - almost overnight. While this total collapse remains to be seen, it is quite evident that major changes, which address the root causes of the present system’s failures, are needed.

K-12 education is, Constitutionally, left to the individual states. While the federal government can set national goals, guidelines, and, in some cases mandate monumental laws, no one is seriously arguing for federal control of our school system. Control of individual school systems will remain within the province of the individual states. The problem of reform is for the states, both individually and collectively, to solve.

Thus, we present a number of fundamental ideas that could be implemented by states, either individually or collectively, to change our current educational systems into Information Age system. Taking our cue from Chaos Theory, which states that all systems have a sensitive dependence upon initial conditions, we suggest a series of small conceptual variations to our present educational system that might, in turn, result in large substantive changes.

Idea 1: Change the endorsement of teachers from certification to licensing

As it now stands, teachers are sanctioned to teach by the state through a process of certification. Prospective teachers take courses specified by the state, from universities accredited by an agency, usually determined by the state. Before becoming a full-time teacher, an individual must receive certification in one or more subject matters from the state. Although there are a few exceptions, this is the rule that operates in most states. It is the primary rule that controls the system.

The university that one attends generally has little choice in determining what courses a prospective teacher studies. The state, in essence, determines the amount of time spent in taking courses, the types of courses studied, the content of the courses, and the acceptable performance level to be declared a teacher. The role of the state is to administer an examination designed by the profession. There is no Department of Medicine nor a Department of Law to specify what a doctor or lawyer should know. In other words, the
state serves as a regulatory agent only and not as the specifying body of content, as is done in education.

Teachers should be licensed and not certified. Furthermore, the state should get out of the business of dictating what skills, knowledge or information a teacher should possess. The consequences of such a change would range far and deep into our educational system. Removing from the state the power to dictate the specifics of curriculum, and other matters to the education profession, would result in colleges of education becoming more proactive and competitive in their preparation of teachers. Certainly, the standards of the profession would increase just from the competition among professional schools of education. The entire curriculum of education, now dictated by the state, would change. Just as in medical schools, specialties would increase, internships would be longer, residencies would arise and teachers would be much more expert in their discipline.

Licensing would give teachers an incentive to become educational entrepreneurs. They might form groups with other licensed teachers to operate charter schools. Supply and demand would come into play. Public and private schools would vie for these new kinds of teachers. Parents would demand that the best teachers are hired and the worst fired. Licensing would encourage the free enterprise system to operate. Vouchers of some sort might gain acceptance. The change from certification to licensing would have a domino effect throughout the system. No one can tell the eventual results. However, we do know that licensing, not certification by the state, is the model for the Information Age.

**Idea 2: Change the school system from a Time Constant – Achievement Variable status to an Achievement Constant – Time Variable status**

Our present school system embraces a model that keeps the time constant and varies the achievement level. We require learners to spend a pre-specified amount of time in the classroom, but allow them to exit with different levels of competency. This model was designed and needed for an industrial economy. School usually lasts 180 days per year. Learners spend six-eight hours in school per day and classes are based upon a strict time allotment of minutes per hour. In an industrial economy, time is the major factor. Workers must be on time, they must work a specific number of hours, and their reward is based upon the time spent at the workplace. Thus, schools were designed and operated to prepare learners to function in this time oriented paradigm. Although some learners accomplished more or less than other learners, all were equally conditioned to punch the clock.

For an industrial economy, this is a good model. For an information economy, it is a bad model. We suggest a simple reversal of the situation currently in place. Moving to an achievement constant – time variable model would change the way schools operate, take into account the different abilities of learners, and conform to contemporary learning theories. For example, schools could be open 24 hours/day 365 days/year. Learners would progress through the systems at different rates. They would enter and exit at different times, and they all could accomplish an acceptable level of achievement. Many different programs could be offered at the same time to accommodate the distinct learning styles and life goals of the learners. The worth of a school would be based upon how well it educated its learners as opposed to how many attend each day. The reverberations through our entire society would be enormous.

**Idea 3: Recognize that it is the individual who learns, and not the group**

It is interesting to note that most measurements about the accomplishment of schools, school districts, and state education requirements are based upon the assessment of the group and not the individual. This is what we call the statistic of the average. We also call it a fatal flaw in education.

Here is a trivial example. We call it Method A vs. Method B. Assume that we want to test the effectiveness of a new instructional method, say, computer assisted instruction (CAI). We set up a comparison experiment between CAI (Method A) and the traditional classroom method of Instruction (Method B). After completion of the experiment, the researchers compile the mean scores and variability measurements of each group, and then use a simple test statistic to determine if a real difference in achievement exists between the two groups. Let us say that the mean score of the CAI group was significantly higher than the traditional group. Based upon this data, the researcher concludes that the CAI instruction is superior to traditional instruction.

However, there is a problem. What we have done is to measure the group’s performance, but in the process, we lost all information about the individual. As soon as we calculate the mean score of each group, each individual’s achievement is lost. We call this the fatal flaw because, from contemporary learning theory, we know that it is the individual who learns and not the group. In other words, classrooms do not learn, individuals do.

All kinds of decisions in education are made based upon group data. State mandated tests and Goals 2000 are all based upon the statistic of the average — the fatal flaw. Although this statistic of the average works quite well for plants in a pot, pigs in a pen and beans in a barrel, it does not work for learners in a school. What we as educators must address is the learning of the individual. We must design systems that are adaptive to the individual. We must design new assessment procedures for determining individual achievement. We must move away from the statistics of the group and derive new statistics for the individual.
Idea 4: Recognize that the learner is the customer, not the product

Although some would argue that the learner is the product of our educational institutions (Glasser, 1990), others would argue that the learner is the consumer/customer (Harris & Baggett, 1992; Tribus, 1997). Most school systems view the learner as the product. We define the educational system as the seller, education as the product and the learner as the consumer. Although it is possible to identify other consumers of the schools’ product, the primary consumer remains the learner.

In addition, we must recognize that our product is education or more specifically information and knowledge. Thus, it is imperative that educators continuously try to improve the product for the satisfaction of the consumer. Given this, then why is it that we in education blame (fail) the consumer when our product fails? Should we not review our product and try to improve it? Of course, but as present educational systems are configured this is not possible until we recognize who is the consumer and what is our product.

Idea 5: Adopt the Deming system of profound knowledge

Most educators know of W. Edwards Deming and his fourteen points of Total Quality Management (TQM). These points are derived from his system of profound knowledge (Deming, 1997).

Deming provides not only a philosophy, but also a process for success. Many educators use the word quality with little or no understanding of its true meaning. Most of us fail to recognize that quality is a process, and that the pursuit of quality is never ending. We contend that if educators concentrate on quality, they can completely restructure the way that administrators lead, teachers teach and learners learn. Combined with technology, Deming’s philosophy is a powerful tool for the design of Quality Schools (Cafolla & Kauffman, 1993).

Idea 6: Change funding method of schools. Funding should go directly to schools, be related to the satisfaction of the customer and established by the quality of the product

The manner of funding schools via school districts must change to the direct funding of the schools themselves. If a school is successful, the money will follow. Alternative ways to fund schools should be examined. If you change the fundamental structure of the system via the ideas presented herein, new avenues of funds will open. Most certainly, a voucher system of some sort will be implemented. This places the money in the hands of the consumer and not the bureaucracies that manage and determine the system’s policies. If vouchers are given directly to individual schools or teachers by the consumer, new school systems, such as charter schools and other models will emerge. Our school system should be placed under the free enterprise umbrella. Schools that work will prosper, those that do not will fail.

Idea 7: Adopt ideas from the new sciences.

Chaos theory, cognitive science, complexity, artificial life, artificial intelligence and criticality are but a few of the new sciences that offer a deeper view into how the human mind works and how humans learn (Bailey, 1996; Dennett, 1996; Coveney & Highfield, 1995; Holland, 1995; Levy, 1992; Kauffman, 1995). For example, Resnick (1997) sets forth a theory of learning called Constructionism that emphasizes two different views of Constructivism.

Other ideas, including emergent systems, simple rules that result in complex behavior, and an evolutionary process that continually adjusts the brain to the surrounding environment by maintaining the brain in a state of criticality are all ideas that relate to learning. (Bak 1996). As educators who have held to the discredited ideas of behaviorism much too long (Gardner, 1987), we must reorient our methods, and revise educational content to fit into an Information Age, and thereby transform teacher training into teacher education.

Idea 8: Emphasize creativity

There is a critical need for a better balance in training divergent thinking, as compared to convergent thinking. Teachers can cultivate learning experiences by providing creative environments that emphasize the comprehension of facts over their memorization. A recent study conducted by Hamza (1996) revealed several factors that seem to promote a creative learning environment. Some of these are the teacher’s knowledge, character traits, teaching style, passion and attitude toward learners, the learning climate, teacher-learner interaction, and learner attitudes. It is also observed that learners favor creative, open, and non-threatening environments over those governed by authority and conformity. Schools commonly do not reinforce creative thinking nor do they aim to foster creative environments. These deficiencies appear to significantly hinder learners’ abilities to become productive workers. (Carr, 1994; Drucker, 1986)

Idea 9: Require that all educational activities be based upon verifiable learning theories

Learning theories, teaching methods, and research are extremely significant sources of ideas for educators at all levels. For example, communication theories can help teachers understand the process of communication between learners and themselves. Systems theories give teachers a better understanding of the working of various systems and their subcomponents. Instructional design theories help teachers build a system of professional expertise for diagnosing learning problems, and prescribing possible solutions. Cognitive learning theories can help educators understand the nature of skilled intellectual performance. (Means, 1994). Theory based learning must be one of the fundamental building blocks of any new educational system.

Educational Leadership — 287
Idea 10: Use technology in new ways

The computer provides educators with a unique and universal tool. It gives educators the resources to simulate real-life events, investigate the nature of living and non-living entities, perform complex experiments, build new systems, and allow learners to create unique environments and systems from scratch (Papert, 1993). The computer combined with the Internet provides learners with immediate access to the largest amount of information and knowledge ever to be collected in history.

Although distance learning is not a new idea, new models are being designed and used. The Internet and the advances in programming tools for implementing learning models via the World Wide Web provide a unique opportunity for educators to broaden their sphere of influence from the local classroom to the cyberspace classroom. Using sophisticated tutorials, educators can reach the individual learner wherever he/she may be, at any time.

Technology gives us the ability to displace both time and place as the main functional components of traditional schooling systems. The possibilities are endless. Within our imagination, it is not impossible to conceive of the end of the traditional schooling system, when it is recognized by educators, learners, parents and legislators that learning does not necessarily have to occur in a place called school.

Distance education, when defined as an educational transaction between a teacher at one location and a learner at another, dates back to late nineteenth century correspondence courses. Today, distance education encompasses a myriad of delivery systems that provide learning opportunities to students of all ages (Moore & Kearsley, 1996).

During the past decade, American high schools began using distance education technologies to offer students courses in math, science, and foreign languages. These courses often use a teacher-facilitator-student model where the teacher is at a remote site and the facilitator and students are in a local classroom (Tushnet, 1994). Teachers and students have always been major components in educational systems, but the classroom facilitator represents a new component. Little is known about roles classroom facilitators play in distance education, how they affect other components in the system, or how they affect system outcomes (Willis, 1992).

This study was initially designed to identify the roles of classroom facilitators and students within the context of a high school distance education course and to examine how those roles affected student performance. However, it quickly became apparent that the school itself played an important part in facilitator and student behavior and achievement. Consequently, the focus broadened to reflect a realm of variables, including school attributes, that influenced distance education in this setting.

Design of the Study
An ethnographic, multiple case study research design was used for this study. Three classrooms from different high schools (South High, Central High, and North High; all fictitious names), each taking the same nationally offered distance education physics course during the 1994-95 school year, participated. The course was delivered live, via satellite. Telephones and a computer keypad system connected the students with the remote teacher. The course design included 30 minutes of instruction and other activities provided by the satellite teacher, as well as a 20 minute off-air period during which the facilitator and students did homework, discussed problems, or did labs.

The research methodology included extensive classroom observation, informal and formal interviews with classroom facilitators and students, and review and analysis of student work products, extant documents and resources used in the course. Each participating physics class was observed daily, in its entirety, for two consecutive units of study. A third unit of study was observed later.

A purposive sampling strategy designed to provide maximum variation was used to select the participants. Case variations included (a) facilitator certification (science, social studies, not certified); (b) facilitator distance education experience; (c) class size; (d) student demographics; (e) match of the school and distance education course bell schedules; (f) number of distance education courses offered by the school; and (g) location of the school (two adjacent states, three school districts).

An inductive constant comparative method was used to analyze the data. Collected data was transcribed, compiled, and coded; and then compared and contrasted to identify patterns and trends. Triangulation of data collection methods and data sources was used to enhance reliability and validity.

School Impact on Facilitator and Student Roles and Performance
The schools in this study had a major effect on facilitators and students. The high school calendar, including student and teacher holidays, and special events scheduling such as pep rallies and assemblies, affected how frequently students missed regularly scheduled distance education classes. This, in turn, affected facilitator roles in terms of planning for students to make up missed coursework. In one school the facilitator just taped the programs and made them available to students; in another the facilitator showed the makeup tape during a later class period; and one facilitator had to plan special make-up periods outside class. Ultimately, student performance was affected when, and if, classes were made up. This was particularly evident at South High where many school holidays failed to match the distance schedule, and where a number of special activities...
disrupted class. In addition, over half the students at South High missed physics once a week for an entire semester as a result of another class. As the South High facilitator noted, “If they miss it and don’t make it up, and then they get lost, it’s a wipeout. They never catch up.” Thus, the school calendar had an adverse effect on student learning in physics if it meant students missed classes to the degree they got behind and couldn’t (or didn’t) catch up.

The school bell schedule also influenced student and facilitator activities. At North High a German class was scheduled at 9:00 a.m., just as the off-air physics time was beginning. As a result, physics students went to the media center for the off-air segment and the facilitator stayed with the German class. This meant the facilitator could not participate in off-air activities with the physics students, and she felt this was detrimental. During previous years, she had used off-air time to encourage students to call the physics teacher with questions they did not understand, or had encouraged them to do homework together on the chalkboard. These activities allowed students who were having difficulty to get help, either from the physics teacher over the phone, or from the other students in the class. However, the 1994-95 North High physics students were reluctant to call for help unless the facilitator actually placed the call. Due to the scheduling of the 9:00 a.m. German class she was rarely able to do this. Cooperative learning through mutual homework review rarely occurred because students spent the off-air time in the media center visiting with each other rather than doing homework. Students in the media center were also unable to complete lab or other activities that required equipment access. At South High School, the bell schedule split the off-air period into two short segments that tended to be wasted by the students.

School registration procedures had a major impact on North High students in terms of pre-requisite skills. The physics course required Algebra I and II as pre-requisites, but a number of North students were misadvised and did not meet these requirements. As a result, most of the North High students had poor math skills and were unable to perform the algebraic procedures required in physics. Consequently, their acquisition of physics skills suffered. While the facilitator became aware of the algebra deficiencies early in the course, she had no way of providing remediation.

Prior school experiences also affected physics students. North High students had chosen physics because they had heard, from other students or the chemistry teacher, that physics was easier than the alternative chemistry course. So, their expectations were that the course and the work required of them would be easy. While a number of the students at South High perceived that physics was a more difficult science, the amount and kind of work they were used to putting into courses did not prepare them for the effort required by the distance education physics course.

Many lacked adequate study skills and discipline. The South High facilitator observed, “I think this class requires more from them than they’ve been used to. They need to look at physics every night, and they just did not do it.” And while all but one South High student met the algebra pre-requisites on paper, most believed that the skills they had acquired in their algebra courses at South High were inadequate.

School drop policies for distance education courses affected some students. None of the three schools allowed students to drop distance education courses after tuition had been paid to the course provider. But, several students at South and North High Schools indicated they would have dropped the course had that been an option, since they were doing so poorly in it. The drop policy may have indirectly contributed to a test retake policy at South High and a lenient homework policy at North. Both policies provided an opportunity for students to improve their grades although the policies did not support student learning. Generally, the South and North High facilitators did whatever they could to help students pass the course since they could not drop it.

Other school responsibilities affected the amount of time the South High facilitator actually spent in the classroom. The South High facilitator was a full-time school administrator, and as a result she periodically missed entire classes for several days or a week due to meetings, workshops, or other school obligations. Since she was an administrator, substitutes were not hired to take her place as facilitator. Missing classes meant she had to catch up on what had been covered in physics, determine what students had or had not done, and then decide how students would make up missed activities. South High students indicated they did not stay on task and found it difficult to pay attention when the facilitator was away, so the regular learning process was always affected when she was absent.

**Facilitator Roles and Their Effect on Student Performance**

Facilitators at all three schools agreed that their primary focus was on classroom management and climate, but noted they engaged in some planning and instructional tasks. Logistical planning and implementation was a major responsibility. All three duplicated instructional materials developed by the physics teacher and distributed them to the students. They maintained lab equipment and prepared the classrooms for lab activities. They also decided how to accommodate deviations between the school and physics calendars and schedules. The physics teacher delivered most of the instruction, but occasionally the facilitators provided supplemental guidance or feedback as they responded to student questions. The South and North facilitators occasionally answered informational questions directly, but more frequently directed students to other resources such as other students, teachers, or the telephone.
tutors. The Central High facilitator had a science background and was able to answer student questions personally. The North and South High facilitators played a major role in gaining (and maintaining) student attention during class and in eliciting student performance during labs and other in-class activities. The Central High students tended to stay on task, paying attention and participating independently, so the Central facilitator rarely had to assume these roles. All three facilitators implemented the testing and student assessment activities planned by the physics teacher. Each facilitator instituted grading policies and procedures that they thought were appropriate for their students and instructional setting. For instance, at South High students were allowed to retake tests for extra credit and at North High students were allowed to turn in homework long after it was due.

All three facilitators assumed classroom management roles, although the North and South facilitators were more active in this area. The Central facilitator reported, and classroom observation confirmed, that Central High students were mature and required little supervision, while the other two facilitators were continuously working to keep South and North High students on task, paying attention, behaving appropriately and participating in classroom activities. At South High the facilitator constantly reminded them to pay attention and participate in class, and she always coached or guided students through labs, since they tended to sit idly without her direct intervention. The students themselves reported that it was difficult to pay attention when the facilitator was absent. At North High the facilitator sat among the students to keep them on task, and frequently interrupted student conversations or other off-task behaviors to get them to focus on physics. Students at North High indicated that they found it hard to concentrate and pay attention and relied on the facilitator to keep them on task.

The facilitators also assumed classroom climate roles, displaying positive attitudes toward the course and instructor, encouraging positive student attitudes and trying to build supporting relationships with and among the students. The South and North High School facilitators tried to work with other teachers in the school to make them aware of special needs or dispensations the physics students required as a result of their participation in the distance education course. In all three schools, facilitators maintained indirect contact with parents through mid-term grading period progress reports. The North High facilitator also maintained direct personal contact with several parents who were concerned about their child’s performance in physics. Students at all three schools attributed their positive attitude toward the class to the facilitators’ enthusiasm.

Other Factors that Affected Facilitator and Student Roles and Performance

Individual student aptitudes and other academic skills and experiences also affected the physics students and facilitators. At Central High, many of the students had taken physics because they were interested in the subject. The facilitator observed that most of these students were gifted, and that all had a great deal of initiative and self-responsibility. The Central students stayed focused and attentive during class, rarely had trouble grasping concepts, and found the pacing of the physics class to be satisfactory. They had good study habits, recognized the importance of solving homework problems rather than copying answers, and had good test-taking skills. They also took responsibility for making up classes they missed by taking tapes home or viewing them before or after school. Consequently, their academic performance was good, and the facilitator rarely had to intervene or provide direct support for class activities.

This contrasted with the students at South and North High, most of whom were average students with average academic backgrounds. They had more difficulty staying on task and paying attention, inadequately utilized instructional resources, occasionally found the pacing of the course too fast, frequently copied homework answers just to get credit, and employed educated guess strategies when taking tests. They tended to accept less responsibility for their own learning, relying on the facilitator to help them focus or to make sure they did their homework or labs. While some of the students at North High reviewed tapes for classes they missed, only one South High student routinely made up missed classes without direct facilitator intervention. Facilitators at these two schools provided a great deal of support and guidance during class to help students to pay attention and participate in class activities, to actively help them complete assignments such as labs, to make sure they turned in homework, and to encourage students to utilize supporting outside resources such as the tutors. While some of the South and North High students performed satisfactorily on tests suggesting that they had mastered physics skills covered in class, a number of students at these schools relied on homework credit and good lab scores to pass the course.

Facilitator backgrounds also contributed to facilitator roles. Since the Central facilitator had a science degree, she could usually provide immediate answers to any content-related questions students might have. The other two facilitators might be able to answer some physics questions based on things they had learned in previous years, but their more frequent information/feedback role was to direct and encourage students to use other resources to find answers. Some of the South and North High students indicated that they called the tutors and found them helpful, but many were
reluctant to call or found it difficult to communicate with the tutors. And, since a student’s ability to clarify and resolve conceptual or procedural questions ultimately affects student learning, the Central High students’ physics performance was influenced to some degree by their facilitator’s ability to answer their (infrequent) questions. Of course, Central High students also turned to each other for help. At South and North High Schools, the students had frequent questions; and whether their facilitators could answer the questions, or direct them to an alternative information source (and get the students to use the resource), also affected student learning. Unfortunately, the South and North High School students rarely took advantage of these resources.

Implications for Theory and Practice

This study supports the position of theorists such as Shale (1990) and Garrison (1989) who contend that distance education, while morphologically different, does not constitute a distinct educational process. The same factors that affect student learning in a traditional classroom also affect student learning in a high school distance education class; that is, learner skills, knowledge, beliefs, attitudes, and course/lesson design.

The study also suggests that responsibility for the quality and outcome of high school distance education courses is shared among all components of the distance education system; the course provider, the high school utilizing the program, and the local facilitators and students who are participating in the course. Specifically, the course provider, instructor, and designers, are responsible for providing effective, efficient instruction in the form of courses that maximize student achievement. This includes designing, developing and providing instruction, materials and activities, that, when utilized as prescribed, result in student mastery of clearly defined objectives. This also includes clear specification of desired student outcomes, required student entry skills (perhaps a specific pre-requisite skills test rather than designation of required pre-requisite courses), instructional materials and activities, a prescribed plan for course implementation, and other student support as required.

The responsibilities of the local school include assuring students possess the pre-requisite entry skills and supporting utilization of the course as designed by the course provider. This includes fully implementing the complete range of instructional activities in the sequence designed by the course provider. Or, if the school can not implement the course exactly as designed, it must assure that other components in the system can compensate for the instructional elements that were not implemented as designed. Specific school responsibilities include registering (and pre-screening) students, establishing school calendars, bell schedules, and selecting and establishing facilitator availability. These are all factors which contribute, directly or indirectly, to facilitator and student roles and performance. Since two of the schools participating in this study deviated to some degree from the course provider’s implementation recommendations (i.e., student pre-requisites, off-air activity block scheduling, and facilitator availability), this may provide evidence that one of the challenges high school distance education course providers will face is getting schools to utilize courses as designed. This is similar to the problems instructional designers have traditionally faced in getting schools to use courseware as designed (Burkman, 1987).

Finally, the study suggests that in addition to course design and school factors, facilitator roles and performance requirements will be defined by the needs of the students themselves. Students who are high on the motivation and willingness continuum but low on the ability continuum may require facilitator support in the form of instructional assistance (if the facilitator has subject area expertise) or encouragement and assistance in using telephone tutor or other external support (if the facilitator does not have content area expertise); whereas students who are high on ability but low on motivation and willingness will require facilitator support to help them stay on task and participate in class activities (Hersey, Blanchard, & Johnson, 1996).

Elizabeth Kirby is Assistant Professor of Research, Media and Technology in the College of Education, State University of West Georgia, Carrollton, GA 30118. Office phone 770-836-44426. E-mail: ekirby@westga.edu.
The role of technology in education has changed over the last five years. Technology is now being recognized as an educational tool. It is being used as a means to an end not as an end in itself. Research consistently shows that technology per se does not make school reform happen (Means, 1993). Many educators are now actively using technology along with effective teaching strategies to integrate technology into their curriculum. These changes or restructuring allow educators to significantly improve the teaching and learning which occurs in their classroom.

Appropriate strategies are the keys to realizing the maximum benefits of various technologies. However, effective strategies need not be utilized only for improved teaching. Effective strategies can and should be used for a variety of other purposes in the planning, implementation and evaluation of technology use in classrooms, schools and school districts. The planning process is where it all begins. Planning allows potentially beneficial strategies to be realized when they are incorporated into a framework that reflects a direction, proper support, and is accepted by the stakeholders. In addition, classroom plans, school plans and district plans must be integrative and mutually supportive.

Effective Plans

Planning, if conducted effectively, can enable a teacher, a school, or a school district to realize beneficial teaching and learning outcomes. Unfortunately, many teachers, schools, and districts are being forced to produce long-range technology plans that don’t really reflect their needs, infrastructure capabilities and effective strategies for implementation. These long-range technology plans often are requested by administrative bureaucracies for the purpose of accountability, justifying the use of resources, and funding which often are initiated as a result of public demand. Many of the plans that have been developed are merely end products. They should really be developed and utilized as a tool, a means to an end. Too often these plans are evaluated out of context and they receive great recognition and awards in schools, school districts and nationally in technology periodicals. Recognition and awards should be given if there are significant improvements in teaching and/ or learning. In particular, when technology is involved, we really want to see if technology is contributing to the improved teaching and learning outcomes. If not, other tools and strategies need to be utilized.

Plans - Components, Steps, Approaches

These recognized technology plans often include very important components that are needed to help insure that most needs and conditions are being addressed. Important components often include:

- Formulating a planning team
- Collecting and analyzing data
- Formulating the vision, goals, and objectives
- Exploring available technology
- Determining training and staffing needs
- Determining a budget and funding sources
- Developing an action plan
- Implementing the plan
- Evaluation

However, many of these technology plans are designed and developed with components or steps that are missing or approaches that are not appropriate. Hence, they may not be valid, accurate, and effective for the particular school and community where they are to be implemented. When the design and development is inappropriate, there is a high probability that many of the stakeholders, especially school and district administrators, are not going to buy-in and support it philosophically and financially. This greatly reduces the effectiveness of the technology plan. The Cradler (1992) study concurs that effects were greater when the development and implementation of a school plan were actively supported by the district.

Although some technology plans lack components or steps, clearly the most critical problem is their approach. Planners and developers often do not realize that the process of planning is just as important and often more important then the plan itself. In addition, the difference between long-range planning and strategic planning is enormous. Long-range technology planning is often required by schools and school districts around the country. Long-range planning is more traditional and product-oriented while strategic planning is mission-oriented, process-oriented, dynamic and change-oriented. Table 1 further lists some of the characteristics of these two types of planning.

Strategic Planning - Benefits and Key Elements

Strategic planning is what we should encourage in classrooms, schools and school districts. Bryson (1995) lists many of the benefits of strategic planning:

- Promotion of strategic thought and action
- Improved decision making
- Enhanced organizational responsiveness and improved performance-flows form the first two.
- Can directly benefit the organization’s people

One key element in strategic planning involves the vision. Strategic planning involves designing and developing a direction, a vision of “what should be” or “what could be” (Herman, 1992). Without a clear vision, other planning efforts cannot occur effectively. Representative participation of stakeholders is critical in providing input and feedback in strategic planning. Stakeholders need to be involved in the process of inquiry, discussion, and decision making by consensus (Burkhart and Reuss, 1993). Stakeholders also need to be involved from the beginning, otherwise, if the organization cannot demonstrate its effectiveness against the stakeholders criteria, then regardless of any inherent worth of the organization, stakeholders are likely to withdraw their support (Bryson, 1988). A third key element involves research and assessment (scanning) to provide important information for decision-making. This information will allow planners and developers to identify and understand our external and internal environments.

Often we know much about our internal environment but not much about our external environment. Bryson (1988) identified a number of key factors necessary when thinking about the scanning process, including:

- Selecting issues and trend “categories.” He suggests political, economic, social, and technological;
- Identifying appropriate “scanning” sources (professional journals, key informants, newsletter, etc.);
- Understanding the cycles that issues in the external environment take: (i.e., How often does this issue come around?; How long does it usually stay within the “window of interest” by policymakers? Can your organization react rapidly to take advantage of the next “window”?).
- Asking effective questions to ensure effective external scanning: (i.e., Is this a new issue or trend: Were you surprised where it came from (source)? Does it fly in the face of the current “conventional wisdom”? Can you determine if there are patterns/trends?).

Lastly, another key element for strategic planning involves continuous improvement. The process can only be effective and efficient if it remains dynamic and involves strategies that encourage and support change.

All of the above elements are especially important when developing technology plans. These elements play a critical role in confronting issues and trends that constantly change and therefore warrant significant input form stakeholders to develop strategies that can be implemented by educators to provide students with the most effective methods and tools for learning.

Strategic Planning - Important Steps

A few of the major characteristics or key elements of strategic planning have been presented. It is also important to present some of the important steps that should be used to bring about the needed changes. The literature reflects several models for incorporating these steps. The following list is an attempt to combine the steps from models proposed by Handy (1992) and Bryson and Roering (1987) and Bryson and Alston (1996) and Burkhart and Reuss (1993):

- Initiate and agree on a strategic planning process
- Identify current resources
- Identify current mandates
- Identify stakeholders and their expectations
- Develop and/or refine mission and values
- Assess (scan) the internal environment- strengths and weaknesses
- Assess (scan) the external environment- opportunities and threats
- Identify and frame strategic issues
• Formulate strategies to manage the issues
• Develop an action plan
• Review, revise, and adopt the action plan with timelines
• Develop an effective implementation process including the evaluation (formative and summative) of programs, projects, and services.
• Continuous scanning and reassessment of issues, strategies, and changes needing to be implemented.

Space does not allow me to discuss these in detail. For further reading, I have referenced the appropriate authors.

PRINCIPAL LEADERSHIP FOR SUCCESSFUL SCHOOL TECHNOLOGY IMPLEMENTATION

Angus J. MacNeil
University of Houston-Clear Lake

Dennis P. Delafield
University of Houston-Clear Lake

There is no shortage in the current education literature about the need to reform our public schools (Sarason, 1997; Goodlad, 1997). Educators are being told they are not keeping up with the real world. Business leaders are complaining that schools are not producing enough qualified workers (Matthews, 1997; Wadsworth, 1997). Educators often are told that the schools of the twenty-first century must be organized differently from the schools of the twentieth century to meet the needs of an increasingly diverse society. Many educators recognize the need for a change and there is a strong call for reform (Glickman, 1998; Goodlad, 1997; Schlechty, 1997; Sarason, 1997; Hirsh, 1996; Sergiovanni, 1996; Barth, 1990).

Researchers (Fullan, 1996; Goodlad, 1997; Sergiovanni, 1996) have begun to question whether we are meeting the varied educational needs of all students. Also being questioned is the structure of schools and whether these structures are appropriate for educational institutions. Each has suggested that there are major changes that need to occur in schools if we are to meet the needs of students now and in the future. Fullan (1996) suggests that rather than think in terms of reforming schools, we need to think in terms of reculturing schools. He suggests that the values, beliefs, and norms of schools need to be examined to determine whether the existing culture of the school is preparing students for participation in a complex society that requires strong problem-solving abilities. To reform our present system, principals must change from their present role of manager to instructional leader. The key role principals play in schools is well documented and acknowledged (Buckner, 1997).

As, Szabo & Schwarz (1997) point out, instructional technology has great but unrealized potential for reforming educational systems. Proponents of educational technology advocate using technology to fundamentally restructure education: the business of how teachers teach and how students learn (Ellis & Fouts, 1994; Wirth, A.G., 1992). Past explorations of why the potential is unrealized have focused upon attempts to get people to change and the complexities of instructional use of computers. An important person in making change happen is the school principal.

Instructional Leadership and Technology

A survey of the literature in education points to the critical role of the principal as instructional leader in the school (LaRocque & Oberg, 1991; Henri & Hay, 1995). Pellicer, Anderson, Keefe, and McLeary (1990) state that "...instructional leadership is likely the most important function in a school for creating a productive and satisfying environment" (p. 41). Daresh (1997) makes the observation that because of the emphasis on instructional leadership, preservice programs have focused on learning experiences that help future school administrators "...oversee the teaching-learning activities in their schools as the primary area of attention and responsibility" (p. 5).

Lou Gerstner, (1994) CEO of IBM, claims that nothing matters more to America’s schools than finding competent principals to lead them. Although the role of the school principal is frequently cited as the key element in school reform, it is not the solitary role of times past. It is a role that demands skills in enhanced team building, shared decision making, and increased technological competency.

Researchers at the Stanford Research Institute and Educational Development Corporation find that technology can be a powerful tool for supporting educational reform (1992). As many states and communities across the country are learning, transforming industrial age schools into information age schools is easier said than done (Dyrli & Kinnamon, 1994). The key to ensuring the success of technology in schools is the way in which technology is integrated into the school’s curriculum. As Kinnaman (1994) observes, successfully integrating technology into education requires basic changes to our current model of schooling; anything less sells short both the value of today’s technology and the future of education. School principals must understand the importance of technology for improving school management as well as its implications for improved instruction.

Technology with the right software equipment and instructional design can enhance the students’ active
participation in his/her learning and encourage problem solving skills by involving them in realistic assignments. This transformation from industrial age schools into information age schools won’t happen without active leadership by the school principal. If schools are to take full advantage of the educational opportunities available through media centers, principals must be knowledgeable concerning their vast potential. One of these potentials was addressed in the Lance study (1993) which revealed that quality school media centers significantly impact students’ test scores.

**Inhibitors to Technology Implementation**

First, there are teachers and administrators who believe the lack of available money for technology is a problem when trying to integrate technology into the curriculum. Research shows that the amount of money available to a school district is not related to the innovative uses of computers. Exemplary teachers work in a representative range of communities and schools. However, they tend to be found in settings where school and district resources have been used to create supportive conditions (Becker, 1994).

Second, principals need to plan professional development programs for teachers. Professional development is essential for technology implementation in the schools (Solomon, 1995). Plans for professional development need to be cost effective and as non-disruptive as possible (Dwyer, 1995).

There is no scarcity of literature when it comes to professional development or topics related to professional development (Parker, 1994). There is a need whenever change or introduction of something new or unknown to a group of employees to have some training or professional development. For school administrators professional development is one of their major responsibilities. Research shows that a factor in creating trust between teachers and their principals involves principals being involved in teachers’ professional development (MacNeil & Blake, 1998). Research also shows that teachers’ job satisfaction is related to how principals’ instructional management focuses on teachers’ professional development (MacNeil, 1992).

Principals need to solve the dilemma of how to provide appropriate technology training for all the faculty. Dyrl (1996) recommends a number of key elements for a successful staff development, including: offering a variety of options, emphasizing skill development, providing hands-on experiences, tailoring programs to local realities, using genuine teaching examples, and providing supporting materials. Principals need to be aware that if the teachers are not the focus of the technology training, then technology will fail (Guhlin, 1996). Teachers have to feel involved in the process of integrating technology into the curriculum. This involvement will ensure that the teachers take personal ownership for this responsibility. Once personal ownership has been established, it is easier for the teachers to work toward goals, because they now have more purpose and meaning. The main thing to remember is whatever training the teachers have, it is crucial that it applies to them as professionals as well as individuals.

Third, principals must be prepared to deal with teacher resistance to technology being integrated into the curriculum. Many teachers perceive technology as another burden of responsibility added to the already overwhelming load of a teacher (Hartzell, 1996). Another area of resistance happens “...because teachers believe that interpersonal relations are essential in student learning, the use of technologies that either displace, interrupt or minimize that relationship between the teacher and the child is viewed in a negative light” (Cuban, 1986, p. 61). Principals have to be prepared to provide extensive teacher training in the integration of technology into the curriculum (Weiss, 1994). Principals need to create an environment conducive to maximizing technology integration into the curriculum. A faculty that becomes comfortable with the ideas of technology will more easily integrate it into the curriculum.

**Methodology**

A survey technique was used to gather data. Specific items were developed for the categories of implementing technology into the classroom and the principal’s perception of what are the inhibitors to integrating technology in the schools’ curriculum. All 112 school administrators, both principals and assistant principals in a school district in southeast Texas were given the survey. 64 or 57.14% of the surveys were returned. Specifically they were asked: How important is technology in your school? How important is staff development for your teachers to learn technology as a curriculum tool? Estimate the percentage of staff development time this year your teachers will use to train on any type of technology? And, what is/are the major inhibitor/s to integrating technology in the classroom? The data were treated by using SPSS to determine frequencies and descriptive statistics to analysis the responses to the questions: How important is technology in your school? How important is staff development for your teachers to learn technology as a curriculum tool?

Respondents were also given the opportunity to add open-ended responses to the following questions: What is/are the major inhibitor/s to integrating technology in the classroom? Estimate the percent of staff development time this year your teachers will use to train on any type of technology. A frequency table was used to show the results of their answers as well a histogram to show the responses for the amount of time designated for professional development. A pie chart is used to show the responses to the inhibitors to integrating technology in the classroom curriculum.

**Findings**

In answering the first question, “How important is technology in your school?” the principals reported
technology to be very important (See Table 1 and Figure 1). 67.2% of the respondents answered that technology is very important and 90.6% rated it a 4 or 5 in importance.

5 is most important, 1 is not important

Figure 1. Ratings for the importance of technology
5 = most important, 1 = not important

Figure 2. Importance for teachers to learn technology for curriculum
5 = most important, 1 = not important

In answer to the question, “Estimate the percentage of staff development time this year your teachers will use to train on any type of technology” the principals’ response was inconsistent with the amount of importance they attached to technology and its implementation as a curriculum tool (See Table 3 and Figure 3). 85.2% of the respondents indicated that 25% or less of the total annual staff development time would be allocated for training to use technology in the curriculum. The histogram visually demonstrates the amount of staff development time principals estimated.

Valid cases 61, Missing cases 3
and focus efforts on facilitating learning (Adams & Jansen, 1997). Learning. Educators must discover and develop how to make technology an age of technology demand student-centered and led learning. The overall quality of education is enhanced. Students raised in an environment combining technology with applicable learning models, the technology is not a panacea for educational problems, but by implementing new technologies into the learning environments sharing, and organize better class presentations. Technology can be used to better display information, and planning. Teacher resistance was not shown to be a high inhibitor perhaps because technology is become more common to the classroom.

Principals and other school leaders must accept the challenge to create supportive conditions which would foster innovative uses of computers. There needs to be closer alignment between the amount of time for professional development with technology and its degree of perceived importance. As one prepares the faculty in the professional development plan for integrating technology into the curriculum, higher level support must be given so that school faculty have access to computers during instruction time and planning time.

**Recommendations**

Technology is the means to increasing learning efficiency. Technology can be used to better display information, increase access to information, improve information sharing, and organize better class presentations. Technology is not a panacea for educational problems, but by combining technology with applicable learning models, the overall quality of education is enhanced. Students raised in an age of technology demand student-centered and led learning. Educators must discover and develop how to implement new technologies into the learning environments and focus efforts on facilitating learning (Adams & Jansen, 1997).

At each level, the funding, training, and leadership issues must be addressed simultaneously if technology in the curriculum is to grow and have an impact on the reform of public education. Principals must use their existing resources wisely and creatively. They must think “outside the box,”; they must think in a fluid environment.

Additionally, state legislatures, corporate businesses, the federal government, and, local school boards must continue to look critically at their priorities. Elected officials must continue (or begin) efforts to “re-tool” education for the next century. Principals and teachers are, for the most part, ready. They must have the resources to proceed.

**Figure 3.** Histogram showing estimated time for annual staff development with technology.

**Conclusion**

Principals and assistant principals in the southeast school district in the state of Texas answered that technology is very important in their schools and that it is significantly important for teachers to learn technology as a curriculum tool. This study also shows that the main inhibitors to implementing technology in the classroom are: 1) lack of financial resources for hardware, software, and infrastructure, and 2) lack of time for professional development and planning. Teacher resistance was not shown to be a high inhibitor perhaps because technology is become more common to the classroom.

Principals and other school leaders must accept the challenge to create supportive conditions which would foster innovative uses of computers. There needs to be closer alignment between the amount of time for professional development with technology and its degree of perceived importance. As one prepares the faculty in the professional development plan for integrating technology into the curriculum, higher level support must be given so that school faculty have access to computers during instruction time and planning time.

**Recommendations**

Technology is the means to increasing learning efficiency. Technology can be used to better display information, increase access to information, improve information sharing, and organize better class presentations. Technology is not a panacea for educational problems, but by combining technology with applicable learning models, the overall quality of education is enhanced. Students raised in an age of technology demand student-centered and led learning. Educators must discover and develop how to implement new technologies into the learning environments and focus efforts on facilitating learning (Adams & Jansen, 1997).

At each level, the funding, training, and leadership issues must be addressed simultaneously if technology in the curriculum is to grow and have an impact on the reform of public education. Principals must use their existing resources wisely and creatively. They must think “outside the box,”; they must think in a fluid environment.

Additionally, state legislatures, corporate businesses, the federal government, and, local school boards must continue to look critically at their priorities. Elected officials must continue (or begin) efforts to “re-tool” education for the next century. Principals and teachers are, for the most part, ready. They must have the resources to proceed.

Facilitating Interpersonal Communication with Technology in Principal Preparation Programs

Angus J. MacNeil
University of Houston-Clear Lake

Stephen W. Harmon
Georgia State University

Technology is often cited as a cause for a more impersonal world. Technology has created speed and efficiency at the cost of personal encounters, long gone are conversations with real live phone operators. We have been inundated with recorded messages that tell you to press a number if you want a place, person, venue or menu. We no longer know the person who delivers the mail or the paper. Our world some would say is increasingly becoming more impersonal as we become more technologically advanced.

The evidence of the need for and the importance of human contact and interaction has never been more important (Adler, Rosenfield, Towne & Proctor II, 1998). Technology has freed our time and made it possible to have better communications than ever before, yet the complaints about the use of technology causing isolation continues to be pervasive in our culture. This paper illustrates and explains the procedures, benefits, and precautions of using technology to personalize the learning experience. Specifically, conferencing technology was used to communicate with the authors of a text book, The Handbook for Teacher Leaders, used in the principal preparation program.

The problem as discussed in the literature

The literature shows that our schools and universities are often being blamed for becoming more detached and less personal in their operations. Much of the literature commenting on the use of technology in education has ominous tones of “use it or lose it”. Sudzina (1993) states that teachers’ traditional beliefs may inhibit them from taking instructional risks and implementing technological innovations. Burke (1994) claims that higher education is trapped in a time warp and that new information technologies present a critical challenge which cannot be ignored if higher education is to succeed or even survive. He suggests that to succeed, faculty must overcome their own fears and resistance to technology and alter the way they teach and, therefore, the way students learn. Technology can help higher education link access and excellence by tailoring learning to the diverse student needs and styles, while also allowing colleges to respond to critics by containing costs and improving quality. Twigg (1994) points out that these new delivery systems for teaching, together with our increased knowledge about how people learn are driving changes in attendance patterns and institutional structures in higher education.

Bagley and Hunter (1992) suggest that changes in teaching will come about because of the synergistic interrelationships among the changes in our views of learning/teaching, the integration of technology, and the restructuring in our educational systems. Jensen (1993) proposes that the emergence of hypermedia is bringing new and different possibilities for college teaching than did previous technology. He predicts that materials available to students, styles of teaching and learning, and the role of the instructor will change dramatically. Multimedia instruction, a computer-based system incorporating video, audio, and digital storage media, provides educators with the tools to bring learning alive. Multimedia may become the most common form of instructional technology with planning, adequate funding, and faculty development.

Thomas (1994) comments on the second revolution that is moving the use of computers into the area of instruction rather than administration. As the world moves into an electronic-driven postindustrial revolution, new realities call for change in the education system. The impact of technological changes will be reflected in more “expert” teaching via use of computers and videotapes, and replacement of the conventional paper, pencil, and book by computers. MacKnight (1995) predicts that colleges and universities will have to support advancing information technology including developing “supertech” classrooms. Whereas the mission of universities in the past was to accumulate, refine, and pass on knowledge, their new task is to educate and train people to manage and gain access to the universal data base of knowledge.

These predictions and trends can often cloud and even remove from the agenda the critical human component in the process of learning. Historically there were predications that...
promises effective and efficient results; therefore, it can become more efficient and effective. Technology often quickly becomes the target for reduction in an attempt to inordinate requirement for human resources compared to cost reductions. The teaching profession has always had an ogy has almost always made promises for revolution and rooms when in fact the opposite is true. The role of technol-

new technologies of radio and later television would given the opportunity to speak with Leonard Pellicer and tional Leadership class at the University of Houston Clear technology was used on October 24, 1995, in the Instruc-

recent book, A Handbook for Teacher Leaders, which was used as a text and resource for this class. This highly readable book, with theory grounded in research, urging best practice was to be the topic of the conference. The purpose was to try and aid the students become more reflective about the content of the book. The premise was that having a visual and auditory communication experience, face to face, students would be able to more readily identify with the authors and be more motivated and thoughtful about the content of the book.

Design of the Cu see Me Conference

In order to use CUSM you must have a computer with a video digitizing card (e.g. any of the AV Macintoshes), a video camera, a microphone, and TCP/IP connectivity to the Internet. The software is free and is available over the Internet. While CUSM can work over a modem and phone line, the data transfer rate is so slow that the audio and video break up considerably and limit conversation. A better alternative is a direct connection to the Internet with a T1 line.

Any two CUSM users anywhere in the world can converse directly with each other simply by entering an IP address into the “Connect” dialog box of the program. If the person with the address you enter is running CUSM and is accepting messages, you will be linked to that person and can begin your interaction. However, if you desire to have a video-conference with more than two people, each person involved must enter in the IP address of a computer running some software known as a “reflector.” This software is also available free of charge over the Internet, and it allows up to eight people to interact in real time. If more than eight people need to hold a conference, you must have a reflector site linked to another reflector site. Using this technique you can theoretically have an unlimited number of sites connected. However, as more sites are added the amount of audio and video data being transmitted will quickly over-

Today a global shift in education is taking place, moving from a teaching focus to a learning focus. In the past decade, theories of the social construction of knowledge have resulted in the widespread use of collaborative learning techniques. Computer technology has been in the forefront of this movement. This technology is most appropriate to complement face-to-face meeting with teachers.

Recent literature contributions about the technological revolution (Bruce & Shade, 1994) write about the potential of compressed video and presents teaching and learning strategies using this technology. One application of this technology was used on October 24, 1995, in the Instructional Leadership class at the University of Houston Clear Lake. Graduate students in the Leadership program were given the opportunity to speak with Leonard Pellicer and Lorin Anderson about their recent book, A Handbook for
Results and student reaction

The conference was not without its problems. The students point out this out clearly in their comments; but the reaction of the students overall was favorable. Over all the comments suggest that the activity was worthwhile. The following examples of comments supports the usefulness of the activity: enlightening, grateful, quite unforgettable, I will refer to it many times in the future, a very worthwhile activity, it was a really innovative approach to meet people whose ideas have been laid out for the world to utilize, thanks for that opportunity; the process was an enriching one, I enjoyed the interview, I found it fascinating and invigorating, very exciting to experience first hand the technology that is emerging.

The comments show that the session made the authors’ messages from the book more personal to the students. On several occasions in later class sessions, the discussion and the reflection of the students turned to the dialogue of the “Cu see Me” conference. The internalization and personalization of the discussion were evident in the students’ comments. “It aided me in internalizing the philosophy, for the words became people.”

Preparation of the students before the session should include instruction about the specificity of the questions particularly about their own situational problems and the search for the answers in this form. Students need to focus on the message of the authors. Questions could have been better planned and agreement if not consensus on the questions planned before hand. Some students still expect that the process will give them the right answers and have difficulty with the role of the reflective practitioner. Some of the students still expect that the process will provide right answers and that “if we just do these things” everything will be perfect. This notion gleaned from the comments became an opportunity to discuss and review the importance of developing as reflective practitioners.

The responses indicate that even when the students did not get the answer they wanted they still could feel that their objections were heard: “We could voice our thoughts, the discussion became important.” It was also suggested that “It would have been especially helpful to have had several conferences throughout the semester as the book was in the process of being read, thus allowing for a more detailed and comprehensive questioning regarding the book’s chapters.” Although it was also suggested that the technology was really important for itself, one student made the observation that:

The format of this allowed me to look beyond the words in the book to the opinions behind them. This helped me to make more practical sense out of the book. The authors’ attitudes led me to believe that the basic foundation of the book was the idea that teachers can solve the problems in schools if they only take the initiative to do so.

Many of the students were affected by the messages of the authors differently than were those who wanted specific answers from the session “...also showed the readers that the authors were trying to communicate ideas and concepts for teacher leaders, not necessarily specific situation solutions.” Another student commented that “…although they did not have the perfect solution to every problem posed that, in effect, became the lesson: that there is no one answer for such a multi-faceted business and that lesson is the most important one for us to learn!”

The session had a motivational effect on the students as well as an informational purpose. A student stated that the session, “... sparked my interest in learning more about technology and how we can use it effectively in education.” Another stated, “I think that this type of activity would be great in the classroom.”

Even with some of the glitches and the newness of the technology the students moved very quickly to the purpose of the conference and the technology moved to the background to facilitate the experience. One student commented that, “... once I became accustomed to the format I had no trouble concentrating on what the authors had to say.”

There are many benefits of this type of conference for the authors. The students as stated earlier made connections that were very important. Being able to put a face to a name made the authors message more important and real for the students. A sample of some of the comments were as follows: I was very impressed with Pellicer and Anderson for taking the time to answer our questions. Both men seemed to have a pragmatic approach, and were in touch with what was really going on in the schools. They both had such a great sense of humor and seemed like genuine people. Both authors fielded the question very well. They are truly concerned with making education better by improving teachers’ abilities and influences Talking with Pellicer and Anderson was a treat. They appeared to be genuinely helpful. Being able to meet the authors Pellicer and Anderson via computer network was an experience I’ll never forget. By meeting Leonard Pellicer and Lorin Anderson, I found them to be quite knowledgeable and practical, giving credibility to what is said in their book. Their personable and genuine natures made me feel as though I’ve known them for years.

Preparing for such a conference requires planning and coordination. You must coordinate the session to take place at a time that is convenient for the authors, the students in our case, the technicians, and the booking of the lab facilities. This all takes a great deal of time and coordination. Is it worth it? Yes. The student comments indicate how much they appreciate the effort. The overall result has had significant and lasting effects on both the learning of the students and their relationship with the course instructor.
The students appreciate the efforts that were made and were genuinely grateful for the experience.

**Discussion and Conclusions**

As can be readily seen from the students' comments, there were some technology problems. For example the slowness of the sound and video and the breaks that were experienced in the transmission. The comments also reflect that the students overall appreciated the experience. It also showed how the same conference affected the students differently. They brought to the conference their own attitudes, beliefs and values, and used their learning experiences to either validate, or modify their positions.

Overall the learning experience was valuable and had many positive results. The student interest and commitment to the content of the course increased. Also, students appreciated the efforts made on their behalf. The material of the book became more relevant as the students connected on a more personal level with the authors. There were longer lasting effects to the discussions as observed in later classes.

SCHOOL ADMINISTRATORS: LEADERS IN TECHNOLOGY?

Nancy Griffin Mims
St. University of West Georgia

During the last five years, education in the State of Georgia received a boost through lottery funds, which were specifically designated for technology and multimedia in all schools. Each school received a satellite dish, computers for laboratories and classroom use, and various software programs. The extent to which this equipment is used, however, often depends on the support of the school administrators. Staff development programs offer assistance to teachers, but few are designed for the administrator. Support or lack of support from administrators regarding computer usage in schools is often a “hot or touchy” topic for teachers who desire more support or who would like the opportunity to explore more current uses of the internet. University courses in technology, at the graduate level, for educational administrators are just becoming part of graduate course requirements. Since many principals received their degrees and endorsements prior to new guidelines, a study of principals’ use and knowledge of multimedia use will provide information for future course work.

Barriers and Common Use of Technology

School administrators, in many cases, excited or not over the hype of technology, have major hurdles to overcome: installation of equipment and curriculum planning. Technology and funding equity are concerns of the past decade (Arch, 1986; Moursand, 1986). Often the schools had to rewire electrical outlets, curriculum had to be rewritten to encourage the use of technology, and teachers needed training. Media specialists seemed to be the faculty members who have accepted and use technology. Most school administrators use the data collected and stored in technology programs for grading, demographics, budget management, and scheduling Picciano (1998), however, these programs are usually programs developed by and for the school district. Additionally, it is usually the support staff who maintains the programs asking only for the administrator’s signature on the outbound copy. The head of any school is the administrator, but are they also the leaders in technology? In order to answer this question, we need to see where the schools are, the perceived attitudes and needs of the faculty, and whether or not administrators have received support through the literature.

What’s in the Texts?

What are the trends of the future? We are concerned about competing in a global economy, and textbooks ask us to think about educational reform and how to prepare students for the next century. Yet most of the discussion involves questions such as: How will teachers react when the students appear to know and/or understand technology better than they do? How do we use the web? Should all students have computers at their desks? Other discussions center on curriculum implementation, instructional approaches and assessment of students’ work (Knapp and Glenn, 1996). Books and articles such as those of Geisert, P.G., & Futrell, M.K. (1995), Becker(1994), Schlumpf(1991), and others discuss teacher empowerment, staff development techniques, and trends, but they do not address the school administrator’s role. If media specialists, curriculum planners, classroom teachers, and students are all in the big picture, where is the school leader? The following questions guided this research. What part does the expertise of school administrators play in supporting technology? What is the extent of their personal use of technology? What is their vision of schools of the future?

Methodology

A survey questionnaire was developed and sent to seventy-three school administrators in eleven counties in northwest Georgia. Fifty-seven were returned on or before the due date given. The questions included a Likert scale addressing school administrator’s perceptions of technology and their personal and school use of technology. An open-ended question asked them about their vision of schools in the future. The demographic data divided the administrators into two groups: principals and assistant principals. The respondents were also asked for the school level, years in this current position, and their gender. Data were tabulated and a content analysis was done with the open-ended questions.

Findings

Responses to the open-ended questions found that more men than women had home computers for their personal use. Women reported that the family had a personal computer, however, the children were the primary users. Women tend to use the home computers for email, or
ordering books. Men indicated that they spent more time on the computers at home, and that the web use was for sports, news, and maps.

School administrators, who used computers or other technology at home, were more inclined to also use computers at school. A few administrators stated that they often worked after school hours, or during brief periods when things seemed to be running smoothly. Women administrators did not report “playing” on computers at school, but more women than men, especially elementary school administrators, said they did much of the district reports themselves.

Most of respondents (89%) male and female, across all school levels were not sure what on-line learning was or if they would implement such a thing. The vision for schools of the future seemed to indicate that a majority of students would attend some or all of their lessons from home or a laboratory. The concern was for students of low socioeconomic areas. A number of administrators also felt that the technology for the future is just being developed. What is the impact for the future? Surprisingly, many stated that unless all areas in all the countries had equal use, there would not be a real impact that made a difference in students’ abilities.

A PLANNING PROCESS FOR CREATING COLLABORATION AMONG DEANS

Mary Queitzsch
Associate Technology Center

Of those who should be on the information superhighway, faculty and students in colleges of education are among the most important. (Hill & Somers, 1996)

In the fall of 1995, the Northwest Educational Technology Consortium (NETC) was funded by the U.S. Department of Education, Office of Educational Research and Improvement. A small portion of the funds was allotted to support teacher preservice education. The northwest region currently has 54 four-year colleges or schools of education (COEs), both public and private: 5 in Alaska, 7 in Idaho, 7 in Montana, 15 in Oregon, 19 in Washington and 1 in Wyoming.

During the NETC Proposal planning stage, a set of outcomes was developed from the input of the three Northwest Deans of Education who were members of the NWREL Board, and from the lessons learned from innovative COEs as described in the Office of Technology Assessment (OTA) report Teaching and Technology: Making the Connections. The outcomes included the knowledge that NETC will be a politically neutral organization and able to facilitate approaches and organize regional meetings that would be more difficult for a single COE or state higher education organization to attempt. In order to meet the needs of COEs, NETC proposed the following outcomes:

- Reconceptualize the role of technology in preservice education.
- Form partnerships and encourage collaboration between interested stakeholders.
- Understand the impact of new technologies in preservice education.

The Strategy

In December 1995, NETC convened the three deans who had helped with the proposal and asked:

- How to best accomplish the three goals (listed above)
- How do we do this with limited funding?

Their unanimous response was, Let us (Deans) get together and talk! We seldom have the opportunity to get together and talk about a specific issue. We are either lectured to or the agendas are too broad, so we send a substitute. The issue of integrating technology into teacher preservice education is too important to ignore.

The three deans suggested for the first year of funding that NETC establish a planning council, hold a conference of deans (Deans Forum), contact state educational technology experts, and hold a regional conference of Deans, faculty and state educational technology experts.

Planning Council Established

In early spring, NETC established the planning council: Dean Allen Glenn, University of Washington, Dean Robert Everhart, Portland State University, Dean Dale Gentry, University of Idaho, Dean Dan King, University of Wyoming, and Dean Don Robson, University of Montana, Missoula.

Deans Forum I

The planning council Deans convened via conference calls and e-mail as to how to accomplish a meeting of deans. The planning council chose to have a Deans Forum focused on Integrating Technology into Teacher Preservice Education. The forum was hosted in April by Portland State University and the participants paid their own travel. Hotel, per diem, forum material costs, and all of the Planning Councils’ expenses were covered by NETC. The forum was held as a post conference activity to the Northwest Council for Computer Education (NCCE) conference. NETC paid for the Deans’ conference registration. The NCCE conference focus was on innovative use of educational technology in the K-12 classrooms. Attendance was encouraged to provide a link between K-12 and preservice teacher education.

The atmosphere and dress for the Deans Forum was casual, and substitutes were discouraged. The environment thus enabled Deans to speak freely among their peers about sensitive issues. The invitation letter asked the Deans to come prepared to discuss the issue of technology. In order to prepare them, a survey and papers written by Dr. Christopher Dede were sent.
The survey provided a snapshot of what was happening at each COE, how technology was used in the preservice teacher education program. The results were provided to the Deans prior to the forum and enabled the Deans to quickly connect with other Deans experiencing the same problems or issues. An added benefit of the results was that time was saved at the forum. The Deans did not have to give an in-depth oral report of the role of technology in their program.

The agenda covered a Friday dinner/social and an all day forum on Saturday. The evening dinner provided time for the Deans to meet. An overview of NWREL and NETC was presented. Dr. Chris Dede, a futurist in the field of Educational Technology was the Saturday morning keynote speaker. Chris Dede is a Full Professor at George Mason University in Fairfax, Virginia, where he has a joint appointment in the Schools of Information Technology & Engineering and of Education. He currently is working with the U.S. Advisory Council on the National Information Infrastructure helping them think about their education recommendations. During the afternoon, representatives from the Intel Foundation, the Murdock Charitable Trust and the Meyer Memorial Trust spoke and interacted with the deans. These specific foundations were invited based on their funding higher education in the Northwest. Time was allotted for small discussion groups with the foundation representatives after the keynote.

The two NETC representatives managed the meeting, yet it was the Planning Council’s responsibility to facilitate the discussions. Each of the Planning Council Members had a visible and audible role in the forum.

There was a total of 28 attendees: 15 deans of Colleges of Education, 5 university representatives, 2 Washington State Department of Education representatives, 3 Foundation representatives, 2 NETC representatives and 1 Keynote speaker. All six states in the region were represented (Alaska, Idaho, Montana, Oregon, Washington and Wyoming).

The major outcomes of the meeting included excitement to continue the discussion, initiate a listserv, and have a second forum in the immediate future.

Deans Forum Listserv

From the request of the first deans forum, a private listserv was established for the deans in May. It has since served as an important link for communication. Of the 54 deans, only three do not have Internet connectivity. For these special cases, fax and phone are used.

Only topics concerning integrating technology into teacher preservice education are posted. The Listserv is housed and moderated at NWREL.

Planning Council Advises

The evaluation of Deans Forum I was sent to the Planning Council. They agreed that the next step was to have a second Deans Forum that was more focused on one or two issues. With the enthusiasm high, it was suggested to have the forum prior to the fall semester.

Dean Carol Merz of the University of Puget Sound was added to the planning council to represent small, private colleges.

Deans Forum II

The second forum was held at the Puget Sound Education Service District in Burien, Washington, August 1996. Again, participants paid their travel. NETC covered hotel, per diem, forum materials, and all of the Planning Council’s expenses.

Dr. Linda Roberts, director of the Office of Educational Technology, U.S. Department of Education, was the keynote speaker (Appendix E). The forum was identical in atmosphere to the first, providing time for discussion and comments. The second forum had a double focus of assessment and technology planning. Much of the discussion revolved around policy and call for action. (Agenda - Appendix D)

In order to prepare the Deans for the forum, a copy of Linda Robert’s proposed keynote address was posted on the listserv prior to the forum. Dialogue was initiated and moderated among the Deans by the Planning Council.

Thirty-four people attended: 25 deans of colleges of education, 2 university representatives, 3 Washington State Department of Education representatives, 3 Northwest Regional Educational Laboratory/Northwest Educational Technology Consortium representatives and Linda Roberts. Five of the six states in the region were represented, Alaska, Idaho, Montana, Oregon, and Washington. Wyoming only has one college of education and the dean was not able to attend due to a previous commitment.

Two of the NETC representatives managed the meeting, yet it was the Planning Council’s responsibility to facilitate the discussions. Each of the Planning Council Members had a visible and audible role in the forum by planning and conducting the seminars. They introduced the keynote speaker, guests and other planning council members. They took responsibility for the meeting room arrangements, acknowledged those involved, and were the center points for discussions and questions. This decision may have helped build a more collegial environment and ensure participation by deans.

Two of the NETC representatives managed the meeting, yet it was the Planning Council’s responsibility to facilitate the discussions. Each of the Planning Council Members had a visible and audible role in the forum by planning and conducting the seminars. They introduced the keynote speaker, guests and other planning council members. They took responsibility for the meeting room arrangements, acknowledged those involved, and were the center points for discussions and questions. This decision may have helped build a more collegial environment and ensure participation by deans.

The major outcomes of the meeting included the desire to collaborate across university and state lines along many veins of interest, initiate research in the area of technology and teacher education, continue the survey of schools of education, and actively seek outside funding.

Future Activities

The second deans forum set the stage for research. It was agreed that action was needed. With the council’s advice and the deans input via the listserv, we plan to submit varying proposals to funding agencies for research.
and professional development activities for teacher education faculty. In the farther future, the deans would like a large conference for faculty concerning integrating technology into their instruction. As NETC and the deans plan, the following issues are key:

- What next concrete activity can we design to sustain interest?
- How best to insure that it is specific enough to lead to something real but at the same time broad enough to engage a diversity of institutions in the effort.
- Where do we continue to get the leverage dollars to keep the group going?
- Who might be the next set of folks we to talk with (K-12, community colleges, and/or private businesses)?

Some specific research projects have been suggested and are to be acted upon in the future:

1. Identifying teams of ‘faculty experts’, faculty who are successfully integrating technology into the preservice curriculum. The teams would travel to other colleges and schools of education to deliver workshops or help develop technology plans.

2. Increase the amount of collaboration between higher education and K-12 on the issue of technology.

3. Examine the preservice teacher education curriculum. Through this evaluation, determines ways to better use the faculty and students’ time to meet the needs of the 21st century classroom.

4. Finalize survey results in an executive summary format to disseminate.

5. Construct a webpage for COEs.

**Conclusion**

During the first year of operation, 93 percent of the Northwest Deans of Education have been actively involved with the project via the listserv, the survey, and/or participation in the forums. A high level of trust has been achieved through these activities. We are in the process of collaboratively writing proposals to outside funding agencies.

Lessons learned revolve around leadership, environment/atmosphere created for the forums, logistics of the forums, importance of keynote speakers, and open communication.

Leadership was provided by the Planning Council. Not only did the Planning Council Deans represent their school in discussions, but also the entire region’s schools and colleges of education, both public and private. Their concern was how to work together and how to get 100 percent participation. Each of the Planning Council members is seen as a leader at their university and in their state. Turf battles were put aside. The Northwest Deans felt at ease to contact the council members and voice concerns, questions, and comments. The Council in turn felt at ease in contacting NETC and focusing the forums on immediate and future concerns of the Colleges of Education. NETC, in turn, does not hesitate to ask the Council for advice and assistance.

The environment/atmosphere set the tone for the forum. It was relaxed, plenty of non-elaborate food was provided, and it was hosted by an institution. Having the meetings at local education facilities allowed the deans to see what was happening on another campus. It was also a way to save funds for other activities. The sites were chosen based on close proximity to airports and in different states.

Logistics of the forum were handled by NETC (all arrangements for hotels and meals). The Deans provided their own transportation to and from the forum. All activities and materials were coordinated through NETC. This simplified and centralized the paperwork. The agenda was organized by the Planning Council and each of the discussion groups was facilitated by a council member.

The keynote speakers were extremely important to the success of the forums. Chris Dede was seen as a ‘framer’. He put educational technology into focus and stretched it into the future. Linda Roberts brought a more down-to-earth approach of what was happening at the federal level and what the deans could and should do. Both speakers stayed for the entire forum and participated in the small group discussions. At the end of the day, they added their comments and helped synthesize the day’s activities.

Having the foundation representatives at the first forum was a major draw for many of the deans. It was presented to both deans and foundation representatives that this was a time for discussion, not a time to badger for money.

Overall, one of the major points of this project has been the limited amount of funding. The deans believe that this is an important issue and needs their attention and support. They have proved the importance of these forums by funding their travel to the forums, communicating through the listserv and assisting with proposal writing. The communication has been a major key to the success. Each of the planning council members is a respected dean in the region. They are easy to approach and are helpful in finding ways to make the forum work. NETC has a toll-free number and Internet accessibility. Even with tight funding, communication is readily accessible.

In summary, the key points for success for those who want to have form a cohesive and collaborative group of deans include:

- Select a topic that deans find worth their time
- Make sure that deans play an active role in deciding and conducting the events
- Utilize technology as much as possible to facilitate communication and to help in pre-conference knowledge building
- Identify key speakers, have them address specific topics; remain for the day to insure interaction between them and participants

Educational Leadership — 309
• Create a series of “do-able” projects that will result in visible products in order to sustain deans interests and participation
• Keep meetings informal with ample time for discussion of key issues

LEADERSHIP FOR A TECHNOLOGY-RICH EDUCATIONAL ENVIRONMENT

Richard Riedl  Tracy Smith  Anita Ware
Appalachian State University  Appalachian State University  Appalachian State University

Alan Work  Peter Yount
Appalachian State University  Appalachian State University

Recent political and media campaigns have suggested that the number of computers in the school building is a measure of the value of that school. School districts and other educational institutions have responded to this public pressure by purchasing computers, installing networks, developing computer curricula, and providing teacher workshops. In spite of these efforts, schools and institutions are essentially unprepared to integrate computer technology into their everyday teaching and instructional responsibilities.

A great deal of discussion is directed at the issues related to preparing teachers to utilize new technologies, but what is abundantly clear is that the people who are expected to provide leadership and participate in key decision making processes regarding technology integration are being left out. Increasingly, educational leaders are expected to provide direction and support in a technology-rich environment without the benefit of understanding the technology and human elements that are necessary to make that technology an effective instructional tool.

Efforts to develop technology-rich educational environments have shown that there are key elements that are critical to the successful integration of computers into the everyday efforts of the people working in those environments. This paper explores the attitudes, skills, and knowledge that will enable individuals in educational leadership positions to function effectively and to provide support to create and maintain technology-rich educational environments. Our discussion is guided by five elements: vision, access, time, support, and assessment; the understanding of which we believe are essential to the meaningful integration of technology into the teaching and learning environment.

Developing A Vision

There are vague notions that using computers in schools is good. These notions are usually based on simplistic ideas that the use of computers will better prepare the student for the workforce and that there are efficiencies to be gained by their use. The truth about the use of computers is a much more complex reality that must be understood before computers and their related technologies can truly support a learning environment. A vision of the role of technology in learning must be developed that can give direction to decisions about the purchase, deployment, support, and use of the technology.

Currently, many educators believe technology and telecommunications are essential tools for supporting a transformed teaching and learning environment. The problem, however, is a lack of understanding about how technology and telecommunications are to be integrated into the educational environment. An important consideration is the role of the administrator in this transformation. The development of a vision to guide the integration of technology into the teaching and learning environment usually begins at the school level with the principal.

Writing on effective schools suggests that the principal can have a major impact on efforts to improve the organization and delivery of services to students (Bossert, Dwyer, Lee, & Rowan, 1982). McCall (1986) added that what is needed in times of reform is principals who understand the problems and critical issues of our education system. In 1994 The Education Commission of the States defined thoroughly restructured schools. Such schools have set high, world-class standards and ensured that those expectations are incorporated into the classroom culture by altering curricula and instituting teaching methods that accommodate the needs of all students. They also change management and administrative policies so they reward teacher initiative and innovation.
There are several modes for effecting change in schools (Sashkin, 1988). In order to successfully foster change in an increasingly technology-rich environment, educational leaders must be adept at influencing change in a way that is appropriate to the specific school population (including teachers, parents, and students). This includes developing a vision, which guides the school decision making process regarding the integration of technology. The effective educational leader must help the school community develop a set of guiding principles about the role of technology in the learning setting that is comprehensive and practical.

**Access, Time, and Support: Inseparable Essentials**

Not only must educational leaders provide the stimulus for meaningful change, but also they must be creators and sustainers of teaching and learning environments that are technology-rich. Particularly, they must be aware of inseparably related issues of access, time, and support.

**Providing Adequate Access**

Many schools are still wrestling with the question of whether to disperse computers in classrooms around the school or bank them in laboratories. This question is really a result of inadequate levels of access to computers. Few institutions have really addressed the question of what level of access is truly required for the successful integration of computers into the life of the school. Few educational leaders understand the importance of all the issues related to access.

The conventional definition of access focuses on the number of computers, the ratio of students per computer, and the amount of other technology in the school. This definition is too simplistic to meet the challenge presented when meaningfully integrating technology into classroom instruction (Office of Technology Assessment, 1995). An effective definition of access should also include the capabilities of the hardware in the school, the physical arrangement of technology in the building, and the existing systems of support related to the integration of technology (Office of Technology Assessment, 1995). And the definition must take into account the intended uses of the technology as articulated in the vision established for the learning environment. This more comprehensive definition of access would be more likely to guide sound decision making related to providing levels of technology that would better support its meaningful integration into the educational setting.

**Providing Adequate Time**

Workshops on the use of computers have, in general, proven to have only minimal value in promoting the use of computers by teachers. There are many reasons for this but one clear problem is the lack of time teachers have to sit down at a computer to try out the things they learn in workshops. The typical workday for teachers does not afford the luxury of sitting down at a computer to learn how to use it. Educational leaders must understand and find solutions to the problems related to time.

**Providing Adequate Support**

Computers and computer networks don't always work properly, but few schools have someone who knows how to keep things running smoothly. In addition, experience has shown that, in order to develop effective integration of computer technologies into their classrooms, teachers need to have access to someone who knows the technology and understands the learning environment. Personnel costs are the largest part of any school system budget. Little flexibility is usually afforded administrators in developing new positions or realigning existing positions. Some of the most critical decisions regarding the successful incorporation of technology into the learning environment can revolve around the educational leader's understanding of the need for support and how to develop that support system.

Because they are limited to physical placement and acquisition of equipment, Maddox (1991) identified current efforts to integrate computer technology as potentially harmful to meaningful technology integration. He identifies three conditions necessary to allow success in meaningful integration of technology in schools: availability of excellent software in all content areas; sufficient access to computers and necessary hardware in individual classrooms; and teacher interest and expertise in educational computing.

The first condition, appropriate software, is a challenge for schools. The Office of Technology Assessment (1988) reports that the quantity of educational software has improved, but quality issues still remain, with much of what is available having programming and technical problems. In addition, schools are further limited in access to excellent software because of the disparity across subject areas, and the lack of software that encourages higher-level cognitive skills. In fact, the majority of available educational software focuses on lower-level skill development in drill and practice and tutorial type software programs.

Availability of computers and necessary hardware in individual classrooms is another condition to be met for meaningful computer technology integration. Maddox (1991) describes current views of computer integration as merely dispersing computers from school computer labs into individual classrooms. Instead, computer labs should be viewed as an important and necessary part of school-wide computer integration. Computer labs offer an environment in which group computer instruction can occur both for students and teachers. By dispersing lab computers into classrooms, access and time for students could be further limited. Improved efforts towards classroom integration would include the placement of computers in classrooms in addition to maintaining existing computer lab environments.

The third condition, teacher interest and expertise in educational computing, must be met in order to integrate...
computer technology appropriately into classroom practice. The Office of Technology Assessment (1988) concluded in a study that the lack of teacher computer expertise produces the most significant threat to the potential of schools to integrate computer technology into classroom instruction in a meaningful way. Teacher expertise will continue to be limited as long as staff development efforts continue to be driven by efforts to increase proficiency in only particular types of software. This practice prevents an increase in teacher self- efficacy related to computer technology.

In order for teacher expertise to increase, training must focus on increasing computer knowledge, not computer experience on specific software programs. Reinen and Plomp (1993) studied staff development and computer integration and concluded that appropriate staff development in computer technology may be the single most influential contributor to computer integration in classroom practice. Teachers identified in this study as exemplary computer-using teachers tended to come from school districts that invested heavily in computer technology staff development. Reinen and Plomp (1993) indicate that staff development topics related to pedagogical/instructional aspects seem to offer the greatest contribution to the integration of computers in the classroom. Pedagogical/ instructional topics include applications, program analysis, programming, and hardware/software knowledge (Reinen & Plomp, 1993).

Three areas of support must complement a comprehensive technology-rich environment: professional, instructional, and technical. Each of these dimensions of support is paramount if technology is to be implemented and used in an effective manner. However, that is not to say that each function needs to be the responsibility of a different person. Often, these functions may overlap and may be administered by one person on the building level. Some duties may be shared by a position that attends to several school sites. The danger in combining these functions is that a single person will have so many responsibilities, none of them will be performed well.

Support is an issue that must be addressed in the technology plan from its conception. Once a plan is in place, it may be too late due mainly to its costs in relation to the one-time investments in much of the plan.

An analogy which describes computer technology as a tool of instruction may be helpful in defining access, time, and support (Maddox, 1991). In contrasting computer integration and handwriting instruction, an example of an instructional tool that is eventually integrated across all subject areas would emerge. We would not approach handwriting simply by placing a pencil in each classroom and expect integration to occur in a meaningful way. Instead, we invest in instructional materials, devote an amount of time each day to instruction, and periodically evaluate progress. Once students develop basic skills, this intensive instruction ends and activity is integrated into the instruction of all subjects. Remediation is provided when necessary. If we also approach computer integration in this way, issues of access, time, and support seem clearer.

Decisions we make about computer integration should not always be limited to placing more computers in every school or classroom. As computer basics are acquired, computer technology could be integrated across subject areas. The important point in all of this is that integration will not occur without an increase in student and teacher expertise.

The Role of Assessment

Existing assessments, to which teachers are held accountable, do not address the types of learning and progress that students using computers make. Understanding that discrepancy and directions that can be taken to reduce the discrepancy become an important element in being an effective educational leader.

In order to assess the impact technology integration has on student outcomes, teacher instructional practices, and administrative organization practices; informal and formal data should be collected from multiple sources. The goal of this assessment and evaluation model is to determine which technology integration models or approaches will best serve schools. Such a determination can be made by creating an understanding the role of assessment in educational technology integration, matching goals and objectives to assessment measures, and creating possible effective integration models from the data collected.

Understanding the Role of Assessment

The assessment process is to be used to guide teachers’ and administrators’ infusion of technology into their daily school environment. The assessment should mirror the School Technology Commissions’ recommendations that expected results of technology in the school environment to increase student learning, workforce readiness, teacher productivity, and cost effectiveness. In addition, the assessment and evaluation information should identify areas on which to focus professional development.

Matching Goals and Objectives to Assessment Measures

In order to match the School Technology Commissions’ recommendations with the objective of expanding teachers’ and administrators’ understanding of both new technology and new teaching techniques, several quantitative and qualitative evaluation methods must be employed. One possible route to match goals to assessment measures is to take strands of student, teacher, and administrator technology practices and apply them to a model of computer use in schools. Such a model matches the relationship between student technology interaction and student cognition. Simply, in the assessment process we match the level of computer interaction to the level of cognition. When this
model is applied, we must consider the role of the student, teacher, and administrator (Makrakis, 1988).

Possible Models and Approaches

According to the three major achievement test publishers, true student performance-based tests are non-existent. At best, the evaluation process can capture student attitudes toward technology and students’ interaction with technology as a learning tool. Conducting interviews with student focus groups can be an effective way to collect information regarding meaningful student interaction with technology across the curriculum. Affective instruments, designed to determine attitudes toward technology, may identify the effectiveness of current classroom technology practices to increase students’ comfort with computer technology. The Educational and Psychological Measurement’s “Computer Attitude Scale” may be used for students, teachers, and administrators (Bannon, 1985). Other attitude surveys include the Estes Attitude Scales (1987) and the Shaver ATTitudes toward Writing with the Computer Scale (1990).

While attitude questionnaires may be employed with students, teachers, and administrators, most systems will seek a more achievement-oriented approach. The Macmillan/McGraw Hill Curriculum Frameworks Assessment test includes basic core curriculum subjects and mathematics technology. While costly, these batteries of tests provide schools with quantitative scores to match to attitude questionnaire outcomes, and student focus group outcomes. Only by webbing these multiple assessment approaches may schools create a learning environment that fosters access, time, and support.

Conclusion

Work with administrators in K-12 schools and with students in educational administration programs have shown that none of these issues of vision, time, access, support, and assessment is clearly understood by decision-makers. Many educational leaders are struggling with what they need to know personally about technology and with ways to support the efforts of their teachers and staff to incorporate that technology into the learning environment. Few educational leaders are users of the technology themselves, and even fewer have had training in their preparation programs or as part of professional development efforts to deal with the larger issues that are introduced when computer technology is brought into their domain. Just as we attempt to discover the best means through which to train classroom teachers in the effective uses of technology in their curriculum, we also must explore the skills, attitude, and knowledge an educational leader needs to be successful in a technology-rich environment. What training and experiences will lead to leadership practices that adequately support teachers as they integrate technology? What support do educational leaders need as they make the effort to bring technology integration into their schools?

A national study conducted by Phi Delta Kappa International resulted in the identification of seven core values which U.S. citizens agree should be taught by schools. The findings of this study have encouraged Phi Delta Kappa to sponsor a research and support system for educational leaders. As advocates of the national values project, Phi Delta Kappa has developed the League of Values-Driven Schools. The mission of the League of Values-Driven Schools is to encourage the centrality of values in the curriculum, structure, and administration of the twenty-first century school. The league is not a product or curriculum, but a network which encourages and supports research and instruction in the core values. Phi Delta Kappa believes that schools must graduate students who espouse the seven core values: learning, honesty, cooperation, service, freedom, responsibility, and civility.

Planning for the Future

The University of Texas at El Paso Chapter of Phi Delta Kappa believes that in the twenty-first century, the educated person must be able to:

- deal in an ethical manner with complex challenges and dilemmas new to the human condition
- apply sophisticated knowledge and skills to daily living and occupational tasks
- function successfully in a technologically complex environment

UTEP's Phi Delta Kappa also believes that, in the near future, schools and universities will be driven by the knowledge and skill assets of the institution. In effect, educational institutions will be highly varied and specialized, and knowledge will become the currency of professional and personal success. Thus, educational institutions must develop a focus and mission based on values and ethics rather than on content. Institutions must mentor students while they obtain knowledge and skills via the most effective medium and agency. Learning experiences will not be limited to conventional instruction, but will include opportunities to utilize such innovations as distance learning, Internet activities, and field studies. Coursework and activities will be available from worldwide educational resources. Students must be provided with opportunities to dialogue with others across the globe. Technological advances have presented new challenges and advantages for leadership and research. Brownell (1997) notes, that content of educational technology has changed from hardware and programming to the use of technology to enhance learning and teaching.

Using Technology to Enhance Educational & Professional Studies

Students in the masters and doctoral programs in Educational Leadership at the University of Texas at El Paso have been offered the opportunity to participate actively in the Phi Delta Kappa national values project. These students can engage in action research as they:

- develop activities and ideas for circulation to league participants via the Phi Delta Kappa-UTEP website
- further investigate the core values for purposes of their own research, instruction, or professional development
- collaborate with other educators within the El Paso area, building networks across school districts and campuses

The League of Values-Driven Schools

The findings of this study have encouraged Phi Delta Kappa to sponsor a research and support system for educational leaders. As advocates of the national values project, Phi Delta Kappa has developed the League of Values-Driven Schools. The mission of the League of Values-Driven Schools is to encourage the centrality of values in the curriculum, structure, and administration of the twenty-first century school. The league is not a product or curriculum, but a network which encourages and supports research and instruction in the core values.

Project Expectations and Challenges for Participants

The purpose of the network is to make available learning ideas and opportunities to participants, with ideas originating in the activities pioneered by league members and others. The ideas and activities generated to foster the...
seven core values will be shared via the UTEP / Phi Delta Kappa website, networking sessions sponsored by the UTEP Chapter of Phi Delta Kappa, and interactions among administrators, teachers, and students.

The Phi Delta Kappa project offers many opportunities to utilize and enhance educational leadership as participants move beyond traditional roles exercising leadership in the transformation as leadership becomes an intellectual process of ‘reimagining’ the learning environment (Sergiovanni, 1993).

In addition, the increased opportunities to conduct action research by utilizing distance technology via the website, e-mail, and the Internet enhance interaction and benefit all involved. Technology supports research efforts because it provides educators with devices for retrieving, storing, and processing great amounts of data (Webb, Montello, & Norton, 1994).

In the Phi Delta Kappa values project, participants at three collaborative levels, students, teachers, and principals, begin to build a community in which:

- learning and teaching encompass specific objectives (the 7 core values),
- learning and teaching are continuous for all participants (collaboration/networking),
- leadership roles are not limited to a given group (only administrators / only teachers)
- activities and conversations are not limited to classroom or campus levels (distance technology provides the means for universal communication)

The alignment of research efforts from the local to regional to state to national to international to forums would strengthen the support for the League of Values-Driven Schools and increase the knowledge base underpinning the seven core values (providing activities, ideas, discussions, etc.).

Problems Confronting Implementation

Time. At the beginning of this project, most of the high school student participants will have to dedicate time outside their normal schedule in order to participate. As the values project proceeds, the hope is that it will become embedded into the high school curricula so that it can be further developed during class time. It is anticipated that many university-level students will incorporate their values research into individual class assignments and into their theses and dissertations. It is also anticipated that teachers and professors will eventually follow the same path as students in this regard.

The time commitment for principals will probably always fall into the “extra assignment” category. However, the concept of everyone becoming a learner in the “community of learners” espoused by Roland Barth (1990), and by many other authors in the area of restructuring or reinventing schools, becomes reality for principals of league schools as they immerse themselves in their campus values research projects.

Logistics. The notion of local campus-to-campus collaborations presents formidable organizational, research, and communication problems which seem to shrink when compared to the problem of coordinating collaborative research efforts on a nationwide basis. But for distance education on Internet web sites and for e-mail, most efforts of this scope would soon fail. The reality is that the phenomenon of asynchronous distance education and research on the world wide web will facilitate the progress and success of the values league. The leadership of university graduate students acting as catalysts and facilitators for research and as mentors for high school project teams will also help to resolve some of the logistical nightmares. Sharing failures as well as successes on web sites as soon as they are known, then following up with e-mail discussions will help many project teams to avoid reproducing failure and allow them to adopt winning strategies already applied by teams throughout the country.

Summary

The League of Values-Driven Schools promises to provide challenges for every level of leadership in schools and universities, especially for students, teachers and professors, and administrators whose campuses are involved. The electronic medium known as the “Internet” has provided the forum through which a project of this scope and dispersion can be carried on successfully.

Asynchronous distance education has also leveled the playing field by distributing leadership roles throughout all ranges of participant — student, teacher, and administrator, affording all the opportunity to become meaningful contributors to their individual learning communities and to the amalgam of values learning communities throughout the nation.

The Need to Train Teachers to Use and Integrate Technology in the Classroom

Edward A. Sullivan
Providence College

Catherine L. Keating
Providence College

An attempt was made to survey a random sampling of elementary, middle school, and high school principals in Rhode Island and Southeastern Massachusetts. A listing of such principals was obtained from the Rhode Island and Massachusetts Departments of Education. Through this listing 266 principals were identified. These principals composed the survey group. One hundred eighty-seven principals responded to the survey. This is a response rate of 70.3%.

A two page questionnaire was designed by the Principal Investigators to gather information concerning the following: the availability of computers in the classroom, the availability of computer labs in the individual school, the number of computers available to teachers and students in each school, and the percentage of computer literate teachers and veteran teachers. In addition the survey instrument gathered information on how teacher preparation programs assist in better preparing pre-service teachers in computer technology and in determining the types of future in-service training programs colleges and universities could offer to better assist local school staffs in computer technology.

A pilot test was conducted on a sub-sample of the final sample population in September of 1996 and the data from this group was included in the final analysis. The purpose of this pilot was to determine if mailing procedures were adequate, and to check branching techniques as well as to alter response categories where needed.

Envelopes containing the survey instrument and a self addressed stamped envelopes were prepared using a computer generated mail labeling system by one work study student supervised by the principal investigators. The initial mailing of the instruments took place on October 11, 1996. The return questionnaires were organized as they arrived back at the education office on a daily basis by the work study student assigned to the project who gave them to the investigators. They were placed into a numerically sequential file according to respondent ID number. The ID number was then checked off in a code book and the date of return was entered. This not only allowed for a system of cataloguing of the returned questionnaires but also provided for a listing of all ID number for unreturned questionnaires. A final date of December 8, 1996 was set for accepting returned instruments so that analysis of the data could begin after the college’s Christmas break.

Coding of the instruments took place on a daily basis and was handled by the principal investigators and one work study student. Check coding was done by the principal investigators. Standard columnar pads were used to tabulate the responses. Analysis of the data was done by the three people, the principal investigators and one graduate research assistant.

A computer technology survey was sent to 266 principals of secondary, middle and elementary schools in Southeastern Massachusetts and Rhode Island. One hundred eighty-seven principals responded to this survey. The survey asked questions relating to the availability of computers in schools and the amount of in-service training in technology available to teachers. A third aspect of the survey related to the training in technology necessary for pre-service teachers.

One hundred-one (54%) of the principals responding indicated that computers were available in every classroom in their school. Of the other respondents 44.4% indicated that computers were not available in every classroom. There were three respondents (1.6%) who left this item blank.

When asked if there was a separate computer lab in their school, 114 respondents (61%) indicated that there was, while 72 respondents (38.5%) indicated that there was not a computer lab in their school. One respondent left this item blank.

The next item on their survey was one in which the principals were asked to indicate the percent of teachers in their schools who were computer literate. Only nine respondents (4.8%) indicated that 100% of their teachers were computer literate; 49 respondents (26.2%) indicated that 75-99% of their teachers were computer literate; 61 respondents (32.6%) indicated that 50-74% of their teachers were computer literate; 65 respondents (34.8%) indicated that less than 50% were computer literate (See Table 1.)
two (17.1%) respondents indicated that there were no plans for in-service training in computer technologies this year. There were 120 (64.2%) blanks and one respondent indicated "maybe."

Item nine on the survey asked whether principals felt that more recently trained teachers (less than three years of experience) had more familiarity with computers than veteran teachers. Of the respondents 112 (59.9%) answered yes, 62 (33.2%) answered no, and there were 13 (6.9%) blanks.

In the final area of the survey respondents were asked to respond to two open ended questions. The first question inquired how teacher preparation programs might assist principals in better preparing pre-service training programs with computer technology. The second question related to how local colleges and universities could offer to better assist principals and staff with computer technology training.

In response to the first question many principals took a personal and concerned response. Several themes appeared. Many felt that teachers need to be given fear-free training in which they could express their lack of or budding knowledge with and about computers freely. They felt this was needed as many teachers were afraid to use the computers and were reluctant to sign up for computer training because they felt that their lack of knowledge would be viewed in a derogatory manner. This response lead many to believe that training should be matched to the participant's level of knowledge and it should include instruction for those with no prior computer knowledge. Others felt that training in computer use should be mandatory for teacher certification.

Further, many note that although most teachers were familiar with computer basics, a lot of teachers were not knowledgeable about available software or how to match their required curriculums to computer based class work. Principals felt strongly that pre-service teachers should be exposed to the latest software and that software use should be mandated in their pre-service course work.

On a rather dim note to this question many principals said that training and software were not as great of a concern in their towns for they just didn't have the computers available. These people felt strongly that every teacher needed a computer and teachers needed to be trained to know how to use them. The second question related to how local colleges and universities could offer to better assist principals and staff with computer technology. The second question related to how local colleges and universities could offer to better assist principals and staff with computer technology training.

In response to what type of in-service training colleges and universities could provide to schools, principals overwhelmingly wanted in-house training to tie the curriculum to technology. Many said these courses should be inexpensive and provide college credit. They felt that the Internet training, software reviews, and subject specific and writing programs should be covered. Others felt that it was important to have various levels of short and frequent courses with a menu of offerings. Repeatedly principals said these sessions should match the computer use to curriculum demand (e.g., Teacher e-mailing to Spanish classes so that

Item five in the survey asked the principals responding whether they were computer literate. Of the 187 respondents 149 (79.7%) indicated that they were computer literate while 37 (19.8%) indicated that they were not computer literate. There was one survey on which there was no response to this item.

The sixth item in the survey asked whether the school system had provided in-service training in computer technology for teachers. There were 155 (82.9%) positive responses to this item with 30 (16%) negative responses and two surveys with no responses to this item.

Item seven asked the principals to indicate how extensive the in-service training in computer technology has been. Results are found in Table 2.

*The investigators doing this research feel that the large numbers of blanks is due to the fact that there has been no in-service in computer technology in these schools. In retrospect there is a feeling that another column "never" should have been included in the frequencies listed for this item.

**The one respondent not listed above indicated that there had been no in-service training since 1990.
students could e-mail students in other countries that speak Spanish. They felt that this training should include long range computer planning (with updated consultation) as needed, should range from basic to advanced and overall be embarrassment free.

Many cited a need for help in trouble shooting such as having someone available to fix computers as well as to advise them on what to do when they meet program glitches. Finally many wanted college based regional teacher training centers established which would provide computer labs for large group training and workshops in class modeling, peer coaching, software and better pre-service.

It was obvious from the responses that these dedicated principals felt that this training was needed and that it was basic to their teachers' and students' needs for remaining current.

These results and conclusions for this study indicate that many teachers are not computer literate, that in-service training in computer technology occurs on an irregular basis in school districts, and that veteran teachers are not as familiar with using computers as newer teachers are.

These findings indicate that there are three basic needs. One is a need for training in computer technology in each education course in a teacher training program. Teachers, new to the field, need an extensive background in the use of the latest technology. They need to be able to search the Internet and develop materials for their classes from the Internet. They need to be able to show their students how to use the Internet.

The second need relates to veteran teachers in a school system. These teachers need to receive extensive training in how to best use the computer in their classrooms as a part of their professional development training. They need to receive training which will build their confidence so that they can become capable of dealing with available technology.

The third need relates to training principals of elementary, middle, and secondary schools to become competent in the uses of technology. This competency should be developed in preparation programs for administrators. For those already in school administration professional development training should be available.

Principals and teachers, new and veteran, should be comfortable in using the latest technology. They need to have continuous training so that they are up to date with the latest technology. If we are willing to provide this training the future will be bright.

Edward A. Sullivan, Director of Secondary Education, Providence College, Department of Education, 322 Harkins Hall, Providence, RI 02918, E-Mail: esullivn@providence.edu

Catherine L. Keating, Assistant Professor of Special Education, Providence College, Department of Education, 314 Harkins Hall, Providence, RI 02918, E-Mail: ckeating@providence.edu
Peer learning has been suggested by many as an innovative way to transform students’ learning experiences (Blumenfeld, Marx, Soloway & Krajcik, 1996). Networking groups provide for a more developmental approach to learning by allowing members to voice their opinions and give input by building commitment to the group rather than to a particular activity and by encouraging more personal and professional involvement in constructing their own learning (Lieberman, 1996). Cooperative learning groups that engage members in the construction of knowledge will help advance the acquisition of disciplinary skills and understanding (Brown, 1995).

Peer learning and collaboration can be a powerful tool (Blumenfeld, Marx, Soloway & Krajcik, 1996). Graduate students in the Curriculum and Instructional Technology program at Iowa State University saw a need for an opportunity to incorporate the skills and concepts acquired in their coursework. The result was a collaboration and peer networking group: The Early Adopters (TEA).

The Early Adopters solicit and complete instructional technology and other related professional projects for faculty, staff, and other graduate students within the Iowa State University, College of Education. This is accomplished through real-world projects supplied by faculty, staff, and group members. This paper will discuss implementation of The Early Adopters group, mission and goals, organization, benefits, and examples of current projects.

The Early Adopters group was implemented by a core group of graduate students interested in achieving a collaborative and interactive peer networking group. The name The Early Adopters comes from Everett Rogers’ Diffusion of Innovations. The Diffusion of Innovations Theory consists of several categories of adoption of new technologies. Early adopters are considered to be the advisor or role model for the average innovators. The best way to alleviate uncertainty of adoption is for the early adopter to use it and share the results of its use. We are The Early Adopters, because we want to provide innovative atmosphere for the growth of ourselves and the college community.

In creating the group, the first agenda item was to consider the purpose and how to sell to the faculty, administration, and graduate students. This broad agenda item included expectations, membership, meetings times, project collection, project completion, organization, and financial support for the group’s projects. The College of Education had already established a strong commitment to an undergraduate technology group, The Educational Computing Club (TECC). TECC was formed as a traditional club with membership dues and the like. TEA did not want to work in a traditional club format, but wanted to focus more on collaboration and peer networking. Membership dues are not collected; financial support of projects come from grants or the Center for Technology in Learning and Teaching, which is located within the College of Education. Planning for the foundation of TEA was achieved in a six month time frame. At that time, TEA sought and gained support from Curriculum and Instructional Technology faculty by communicating with them the mission and goals of TEA. This past fall, TEA gave a presentation at a Curriculum and Instructional Technology seminar for graduate students. This enabled TEA to promote membership and reinforce our existence. With foundation work established, TEA now sought projects from faculty, staff, and graduate students.

The goal of The Early Adopters is to share and enhance graduate students and the graduate college community’s technical and professional knowledge in the field of Instructional Technology. Our underlining theme is as students converse and share knowledge they are exposed to and draw upon the expertise of others and learn from them. The founding members of TEA determined that the organization and leadership of the group would be based on a team concept with collaboration as the key component; therefore,
TEA does not believe in enforcing a hierarchical approach to management. This approach allows students to incorporate their technical skills in multimedia, web page design, video and audio production, photography, and other traditional instructional media with current theories of instructional design and learning and gain real experience in research, grant and proposal writing, and project management. In addition, group members’ commitment to the network, personal and professional associations, and visions of possibilities for change is strengthened. This provides numerous opportunities for leadership to emerge.

To keep TEA alive and visible, the following positions were implemented: chair, vice chair, secretary, historian, and treasurer. TEA also has experienced advisors who guide and oversee projects. These advisors are technical, grant, and project advisors. The positions were democratically chosen and filled through the same process. These positions are for communicating to members and interested parties. It is important to note that the members initiate and guide TEA; not the above noted positions. We are interested in a group effort and not individuals. To aid in the formation of “work” groups for selected projects, members are asked to fill out a proficiency sheet. Members rate their understanding and ability in several venues ranging from programming to grant writing to video production to web design. TEA does not limit itself to traditional mediums, but wants to provide a variety of opportunities for its members to grow professionally.

Therefore the primary motivation of TEA is to urge graduate students to take ownership and responsibility for their learning through peer interaction. A second motivation was for the students to gain practical experience in an instructional medium that is becoming more prevalently used. McInerney found, along with Wilkes and Byron (1991), that a cooperative learning format made possible a kind of discovery learning and interactive, experimental education that is very appropriate for adult learners who appreciate the opportunity to direct their own learning. Students also benefited from the networking opportunities created by projects and involvement in a group activity.

With the beginning of a new group, TEA sought meaningful and manageable projects. After the first call for projects made by the group, TEA received several possibilities from faculty. One of the most prominent that TEA accepted to tackle was Section Editors for SITE Annual Proceedings. These projects have provided great opportunities for us to collaborate and to reinforce our mission and goals. Other projects that the group is currently working long-term on are:

- professional organization list: Enable students to contact professional organizations for membership, publication, and conferences.
- management of Project Opportunities’ web page: Maintain and develop Project Opportunities’ web page.
- electronic graduate survival kit: Give new graduate students information on forms to be completed, committee selection, and basic procedures in graduate life.
- Science and Technology Fair Presentation: Provide information to middle school and high school students on uses of technology.
- multimedia presentations

More and more, technology is changing how students gain access to information and how that information is presented. Computer-assisted learning environments such as the Internet, interactive laser discs, and CD-ROMs are becoming more prevalent in the educational world of today. Yet much of the effect that this has had has been to isolate students from each other and foster the development of asynchronous learning environments that are not unlike electronic correspondence courses. Cooperative learning is an important part of the educational experience that needs to be integrated into the instructional design of these new learning environments. These new technologies are going a long way toward fulfilling what Morariu (1988) called “the dream of creating information-rich, learner-directed instructional environments” (p. 17). Yet, TEA affords the opportunity to continue group work and lessen the opportunity of isolation. The Early Adopters intends to lead Iowa State University, College of Education into the future of Instructional Technology.

322 — Technology and Teacher Education Annual — 1998
In this paper, we present a performance-based assessment model designed to measure the impact technology makes on student achievement in the four domains tested on the North Carolina Technology Performance Test. These four domains consist of keyboarding techniques, word processing and editing, database use, and spreadsheet use. As part of this research, a model of qualitative and quantitative evaluations are presented to enable public school administrators, public school teachers, and university/college professors to establish curriculum environments in which students control technology’s interaction with the real world. Our research is based on the School Technology Commissions' recommendations that expected results should impact student learning, workforce readiness, teacher productivity, and cost-effectiveness. Further research implications are based from Martinez and Mead’s 1988 “First National Assessment,” which provided a comprehensive list of recommendations on the topic of computer competence and implications for administrative practices.

We address these recommendations by developing professional development from performance-based assessment data. (This will enhance teacher productivity.), using a collaborative partnership to share resources, strategies, and evaluation reporting systems (This is cost-effective.), using technology in English-math-science courses that allows students to be interactive learners (This is student centered learning.), and establishing core-curriculum learning experiences that relate to work maturity skills and work transferable skills outlined in the School-to-Work Opportunities Act [STWOA] (This incorporates workforce readiness.).

The Research Participants

In North Carolina, all eight graders who fail the North Carolina Technology Assessment Test will retake the test in high school. Of the rural counties participating in this performance-based study 42.35% of their students will retake this test. This places the burden of student technology skill remediation at the high school level. It is not known to administrators or teachers if the 57.65% who did pass the test transfer or maintain these technology skills over a given time period. Three rural North Carolina public school systems, faculty members from one state university, and faculty members from a private historically minority college (Chowan College) formed the Rural Technology Challenge Partnership (RTCP) to address these problems. Collectively, these counties represent rural foothill, mountain, and sandhill geographic regions representative of the state.

The Research Project

The research and evaluation design employed will serve as the tools to combine performance-based assessment outcome scores with administrator professional development strategies designed by the partners (university, college, and public educators). In addition, these technologies will expand teachers and principals understanding of both new technology and new teaching techniques. Evaluators will report past technology scores (pre-test) in the Fall of 1997. From this information teachers and partnership members will plan curriculum integration and technology purchases (hardware and software) that are directed at impacting student ability to use technology as a learning tool in specified performance domains. Throughout the year students will be re-tested (post-test) and their findings reported. This quantitative data will be compared to qualitative analysis of teacher and student descriptive responses. Basically, the partnership believes rural administrators, teachers, and their university/college partners can successfully overcome student technology barriers if clear identifiable benchmarks are established.

Our plan recognizes three “Technology Development Stages” that target commonalities of our participating rural high schools. These technology development stages
consists of (a) a performance-based assessment model that measures students' mastery in four technology domains that can be impacted by alternative learning practices; (b) professional development tied to performance-based outcomes; (c) acquisition of technology equipment that supports professional development plans and needs identified in performance-based outcomes. Through these development stages technology and telecommunications strategies support a transformed teaching and learning environment. This approach is designed to enhance the transfer and maintained effect of technology performance-based assessment skills. If properly integrated into the curriculum, these technology development stages create a systematic approach to create a more equitable school environment.

Research (Cole & Griffen, 1987) reveals economically poor students spend their time on drill-and-practice exercises while better off economically students spend their time in more meaningful activities. It is the intention of the technology development stages to create a more equitable technological environment. This is accomplished by principals emphasizing professional training and acquisition of equipment based on students' needs found in performance-based outcomes. Historically, businesses match every dollar spent on hardware or software with a dollar spent on training and assessment (Sikula, Buttery, & Guyton, 1996). Statistically, educational organizations spend twenty-five cents on training and assessment for every dollar spent on hardware or software. Only through the leadership efforts of the principal can appropriate acquisition of equipment and staff training be established. We identify appropriate acquisition as the criteria set in "President Clinton's four national technology goals" which include the following: (a) all teachers will have training and support to help students learn using computers, (b) all teachers and students will have modern, multimedia computers in their classroom, (c) every classroom will be connected to the information highway, and (d) every software or on-line learning resource will be part of the curriculum.

The model established to augment these four acquisition priorities combine performance-based assessment outcomes with the professional development guideline. By doing so, we promote the acquisition of technology on an expanded understanding of both new technology, new teaching techniques, and existing student learning outcomes. Our principals have established the following professional development and technology enhancement schedule.

1. Teachers meet in their core-curriculum groups for six days with university faculty. Prior to these meetings all stakeholders are briefed on student performance-based outcomes. Specific instructional strategies and practices are designed around assessment learning outcomes.

2. Teachers receive six days of instructional support through a combination of their principal, peer teacher, or college faculty members. This support allows strategies to be tested, promotes implementation, and allows team collaboration to remove obstacles.

3. Technology acquisition, teacher technology training, and in-school support plans are designed with the principal, teachers, and professional development facilitators. All participants use telecommunications to articulate strategies.

4. Principals at each of the participating high schools receive professional development in the areas of leadership and technology implementation. The goal of principals is to be lead facilitators and participants in the technology performance-based assessment model implementation plan.

Administrator’s Integration Role

Wolf's 1993 research revealed that public school principals' use of technology is found in general administrative areas. These areas consisted of office administrative use, office word processing, budgets, and the maintenance of records. While the use of technology in these areas is beneficial for the administrators, it fails to support the impact principals can deliver to the school's technology climate. Writing on effective schools suggests that the principals can have a major impact on efforts to improve the organization and delivery of services to students (Bossert, Dwyer, Lee, & Rowan, 1982). If principals are to be effective technology leaders they must establish the framework and climate in which goals will be achieved (Wolf, 1993). We suggest that administrators must integrate technology climates that cause daily interactions between principals and teachers and/or principals and students.

These daily interactions are based on the four fundamental factors associated with successful technology integration. The four factors consists of national context, school organization, external support, and innovation characteristics (Fullan, Miles & Anderson, 1988; Van den Akker, Keursten & Plomp, 1992). Note, one of the main reasons these for the failure of these four fundamental factors associated with successful technology integration is lack of support from school principals (Bummelhuis & Plomp, 1993). For the purpose of this paper we will relate these four integration factors to each integration stage contained in our statewide initiative.

The Performance-Based Model

Students

Technology integration into core curriculum classes creates three student learning outcomes. These outcomes consists of an achievement learning outcome, affective learning outcome, and a skill learning outcome. In order to gain a performance measure in these areas, the initiative
utilizes three instruments. First, the Iowa Achievement Test of Basic Skills is used to measure students' English and Math performance. Second, a questionnaire administered to students measures technology frequency interactions, attitude toward technology, and quality of those interactions. In addition, focus groups are held with students so descriptive data may be compared to affective questionnaires. Finally, the students are administered a personnel test containing basic employment skills.

**Implications For Principals**

As principals, the implications of technology integration is not found in what teachers do or what students experience. The implication of technology integration is found in what measurable conceptual and skills relative to computers can students demonstrate (Anderson & Collis, 1993). In short, these are the exact outcomes principals are accountable for by their constituents.

The normal school day is not conducive to teacher interaction or research planning needed to accommodate the integration of technology into the classroom. As a transformational leader, the principal must create bi-directional situation of research-technology integration and technology integration research to occur. In order to accomplish bi-directional situation, plus overcome rural isolation, teachers and principals employ telecommunications home through the use of Internet and e-mail. In each of our three counties principals took the lead in negotiating a more competitive on-line charge so more teachers could participate. Principals should be able to negotiate the cost of these home on-line hookups and cover the cost through professional development funds. The telecommunication link allows principals and teachers to communicate strategies via e-mail and download instructional materials. In addition, principals had their administrative staff participate; thus, placing the entire school in the bi-directional transformation.

The practice of principals using technology to communicate with teachers in this manner causes the school environment to rely on technology as an essential irreplaceable learning tool (Wark, 1997). In addition, the principal, with his or her teachers, change the culture of the school by altering the flow of information and communication. An example of this communication is illustrated in the methods that performance-based outcomes are used.

CREATING A PARTNERSHIP TO ENHANCE TECHNOLOGY STAFF DEVELOPMENT

Sara Olin Zimmerman
Appalachian State University

Alan Wark
Appalachian State University

There is a concern that without access to technology there will be no changes in students’ learning (Grabe & Grabe, 1996). As schools become more technologically rich, teachers are lacking more of the skills necessary to benefit from new instructional capabilities. While teacher preparation programs are creating technologically prepared teachers, there must be appropriate staff development to get experienced teachers “up to speed” in the use of technology (Maurer & Davidson, 1998). Factors that have traditionally accounted for limiting the involvement of teachers using computers in the classroom have included: lack of time to plan, lack of teacher training, scheduling difficulties, and lack of available computers and software (Becker, 1991; Sheingold and Hadley, 1990).

The North Carolina Department of Public Instruction recently adopted teacher competencies for all school personnel requiring certification. The general goal for teacher competencies are to assist an educator in acquiring the knowledge and skills necessary to introduce students to the computer skills identified for all students. This will aid new teachers seeking licensure in North Carolina, but it does not address the need for staff development with teachers currently in North Carolina public schools.

The initial student testing is completed in the eighth grade. All eighth graders who fail the North Carolina Technology Assessment Test retake the test in high school. Thus, the majority of student technology skill remediation is completed at the high school level.

Purpose

The purpose of this study was to aid public school teachers in their development of technology skills and the integration of these skills into their content area classrooms. To accomplish this the Rural Technology Challenge Partnership Grant was secured from the state of North Carolina in three rural county school systems. These counties were chosen because 42.35% of their students had to retake the technology assessment test last year.

Universities can provide technological network assistance to schools in numerous ways. Access to a university computer network allows schools to connect to a vast system of resources. E-mail and other telecommunications systems can enhance communication among educators who are geographically dispersed. Cooperative grant writing can enable schools to appropriate needed hardware, software, and support (Zimmerman, Greene, Schlagal, Trathen, & Blanton, 1997). These necessary underpinnings for successful telecommunications use may be frequently found in partnership relations between public schools and universities. However, assistance in the application of technologies is far less common in practice than it should be. It is through shared activity that learning best occurs (Rogoff, 1994).

Connecting system-building components, evaluating, technical sharing, and creating technologically advanced high schools in the three counties was the responsibility of a team composed of public school and university faculties. This team collaboratively provided a systematic approach towards the creation of a technology implementation effort based on student needs found in performance-based outcomes. The approach during implementation of this model involved changes in each high school’s use of technology and its relationships that impacted classroom instruction, policy-making, collaboration with existing initiatives, and leadership functions.

Project Implementation

The partners (university and public educators) were contacted to create strategies to expand teachers’ and principals’ understanding of both new technology and teaching techniques. This team also worked directly with a curriculum specialist in technology and a technology specialist to explore software and implementation strategies. All participating teachers were given access to on-line resources in their classrooms. In addition, all partners in the public schools and universities were loaned identical laptop computers for ease of interaction and teaching.
Before this study began, participating teachers completed a questionnaire listing demographics, technological proficiencies, current uses of technology, attitudes and hindrances to usage of technology.

Methodology

Student Qualitative Evaluation: Students' descriptive responses were collected in each English class (grades 9-11) as part of an integrated technology-English composition assignment. They were asked to construct a five-paragraph essay to describe the integration of technology in their learning experiences. Descriptive responses were collected from all three partnership counties.

Teacher Qualitative Evaluation: Core-curriculum teachers (English, math, science) were asked to complete an open-ended questionnaire at the end of the school year to reveal current strategies they used in integrating technology in their classrooms.

Quantitative Evaluation Design: The North Carolina Test of Computer Skills (Performance Part) was administered to all students grades 9-11. This part of the test consisted of four domains: keyboarding techniques, word processing/editing, database use, and spreadsheet use. Individual student scores were reported in each of the four domains. An analysis of covariance was used to correlate the individual student scores with cohorts of classes.

Results

When the participating teachers were surveyed on current uses of technology and availability several facts came to light. There were computers in all classrooms. The number of these ranged from 1 to 30 per classroom. There were computer labs in both participating schools. All teachers reported a lack of telecommunications options. Computer training had been received through self-teaching and workshops. All teachers were currently using word processing, data bases, and spreadsheets within their classrooms. E-mail was used by one-third of the teachers. All teachers, except for one, supported the use of technology to support curriculum, increase subject-specific knowledge, design and manage learning environments and resources, address diversity among students, and in ways that are appropriate socially, legally, and ethically. One teacher responded that he thought the technology should only be used to address diversity among students. Limited access to equipment, limited time, and lack of modem/telephone lines were the top three hindrances listed to the usage of technology.

Teachers requested further information and training to use technology in alternative ways than they had experienced. Their immediate concern was that in math and English courses the researchers would discuss spreadsheets and word processing. They also initially requested software catalogs and funding thinking that the Internet had little value to their teaching. After extensive sessions and training, the researchers were able to convince teachers to integrate Internet searches, web authoring, World Wide Web boards, and video-conferencing into their lesson planning. Teachers were also linked together on a listserv to provide a community of educators to share cultural experiences, write to an audience, and make comparisons about teaching, learning, and schools. Teachers were able to communicate with each other about issues that affect all of them.

The team provided partnership schools with four components: 1) county level technology performance-based assessment, 2) professional development opportunities that link performance-based outcomes with the North Carolina Standard Course of Study, and 3) technology resources.

Implications

Only a portion of the data from this study has been archived and analyzed. Individual self reports suggest that the process is on target for completing its goals. Additional benefits of this project may be seen in a comparison of partnership counties with comparable children in other counties. A community of learners using technology has been created. Funding has been provided for an additional four years and careful examination and adaptations of this project are currently being made. The direct value of this community to teaching practices and to individual student achievement needs further assessment.

Alan Wark is a Doctoral Student in the College of Education, Appalachian State University, Boone, North Carolina 28608.
Given the emphasis on using technology in education to impact student learning, teacher education programs must prepare teachers who can design learning environments where K-12 students are actively involved in the purposeful use and integration of technology for learning tasks. Because of technology's potential as a cognitive learning tool, it is assumed and expected by many that teacher education faculty will learn about and use various technologies in the preparation of teachers. Although most teacher education faculty indicate that technology is important, they still do not feel comfortable using technology with students (U.S. Congress, 1995).

There are many barriers that confront teacher educators in their attempts to use technology. Common barriers listed by College of Education faculty include "time, limited resources, faculty comfort level and attitudes, and little institutional encouragement for technology use" (U.S. Congress, 1995, p. 187). Even though these barriers are difficult to address, many teacher preparation institutions are seeing the need to overcome them and are beginning to provide professional development opportunities for faculty. Hence, Colleges of Education are designing staff development programs that provide support for faculty as they learn about using technology in the preparation of teachers.

The papers included in this section describe a variety of innovative models and unique initiatives that have been designed and implemented to improve the use and integration of technology at colleges and universities. Collectively, these papers describe the specific processes that several institutions have taken to improve the use and integration of technology by faculty and students, but separately the papers document the unique approaches that each institution has implemented to meet the challenge of technology integration. Rather than categorizing these papers into subgroups within various faculty development themes, I have chosen to summarize each paper to highlight the individual and unique approach the authors have taken to address the faculty development issue as it pertains to technology at their institutions.

Two professional organizations, The International Society for Technology in Education (ISTE) and National Council for the Accreditation of Teacher Education (NCATE), have both identified as part of their organizational standards technology skills that teachers are expected to have when they enter the teaching field. Handler, Strudler, and Falba describe a planning model that will assist faculty with the identification of ISTE standards that can be applied to the specific courses they teach. The authors will offer strategies faculty can use to model the effective use and integration of technology for instruction using the ISTE standards. This model's framework places emphasis on the articulation of technology integration between teacher education courses in the professional sequence.

Matthew, Parker and Wilkinson report the results of a research study based on the Stages of Concern model developed by Hall, George, & Rutherford (1997). In the Spring of 1996, faculty at Louisiana Tech University gained more access to technology and this study identified faculty concerns related to having access to these technologies in their offices and classrooms. As part of the study, faculty were to indicate what type of faculty development workshops would help them with using these technologies as personal productivity and instructional tools. These results will assist other Colleges of Education in determining the technology and staff development needs of the faculty and how those needs might be met by providing faculty a variety of staff development opportunities for faculty.

Woods, Peterson, Richardson, Davis and LeJeune describe their efforts to design a Web-based faculty development workshop. This dynamic, learning environment provided time for participants to reflect upon their teaching philosophies and practice, while using the World Wide Web to share their ideas with others. Findings from this pilot study, indicate that a Web-based staff development framework has promising applications for a broader audience that might include K-12 teachers and media specialists.

In the Faculty Computer Use Project at Buffalo State College, Stevens and Lonberger describe their project that focuses on three major themes: access, training and context. All faculty who participate in the project are given access to...
equipment in their office with the guarantee that upgrades will be provided in the future. The training component of the project was designed to meet the needs of the participants at their level of technology expertise. Lastly, and often ignored in technology integration models, faculty were given the opportunity to dialogue about and explore the contextual issues that confronts users of technology as well.

Similar to the Faculty Computer Use Project described above, one goal of the instructional technology training program at Moorhead State University is for faculty to utilize technology in ways that expand and enhance course objectives. Ficek characterizes this initiative as an instructional training program designed to accommodate different learning styles of faculty. Actual training opportunities for faculty are delivered in a variety of formats which include group training, cooperative teaching, department-specific training, and student/faculty mentorships. This design provides a variety of learning opportunities that will evolve to meet the ever-changing needs of the faculty involved.

At Eastern Kentucky University (EKU), the teacher education program is considered a function within the nine colleges at the university. Therefore, it was the goal at this institution to create a faculty development program that would meet the needs of the entire EKU learning community. Dickey and Davis document the process of creating a needs assessment which addresses faculty promotion themes such as instruction, scholarly activity, and service. Although the results indicated that faculty requested staff development opportunities in seven different categories, the category requested most by respondents was technology. To meet faculty needs, this model provided technology instruction in a variety of formats such as workshops, presentations, training sessions, satellite broadcasts and a two-day exposition.

With the establishment of the Office of Educational Technology (OET) at the University of Illinois Urbana-Champaign, faculty in the College of Education who are interested in using and integrating technology are supported by multiple means. Thurston, Stuve, Pianfetti and Thomas present a staff development model that supports faculty through co-teaching of technology strands in courses, individualized one-on-one faculty consulting, workshops and technical troubleshooting and repair. Unique to this model is the notion of integrating technology into several sections of the pre-service teacher education courses within a Year Long Program (YLP), rather than offering a semester long technology course. To support the initiatives of the Year Long Program, OET staff provide support to the course instructors, provide laptop computers for students, conduct workshops, and help co-teach the classes that involve the use and integration of technology. The OET’s technical support component is one that can serve as a model for other institutions in their quest to effectively support faculty in their use of technology.

Carbone and Mitchell document the process of developing a training program designed to prepare postgraduate students for their role as educators. This training program at Monash University, which initially began in 1996, and has evolved into an effective tutor training program where the tutors and demonstrators focus on improving the quality of teaching and student learning. Currently, this tutor training program is used with students enrolled in computer science courses, but its approaches for conceptualizing teaching and learning could be applied to any educational situation.

Zhao, Rop, Banghart, Hou and Topper from Michigan State University provide readers with an interesting ‘look’ at two distinct cultures within technology and education. The authors refer to these two cultures as the ‘techies’ and the teachers. Documented in this paper are narratives from four techguides who were involved in the attempt to create a culture where ‘techies’ and teachers would interact and therefore establish a shared culture of teaching and learning with technology. The techguides’ descriptions of their experiences offer us insight into the diverse nature of our background experiences and how these experiences effect our ability to learn from and share our knowledge with others.

The majority of faculty development models that have been described in the literature are those that involve staff development opportunities for faculty and students within the same teacher education program, college or university. Little-Reynolds and Takacs propose a model which involves the collaborative efforts between the faculty and graduate students at two different institutions (approximately 260 miles apart), as participants from both institutions assist each other with technology integration efforts at a distance. In the Collaborative Technology Integration (CTI) model, the faculty from Mary Washington College (MWC) and graduate students in instructional technology from West Virginia University (WVU) work collaboratively to identify effective uses of technology and to facilitate technology integration into courses. For the duration of the project, the participants communicated with each other by the use of email, faxes, and the telephone. Two of the participants in the program offer their reactions to the successes and limitations of the project. As this model illustrates, educators and students are no longer confined to a room or a building to access support for technology integration.

Providing access to the technology for faculty and students has been a priority for teacher education institutions in recent years and often is seen as one of the critical issues that impacts the successful use and integration of technology throughout teacher education programs. It seems, faculty, staff and students at Valley City State University (VCSU) solved the access barrier by implementing an innovative and comprehensive plan for institutional change that involves the distribution of notebook comput-
ers to all faculty and students. To support this initiative, the campus network connects all offices, residence halls and classrooms. In fact, all of the classrooms at VCSU have Internet access at each seat. Students graduating from VCSU will be required to create an electronic portfolio that will document and demonstrate their progress through the teacher education program.

Finally, Byers, Hoadley, Pike and Byers provide us with an update on the progress made by the Center for Instructional Design and Delivery (CIDD) at the University of South Dakota (USD) specifically, in their efforts for assisting faculty with the application of technology for professional activities. Each semester, at least twelve faculty members from across campus are given release time to participate in a semester long training program. Some of the requirements for the faculty involved in the CIDD program include serving as a liaison between CIDD and their academic units, attending CIDD training sessions, and assisting the CIDD with grant writing. This faculty development model illustrates the commitment and support required by the entire university community to incorporate technology into the learning and teaching process.

Collectively, these papers offer us a variety of models and approaches for assisting and supporting faculty, staff and students with technology use and integration throughout our college and university programs. Faculty development initiatives such as these can help us assemble communities of learners and teachers who are striving to design educational environments that use technology in powerful and compelling ways to impact learning.

SUPPORTING FACULTY IN EFFORTS TO INTEGRATE TECHNOLOGY INTO TEACHER EDUCATION

Marianne Handler  
National-Louis University

Neal Strudler  
University of Nevada - Las Vegas

Christy Falba  
University of Nevada - Las Vegas

The recent report, Teachers and Technology: Making the Connection, (U.S. Congress, 1995), confirmed that "technology is not central to the teacher preparation experience in most colleges of education. Consequently, most new teachers graduate from teacher preparation institutions with limited knowledge of the ways technology can be used in their professional practice" (p. 165). According to the report, "Helping teachers use technology effectively may be the most important step to assuring that current and future investments in technology are realized" (p. 2). How, though, can we best prepare preservice teachers to develop the skills needed to incorporate a variety of technology tools in their professional practice? Most leaders in the field agree that this cannot be accomplished by educational technology classes alone. In addition to specialized courses in educational computing and technology, preservice teachers should experience widespread integration of technology into "non-technology" classes and field experiences; thus having opportunity to apply the skills gained in the educational computing class.

At the center of this problem is the need for university faculty to develop skills in the instructional use of technology tools; to model their use while teaching and to provide authentic experiences for the preservice student. We know from the work of Roberts and Ferris (1994) that it takes many hours for faculty to become comfortable with technology, let alone be ready to consider how to integrate these tools into their own teaching. Systematic approaches to achieving this type of technology integration, however, have been lacking. In the recent past, several outside driving forces have come into play and may move the use of technology in teacher education forward.

The movement among professional organizations is to develop standards that provide a framework of expectations. The International Society for Technology in Education (ISTE) has developed a series of standards for the field. We are concerned with the Foundation Standards; standards that recommended the skills all new teachers should have as they enter the field. The other influential set of standards come from NCATE (1997), the accrediting body for colleges of education. This group has provided more emphasis on technology than it has in the past, but it has not yet included meeting the Foundation Standards as a part of the precondition report.

A New Model

We will describe the efforts made at two colleges of education to systematically address the needs indicated above. Specifically, it will focus on a planning model and supporting materials that address the Foundation Standards established by the International Society for Technology in Education, that all teachers should meet. The model provides a structure that can assist university faculty select where each of the standards could appropriately be applied in specific courses, identify technology tools that faculty could model and use in their own instruction, and specify experiences and particular software that would help preservice teachers plan lessons for use in their future classrooms. A key assumption of these materials is that the ISTE standards should be addressed in a systematic way that requires structured planning across courses and specialty areas. Handler and Strudler (1996) developed this framework, the materials, and strategies for their use. The model was piloted in two teacher training institutions; one a midwest private, the other a western public university. Despite these differences many similar experiences were encountered.

The paper session will describe the experiences, similar and different, that were encountered and the restraining forces that were met. It will conclude with recommendations for future efforts in this direction, including the impact of the now changed ISTE Foundation Standards.

The supporting materials developed for the model may be found on the CD for this conference.

Multimedia, pentium computers with Windows95, Microsoft Office, and Internet access can be overwhelming for education faculty who are accustomed to using IBM PS2 Model 30-386 computers with 4MB RAM and 40MB harddrives with WordPerfect for DOS. Internet access was through huge, IBM mainframe terminals with blinking green cursors that repeatedly froze. In the past two years as new faculty were added, they received Pentium computers that lacked CD-ROM drives and sound cards, but did, however, have both 3.5" and 5.25" disk drives, or they received CD-ROM drives with no sound cards and 3.5" disk drives. Lack of technology and easy Internet access in the College has not kept all of the faculty from learning about and using technology. Some faculty have hiked across campus to the 10th floor of the library or to an engineering building to gain Internet access and to take faculty development courses on the Internet. Other faculty accessed the Internet through local service providers in their homes.

In the Spring of 1996, technology resources began to change when a technology grant was awarded and an accreditation visit from the National Council for Accreditation of Teacher Education (NCATE) was eminent. NCATE standards require that faculty be “knowledgeable about current practice related to the use of computers and technology and integrate them in their teaching and scholarship” (NCATE, 1995, p. 24). The Louisiana Board of Regents funded a technology grant that replaced the Apple Ile computer lab in the College of Education with a Macintosh computer lab. During Spring, 1997 university funds became available to wire the College for Internet access in offices, classrooms, and the Macintosh computer lab. Additionally, the Board of Regents funded a second technology grant that provided a networked statistics lab. Multimria, pentium computers with Internet access were placed in faculty offices and networked laser printers were installed in Fall, 1997. Other grants provided for a technology-rich classroom, software, and peripherals, such as digital cameras. The state is funding a distance education classroom that will be installed in the College in Spring, 1998. The changes in the technology available in the College are having a profound impact on the faculty with their office computers having the most direct impact on them.

Faculty have very personal concerns about these changes which may be manifest as resistance to change. Resistance to change can be attributed to the following fears: 1) fear of change, 2) fear of time commitment, and 3) fear of appearing incompetent (Rutherford & Grana, 1995). Fear of change is evidenced by faculty members resisting relinquishing mainframe terminals, old computers, and old printers even though the new technology has been installed and they have been given personal instructions on its use. Fear of time commitment is manifest by faculty who indicate they would like to attend faculty workshops and enroll in faculty technology classes. However, they do not enroll in the classes because it takes so much time to learn to use technology, and because they have so many other things demanding their attention. Some faculty openly express their technological incompetence, others quietly whisper this fear, and others simply continue to avoid using technology. Faculty fears and concerns are affected by individual faculty personalities. Some faculty are willing to take risks, eager to learn new things, and flexible enough to cope with new technology. Other faculty are not.

Individual faculty convictions influence their willingness to adopt an innovation. This adoption usually involves a five stage process: 1) awareness of the innovation, 2) judgment of the value of the innovation, 3) decisions based on the judgment, 4) implementation, and 5) confirmation of the viability of the innovation based on personal decisions and in collaboration with others (Wells & Anderson, 1997). Faculty beliefs and experiences with the innovation impact their acceptance and use of the innovation. Only if they find the innovation personally relevant and of value to themselves will they use the innovation and explore ways to use the innovation with others. The acceptance of an innovation is highly personal and individual concerns about the innovation can hinder or even obstruct the change process (Linnell, 1994).

Innovation requires change, and a natural part of the change process is resistance. Resistance to technology integration in colleges of education is multifaceted (Roberts & Ferris, 1994; Cummings, 1996). Frequently encountered problems include: 1) lack of active support from the adminis-
Technology workshops were offered each month and will be open to members who are not technology users. Last year with the support of the college administration, faculty members use technology for their own benefit, but also share their knowledge of technology (Parker, 1997). Some integrate it into their classes, and work collaboratively to share their knowledge of technology with their students. The willingness of faculty to take risks and make commitments is on a continuum. Some faculty members use technology for their own benefit, but do not teach with technology. Then, there are those faculty members who are not technology users. Last year with the upgrading of the College computer lab, faculty development technology workshops were offered each month and will be offered throughout the year. Further, faculty are provided with individual, personal assistance and assistance with their classes in the computer lab when requested. Successful implementation of an innovation requires not just technical support, but also support that addresses the affective concerns of those instituting the change (Linnell, 1994).

The Stages of Concern Questionnaire assesses the intensity of concerns experienced as an innovation is adopted (Hall, George, & Rutherford, 1977). These concerns occur in a natural, developmental sequence marked by stages. Since movement through these stages is developmental, not everyone achieves all of the stages. These stages include: 1) awareness, 2) informational, 3) personal, 4) management, 5) consequence, 6) collaboration, and 7) refocusing. The first four stages focus on internal concerns of the individual, and the last three stages focus on external concerns relating to how the innovation may impact their associates and their students. The awareness stage is indicative of a knowledge of the innovation with little or no involvement with the innovation. Characteristic of the informational stage is a desire to learn more about the innovation with little concern for its impacts on the individual. The personal stage is characterized by knowledge that the innovation personally affects the individual accompanied by uncertainty as to the demands of the innovation, uncertainty as to the individual’s ability to meet the demands, and uncertainty as to the individual’s role with the innovation. At the management stage, the individual’s concern is with the amount of time required to use the innovation effectively and efficiently. At the next stage of development, internal concerns shift to external concerns. The consequence stage involves focusing attention on the impact of the innovation beyond the individual. This stage is followed by collaboration which sees the individual focusing efforts on using the innovation in coordination and cooperation with others. The final stage of development is refocusing, whereby the individual focuses on other ways to benefit from the innovation and explores alternatives to the innovation. It is expected that movement through the stages leads to a decrease in internal concerns with a corresponding increase in external concerns related to the innovation.

The purpose of this study is to determine faculty concerns about the changes in technology in the College, specifically their office computers with Internet access. The Stages of Concern About an Innovation Questionnaire (SoCQ) (Hall, George, & Rutherford, 1977) is being used to assess faculty concerns. Three questions frame this research. At what stages are the faculty in their concerns about using their computers with Internet access? What impact will faculty development technology workshops and one-on-one assistance have on their stages of concern? What changes will occur in the faculty’s stages of concern overtime?

Methodology

Sample

The participants in this study are the 41 faculty members in the College of Education. Three departments constitute the College: 1) Curriculum, Instruction and Leadership, 2) Health and Physical Education.

Instruments

Two instruments are being used to gather data for this study: 1) Stages of Concern Questionnaire and 2) Faculty Development Technology Workshops Survey.

Stages of Concern Questionnaire. The SoCQ (Hall, George, & Rutherford, 1977) measures changes in concerns over time as an innovation is adopted. The questionnaire consists of 35 concerns based statements, five for each of the seven stages of concern assessed by the questionnaire. Responses to the statements are on a scale of 0 to 7 with 0 indicating a very low concern or irrelevant at the present time and 7 indicating a very high concern. The instructions direct the participants to indicate their present degree of concern for each statement. The original version of the questionnaire uses the word innovation, which for the purpose of this study was changed to “office computer with Internet access.” For example, number 6 states “I have a very limited knowledge about the innovation.” This statement was changed to read “I have a very limited knowledge about my office computer with Internet access.”

Faculty Development Technology Workshops Survey. In order to best determine the needs of the faculty for technology workshops, a faculty development technology workshop survey was sent to the faculty members. The survey asks them to indicate if they are interested in workshops on software applications for word processing, presentations, statistical analysis, a mail reader, and Internet explorations. A blank line allows for them to indicate if there are any other workshops they are interested in attending.
Additionally, the survey asks what days of the week are convenient for them and whether they prefer morning, afternoon, or evening sessions. The survey also asks for volunteers to teach or help teach the workshops.

Procedure

In December copies of the Stages of Concern Questionnaire and the Faculty Development Technology Workshop Survey were distributed to faculty members. They were requested to anonymously complete the questionnaire and the survey, then return it to the researchers. The instructions on the questionnaire ask them to read each question and answer it in terms of their present concerns. Data from the questionnaire and the survey will be used to determine staff development needs, specifically what staff development is needed based on the faculty’s levels of concern. During the remainder of the academic year, technology workshops will be offered to the faculty as well as one-on-one support. At the end of April, both the questionnaire and the survey will be redistributed to the faculty. This data will be used to determine growth in faculty stages of concern. Further, data from the questionnaire and the survey will be used to assist in planning the faculty development workshops to be offered during the following year and to help determine other ways to assist the faculty as they discover new ways to use the technology. Faculty will be at differing levels of concern and will need different types of support as they learn to use and teach with the available technology. Faculty development workshops will be more effective if they are tailored to address the immediate faculty concerns.

Data Analysis

Responses to the SoCQ will be tallied on the SoC Quick Scoring Device as both raw scores and percentiles. Raw scale scores will be tabulated for each of the 7 subscales and converted to percentiles. In order to determine the range of peak scores within the faculty, the number of individuals scoring high on each stage will be tallied. Then, individual data will be aggregated to deduce the mean scores for each stage. This will provide information as to the dominant high and low stages of concern of the faculty that will be interpreted based on the definitions of the Stages of Concern. To provide additional insight into the faculty’s stages of concern, the second highest stage scores for the group will be analyzed to determine if the second highest Stage of Concern is adjacent to the peak Stage. This pattern of highest and second highest stages of concern being adjacent is related to the developmental nature of concerns often associated with innovations.

Discussion

Many factors impinge on faculty’s movement through the stages of concern. This progression requires more than knowledge of the innovation, time to use the innovation, and successful experiences with the innovation. Faculty movement through the stages is highly personal and impacted by faculty capabilities and other demands on their time (Wilkinson, 1997). Providing hands-on workshops and one-on-one assistance will foster movement through the stages for most faculty. However, for some faculty their “history, dynamics, and capabilities may make resolution of certain concerns nearly impossible” (Hall, George, & Rutherford, 1977, p. 15). Hence, every faculty member is not expected to progress through all of the stages. Support must be provided to them at their stage of development, as they learn to use their office computers with Internet access and the other technology available to support their teaching.

Determining the faculty stages of concern and providing support as they learn to use the new technology is the first step. The next step will be having them integrate technology into their classrooms. Realizing, as have others (Roberts & Ferris, 1994), that the acquisition of computers and using them for personal benefit is only the beginning, an ongoing area of focus will be on working with faculty to integrate technology into their classroom teaching. Teachers’ self-perceptions of their expertise are highly correlated with the implementation of technology into their teaching (Harvey, Kell, & Drexler, 1990). If faculty are to integrate technology into their classes, they must feel comfortable using the technology. According to Roberts and Ferris (1994) this takes approximately 1,000 hours of training. Training, support, time, and leadership are necessary for the successful integration of technology into classrooms. Technology integration into classes will require faculty who feel comfortable using the technology, as well as changes in their teaching methods, and changes in their roles as teachers.

The ability to think reflectively about teaching has been suggested by many as a key aspect in developing effective teaching practices (Schön 1991; Stevens, 1988; Stevens, 1989). Faculty development efforts have recently been directed towards fostering reflective thinking. The goal is to assist teachers in uncovering personal philosophies of learning and the impact of these philosophies on their practices. The assumption during this effort is that changes in teaching practices occur most effectively when people know why they do the things they do. A faculty development workshop (originally presented in a traditional setting) was created to foster reflective thought about teaching philosophies and practice. To make the workshop accessible to a larger population and to integrate the latest technology, a decision was made to “put the class on the Web.” The process of creating, redesigning, and piloting the Web-based workshop as well as results are described.

The major challenge in designing a Web-based version for this workshop was the creation of an environment that facilitates the same type of reflective thought that was generated by small group discussions. A reexamination of theories that define effective teaching and learning was our first step in addressing this challenge. Typically the emphasis on quickly generating a Web-based product takes precedence over careful consideration of what is being done and why. Often what occurs is the presentation of lecture notes in a Web-based environment (Hirumi & Bermúdez, 1996) where little has changed except the method of delivery. However, changing the delivery method should redefine the content and/or presentation. According to Morrison, Ross, and O’Dell (1991) technology that facilitates learning can also limit the experience. It is in the process of integrating technology into teaching practices that the boundaries between facilitation and limitation are clarified.

The purpose of this paper is to describe the process our team used over a six-month period creating, redesigning, and piloting the Web-based workshop as well as the results from our efforts. The motivation for the workshop, the value of the workshop, the way theories informed design decisions, the prototype implementation and evaluation process, and the results/lessons learned are presented in the following sections.

**Motivation for Workshop Creation**

Moving this workshop from a traditional classroom-like setting to a Web-based environment was motivated by the desire to make it accessible to a larger population and to integrate the latest technology. The very nature of Web-based instruction implies benefits in terms of control over accessibility, convenience, self-containment, and cost effectiveness (Kahn, 1997). However integrating technology in the learning process is not a simple procedure. If we, as a group of instructional designers, were challenged with the transition to a Web-based environment, then teachers (the intended workshop participants) must be equally challenged. By creating this workshop which utilizes Web-based technology, we are providing teachers a “hand-on” experience of learning in this new environment.

Participation in this workshop supports teachers in creating a vision of using Web-based instruction in their own practices in two different ways. First, it supports teachers’ critical reflection of their practices through structured reflective activities. Critical reflection is a skill that helps a teacher to develop professionally, make informed...
choices, and develop a rationale for practice (Brookfield, 1990). It is a subset of the much larger process of reflection. It specifically encourages a teacher to examine dynamics that sustain all educational practices and to question assumptions and classroom practices (Brookfield, 1990). Each of the workshop activities provided a framework for teachers’ critical reflection on their own teaching philosophies as well as their practices.

Secondly, it provides hands on experience with technology. Progressing through the activities, teachers experience and can appreciate the elements of navigation, design layout, on-screen text presentation, and facilitated communication with others. According to Willis (1994), providing a “hands on experience” with technology is an effective strategy for faculty development using distance education technology. Participants in the workshop were provided an opportunity to experience the logistics of learning in a Web-based environment and experienced an effective design that encourages critical reflection.

Potential Value of the Faculty Development Workshop

Promoting discourse on the rationale and methodologies of instruction may be one of the most valuable applications of this workshop. The noticeable absence of conversations about teaching among professors may be partly the result of either a lack of experience or of pedagogical knowledge. Pedagogical knowledge, knowing appropriate teaching strategies, distinguishes reflective from non-reflective teachers. Copeland, Birmingham, DeMeulle, D’Emidio-Caston, and Natal (1994) summarized meaning making in classrooms for novice, apprentice, and master teachers. Apprentice and master teachers appeared to focus more on the quality of students thinking, engaging students in the process of learning, and improving their disposition toward learning than did the less experienced group.

Introspection and reflection may promote improvement in teaching but may not happen intuitively for all adult learners. In an exploration of the myths of adult learning theory, Brookfield (1992) identifies the misconception that all adult learners are self-directed. Some teachers may wish to be reflective about their practice and philosophy but hesitant about whether or not they can effectively reflect in isolation. The unique environment of facilitated discovery in a Web-based environment provides an opportunity to reflect regularly and conveniently about their philosophy and teaching practices. This reflection could result in clarification and alignment of teaching perspectives and practices (Brooks & Brooks, 1993).

Theory Informs Design Decisions

One of the primary questions we wrestled with as a group of designers was whether or not the Web-based environment is an appropriate medium for facilitating critical reflection. Further if this environment were appropriate, then how would it be designed? What would it look like? These questions stimulated our subsequent design decisions.

Extending the workshop to a Web-based environment necessarily altered the roles of the facilitator and the participants. However, the basic assumptions and learning objectives from the original workshop remained constant. In a traditional workshop setting, the facilitator designs the specific activities, manages their order, determines the amount of time spent on each activity, and relies on visual cues to motivate and engage participants. The facilitator is in control of the learning environment. The transition to a Web-based environment shifts the control of the learning activity from the facilitator to the participant.

This shift in control of learning forced us as workshop designers to reexamine theories of adult learning, instructional design, and motivation. Creating learner control in a Web-based environment requires detailed attention to the design, layout, and presentation of the workshop. Several different strategies were used to shift the control of learning from the facilitator to the learner. One strategy was to use a table of contents to organize the activities and to provide a vehicle for navigation throughout the workshop. Using this tool, participants had the freedom to choose from five distinct activities. Participants selected which ones to complete, the order, and the time spent on each. Every activity included statements regarding the potential relevancy of the activity and invited participants to think about their teaching philosophy and their classroom interactions. As a second strategy, the workshop was designed as a closed environment. Unlike other Web-based environments which contain multiple hot-links to other outside sites where a user can easily “get lost”, this workshop is self-contained. Teachers can work through all the reflective activities in an arbitrary manner, but are provided no links to remote sites. This design feature reduces cognitive load on teachers and supports the less experienced user.

We also examined ways to motivate participation in the activities. This was realized through the use of pictures, readings, quotes, animation, and poetry (Williams & Tollett, 1998).

In addition to the structural changes made to the workshop, specific activities needed to be redesigned to fit the Web-environment. For example, in the original workshop participants were asked to draw a timeline of the highs and lows of their teaching experiences on a large piece of paper. This timeline provided a framework for examining their teaching history and led to an examination of potential new directions. Obviously this type of exercise presented a challenge in the Web-based environment. The “Map” activity was transformed into a guided journaling activity called, “My Journey: Finding Direction by Reflecting on the Past.”
Adult learning theory suggests the social construction of knowledge is an important element of any learning experience. Due to the asynchronous nature of the Web environment, social interaction must be carefully constructed. In the pilot of the workshop, we created the role of a “facilitator” to address this concern. As participants completed each activity, their reflections were sent to the “facilitator” with the expectation of receiving a meaningful response in a timely manner. According to Wlodkowski and Ginsberg (1995), and Pintrich and Schunk (1996) facilitators may promote motivation by providing positive, accurate, personal, and timely feedback. This facilitator component of the design emerged as problematic in addressing the need for social interaction during prototype testing. This aspect of the workshop needs to be redesigned.

Prototype Implementation and Evaluation

The development of the workshop and its implementation was a dynamic, ongoing collaboration that we characterized as iterative enhancement. As we explored various theories of adult learning, instructional design, and motivation, we were challenged to define ways these theories would be realized in a Web-based environment. After launching and tinkering with the workshop, we reexamined whether or not the translation met expectations. Extensive changes were entertained. Then it was back to the drawing board to refine the implementation. After multiple iterations of this process, we agreed that formative feedback was essential before proceeding further in our design, redesign process. We invited two graduate instructional design classes to complete the workshop during their class time. 35 students independently accessed the Web-site to test our prototype.

The pilot population consisted of teachers, library media specialists, instructional designers and ranged in age from 22 to 50 (mean = 37). Approximately two thirds of the population were women. An interesting side note: while 71.5% of the participants labeled their level of computer expertise as competent, highly skilled, or expert, over half of the participants (51.4%) reported this as their first on-line workshop experience. This testing provided feedback on the content of the workshop as well as its design. Five different methods for data collection were used: students’ responses to workshop activities, observations of students and faculty, individual interviews, focus groups, and the workshop survey. These five forms of data collection provided multiple views of workshop activities in promoting critical reflection as well as specific feedback on the design layout and presentation. The data collected contributed to a framework for reflection on the highlights and pitfalls of the workshop thus allowing for a thoughtful redesign.

Redesign and Lessons Learned

Two major successes of the workshop were brought to light through this formative evaluation process. It was clear from comments, observation, and written responses that the Web-based environment is a viable medium for delivery of the faculty development workshops. Our findings revealed that the participants were able to overcome technological challenges and successfully work through reflective activities. This validated our assumption that the Web-based environment can be used to facilitate critical reflection. Additionally, we discovered that the workshop is applicable to a larger population than originally suspected. The target population in development of this workshop was college teachers; however, the prototype evaluations and reflections revealed that other groups of professionals, such as librarians, K-12 teachers, and instructional technologists, also found the experience valuable and thought provoking.

Students said that they particularly liked the poems and graphics of the workshop. One student wrote, “the poems selected were appropriate and fit with pictures.” Another student said, “readings-poems fit exercises.” Students also felt that the reflection exercises associated with each activity did serve their intended purpose (i.e., to stimulate thought and critical reflection). Comments like, “open-ended questions did stimulate reflection” and “the program forced you to reflect in a way that you otherwise seldom take time to do,” led us to conclude that the workshop had succeeded in promoting reflection among its users. Lastly, the data revealed that students were pleased that they were able to navigate freely through the workshop. Students made the following comments: “I liked the open-ended questions - no correct answer” and “I liked being able to move from one activity to another.”

One major concern arose from our study of the data. The pedagogical inventory activity appeared to be the weakest of all five activities. Students felt the response choices in the inventory did not relate to the questions asked. Students also questioned the rationale for selecting only one teaching practice for redesign. “The inventory only asks for one change to make. How could someone only have one if they were really reflective?” These concerns strongly implied a redesign of this activity is necessary.

Another important piece of information revealed from the data focuses on the design of Web-based instruction. There were aspects of the workshop design that were positive and others that were irritants. For example, students liked the background design used on all the Web page activities and felt it was not distracting. One student said the background let them know that they were still in the workshop and hadn’t “gotten lost on the Web.” However, students did not like the use of different fonts of varying sizes, the size of the answer boxes, nor the verbosity of the text. The feedback from the pilot emphasizes the importance of utilizing...
consistent design principles throughout a Web-based environment.

**Conclusion**

The faculty development workshop was created through multiple iterations of conceptualizing workshop activities, implementing design decisions, and examining theories of learning, motivation, and instructional design. The result of this process was a Web-based instructional workshop piloted with a group of 35 participants. Our findings suggest the Web-based environment is a powerful medium for workshop delivery and for the promotion of reflective thinking. An equally significant revelation is the importance of a good instructional design on the Web. Nonetheless, consideration of technological limitations and their implications for student learning and motivation are among a number of important issues to focus on in future research. Although the workshop was originally designed for college faculty development, the pilot revealed a broader application audience to include other groups of professionals such as K-12 teachers, library media specialists, and instructional designers. The lessons learned from our Web-based design experience will be foremost in our minds when we redesign the workshop prototype into a functional online workshop.

The Information Age has arrived at a time when a revolution is taking place in education, with many groups seeking to address identified problems within U.S. schools (Boyer, 1985; Carnegie Task Force, 1986; Holmes Group, 1986; National Commission on Excellence in Education, 1983; NCATE, 1997). Studies reporting that our system of public education is failing to meet the future needs of our country or our students, and pointing to the desperate need for revitalization are plentiful. Three decades of research in the cognitive sciences now serves to support change in teaching practices. School districts recognize the need for teachers to help improve classroom practice by moving away from teacher-centered, single discipline, product-oriented environments in favor of student-centered, multi-disciplinary, process-oriented centers for learning that integrate computer technology in educational settings (NCATE, 1997; OTA, 1995; West Seneca, 1996; Riel, 1989). In order for entry-level teachers to integrate technology as a meaningful part of new instructional practices, teacher education faculty need to both demonstrate and support technology as an integral part of coursework.

Educational use of and emphasis on Information Age technologies has resulted in an increase in both the number of computers and the quantity of computer-related equipment in public schools despite ever-decreasing fiscal resources. According to a recent report issued by the US Office of Technology Assessment (1995), however, teachers are neither regularly using nor integrating computers for instruction on a regular basis. One factor believed to contribute to this problem is that technology-using teachers need to be trained by technology-using faculty in teacher preparation programs. Both new and veteran educators feel inadequately prepared to use computer-based technologies to deliver and support classroom instruction (Hirschbuhl & Faseyitan, 1994; Sheffield, 1996).

Whether in public elementary, middle, and high schools or in institutions of higher education, breaking away from traditional instructional approaches can mean taking risks and plunging into unknown territories. Faculties in college and university teacher education programs, as well as teachers currently practicing in public schools, need support and encouragement in their efforts to transform instructional practices through professional development. Support such as faculty professional development opportunity related specifically to use of technology in teacher education often lacks organizational support, however, and may not be available (Hirschbuhl & Faseyitan, 1994).

The US Congress, Office of Technology Assessment report (1995) devoted two chapters to the importance of professional learning. Entire issues of publications such as the Journal of the Association of Teacher Educators, Action in Teacher Education, and the Journal of Teacher Education, this last published by the American Association of Colleges of Teacher Education, have been devoted specifically to technology and teacher education. In addition, a rapidly increasing number of electronic resources are available to those teachers and teacher educators who recognize the critical importance of sharing ideas about technology, subject matter content, teaching practices, student achievement, assessment issues, as well as both positive and negative aspects of using technology in classroom settings.

In recognition of the need to improve preparation of future teachers and following a series of discussions, the faculty of one mid-sized college’s department of elementary education devised a plan to integrate technology into their preservice teacher education courses. The approach taken in developing this action plan was based on beliefs similar to those presented by Fox, Thompson, and Chan (1996). In general, faculty members on the ad hoc technology implementation committee agreed that all prospective teachers need to be confident in their ability to use computers, that cooperative learning projects and activities support knowledge construction, and that integrated curriculum promotes meaningful learning. The program devised by this committee also reflected a belief that offering a single core course in computer technology for education might imply that computers were an “extra” feature in education rather than an integral part. A further consideration of the committee was that a core course would be difficult, if not impos-
sible, to staff and include in students’ already full schedule of professional sequence courses.

In a move to empower faculty and to promote the integration of technology into instruction and professional activities, faculty members agreed to participate in a three week preliminary group experience. Consideration of faculty input, review of current literature, and dialog with teacher educators already incorporating technology into their instruction revealed three conditions that have a strong impact on the quality and nature of teacher education faculty use of technology: training, access, and context. The program devised by the committee, therefore, included a training program designed to meet the needs of faculty members with varying levels of expertise. Issues dealing with access to computer equipment and related materials were given increased priority. Following the training program, both full and part time faculty who had participated were given access to office equipment (with some assurances of upgrading in the near future). Finally, issues relating to context included a commitment to group support, shared experiences and materials, and more integration of educational technology in classroom instruction and assignments. These elements formed the foundation for preliminary program development and they are expected to be critical in the ongoing integration of technology in our teacher education program.

Inservice Technology Training Program

When the Faculty Computer Use Project began, those involved had varying levels of expertise with computer application software. It was determined that the following three applications would be featured in the preliminary inservice instruction: word processing, presentation software, and computer-mediated telecommunications including Internet access. This selection was based on expressed needs of participants as well as on the belief that these applications might support computer self-efficacy, utility beliefs, and general computer aptitude (Hirschbuhl & Faseyitan, 1994). It was also believed that these applications might best support the use of computer-related skills in the context of instructing undergraduate elementary education methods classes, an essential part of integrating technology into an existing program.

At the outset of the instruction, time needed to be spent explaining some of the basics regarding a Windows environment and ways in which this was similar to and different from a Macintosh environment. Icons and other supportive features of this technology needed some explanation as this otherwise served as an impediment to work planned for this three week session. Group members each were assigned to individual computers, but were seated in pairs such that one member had some knowledge of computers and would, therefore, be in a position to help their partner with these introductory concepts.

According to *Teachers and Technology: Making the Connection* (OTA, 1995), many teacher education faculty neither model the use of technology as a means by which to meet objectives in the courses they teach, nor do they teach ways in which information technologies support instruction. The first application presented in the Faculty Computer Use Project was word processing with a specific focus on developing materials that would directly support faculty work in preparing for and teaching undergraduate methods courses and would also reduce time spent attending to committee obligations such as producing reports and minutes of meetings. Faculty reported that this training had immediate application to their work and might help them connect word processing skills to their students’ work and to work that these students might be expected to complete in elementary classrooms. Those involved in this project quickly gained some facility with incorporating graphics into their materials design and found this to be a most rewarding aspect of word processing.

The second set of applications presented included both the college e-mail system and access to the Internet. Faculty eagerly engaged in sending and receiving e-mail almost immediately. This prepared them for the somewhat more complex processes involved in using the Internet. All participants, including the authors, were very excited about the practical uses of technology to promote lifelong learning environments for themselves, for prospective teachers, and for elementary students. Assignments were tailored to individual faculty needs. This was done so that faculty might more easily see technology as a learning tool and, therefore, as a natural inclusion in their coursework and class assignments. Lists of locations of particular importance to various content areas were quickly compiled, and while there was more than a little regret that not all offices were equipped for e-mail and the Internet, faculty nevertheless moved forward in their explorations and attendant alteration of course goals to reflect their newly found skills and awarenesses.

The final application introduced as part of the Faculty Computer Use Project was a presentation package that is available on either PC or Mac platform. Faculty were encouraged to modify an existing presentation, discuss effective slide or overhead presentations, prepare their own materials for class, and consider developing a department resource list of available presentations. This last application proved, in many ways, to be the highlight of the project as faculty used all of their other skills in using technology to develop course materials and to share both materials and ideas with their colleagues.

Contextual Issues

The situation faced by faculty members on campus mirrored, to a large extent, the school settings in which prospective teachers worked. While there was some selection of facilities available on campus, the Faculty
Computer Use Project members had to travel to various locations in order to access appropriate resources. In general, the faculty agreed that there were more opportunities to use technology within a single building in elementary settings than we had on campus. Some discussion was entertained regarding the degree to which elementary teachers were incorporating technology into instruction and the ways that school districts were promoting student development with or without attendant staff development. Project members agreed to become more aware of staff development opportunities available in the districts where their prospective teachers were placed for field experience.

A further contextual issue that became important in the success of this project was related to the support that faculty found and nurtured through their shared experiences. The following excerpts are taken from messages transmitted during this project:

"I don't want to miss class. Could some of you write to me please and let me know what you did?"

"...if you will put any handouts in my mailbox I'll catch up at home or in the lab after hours."

"My PowerPoint is 3.0. I need to get 4.0. My menu doesn't have the neat option you showed me yesterday. How do I go about getting the new version?"

"I wanted to pass on some information that may be of interest to you. Teachers.Net, the teacher's Internet resource that brought you the Homepage Maker (http://teachers.net/sampler/) and the Reference Desk (http://teachers.net/library/) is pleased to announce the addition of a new resource to the on-line teachers tool kit."

"Cut and paste is a challenge. Specifically, I need to know how to put pictures from Netscape into my Word Processing Documents. Any ideas? See, I have a question everyday. I can't wait to go home and get on PowerPoint and see if I have the effects options."

"I recommend selecting the picture on Netscape by using your right mouse button, saving the picture to your disk (or to your hard drive), and then using Insert command word and choosing Picture. Personally, I have every confidence that you will get past this little hurdle with NO PROBLEM. However, if you have any difficulty, send me e-mail and we will work it out."

"We've gotten through half the workshop with no casualties. I find that I am doing tremendously well in my dreams. Yes, I not only am working on the computer during the day but also during the night."

"It's just great to be surrounded by such talent. I've noticed everyone has become an authority on something...Rosemary you know how to paint, Leslie you're terrific at sending messages, flowers and word association, Joan demonstrates strong ability in SC, GE and GM skills. Kathy's great at taking notes and sharing her knowledge and Marilyn—oh Marilyn, you're the best at giving us laughter!"

This sense of camaraderie continues to support and encourage use of technology by the faculty. Of the nine participants, all now have a computer and modem in their office and two also have purchased new equipment for home use. Thus, while we continue to work toward gaining easy access to technology on campus, faculty continue to support infusion of technology in their personal and professional contacts and associations.

Summary

Both NCATE (1997) and the Office of Technology Assessment (1985) point to the need for teacher education instruction in technology. In order for student teachers and other preservice educators engaged in field experiences to integrate needed technology skills, they first need to be taught by those who value such experiences and who use these skills in their own professional practice. In the Faculty Computer Use Project, we have learned that when technology is infused and supported through meaningful, contextualized experiences in a college setting, faculty are inclined to incorporate technology into their planning and coursework and express interest in sponsoring their students to do likewise.

It is recommended that appropriate training be given to faculty in order to overcome their fears of using computers for instruction and to increase their technological literacy. While many barriers may be seen to exist in infusing technology into a lifelong learning program, faculty who have successfully completed projects such as presentations and gathering course materials from electronic sources may well experience an increase in confidence and enthusiasm that will only increase over time. The importance of providing opportunity and time for faculty training cannot be overstated if infusion of technology into educational settings is to be accomplished.

During this era of accountability, institutions of higher education share the common concern of how to present themselves as effective and efficient places of learning. Public scrutiny of academic programs, research projects, faculty workloads, and overall performance has led colleges and universities to take a closer look at how they are using and developing their resources. The use and development of resources is often a crucial factor when making decisions for financial allocations or applying for external funding (Weber, Engle, & Knaub, 1995). Therefore, institutions of higher education, must create plans of action to effectively use, develop, and expand the resources that they have.

One of the most important resources in a college or university is the faculty. The faculty plays many different roles in the education process. They provide instruction, research, and service. All three areas of activity are vital to institutional and community programs at the local, national, and international levels. Because the faculty is so important to the survival and growth of institutions of higher education and other communities, it is essential that programs of professional development opportunities be made accessible to the faculty. A faculty development plan should include professional activities for individual, instructional, curriculum, and organizational development (Jussawalla, 1990).

There are many factors to consider when planning a program for faculty development. Staff development can be systematic and incidental. Institutions may consider the type of professional development plan that is created such as: (a) the management centered type of plan determines what instructors do over a period of time; (b) the instructor centered type lets the individual plan for personal improvement in an educational environment; and (c) a partnership type of plan that includes input from both the management and individuals (Ediger, 1996).

A three dimensional approach to planning programs may be most effective. The first dimension is based on the amount of experience that the individual faculty members possess. The second dimension describes faculty roles which can include instruction, scholarship, creativity, service, or personal growth. The third dimension deals with the organizational level at which the development opportunities are targeted. Opportunities can be offered to individual faculty members, particular units, the academic profession, and the non-academic community (Menges, 1990).

No matter what type of opportunity, program, or approach is used, each institution should create a plan for faculty development that is successful at meeting their unique needs. Successful faculty development programs provide training that will provoke, stimulate, and guide educators to use and integrate new concepts (Imants and Tillema, 1995). Faculty must be given the opportunity to acquire materials, skills, and ideas that they can use for their own professional growth. These opportunities must be accessible, timely, pragmatic, and easily adaptable in order to be effective.

Most faculty/professional development in higher education revolves around the premise that faculty responsibilities are in three areas, teaching, service, and research. Therefore, faculty and college administrators may need to agree on and consider some of the following as key development areas for faculty:
1. Vitalizing students' interest in learning by using exciting teaching techniques including technological media.
2. Creating assessment techniques with the goal of improving teaching and learning.
3. Using techniques for teaching critical thinking and developing creativity in students.
4. Increasing skills for mentoring and advising students.
5. Forming an educational environment that includes instructional computing techniques such as on-line instruction, where quality of time may be as important as quantity of time spent in instruction.
6. Increasing one's knowledge of how to use technological tools for instructional purposes.
7. Synthesizing past experiences with students with new instructional strategies.
8. Developing skills in the ethical use of new technologies.

The primary purpose of this paper is to share the experience of conducting a needs assessment survey to help determine and create a faculty development program that would best meet the needs of the Eastern Kentucky University (EKU) community. Eastern Kentucky University is a regional university with approximately 15,000 students.
This institution of higher education honors a tradition of providing excellent undergraduate and graduate teacher education programs. All nine colleges participate in the development and governance of the teacher education programs. Teacher education is a university function which includes all of the faculty, staff, and services. Therefore, it is vital to offer a faculty development program that meets the needs of the entire university community yet still focuses on the trends and issues concerning teacher education, especially in the area of instructional computing.

It was determined that the planning goals for such a program should include systematic and incidental opportunities. Planning was to include experience, faculty, and organizational dimensions. And, the development process would be a partnership plan that considered both management centered and instructor centered types of information. In order to meet these goals, faculty input was essential. To obtain the desired information from the faculty, a needs assessment was conducted. This assessment instrument elicited data from the faculty about their desired types of professional training topics. This paper will provide information about the procedure used to conduct the faculty needs assessment survey, a description of the survey results, and information about how these results were used to create a faculty development opportunities program for the academic year of 1997/98.

Procedure

The topics and themes of the previous year's professional development workshops, presentations, and seminars were listed and reviewed. The list of these topics was acquired through studying the scheduled events of the 1996/97 academic year as well as the suggested topics that were generated at a faculty breakfast conducted in April, 1996. Faculty were invited to attend a breakfast meeting where ideas about faculty development were exchanged. These ideas were organized, compiled, and given to the office of the Associate Vice President of Academic Affairs and Research.

The best way to discover what the faculty wants and needs to learn in the area of instructional computing skills is to ask them. Information will be relevant and the faculty can feel ownership in the planning process. In order to provide the opportunity for faculty to become involved in the process of planning a program for faculty development for the academic year of 1997/98, a survey was mailed in the early Spring of 1997. This survey included information and questions to help faculty list the type of topics they wanted scheduled for professional development. Themes that matched the professional development areas used for faculty promotion, tenure, and evaluation were included as a guide to an awareness that a distribution of topics across all areas of faculty development was needed. These themes (instruction, scholarly activity, and service) also reflect the mission of the university. The following information was provided on a survey form entitled Faculty Development Opportunities Needs Assessment and distributed to each faculty member.

The Office of the Associate Vice President of Academic Affairs and Research has begun to plan faculty development opportunities for the 1997-98 academic year. Although it may seem to be very early, faculty input at this time is valuable and necessary to designing opportunities that best meet the needs and schedules of the faculty.

Listed below are three professional development themes (instruction, scholarly activity, and service) as well as input lines for several suggestions per theme. Please provide your name, campus address, campus phone number, and a brief description for each of your faculty development ideas. The list on the back of this page contains a compilation of topics that have been previously offered or suggested. You are invited to use this list as a springboard to create your own ideas or to choose a 1996-97 topic that you think should be repeated.

Lines for each theme were provided for the faculty member's name, campus address, phone, and description. At the end of the needs assessment survey, a call for faculty involvement was included as follows:

"Are there any workshops or other types of faculty development opportunities that you would like to host or present? Please list the titles or topics in the space provided below."

The faculty were asked to complete the survey form and return it by February 21, 1997. A campus address was given.

Survey Results

The topics for professional development that were listed by the faculty were placed into areas of common concern called themes for the purpose of planning development opportunities. These themes and the number of suggested topics were organized as follows: (a) technology with thirteen suggested topics, (b) instruction with six suggested topics, (c) assessment with five suggested topics, (d) professional activities with five suggested topics, (e) learning styles with four suggested topics, (f) health and wellness with four suggested topics, and (g) service with three suggested topics. Results from the survey suggest that the faculty had an interest in training in the area of instructional computing. The specific topics for this theme for professional development were requested as follows: computer assisted instruction, using the computer, database management, desktop publishing, SPSS for Windows, changing library services, Web workshops, how to create a course for the Internet, Internet seminars, instructor's guide for teaching by television, PowerPoint, teaching on the Kentucky Telelinking Network (KTLN), and Word Perfect 7.0.

A review of the suggested topics as listed by the faculty revealed that some topics were very general in nature such...
as computer assisted instruction or using the computer. Some were somewhat specific to particular type of purpose such as database management, desktop publishing, changing library services, Internet seminars, etc. While other topics were quite program specific such as SPSS for Windows, Word Perfect 7.0, or PowerPoint.

The Faculty Development Opportunities Plan

Information from the needs assessment survey was analyzed and a plan for the faculty development program was developed. This plan had to address budgetary and other major concerns such as: (a) time and duration of the training; (b) types of presenters and speakers; (c) location of the services; and (d) types of formats that would best meet the needs of the participants. When providing training in the area of instructional computing, such variables as time, duration, and location are extremely important to consider because equipment and laboratory space must be reserved for such service. Presenters and speakers must have content knowledge as well as presentation skills that can assist audiences in understanding technical information. The format must meet the need of the skill requested. Short term workshops or long term courses must be carefully selected to meet the time needed to appropriately cover the topic and for the participant to adequately assimilate the information.

After reviewing resources, suggestions, and concerns, faculty development opportunities were offered to the faculty that were diverse in format, location, and schedule. These opportunities included instructional computing training in the form of: (a) short and long term workshops; (b) live satellite Public Broadcasting Service (PBS) presentations; (c) short courses offered by Special Programs; (d) a two-day Instructional Computing Expo; and (e) full term courses. Although a calendar of events was created and distributed to the faculty for the Fall 1997 term, incidental types of opportunities for faculty development were added as the need was identified.

A variety of institutional resources were needed to fund, locate, and equip the faculty development opportunities. These resources included: (a) faculty scholarships; (b) mini-grants for faculty research; (c) training sessions provided by the Academic Computing and Telecommunications Services (ACTS) staff; (d) training sessions provided by the Extended Programs staff; (e) training and services provided by the Media Resources staff; (f) services provided from the Library Resources staff; (g) services provided by the staff from Special Programs; (h) services provided by faculty and staff willing to share their expertise; and (i) outside speakers and services. It should be noted that faculty with skills in the area instructional computing were invited to participate in the Instructional Computing Expo. This expo was a two day event that invited the university community and education reform partners from the local area schools, community colleges, technical schools, and business community to attend.

Conclusion

The faculty at Eastern Kentucky University were asked to participate in the planning process of a faculty development program for the 1997/98 academic year. Participation was elicited from the faculty by asking them to provide information about the topics they would like presented. A needs assessment survey was used to obtain this information.

Analysis of the data collected from the completed surveys revealed that the faculty requested development opportunities in seven categories or themes. One of theses themes was technology. Further study of the suggested topics for this theme indicated that some topics were very general in nature, some targeted a specific purpose, and some were very program specific.

When planning faculty development in the area of technology, instructional computing topics as listed by the faculty were used. A variety of formats such as workshops, presentations, training sessions, satellite broadcasts, and a two-day expo were planned. Different locations, schedules, speakers, and materials were used to address the variety of faculty needs, experience, motivation, and depth of understanding. A variety of funding and staff resources were used to provide many different types of activities. The faculty were asked to participate as learners and presenters and the calendar of events remained open to requested, incidental activities.

It is recommended that institutions of higher education make a cooperative effort between faculty, staff, and administration to plan professional development opportunities and that all perspectives be considered during the development process. Part of the planning process should include an invitation to all of the members in the university community to actively participate.

INSTRUCTIONAL TECHNOLOGY TRAINING: MULTIPLE STRATEGIES FOR MULTIPLE LEARNING STYLES

Rhonda Ficek
Moorhead State University

Training in instructional technology should be provided in a variety of formats to accommodate different learning styles. At Moorhead State University, several strategies for faculty and staff development are underway. Group instruction, instruction tailored to the needs of individual departments, faculty/student mentorships, and individualized instruction are provided.

Background

Until recently, most faculty and staff at Moorhead State University did not have access to a computer on their desktop. The addition of a Student Computer Fee enabled the university to secure personal computers for faculty and staff as well as additional computer laboratories for students. Now that nearly all faculty and staff have computers on their desktops, there is an ever-increasing demand for training in the use of products and software designed for personal computers rather than the mainframe applications previously used.

In the past, workshops have been offered for training in virus checking, basic Internet activities (e-mail, Web browsers, ftp), and a variety of personal productivity applications. However, there is an increasing need for training that is tailored for individuals and departments. In addition, faculty need to be exposed to the ways in which instructional technologies can be integrated into existing courses.

During fall semester, six hours of load from a faculty position were earmarked for providing training in the use of instructional technologies. I indicated an interest in providing training in instructional technology. In addition to my background in computer science, I have an undergraduate teaching degree and previously taught high school mathematics. I developed a course ITechnology for Teachers which has been offered for two years at Moorhead State University. Several years ago, I also developed an Introduction to the Internet course for the university. In the past several years, I provided a series of training sessions for faculty interested in Internet technologies and another series for administrators at MSU. These activities have now expanded into a defined role for Instructional Technology coordination at our university.

Goals for instructional technology training at MSU include the integration of technology into existing courses, effective use of appropriate technologies for the desired learning outcomes, and provision of training in a variety of formats to address different learning styles.

Integration of Instructional Technology into Existing Courses

An introductory education course was developed several years ago which serves as a model for the integration of instructional technology into an existing course. Dr. Ficek collaborated with a professor from the education department to retrofit the entry level course for preservice teachers. The goal was to utilize the Internet as an information source and as a means to improve communication among students in the class, students working in cooperative groups, and students with their professor. Students were instructed in the use of an Internet browser, e-mail, and a presentation tool. Gradually the course added additional instructional technology tools to assist in the goals for the course. For example the cooperative groups now create a Web-based research project. The entire class has access to each group project, and each individual utilizes the information in these projects for an assigned paper. The members of the class also subscribe to a local listserv (to enable sharing of information/discussion) and a listserv devoted to disabilities.

Effective Use of Appropriate Technologies for the Desired Learning Outcomes

This goal is vitally important if the professors are interested in utilizing technology in ways that enhance and augment the course objectives. Most are not interested in adding technology simply because it is available. Many of the group workshops begin with comments about how and where the tool has been used effectively in instruction. Ideas about how to utilize the tool within the context of a specific discipline are typically discussed as well. In other words, the
instruction is not simply on the keystrokes required to perform certain functions. Instead, each function is introduced in the context of how it can be utilized in instruction or for preparation of course materials.

**Provision of Training in a Variety of Formats**

Training for faculty and staff has proceeded in a variety of formats, including:

1. **Group training**
2. **Cooperative teaching**
3. **Department-specific training**
4. **Student/Faculty mentorships**

**Group Training**

Group training in a lab containing 30 personal computers provides an opportunity for hands-on training. The following three series of workshops were developed to address some of the training needs at MSU:

1. **Personal Productivity Series**
2. **Internet Series**
3. **Instructional Technology Series**

The Personal Productivity Series consisted of nine hour-long sessions providing training in Windows 95, virus checking, word processing, PowerPoint presentation software, a scheduler/on-line calendar and Eudora e-mail. The workshops were held on Monday, Wednesday, and Friday from 9-10 AM, and pre-registration was required. Most faculty and staff made use of their tuition waver to take the series as a half-credit course. However, the publicity for the workshops encouraged people to sign up for individual workshops if that fit into their schedules and needs at a cost of five dollars per session.

The Internet Series consisted of nine hour-long sessions providing training in the use of Web browsers (Netscape), Internet search engines, listservs, ftp, e-mail, and downloading/installing software from the Internet. The workshops were held on Monday, Wednesday, and Friday from 9-10 AM, and again, pre-registration was required. For those who needed information on selected topics, registration for individual workshops was allowed at a cost of five dollars per session.

The Instructional Technology Series consisted of nine hour-long sessions providing training in the use of technology in instruction. It was tailored for faculty, primarily. The initial session provided an overview of ways the World Wide Web has been utilized in instruction. The participants visited sites at various virtual universities.” Other sessions led the participants through the process of creating an individual Web page using a WYSIWYG environment, using four kinds of hyperlinks within and between documents (links to the Internet, to another local page, anchors within a page, and e-mail links). Next, design and organizational issues were presented to illustrate how to create a Web for an individual course. Microsoft FrontPage was utilized as an example of software which not only facilitates the creation of individual Web pages, but also provides mechanisms to assist in the maintenance of the entire collection of Web pages for a particular course. Conferencing environments were explored, with hands-on exposure to Microsoft's NetMeeting product, which allows for video and audio conferencing, electronic whiteboard, and collaboration on a virtual document.

The group hands-on training situation works well for some individuals, but some people are not able to keep up with the group. For some of the sessions, an assistant was available to provide assistance for those who fell behind. Generally, the approach was one of showing the group the features of the software that were most practical and useful for instructors. No out-of-class work was required. The participants were given detailed handouts which covered the material so that when they left the workshop, they could practice on their own with the instructions nearby. Handouts were also made available via the Web.

An evaluation was distributed to participants at the end of each of the three series. The majority of respondents indicated they were very satisfied with the training and would recommend it to a colleague.

**Cooperative Teaching**

A second method used for faculty development was cooperative teaching. This provided a means to incorporate technology into an existing course even before attaining a comfort level with the technology that is usually necessary to teach that technology.

Several professors who had taken the iTechnology for Teachers course last year were contacted to participate in a pilot project which would utilize a Web-based writing project. The professors had received hands-on training in the creation of Web pages using a WYSIWYG environment (Netscape Gold), and their classes typically required a substantial writing project. However, the professors were not yet comfortable enough with the technology to provide instruction and technical support for their students. The idea was to incorporate the use of the Internet as an information source along with traditional library sources. The students would be allowed to incorporate links to Internet resources, images, and color as they saw fit.

A cooperative teaching arrangement was made, where the students were given two hours of instruction on basic Web-page creation at the beginning of the semester. The technology instruction was provided by Dr. Ficek, as part of the six-hour release for coordination of instructional technology. Throughout the semester, students were to gather appropriate materials (both traditional materials and materials from the Internet). The students were allowed to use either a traditional word processor or a Web-page creation tool for the initial draft of the paper. Near the end of the semester, two additional hours were provided in the lab.
for incorporating the materials into a Web page. Technical assistance was also made available for the students during the semester by providing the e-mail addresses of several student assistants who could provide help as needed.

Three courses were involved in the pilot Web-based writing project. Two were graduate level education courses, and the third was an undergraduate English course. The graduate student projects were well done, and the participants were generally very satisfied with their final product. The undergraduates were asked to present their projects for the class at the end of the semester. Most were able to locate additional resources on the Internet, and they enjoyed incorporating a photograph of their author in the paper. All participants felt they had extended themselves and had worked very hard to achieve their final product.

**Department-Specific Training**

Hands-on group settings provide a general background in the use of software applications, but each department has needs particular to their discipline. A pilot program targeted professors in the College of Business for training at the department level. The dean was asked to provide a list of 10-12 professors who would be willing and interested in developing materials for on-line instruction. Several members of the faculty in this college currently use ITV to deliver distance education. The addition of Web-based instructional materials, a listserv to enhance discussion among class members, and e-mail access between the professors and their remotely-located students would enhance the distance delivery.

Eight hours of instruction were provided for ten faculty members from the College of Business. Training primarily focused on the development of on-line course materials. Participants utilized a scanner, participated in a local listserv, and learned about organization and management of a Web site. They were also exposed to newer technologies such as the SmartBoard to enhance their distance delivery. The FrontPage Web development software was utilized to create the instructional Web materials and provide an overview of the linkage of the various documents.

**Student / Faculty Mentorships**

Group instruction is not effective for every faculty member. Some learning styles prohibit participation in group settings. For these people, an individualized environment with readily available technical support is optimal.

Six students were trained in the use of various software and hardware tools. They will each be assigned to two faculty during the spring semester. Funding for the students was provided by a regional grant pertaining to technology. Training was provided by Dr. Ficek during fall semester as part of the six hour instructional technology assignment.

Faculty were expected to provide an idea for a specific project which could be completed in one semester. The student assistants will work with their assigned faculty member for 2-3 hours per week for 15 weeks. Examples of projects which were selected include:
1. Web site for library instruction
2. on-line advising site
3. Web site for internship information
4. on-line instruction for the College of Business MBA degree

The students are expected to work with each individual faculty member to assist them in the use of the software and hardware needed to support the goals of the project and to provide technical assistance and support throughout the semester. The students will be available via e-mail as well for their faculty partner.

**Future Directions**

While training in instructional technology is vital, ongoing technical support must be provided to assist faculty and staff in their efforts to utilize their newly acquired skills. In the future, we plan to train students to provide technical assistance for faculty and other students. Funding will be secured through internal and external grants. The need for technical support will continue to grow, and all training efforts must address the need for support after the training is complete. A core student technology team has already been formed. Now, it needs to be expanded to serve the needs of more faculty and staff.

MULTIPLE MEANS OF SUPPORT: THE ROLE OF THE OFFICE OF EDUCATIONAL TECHNOLOGY IN FACULTY DEVELOPMENT

University of Illinois at Urbana-Champaign

Ryan Thomas  
University of Illinois at Urbana-Champaign

Technology development in colleges of education has become a high national priority. The reality is that “technology is not central to the teacher education preparation experience in most colleges of education.” (Office of Technology Assessment); according to a May 1996 survey of schools of education, only 45% of the faculty regularly used computers, TV’s and VCR’s as interactive instructional tools during class period. 58% do not have any classrooms wired for the Internet, and 19% have no web site, (Zehr). As a result, many are calling for an acceleration of the integration of technology into the delivery and content of courses as a key to preparation of future teachers. In a recent report, the President’s Commission of Advisors on Science and Technology have indicated that “colleges of education should be encouraged to find ways to reward faculty members who include new technologies in the methods of content of their courses (President’s Commission). Another influential group, the National Association of Secondary School Principals, has also called for reform. “Preparation to work with technology ought to be basic to teacher education. Teachers should learn to use technology as an ally in helping students make better use of inquiry-driven knowledge construction strategies. Colleges and universities that prepare and certify teachers must accept responsibility for ensuring that those who embark on careers in the classroom reach this level,” (NASSP).

To further these goals, the College of Education at the University of Illinois Urbana-Champaign established a new Office of Educational Technology in the fall of 1996, which is supporting faculty with the integration of technology using multiple means. The means of support include co-teaching of technology strands in courses, individualized one-on-one faculty consulting, workshops, and technical troubleshooting and repair. The staff of the OET recognize the need for this broad range of support to facilitate successful integration of technology throughout the various academic programs in the College, and to provide continued support for technology development for faculty and staff.

Technology strands through course work

Within the College of Education, OET staff and College faculty have piloted a stranding approach to technology integration into course work. Rather than presenting technology in semester-long courses in isolation, we have integrated technology into a number of sections of pre-service teacher education courses. The most significant use of this stranding model is in the Year Long Program (YLP), which is an option for elementary education student teachers during their senior year. In the YLP, students concurrently teach in cooperating classrooms while they complete their methods courses. The course work allows the students to reflect upon their practice while they gain more time in the classroom compared to the regular semester-long teaching practicum. Since technological literacy is viewed as an integral part of what it means to be a teacher, course time is provided for training in the use of technology, with the requirement that students test and incorporate technology into their student teaching experience.

The role of OET in this process has been to (1) provide on-going support to the primary YLP course instructors, (2) provide laptop computers for the YLP students, (3) conduct workshops designed with YLP instructors, and (4) co-teach sessions that deal with teaching techniques, integration, and
critical issues of technology. This co-teaching of course sessions goes beyond what is often expected of a college technology support office. We recognize that most faculty are often learning about technology with their students. With co-teaching, we are helping faculty become better “models” of technology users for their students. Co-teaching helps the OET staff stay current with the more important issues of teaching and learning. In that way, we become a more valuable resource for faculty.

The YLP has served as a pilot for redesign of the entire student teaching program. A central construct of the redesigned program is the use of reflection on practice in learning to teach. Technology should be one of the elements of teaching upon which the student reflect. With the redesign, the notion of strand takes on heightened meaning in that all of the courses are connected along multiple strands which include technology. Our goals of technology integration are based upon ISTE technology competencies. We are currently devising a methods to manage this strand of technology, which already include the use of web-based support environments for evaluation, technical support, and courseware development. We are also pursuing new techniques of synchronous and asynchronous support for co-teaching, which include video conferencing with cooperating schools, digital interactive video of student and faculty teaching, and increased development of more interactive course web pages.

Individualized Consulting

The success of the first year of operation of the Office of Educational Technology was due in part to its in-house workshop efforts aimed at faculty training. Upon reviewing the role the workshops played in faculty development, however, it was clear that the OET workshops were meeting the general needs of the faculty, but the individual needs of many faculty members were not being met. As a result, a model for consulting within the Office of Educational Technology (OET) was designed.

We assessed the technology needs of the faculty both in terms of hardware acquisition and software application training. This was based on feedback given on the workshop evaluation forms and on requests sent to the OET office staff for help in specific areas. The needs of the faculty fell into two categories. Some faculty needed training on specific hardware or software technologies which they believed could be integrated into their curriculum. Others did not have a technology plan and thus wanted help in determining their technological needs and how those needs could be addressed.

At the beginning of this year, the part-time OET graduate students identified their individual areas of specialization and established the office hours which they would devote to consulting. Each graduate assistant was required to devote 80 percent of his or her assistantship to office hours. Most consulting is done by appointment after a brief meeting with the faculty member to determine how much time to set aside for a future meeting.

Faculty have been apprised of the consulting hours in three ways: 1) the consultants’ hours and areas of specialization are listed on the OET Web pages; 2) within workshops, announcements are made regarding consulting hours; and 3) announcements are made via email. The greatest response for consultation with the graduate students has been via word of mouth during the workshops.

Finally, we have been logging the hours that the graduate students spend consulting. The goal of the tracking is to determine which departments are using the consultants’ hours, what topics are being covered, and determining if there are topics which may be better addressed by a workshop that would be geared to departmental or unit needs. This fall, the majority of the consultants’ hours have been spent teaching faculty how to use Windows applications and Web authoring software, discussing hardware and network protocols, and helping faculty learn to use multimedia technologies like digital images and digital video.

Workshops

Hands-on workshops are held regularly in the Instructional Computing Lab on a variety of topics for faculty and staff. Topics have been generated by faculty surveys, informal requests, and at the suggestion of OET and ICL staff. Workshops are taught by graduate students, faculty, and staff. We try to keep workshops small, hands-on, and when possible, we attempt to have one or two helpers circulate around the room for assistance to participants in addition to the main presenter.

This year we have tried to better organize and standardize workshop procedures. One graduate student helps to coordinate workshops, and he has prepared a workshop packet for presenters. This includes an information sheet detailing the materials to be covered in the workshop, a request for copies of handouts, suggestions for presenters, a sign in sheet for the workshop, and an evaluation sheet for participants to complete.

Workshops are announced at the beginning of the semester both electronically (by an email reflector and on the web site) and by print brochures distributed in mailboxes. Participants can sign up for workshops (which are limited in attendance to the number of computers in the ICL classroom, approximately 15) by phone, by email, or by coming to the office and signing up. The secretary handles records of sign-ups and collects copies of handouts, materials, sign in sheets, et al. and archives this information in a file as well as enters it in a data base.

The actual content of a few of the workshops is posted on the OET website electronically. For example, one workshop on creating slide presentation using PowerPoint was conducted using PowerPoint; that presentation was saved as html and posted on the OET web site.
The Instructional Computing Lab is equipped with PowerMacs (most of which have a PC card) and Pentium machines. The room has a new ceiling-mounted projection system which has been very helpful for instruction. We have found that with both Mac and Windows users in the College of Education, it is better to offer training separately on each platform. We have tried, for example, to conduct a workshop in PowerPoint simultaneously on the PC and Mac platform but have found it too confusing for participants.

Many workshops are on short topics, offered for a two hour time period (such as Using Internet Search Engines). More complex topics are often spread out to a series of three consecutive workshops, each a week apart (such as Creating Your Own Website).

A sampling of workshop topics for this year includes the following: Internet Search Tools, Introduction to Windows 95, Creating Slide Presentations Using PowerPoint, Troubleshooting Your Computer, Using the Internet to Access Library Resources, Introduction to HTML Coding, Introduction to Front Page, Introduction to Data Bases Using FileMaker Pro, and others.

Technical Support

Our technical support efforts have been enhanced significantly in the past 18 months. One of the most important changes has been the implementation of a "trouble ticket" system that allows our support staff to better track requests and to work with minimal supervision. Another, more proactive change, is the implementation of a program known as the "Unit Reps" program designed to distribute technical knowledge and skills.

The hub of the so-called "trouble ticket" system is the full-time OET secretary who plays the role of dispatcher. All requests for help come by telephone to her. She uses Meeting Maker to identify who is on duty and when (and can schedule appointments when necessary), FileMaker Pro to record all "trouble ticket" communications (e.g., requests for support) and to search for related information, and Eudora to communicate more urgent messages to involved parties, including pages for emergencies. The troubleshooter on duty carries a pager and a cell phone.

While the secretary is the hub of the system, the FileMaker Pro database is the primary cog. In addition to providing support staff with a dynamic tally of all open tickets (sortable by many criteria), the data base contains information such as how long trouble shooters spent working on a particular ticket, what was done, and other information for reporting purposes. FileMaker's relational features are used extensively to maximize the utility of the system — related tables include hardware inventory, IP addresses, b-jacks, a faculty/staff table, etc.

Trouble shooting staff currently serve faculty and staff in three buildings, approximately 300 computers. The staff includes one full time and one half time network administrator, a team of three part time graduate assistants (who together comprise one f.t.e.) and an additional hourly network support person from campus computing services. They are hoping to add another half time network administrator soon. In its first year of operation, the Office received over 1000 calls for help. The troubleshooters are often overwhelmed. At particular "crunch" times, we have had to supplement this group with additional part time hourly help.

In addition to the trouble ticket operation, a newly established group is meeting to discuss technical problems. The "Unit Reps" group meets twice a month for training and to discuss common computing-related problems. The goal of this program is to raise the level of technical expertise throughout the college by strategically selecting and training a member (representative) of each unit to communicate what they learn with those whom they work on a daily basis. Units include traditional departments (such as Curriculum and Instruction) and other units (such as the Bureau of Educational Research). The Unit Reps tend to be administrative secretaries in each unit, but the meetings are not restricted to this group. Others are welcome to attend. By emphasizing the fact that they are expected to be role models or teachers rather than "troubleshooters," we communicate our desire to have them show others how to
help themselves, rather than become burdened by demands for technical support.

Conclusion

Now in its second year of operation, and in its first year of permanent funding, the Office of Educational Technology has supported faculty and staff by multiple means, including stranding, consulting, workshops, trouble tickets, and regular unit rep. meetings. As the Office evolves and matures, we will continue to refine these approaches and, most likely, try others. The exponential growth of technology and its inherent needs for technical and developmental support makes centralized, equitable support a desirable option for Colleges of Education.

Acknowledgments

The authors wish to acknowledge the support of Apple Computer and Microsoft Corporation. They would like to thank Professors Jim Levin, Michael Waugh and Karl Koenke along with Shwu-Yi Leu, Gary De-Paul, Lulu Kurman, Nancy Brown-Smith and Linda Alexander, all of the University of Illinois.

In 1994, the Dean of the Faculty of Computing and Information Technology (FCIT), at Monash University, approached the Dean of Education for assistance in tackling a perceived problem in the teaching of programming.

Two education faculty academics (Macdonald and Mitchell) were assigned to make a preliminary investigation on the quality of teaching and student learning and understanding in the departments of Computer Science and Software Development. The initial investigation was performed by a project team called “Edproj” which was established towards the end of 1995. Edproj consisted of members from the Department of Computer Science, Software Development and Education.

Monitored observations by Edproj showed that some tutorials degenerated into pseudo mini lectures. The initial observations made by group revealed the following:

1. A wide range of teaching skills, some were excellent but these practices were isolated and rare.
2. A majority of tutors had very primitive teaching skills; with the quality of questioning being particularly low. Some tutors spent the majority of class time talking and writing with few students paying attention. Several tutors spent the tutorial dictating code, another spent much of the tutorial talking with his/her back to the class, and another spending the whole lesson explaining answers.
3. Tutors often were not aware of the main ideas put forward in the lectures, and introduced their own interpretations and idiosyncratic methods.
4. There were very low levels of student talk and participation (sometimes only 2-3% of class time) and during some weeks less than half the students were attending classes.

Many tutors and demonstrators also lacked the skills to build student interest, intellectual engagement and motivation which had a number of negative consequences on student learning, such as:

1. Concepts which were not stated as being for assessment were ignored. Tasks intended by lecturers to be gateways to exploration and reflection were seen by students merely as hurdles to be negotiated.
2. Students wanted to get set tasks done, then they stopped. Students were satisfied once they had the solutions written down in their notes.
3. Many students believed that if they could follow the dictated code they learned the ideas behind it.
4. Students remained passive and tried to learn by listening and note taking rather than by doing.

The 1996 Tutor Training Programme

The Edproj research led to the development of a training programme to prepare postgraduate students for their role as teachers. The programme consisted of a teaching intervention that comprised an initial 3-day programme and ongoing fortnightly training/meeting sessions (Mitchell et al, 1996).

The initial training discussed the nature of good learning and set out a framework of good teaching theory and practice. The Programme discussed Edproj’s insights into barriers to learning programming, exposed postgraduates to a bank of strategies for promoting better learning, and introduced a set of fundamental teaching principles that stressed the importance of questioning and linking. The fortnightly meetings provided tutors and demonstrators with the time and skill to discuss student learning needs and made it possible for tutors and demonstrators to share teaching ideas and discuss ways of dealing with student learning difficulties (Carbone et al, 1996).

Goals of the 1997 Tutor Training Programme

Budget cuts in 1997, meant that the Department of Computer Science could no longer afford the expertise of the intervening Education faculty experts, and as a result the Tutor Training Programme was delivered by a staff member of Computer Science and adapted accordingly to reflect the findings in 1996.

In 1996, the Tutor Training Programme began with the following objectives:

1. To share teaching techniques.
2. To improve the teaching skills of tutors.
3. To make tutors aware of the main ideas put forward in the lectures, and avoid different interpretations and idiosyncratic methods.
4. To increase the level of student talk and participation.
5. To promote tertiary level study skills within students.

By the end of the year, the project had built momentum to improve the quality of teaching and student learning. Improvements in the quality of teaching were characterised by the high level of energy, interest and enthusiasm demonstrated by the front-line teaching staff. Observations on the quality of teaching and student learning were made via monitoring classroom activities and interviews with tutors and demonstrators in 1996. Data showed vastly improved teaching practices that linked more closely to the lectures and course aims. As a consequence two new teaching innovations were initiated and developed; the Scavenger Hunt and the First Year Advanced Student's Project Scheme (Carbone 1996). Improvements in student learning were monitored by increased student attendance at tutorials and higher levels of student engagement in these classes (Carbone et al, 1996).

The 1997 Tutor Training Programme

In 1997, the Tutor Training Programme in the Department of Computer Science was delivered by a member from FCIT, without the intervention of Education Faculty experts. The Programme drew on the experience gained from Edproj's research in the previous year, which led into insights of barriers to students learning, a bank of strategies for promoting better learning, and a fundamental list of teaching principles. The initial Programme consisted of six sessions (each of 90 minutes duration) and ran over one and a half days.

Below is a brief description of the material covered in each session.

Session 1

The first session outlined the objectives of Edproj; to improve the quality of teaching and student learning and to understand a technical discipline such as Computer Science. Tutors and demonstrators were introduced to the importance of student learning in the tutorial and laboratory environment. They were exposed to an icebreaker activity and the importance it plays in the initial stages of establishing trust between fellow students and the teacher. Following that, postgraduates worked in small groups to compile a list of statements about their role as a demonstrator and tutor, and the students' role as a learner. The list brought out attitudes that were challenged and collectively discussed.

Session 2

Session 2 covered factors that affect learning; such as lack of student motivation, the nature of student/teacher interaction, transition issues and the nature of programming. The tutors/demonstrators were asked to draw from their own experience and identify barriers to their own learning. Findings from the Edproj investigation were also discussed with the focus on ways to overcome barriers to quality learning. Some of the barriers to learning observed by the Edproj group included:
1. Lack of teaching skills (due to absence of training)
2. The nature of programming (very cumulative)
3. Lack of a clear and coherent view of the entire course
4. Big Ideas are obscured from the high task demands of coding
5. Lecturers view course in terms of abstractions - students saw course as getting programs to compile
6. Low levels of student talk
7. Laboratory situations overloaded students' short-term memory
8. Lack of consensus within experts in the domain

Session 3

Session 3 examined conditions of learning (choice, time and abilities) and the process of learning through selection, translation and storing. Two example role plays were given by experienced tutors highlighting different approaches to teaching; one that encouraged active student participation and one that involved passive listening. Postgraduates were exposed to a small set of fundamental teaching principles which lead to a vigorous discussion on the outcomes of a successful lesson. These included:
1. Good learning involves making links between items of knowledge and with the real world.
2. Students construct their understanding based on the knowledge they bring into learning situations.
3. Active engagement not passive reception, characterises quality learning.
4. Student talk is a vital medium for the above to occur.
5. Student talk requires trust between student and teacher and with fellow students.

The principles selected were ones seen relevant to the most urgent needs of tutors and demonstrators as revealed by Edproj, and feasible to implement in the short time available. These concepts were used for subsequent planning and linked to the context in which the tutors operated. The course stressed the importance of reflection on practice as an essential tool for effective teaching and there was particular emphasis on the important role of student talk in different learning situations.

Session 4

Session 4 included an overview of positive tutor/demonstrator strategies that were generated as part of the training programme in 1996. These are contained in Appendix A. The strategies covered ways to promote better learning and were obtained from a data bank of innovative teaching ideas collated during the previous year. Postgraduates worked in small groups to apply some of the strategies to a range of small programming tasks that involved teaching...
concepts such as Strings, Functions, Arrays, Looping, Structures, Sorting, Searching, Files, Input/Output. The session was concluded by tutors and demonstrators participating in the first year student orientation programme.

Session 5
In session 5, the lecturers were invited to meet with the tutors and demonstrators and present their 'Big Ideas' of the course. The session was aimed at helping postgraduates promote the linking of key ideas. After the lecturers had concluded, tutors/demonstrators were issued with information on how to prepare for their lessons, and attempted to organise their first two lessons for the semester.

Session 6
The final session was devoted to preparing the first two laboratory and tutorial sessions. Demonstrators/Tutors registered themselves on their accounts and systematically worked through the exercises in the first two laboratory sheets, planning their ice-breaker and other activities for their lesson. The remainder of the session was devoted to administrative details including: entering students’ marks into a database called the Marks Entry System (MESS) database, the method for casual staff to claim the teaching hours via the Payment Entry System (PESS) database, and a review of the teaching evaluation forms available at Monash (known as MonQueST).

Evaluation of the 1997 Training Programme and Evidence of Effectiveness

Ranking the sessions
After the initial training, a survey was distributed to the participants to find out what they thought about the initial training. Participants were asked to rank each session and provide comments. Twenty two surveys were completed. Of these, all the participants found the Programme well organised and presented. Ten found the material useful and twelve found it interesting. All participants believed that the Tutor Training Programme addressed their needs and recommended that it be continued in the following year. Typical comments from participants in relation to the sessions, included:
1. The ice-breaker was a useful activity for people that find it difficult to remember names.
2. Session 1 was very useful to develop trust between the tutor and fellow member.
3. Session 1 helped tutors start to get their mind on the job and handle it professionally.
4. Session 1 helped tutors know that students should be aware of their responsibilities.
5. It was beneficial in that some of the important points which don’t come to mind at first (i.e., “making friends”) were reinforced.

6. The discussions in session 2 appeared to be to general, it needed to be adapted to a particular situation.
7. The group work in session 3 that converted code to diagrams and used analogies and role plays was a good way to liven up boring stuff.
8. I found the orientation seminar in session 4 useful because it synchronised the information between the tutors and the students.
9. The preparation check list, in session 5 was a good idea.
10. In session 6, PESS was confusing, an online demonstration would have been better.

The training also had the effect of instilling some positive teaching behaviours amongst the new tutors, which included:
1. I will prepare for my lessons from the viewpoint of the student - catering for students of all types.
2. I will aim to use role plays and analogies in my first two lessons.
3. I will aim to learn my students names.
4. I will refer to the list of teaching strategies, and realistically look at my teaching methods and their effectiveness.

Table 1 gives a summary of how participants ranked each of the session. Sessions were ranked from 1 to 5 (i.e., 1 being the most useful and 5 the least). From this data a final overall ranking of each session was obtained. The data shows that session 5 (the lecturers presenting their Big Ideas of the course) was the most useful session, then followed by the introduction, barriers to learning and teaching strategies. The session considered least useful was the session covering the administration details.

</tbody>
</table>

*Numbers inside the table represent the number of participants giving that rank

Feedback received from the twenty two completed surveys was very positive. Eighteen participants believed that the Programme did address their needs and nineteen participants recommended that the training be continued in the following year. More general comments about the initial training and the ongoing fortnightly meeting included:
"When I began my Honours year in Computer Science (in 1997) I decided to become a demonstrator. I found the initial training course for demonstrators to be a very informative and energetic introduction to the life of a demonstrator."

"The fortnightly meetings between demonstrators and lecturers were used to gauge how students are progressing and coping with the course, and whether of not any changes need to be made. If changes were needed they were made during the course and not after the course had completed. We could compensate for the problems now rather than taking the approach, 'We'll get it right next semester.'"

Impact of the Training Programme on students' marks

To determine the educational impact of the Training Programme on the students' academic performance, the correlation of students' test, practical mark and exam marks during 1996 and 1997 was examined. Average marks of students were monitored for the mid-year exam, and at the mid-semester test, to determine if the average students' marks increased or decreased. Table 2 contains the average mark and standard deviation of the students in 1996 and 1997 respectively.

<table>
<thead>
<tr>
<th>Student Year</th>
<th>Practical mark (standard deviation)</th>
<th>Mid year exam</th>
<th>Test 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>1996</td>
<td>76.00 (4.2)</td>
<td>56.10 (15.8)</td>
<td>57.75 (6.4)</td>
</tr>
<tr>
<td>(328 students)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1997</td>
<td>78.00 (7.8)</td>
<td>58.00 (32.5)</td>
<td>60.4 (7.5)</td>
</tr>
<tr>
<td>(375 students)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The average marks for the 1997 practical component, the mid-year test and exam, was slightly higher than their respective 1996 scores. Although the three assessment instruments are comparable and at the same level in each year, it is not possible from the above results to draw any firm conclusion regarding the contribution of the Tutor Training Programme on the students' academic performance, it is reasonable to conclude that the training did not appear to be detrimental.

Conclusion and Future directions

The overall reaction to the Training Programme by its participants was highly favourable. Both the tutors/demonstrators and lecturers showed healthy signs of interest and dedication. Participants enjoyed the training and the Programme is working towards fulfilling its objectives of:

1. Sharing teaching techniques,
2. Improving the teaching skills of tutors,
3. Making tutors aware of the main ideas put forward in the lectures, and avoid different interpretations and idiosyncratic methods,
4. Increasing the level of student talk and participation,
5. Promoting tertiary level study skills within students.

Analysis of students' academic performance, in particular performance of the tests and mid-year exam results tends to indicate that the Programme does not appear to be detrimental. However, there is scope for some fine tuning if it is to operate again in 1998.

Currently, funding for the Training Programme comes from the Department. Only with continued funding can such programmes be introduced, improved and sustained. However, under the current economic climate it is unclear whether any funding can be devoted to address the needs of postgraduates and Honours students who are newly appointed tutors and demonstrators.

Credits and Acknowledgments

The authors wish to thank the late Emeritus Professor Cliff Bellamy, Dean of the Faculty of Computing and Information Technology, for his initial concern into the quality of teaching and student learning in the programming field. The authors also wish to thank Associate Professor Trevor Dix, for realising the value of this type of training and wishing it to continue into 1997 after faculty funding had ceased, and to Bernie Meyer, a postgraduate student employed as a tutor, for his dedicated efforts in providing a role play in session 3.

Ian Mitchell is a Lecturer for the Faculty of Education at Monash University, Clayton, Victoria, Australia. Phone: (03) 9905 2770, Fax: (03) 9905 2779, E-mail: ian.mitchell@education.monash.edu.au.
Appendix A  Positive tutor/demonstrator strategies generated (semester 1, 1996)

1. Find ways to liven up boring topics
2. Admit to past mistakes
3. Know students by name
4. Ask questions for discussion
5. Pick up and follow student responses
6. Spread questions around
7. Plan some approaches before hand. Prepare several solutions
8. Closure on student questions
9. No answer without some student response first
10. Relevant anecdotes
11. Reward good thinking
12. Use small words and simple concepts
13. Provide information about the course
14. Find out what student does and does not understand
15. Help set mastery goals
16. Pass understanding, not just quantity
17. Localise problem area
18. Have students step through and explain
19. Rephrase questions
20. Praise students for what they have done
21. Question students regarding content of the lecturers, tutorials and labs to encourage linking
22. Admit to mistakes, work through them and praise student
23. Establish an environment where students feel free to dispute tutor/demonstrator or other students
Traditionally in the intersection of technology and education, two distinct cultures have existed side by side. There have been the “techies”—the technologically sophisticated or enthusiastic experts on one hand, and the teachers—elementary through higher education—on the other. The two groups have tended not to see each other as resources and collaborators but rather as opponents, competing for the same available resources. The techies are inclined to favor as much technology as possible, as soon as possible, for all possible uses. The teachers, although committed in general to the importance of students learning technology, are inclined to feel that within their own realm of operation they are doing just fine, thank you, and really don’t need another expensive, time-consuming task added to their already heavy loads. The two groups have also quite negative perceptions of each other. While the “techies” perceive the teachers as “resistant to change”, the teachers see the techies as nerds who do not really understand teaching and learning. The two groups attend different conferences, read different journals, and participate in different professional communities.

Neither one of these two cultures is sufficient for successful technology integration, which requires both deep understanding of and caring about teaching and learning AND sophisticated knowledge of and skills in modern technologies. What we need is a third culture. Members of this new culture are marginal members of the other two cultures. In other words, they are techies who deeply appreciate the culture of the teachers or teachers who are thoughtful and enthusiastic technology users. Traditionally, this third group has developed as a result of accidental events occurring to individual members. Many technology-using teachers, for example, take on technology because of an unplanned event. Likewise, many technology people who become really interested in teaching and learning do so because a circumstance of their lives necessitates interaction with teachers and students. This paper describes a deliberate effort to bring the two traditionally separated cultures together to engineer a new culture.

To support technology integration at a large teacher preparation institution, a group of nine graduate students were recruited to serve as “Techguides.” One of the primary responsibilities of each techguide is to partner with teacher educators to help them integrate technology in their courses for preservice teachers. These Techguides are pioneers in what we call the “third group.” We have deliberately recruited students with diverse backgrounds in technology and teaching and have tried to create a physical environment which is conducive to interactions between “techies” and “teachers”. In short, we are trying to foster a culture that enables the two groups to interact with each other, challenge each other, and learn from each other in an explicit fashion.

This paper reports on the preliminary result of such an effort by looking at the developmental trajectory of four Techguides over a course of three months, by attending to the ways in which the physical space in which this project is housed provides a middle ground for the two disparate groups to interact in and impact the development of a new culture for teaching and learning with technology. Two of the Techguides are the stereotypical “techies.” Both are male in their 40’s with a strong technological background. Both are doctoral students in the Educational Technology program. One of them had been a computer consultant and owner of a computer store. The other works as an engineer at a local broadcast service. The other two Techguides are female with a teaching background in literacy and language arts. They are both doctoral students in the Teacher Education program. They had little knowledge of technology. Two of the themes that surface in the following informal stories are role of the room in the development of the Techguide culture and the impact of this culture’s interaction with the broader Teacher Education culture of the College.
Stories of the Techguides

Andrew Topper, Ph.D. student, Educational Psychology

I had started my fourth year in the Ph.D. program when I was asked by Dr. Zhao to coordinate and lead the Techguides. I worked closely with Dr. Zhao as he developed the ideas that became what I call “the shop”, part of a new approach to supporting technology adoption in the MSU college of education. My own background is in computer science, with over thirteen years of experience as a software engineer, so I bring substantial technology experience to my work as a techguide.

I was one of the first people to occupy the room, working with a few other Techguides as we moved the desks and chairs into place and installed all the computer equipment. I feel a sense of belonging there and feel strongly that the room is a powerful and productive environment for learning about all aspects of educational technology. While I bring a wealth of technical expertise to this learning community, I am deeply interested in learning how technology shapes and is shaped by the practices of ordinary teachers. I enjoy working with TE instructors, as well as with students in the college, who bring teaching experiences I don’t have to my attention and help me understand the complexities of classroom life and the challenges of using technology in pedagogically appropriate ways.

I think the thing that strikes me most about the ethos of the room is the way it supports a spectrum of social and intellectual activities. At various times during a single day, you might observe or participate in conversations about how to install specific software or hardware, work collaboratively to locate specific educational resources on the Web, discuss papers and presentations for conferences or journals, have philosophical or epistemological conversations about teaching, learning, and knowing, and engage in humorous story telling about personal experiences with technology. I believe the power of the room is in its’ ability to support all these, and various other, forms of stimulating intellectual conversations that provide students and faculty alike with numerous opportunities to engage in meaning making around, with, and through technology. At its core, the shop is a social context for thinking, talking, working, and experimenting with various forms of educational technology that is supportive but challenging, critical but friendly, and at all times helpful to those who assemble there. One measure of how successful the room has been in cultivating an environment for educational technology research are number of people who inhabit it at all hours of the day or night.

The learning community that meets regularly in formal and informal ways in The Shop includes Techguides, TE instructors, classroom teachers, faculty members, undergraduate and graduate students. The learning that occurs in The Shop is at times intentional, and at other times inciden-tal. We hold classes and workshops; we have social gatherings; we work collaboratively with teachers. Perhaps most importantly, we engage in a variety of ongoing scholarly activities that focus on the intersection of technology and teaching in The Shop.

I am thankful for the opportunities I have had to learn, laugh, talk, share, and know in The Shop and I hope to continue being an active member of The Shop as a techguide in the future. I am also interested in knowing more about why The Shop has been so successful as a learning community and what we might do to support similar efforts in other settings.

Andy’s story highlights ways in which the environment of Room 130 is a supportive and challenging environment for a “techie.” It also illustrates the way the room provides Andy with interactions with teachers and teacher educators which most likely would not be available to him without a place like this. But although the vigorous and varied ways that the room is used provides evidence that it supports a vital culture, it is not clear the extent to which that culture is indeed a newly developing culture combining the two groups introduced earlier—the techies and the teachers.

Rick Banghart, Ph.D. student, Educational Psychology

I call it “the room.” (In an early meeting we decided that it was “The Shop” but the name hasn’t stuck for me.) The room is the focus of activity for the Techguides. Although I’m not an official techguide (i.e., I don’t hold a paid position), I feel like I’m part of the room. Becoming part of this group of people was my explicit goal at the beginning of the semester, and I feel that I have met my goal. I had been pursuing my Ph.D. in Educational Psychology for three years while working full time as an engineer at the University’s public television station. For the first three years I enjoyed my classes and my colleagues, but I found that I was unable to find a place for myself as a scholar. Dropping in for classes and returning to work and home resulted in my lacking any sense of connection with the broader college community. The room has provided me a place in which to become a member of a community of scholars.

I think of the room as an ideal facility for a number of reasons. It is a six-minute walk from my office at the television facility, through a beautiful campus. The room has a high ceiling and windows on the east and west walls that extend from the ceiling to near the floor with views of trees and sky. The result is a large, airy space filled with natural light. The furniture consists of about a dozen desks with open shelving units on them. The technology in the room is very current. We are connected to a dual Pentium Pro NT Server with SQL Server and Internet Information Server. The workstations consist of a half-dozen Macintosh 7300s and five Pentium machines running Win 95. The college has made a commitment to providing software as needed. From
my perspective, these factors combine with the people with whom I am privileged to work to create a work environment that is ideal.

I see that Andy mentioned the ethos of the room. The word “ethos” had not entered our discussion of the environment until we started work on this paper, but its introduction to the discourse is appropriate. Unlike the typical graduate student cubicles, we work in a very open space. We intentionally make the room inviting to passersby. We regularly seek help from one another in all matters from the phrasing of a sentence, to the proper HTML tag syntax. The ethos that has evolved encourages us to be open with our knowledge and with our lack of knowledge.

My involvement in the room as a techguide has affected me in a number of ways. I might say that I’ve experienced an epistemological epiphany. I entered my Ph.D. program after being out of the academic field for nearly 20 years. When I was last learning about education, Piaget was just being integrated into the curriculum. Over the last three years I’ve been introduced to a wide range of ideas: post-modernist, socio-cultural, cultural-historical, Vygotsky, constructivism, constructionism, and evolutionary epistemology. Reading about such things brought about an intellectual understanding of these ideas, but the room is a place where all of these ideas can be experienced. Through the combination of learning the very technical processes of creating interactive Web-based learning environments, and helping others learn such technical skills, I’ve come to have a much deeper understanding of how knowledge is acquired and what knowledge is.

Early in the semester I embarked on a Web development project. My goal was to create a Web-based application that would allow students to store and graphically display data in support of a high-school physics class. Although I had some programming background, this project required the use of a number of technologies I had no experience with. As I began, I sought information and assistance from my colleagues, as well as from technical experts employed by the College. I quickly learned that the information I got in answer to my questions was very often wrong. At the same time, others regularly consulted me for technical assistance. I became acutely aware that I needed to be as skeptical about the “knowledge” I was giving others as I was about the knowledge I received from others. In a field where what was true yesterday is not true today, knowledge claims have to be qualified.

It is clear from Rick’s story that the kinds of learning about technology afforded by the culture of this room are at least potentially transformative. In addition to the learning which Andy mentions as coming from interactions with teachers and teacher educators who bring a completely new set of perspectives, understandings and skills, the kinds of interactions among the residents of the room in themselves contribute to reflections about teaching and learning with technology.

This space seems to have great creative potential but it also erects barriers. Rick’s statement that the Techguides have made a deliberate attempt to make the room welcoming to passers by indicates that the room is clearly techguide territory. Although the Techguides have attempted to make it a public space there are clear constraints to this. Although it may be a space that is comfortable under certain circumstances to non-techies, and although it may be used by a wide range of people for a wide range of purposes connecting technology to education, in fact it is not a public space. The room is locked for security purposes whenever a techguide is not present and individuals working in the room must be consciously identified as either insiders or outsiders in order to maintain the security of the room.

Kaijun Hou: Ph.D. student, Teacher Education

As a student of teacher education majoring in language teaching, I started my role as a techguide without much computer technology knowledge, but with strong interests and longing to learn about technology applications in language teaching and learning. I saw the promise of technology as making teaching and learning more creative, effective, efficient. But it was a big challenge for me.

Challenge #1: Entering the room: I entered the room as an outsider. I mean that the room was already occupied by some tech experts. I was hesitant to use some of the computers that they owned. Whenever I needed to use some computer, I would ask for permission. But, the answers I got made me feel welcome; I could use any computer if it was available. This made me feel that I was part of them. But being part of the Techguides was not only that I could use the computers in the room, there was something else.

Challenge #2: Entering the conversation: Just being in the room didn’t make me part of the Techguides, even though I thought I was. I felt that they were standing on the mountain talking to me and that I couldn’t hear clearly what they were saying. I had to make the effort in order to hear and understand what they were talking. Therefore, I stayed in the room more often and tried to join their conversations. I figured out that I came from a different discourse group. In order to be familiar with the discourse in the room, I needed to become familiar with the language and the knowledge base that they all used in the conversation. The conversations that I had with other experienced Techguides provided opportunities to construct knowledge together. Our talk ranged from basic software use to higher level discussions about technology and pedagogy, virtual communities, learning communities, technology and schools, and what teachers need with educational technologies. Like Andy, I am deeply interested in learning how technology shapes and is shaped by the practices of ordinary teachers.

It seems there were three stages to the process of becoming an insider:

1. Beginning techguide (a language teacher): During this period as a techguide, my conversations with other experienced Techguides was very basic, such as “How
can I find ...?" "How can I open...?" "What is ...?" At this moment, technology to me was still thought of as a tool. If I knew how to use the tool, that would be enough for me.

2. Intermediate techguide (a language teacher): During this period as a techguide, I grew a lot. I could join the conversation and begin to ask some more in depth questions, such as "How could I make it work this way?" "What could I do that I can make it better?" "Is there any other way to represent this idea?" "What are the possible ways that I could do to reach what I want?" Now, I could make connections with what I knew and what I would like to have happened in my work as a techguide.

3. Experienced techguide (a language teacher): Now, I could discuss with other Techguides how we could combine technology with teaching and learning. I worked with some TE instructors and interns. I could offer ideas on how and what technology could do in teaching and learning. These ongoing conversations stimulated my thinking about technology applications in education, broadening my knowledge base of educational technology.

The room and the conversation: Being in this room and being part of the conversation is challenging, exciting and stimulating. There is always something new evolving in this environment. Incidental and mediated learning always happens in here. I enjoy this community and the dialogue with all the people. It’s really a learning environment. It’s challenging in a sense that the new knowledge occurs any time and knowing the new knowledge is exciting and stimulating. This social matrix weaves diverse cultural backgrounds and knowledge together. This reminds me of Burbules’ "Dialogue in Teaching." He believes that: "Dialogue is an activity directed toward discovery and new understanding, which stands to improve the knowledge, insight, or sensitivity of its participants. The pursuit of mutual understanding or agreement on some matter of common concern, therefore, does not necessarily threaten, and is not threatened by, difference. The key criterion to be applied here is whether understanding or agreement is achieved in ways that allow participants a full range of opportunities to question, challenge or demur from each other's view" (p.8).

Kaijun has experienced many of the same kinds of learning experiences from her participation in this environment as described by Andy and Rick, but in addition she suggests that there is a substantial insider-outsider issue even among the permanent inhabitants of the room, primarily based on technological expertise. This is an important issue, since previous descriptions of the techguides as "we" suggest a homogeneous solidarity which Kaijun's story breaks down. If insider/outside groups exist even among the Techguides themselves it is interesting to wonder how this might facilitate or impede the new culture which the program is designed to engineer. Examining how those insider/outsider distinctions are broken down may provide insights into ways to help break down barriers that make teachers and teacher educators perceive themselves to be outsiders to a technology culture. Three important features emerge in Kaijun's journey from outsider to insider. First is her determination. She set herself a challenge to overcome the barriers to full participation in this culture. Second is Kaijun's identification of those barriers as her lack of technology skills and her lack of a common language for discourse with this group. So she set herself the task of learning the skills and the language. The third feature is the time and the authentic tasks that made it possible for her to function as a member of the culture. She had the time available to her to immerse herself in this culture, and she had work to do in common with the other members of the culture. It is difficult to imagine how she might have made the transition with any one of those pieces missing.

Sheri Rop, Ph.D. student, Teacher Education

I became a techguide this fall with very little technology experience. I was interested in the ways that technology could be thoughtfully used in classroom teaching, but e-mail and word processing were the extent of my experience. Like Kaijun, I experienced severe cultural discongruity, primarily focused on the room itself and the language of technology. I find this discussion interesting because I feel that issues of the constraints and affordances of physical space and materials are an important part of helping people become comfortable, competent, and thoughtful users of technology. I was happy to know that officially I "belonged" to Room 130 but I was definitely an outsider. As we began to set up the room, I noticed that the six spots by the windows were immediately occupied by the "experts." It took quite a while for the rest of the room to "gel"—it wasn't immediately clear who all the grad students were who were assigned to the room and all the furniture didn't arrive immediately—so a number of us were sort of "floating." Like Kaijun, in spite of all the words to the contrary I did not feel comfortable using someone else's computer and I did not have one to call my own. I also noticed that no one else really worried about us; those who had claimed a space set to work and we were left to fend for ourselves. I think this was a very valuable, although uncomfortable, time. It forced me to decide how to establish myself among this group.

As I began my work as a techguide, like Kaijun, was continually challenged. I had entered a foreign country. When I needed help—which was pretty consistently at first—I felt that the other Techguides were speaking a foreign language. Learning the basic computer skills that I needed in those first weeks was the most intellectually jarring experience I have had. I had to learn from scratch a new language and a new way of thinking. I thought I had known from the time I was two years old what the preposi-
tion “in” meant. But when Andy said to me “You have to open the document in Netscape”, all of my previous understandings of that word were defeated; I had no way to process what this might mean. I had to find my way through uncharted territory. The computer not only spoke a foreign language but was also a tyrant; either I did things its way with perfect precision or we had no interaction at all. Hand signals and rough approximations of words, standby tools of communication in foreign countries, were powerless.

This whole experience has given me valuable insight into the way teachers must be feeling faced with the pressure to incorporate technology into long-established patterns of classroom interactions. If I got stuck, I knew someone in Room 130 would be able and willing to help me out. I knew the resources available in the room in terms of people and equipment. How much more difficult for those who did not have, or were not familiar with these resources. However, I also felt guilty that I was taking up a lot of people’s time. I countered this in my mind with the reminder that Dr. Zhao had stressed that we were all here to help each other—(although from my perspective there were only a few who really needed much help and no one who needed as much as I). I also reminded myself that I was probably a good test case for these technology experts—if they could be patient enough to work with me, they would be well prepared to work with the TE instructors who would be coming to us.

During this semester, I have gained a great deal of knowledge and confidence, but I have not become part of the culture of the room to the extent that Kaijun has. A big part of the reason, I believe, is the limited amount of time I am able to spend in the room. Since I live an hour and a half from the university I am only able to be on campus two days a week. Time to just “hang around” working on projects in the room seems vital to real membership in the culture.

The stages I have experienced haven’t occurred for me in quite the same way as they did for Kaijun. I feel that I have passed the beginning stage. I have some pretty good basic skills and I have successfully learned the language, at least to a workable degree. These accomplishments make it possible for me to participate in what Kaijun identifies as stage three—participation in discourse about the ways that technology and teaching intersect. However, I have not reached the stage of facility with technology that she describes in stage two, nor have I reached a point where I am comfortable helping a teacher use technology in his or her classroom, although comfort no longer seems to me to be a necessary qualification to initiate such a relationship.

These stories provide valuable commentary on issues of culture around technology. Barriers are revealed to be more permeable than might appear. While Techguides might seem to all be “techies” to outsiders, in fact they possess widely varying degrees of expertise and comfort with the culture of technology. Sheri’s story reinforces the inferences drawn from Kaijun’s story that participation in a culture of technology in education involves four factors: 1) determination, 2) skill with technology and the language of technology, 3) authentic tasks to work on, and 4) time to get comfortable with the technology and those who use it. It is clear that the room can support this process for the Techguides, and that it can provide a place for Techguides to interact with teachers and teacher educator in effective ways. However, Kaijun’s and Sheri’s stories raise the possibility that the extent to which the room helps to create and support a culture of technologically proficient individuals, it may inhibit the creation of a marginal group in which teachers and teacher educators can participate as equals; it is possible that the two purposes of the room work at cross-purposes with each other.

Summary

As the stories suggest, the four Techguides, with quite different backgrounds in technology and teaching, were able to (sometimes forced to) interact with each other to construct a shared culture of teaching and learning with technology. While we have not achieved the goal of developing a third group yet, representatives of the two traditionally separate groups—techies and teachers—have been drawn closer through this interaction in about three months. It is our expectation that this interaction will continue and the Techguides will continue to develop this new culture.

Collaboration is among the most discussed topics in education today. Teachers are being encouraged to collaborate with each other to improve instruction for their students. Most notably, collaborative efforts between both students and teachers work well with technology integration into the curriculum. In addition to the use of technology to enhance students’ learning, technology can also be used to support teachers in the classroom.

Each Spring, Mary Washington College, located in Fredericksburg, Virginia, hosts a faculty workshop. The workshop is a part of Mary Washington College’s Faculty Academy that provides a forum for faculty to share innovative teaching practices involving instructional technologies. In April 1997, we became involved in a Faculty Academy project called Collaborative Technology Integration (CTI). The project consisted of workshops that involved collaboration efforts between faculty members from Mary Washington College (MWC) and graduate students in instructional technology from West Virginia University (WVU), in Morgantown, West Virginia. The workshops were hosted by MWC and served to assist the faculty at the college in determining effective uses of technology in the curriculum.

The CTI project paired up individuals from the two schools to work together on the integration of technology into curriculum. Under the leadership of Dr. W. Michael Reed of WVU and Dr. David Ayersman of MWC, 10 MWC faculty and 10 WVU graduate students worked in pairs to facilitate technology integration efforts and to demonstrate the results of integration at the conclusion of the academy. To close the session, each pair presented the products they had produced and discussed the various points related to technology integration, the collaborative process, and the role that distance played.

The Collaborative Process

Most collaborative work consists of a group of individuals working on different aspects of the project. Usually, the group of individuals involved in the project are experts in one or more fields that deal with the content of the project. All of the individuals involved in the project are working together to arrive at the common goal of completing the task (Armstrong 1996).

MWC and WVU participants used a collaborative approach to integrate technology into the curriculum. In the CTI project, the collaborative group consisted of one MWC faculty member, who served as the content area specialist, and one WVU graduate student, who served as the instructional technology specialist. The two project leaders worked together to try to pair up individuals with similar interests whenever possible. Once the partners were determined, they were given the tasks of making the initial contacts and identifying curriculum needs. After the needs assessment, it was up to each instructional technology specialist to begin looking for various solutions to solve the problems. The partners worked together examining pre-integration syllabi and targeting areas for possible integration.

Because the participants were separated by quite a distance (260 miles, about 4 hours driving time), a face-to-face collaboration was not possible. To overcome the distance barrier, the partners of the project relied on e-mail, file transfer protocol (ftp), faxes, and the telephone to share ideas, works in progress, and ideas for future work. There was only one face-to-face meeting during the course of the project. This meeting took place the day before final project presentations. In this meeting, the participants finalized plans for the presentations and ensured that the projects fulfilled the original vision. The final project resulted in a presentation to show the work completed by each group to each of the teams involved in each of the other groups.

Technology Integration in the Classroom

Several authors have described the integration of technology in the classroom. Bergeron and Bailin (1996) state that “in many instances, there is a need to educate authors and editors as to the possibilities of hypermedia...and the features of available authoring and editing tools” (p. 19). The instructional technology specialists, because of their experience and research in the area of hypermedia and technology in the classroom, served in this educational role. Armstrong (1996) lists three levels that
The first level is the basic level. At this level, faculty use technology to help present their ideas to the classes. They often use presentation packages as another way of organizing and presenting the information to their classes.

In level two, the intermediate level, faculty expand on these basic packages and change them into something that is more interactive. Faculty work with instructional designers in the areas of storyboarding and multimedia incorporation to involve their students more in the use of hypermedia.

At level three, the advanced level, faculty refine their skills. They are now considered the experts, and will continue to incorporate hypermedia technology in their classes. Now, they are at the level where they can help the faculty members at level one.

This process is a very rigid, defined one. It assumes an abundance of on-site technical expertise, which is not always the case. In this particular project, there were more faculty members that wanted to learn about technology integration than there were experts in this area. For this reason, the program was set up for the benefit of both groups. The faculty benefited by being able to work one-on-one with an instructional technologist to implement computer technology into the classroom, while the graduate students benefited from the experience of working collaboratively. The distance was expected to be a complicating factor as well.

Computer Use in Education

Computers, when used effectively, can significantly enhance students' educational experience in many ways. Kern (1995) found that college French students who used a computer-mediated-communication program interacted in French more often and were more likely to make longer, more complicated expressions in French. Liu and Reed (1995) found that a hypermedia program incorporating sound, video, pictures, and other explanations was effective in helping college English as a second language students learn vocabulary. Moore (1988) found that computer-assisted instruction was effective in improving low-level math students' performance. In an overview of hypermedia and education studies across content areas, Burton, Moore, and Holmes (1995) concluded that hypermedia is at least as effective as conventional teaching methods, and sometimes more effective. It is more efficient than conventional methods in terms of time.

However, not all research has been as promising. In a review of the literature dealing with the effectiveness of computers in the social studies, Berson (1996) concludes that there is simply not enough research in this area, and encourages more. He advises teachers to wait until there is more research with positive results before investing a large amount of money and effort into CAI (Berson, 1996). In explaining the mixed reviews, Wang and Sleeman determine that "until the computer is viewed as an integral part of the educational process, rather than a separate instructional tool mainly for teaching computer literacy and programming, the learner will not have the full benefit of this instructional delivery system." (Wang & Sleeman, 1991, p. 343).

Prior Computer Use

The faculty members involved in the project had a variety of prior experiences with computers, ranging from programming skills to almost no involvement with computers. We assumed that the faculty members with more experience with computers would be more likely to integrate technology into their teaching, and that those with fewer experiences would be hesitant to integrate technology.

The Process and the Finished Projects

After the initial pairing, the instructional technologist made initial contact via e-mail with their faculty partners, who then provided syllabi from classes in which they wished to integrate technology. During the next six weeks, the participants communicated via e-mail, fax, telephone, and postal services to discuss the areas of the syllabus in which computer integration would be beneficial and to exchange materials used in the final product. Some of the faculty had already integrated computers into their curriculum, usually at Armstrong's level one (1996). These content specialists were seeking information from the instructional technologists to suggest further areas for integration. The instructional technologists created a variety of final products in order to meet the needs of the faculty members.

Roblyer (1997) states that for teachers to perform effectively as multimedia authors, they need to acquire knowledge and skill in instructional design as well as other things related to development. The instructional technologists brought their skill and experience in this area. The integration of technology in the curriculum will enhance the learning experience. Berson (1996) indicates that part of the problem with CAI is that it can be disruptive to the usual classroom proceedings. In order to avoid these problems and to integrate technology effectively, there must be a tight focus between technology and traditional methods.

The faculty academy provided this focus. Focusing on the issues of pedagogical innovation and education techniques, the academy expanded on the facilitation of learning and teaching experiences through applications of technology to school curricula and instruction.

Case Studies

The case studies that follow demonstrate two extreme examples that comprise the entire CTI project. In one case, the instructional technologist and the content area specialist had little contact over the time period, while the other project involved a team that was in almost daily contact with each other. When we looked at these two extremes along with the examination of the computer background experience instrument, it revealed that the content specialist who had
the most prior experience had the least amount of contact with his development partner. Conversely, the content area specialist who had little computer experience had high expectations for the possibility of using computers in his class.

**Highly Interactive Collaboration: A Case Study**

I initiated my first e-mail contact with John, an art professor, on March 17, 1997. I received a reply from a staff member, Shirley, explaining that John had just had surgery and that she would be working with me until he recuperated. Shirley faxed a message explaining John’s prior experience with computers. In the message, John stated, “I have ideas of what might be done in my computer applicable studio art courses but not always enough knowledge and background to know how to do what I want.” I quickly saw that John knew what he wanted to do, but he did not know exactly how to do it. I was encouraged that he had several ideas for this project. Along with this fax were syllabi for two courses into which he wished to integrate computer technology. I told him that he should pick the one in which he thought the students would benefit the most. John decided to emphasize the Color Theory course.

Later that day, I received another e-mail from Shirley which said, “I will be working with John and you on this project. I hope I can help you both!” Shirley was expressing her commitment to the project, along with John’s, which reassured me. They wanted an interactive form of technology, and we clarified compatibility issues. The next day Shirley sent the problem statements for the class to me via Fed-Ex. Reviewing the materials helped me to get an idea of how the course was handled off line as well as giving me an orientation to the class material.

On April 23, John e-mailed that he has been “quite overwhelmed with sundry obligations over the past few weeks, and I don’t see the end in sight....I’d like to make up for lost time.” This exchange shows the level of commitment John had to the project, which is necessary for it to be completed. Shirley’s commitment and interest were equal. On May 4 she expressed a great interest in interactive multimedia. Although our interests were not exactly the same, they complimented each other. The next step was to organize the material I had gathered. I integrated some of our ideas and sent the file electronically to both of them. Fortunately, they were “very impressed” with the first draft of the project.

On May 20, 1997 our first face-to-face meeting took place. During this meeting, we worked on several aspects of the project. We were able to work together to fine tune what I had previously sent to them and to incorporate a few more ideas. Together we reflected on the process in the final presentation and agreed that the collaborative experience was beneficial for all of us. John and Shirley had the content knowledge, and I had the technical expertise. They knew how to express their ideas visually, and I knew how to express ideas verbally.

**Low Interactive Collaboration: A Case Study**

I was invited to take part in the Faculty Academy at MWC. In the project, my advisor worked with a faculty member from MWC and arranged for teams to be created to integrate technology into curriculum. I looked forward to participating in the project because I would serve as a technology specialist.

I was paired with Dr. C, an MWC faculty member. We had little chance to discuss the project before the start of the academy as we had problems getting started. I e-mailed him to introduce myself and to make the initial contact prior to the workshop, but I received no response. After a period of about three weeks, I tried to make a second contact, but received no reply. After discussing the results of my contact attempts with the project coordinator, I was told that it was almost too late to take part in the workshop, so I made one final attempt to contact my partner. This attempt was successful.

I received an e-mail from my faculty partner containing a syllabus from a Sixteenth Century Studies course along with the URL (Uniform Resource Locator) for a technology integration project that he had previously tried to implement. His ideas for technology integration consisted of constructing a Web scrapbook, a place for students to put together ideas about what they had learned in the course (a knowledge construction approach).

After reviewing the syllabus I received, I took a look at the Web site address. Dr. C’s first attempt at technology integration had resulted in an unfinished product. He reported that the project he started “was a one-third-of-the-way-through inspiration last time—by the way, you can see what’s up of it now (not much, I’m afraid—I have all the materials but I haven’t yet assembled them).” The Web site was just a start of what he wanted to do. The students were collecting Web resources that dealt with the sixteenth century and turning them in to him. Then, during his own time, he was taking those gathered resources and attempting to build a Web site to use in his teaching. Time was the issue in assembling them by the start of the Fall semester.

In the next e-mail message from Dr. C, he stated, “Jim, I’m behind on this: I have had the materials for about 4 months now—images, music, etc.—and I haven’t yet put it all up, for a variety of reasons.” He also informed me that he had purchased an HTML editor to assemble the materials. Dr. Carpenter welcomed any ideas from me and stated, “I’d like to work with you on designing a project like this one for my 16th-century studies class coming up this fall. Anything you can advise on regarding content, design, and *especially* how to pace the project through the semester (so I don’t have a big bag of stuff I have to put together myself) would be most welcome.”

It seemed that Michael was looking for ideas about how to incorporate some basic HTML (Hyper Text Markup Language) training into the syllabus so that students could...
do some of the page design and assembly of on-line resources. Then, Dr. Carpenter could focus on fine-tuning the students’ work. He had tried this approach with another class, but it was also incomplete. He stated, “In this case they’ve done a little more of the work than the 17th-century people did (I’m getting a little more experienced at this!),” but the need for basic HTML instruction resurfaced.

We had both used a commercial HTML editing package, but we felt it was a bit complicated for use in the class. The major problem was that he had a lot of materials, but didn’t have time to put them all together. Teaching HTML seemed to be a good way to get student interaction by having them do the developing. I had previously taught beginning classes on HTML using a simple text editor along with a browser to view the results. My beginning sessions included a lesson that covered such topics as tags, heading sizes, images, and anchors. The whole session focused on a three-hour training session that could supplement his standard instruction. Michael stated “This sounds ideal! I’m very pleased. I did want to walk students through the basics of HTML, but I hadn’t wanted to teach them a specific application (at least, not now).”

After receiving his response, I proceeded to develop materials in a presentation package. I felt that Dr. Carpenter could go over the presentation with his class for one three-hour period to teach his students the basics of HTML authoring. I put the presentation in a PDF (portable document format) file for distribution on the Web so that Michael could make the presentation available to students via his Web site. I suggested that he could start the teaching with the three-hour discussion and then follow up by providing the information on-line.

I e-mailed Dr. Carpenter with the attachments and he seemed pleased with what we had accomplished. Our technology integration plan consisted of one three-hour basic HTML authoring session for students who registered for his class. Without investing a lot of time or collaboration techniques, we were both happy with the outcome of our project. It seems that those who know most about technology do not require major technology integration.

Conclusions
In analyzing the communications and the processes of these two case studies, several themes were evident. We observed varying degrees of commitment to the project in both cases. The degree of commitment was related to the clarity of the vision for the project. In the high-interaction collaboration, the content specialist had a clear vision of the project from an early stage. This vision allowed the participants to retain their commitment to the project through the stress of other responsibilities. In the low-interaction project, because of a lack of vision of the project, it was easier to push the commitment to the project aside in favor of other commitments.

Communication was an important issue. In the high-interaction collaboration, the participants used various means of communication available. This interaction featured five faxes, numerous e-mail messages and numerous telephone calls. In the low-interaction collaboration, the participants e-mailed each other three times. The participant with little experience had a concrete idea of a project that would integrate technology, but required assistance in translating his idea into a program.

Due to the use of modern communications technology, distance was a non-issue. E-mail and faxes provided almost instantaneous feedback, and the telephone provided real-time communication. Only one technology that was anticipated to be helpful was not: videoconferencing. The lack of videoconferencing, however, did not have a detrimental effect on the collaborative process.

We discovered that, in spite of the different degrees of communication, each project had met the goal of technology integration into the target course, demonstrating that modern communications technology enables instructors to be able to tap into the knowledge of experts at different locations. This implication holds much promise for the future of technology integration into the classroom.

In an age when change is a norm, lifelong learning a critical mandate for prosperity, and technology a revolutionary force, transforming traditional practice is a central theme for Valley City State University (VCSU). VCSU faculty and staff assumed the responsibility for initiating and promoting change directed by the needs of learners. Faculty members from the teacher education unit not only altered their traditional practice, but stepped forward in significant ways to provide institutional leadership in developing the culture of innovation VCSU adopted several years ago.

Specifically, the VCSU goal is substantive reform of educational practice to improve learning and ensure success of students. In order to achieve the goal, the University (http://www.vcsu.nodak.edu) has implemented a comprehensive and multidimensional agenda for institutional change. A central component, Improving Learning with Technology (ILT), involves a powerful integration of learning and assessment that is facilitated by, and contingent upon, universal access to notebook computers.

Beginning with distribution of IBM notebook computers to all faculty in January of 1996 and to all students at the start of the 1996-97 academic year, VCSU became the first notebook university in North Dakota and one of a small number across the country. A sophisticated campus network connects offices and residence halls. Throughout the campus, classrooms have Internet access at every seat, as well as multimedia stations for student and faculty projects.

Specific features of the ILT innovations involve three aspects of the teacher education program: clear specification of abilities or outcomes; adaptation of a specific software package, Skill Command, for tracking learner progress on professional skills and abilities; and increased student responsibility for documenting performance through creation of an electronic portfolio. As a result of the ILT initiative, VCSU students:

- use the portfolio concept in the learning activities to document their progress (beginning with the first semester)
- demonstrate their progress through performance and use of the portfolio
- complete a portfolio for graduation from the teacher education program.

Teacher education faculty members and their students continue to provide service as leaders for the various initiatives at VCSU. Technology and the New Professional Teacher: Preparing for the 21st Century Classroom, a report from an NCATE Task Force on Technology and Teacher Education, recognized our Division of Education & Psychology. A letter our president received from Arthur Wise, President of NCATE states in part:

The report derives its credibility from the expertise of its members and their selection of exemplary practices to highlight. The task force cited a project at your institution as a case illustration. Your selection makes clear that you are at the cutting edge of teacher preparation practice. Your inclusion in our report should extend your influence and help change the norms of practice.

Through ILT, technology has provided VCSU faculty in the teacher education unit with a tremendous capacity to revolutionize education both on campus and for future students through dissemination of innovations in the public schools. Effective use of instructional technologies in a learner centered environment is providing new ways of learning in which access to information is virtually limitless, communication improved, learning more meaningful and fun, and motivation enhanced. Universal notebook computer access, classrooms with Internet connections, and state of the art multimedia resources combine to form the tool kit which faculty and students use to increase learning productivity, learning accountability, and preparation for professional careers that will extend into the next century.
Just putting the technology into the hands of all the students will not create significant gains in student learning, however. It is the use of technology in support of the clear specification of abilities or outcomes; adaptation of a specific software package for tracking learner progress on professional skills and abilities; and increased student responsibility for documenting performance that creates the powerful integration of learning and assessment. We believe this integration will revolutionize the quality and effectiveness of our students' learning.

The Plan

To realize this revolution, the faculty of Valley City State University have specified eight abilities that form the foundation for student projects which will become part of the Title III electronic portfolio project.

Eight Abilities for VCSU

Academic courses offered on campus will use performance assessment tasks that require students to demonstrate what they can do (ability to perform) and what they know (content knowledge). The abilities will be assessed in all areas of the curriculum, including general education courses as well as courses required in the teacher education program. These eight core abilities are:

1. Communication,
2. Aesthetic Responsiveness,
3. Problem Solving,
4. Effective Citizenship,
5. Global Perspective,
6. Collaboration,
7. Wellness,
8. Technology.

To support assessment of the eight abilities, SCANS ( Secretary's Commission on Achieving Necessary Skills) research has been integrated into the VCSU model. The SCANS research identified 37 skills considered essential for workplace and school success. The VCSU model includes specific SCANS skills within each of the eight abilities. Students will be responsible for demonstrating two different SCANS skills from each of the eight categories. Each student will document achievement of the SCANS skills through the production of an electronic portfolio that will be required for graduation from the teacher education program.

The Communication ability refers to applying skills of writing, reading, speaking, listening, using media, and using quantified data. Four levels of achievement are defined: Level 1: Demonstrates knowledge of vocabulary, principles, and criteria of effective communication. Level 2: Demonstrates ability to read and listen critically, and demonstrates literacy in written, oral, and quantitative communication. Level 3: Demonstrates communication that integrates information from multiple disciplines. Level 4: Analyzes own strengths and weaknesses as a communicator. The SCANS skills for communications are Reading, Writing, Arithmetic, Mathematics, Listening, Speaking, and Visualization.

Aesthetic Responsiveness levels are: Level 1: Articulates a personal response (such as a journal or sketchbook) to artistic work. Level 2: Explains how personal experience, exposure, and formal factors (vocabulary) shape one's own response to artistic work. Level 3: Demonstrates an understanding of the historical, societal and cultural context of artistic work. Level 4: Based on acquired knowledge and experience demonstrates the ability to analyze and evaluate artistic work. SCANS skills identified for Aesthetic Responsiveness are Writing, Mathematics, Listening, Speaking, and Visualization.

Problem Solving and Decision Making levels are: Level 1: Demonstrates understanding of own problem solving process. Level 2: Develops understanding of specific strategies used in different disciplines to identify and solve problems. Level 3: Designs appropriate frameworks and strategies to solve problems. Level 4: Implements and evaluates solutions to problems in new situations. SCANS skills identified for Problem Solving are Creative Thinking, Decision Making, Problem Solving, and Reasoning.

Effective Citizenship levels are: Level 1: Assesses own knowledge and skills necessary for understanding local issues. Level 2: Participates in the decision-making process related to community issues. Level 3: Evaluates organizational structures and collaborates with others to facilitate achievement of mutual goals. Level 4: Applies developing citizenship skills to a community setting. SCANS skills identified for Citizenship are Teaches Others, Exhibits Leadership, Works With Diversity, Understands Systems, and Monitors Systems.

Global Perspective levels are: Level 1: Assesses own knowledge and skills in thinking about global concerns. Level 2: Analyzes global issues from multiple perspectives. Level 3: Demonstrates understanding of connections between local and global issues. Level 4: Applies strategies in forming a response to local and global issues. The SCANS skills for this ability are the same as those for Effective Citizenship.

Collaboration and Wellness levels are: Level 1: Observes and assesses own behavior patterns in working with a task-oriented group. Level 2: Develops an understanding of behavior patterns of others in social situations. Level 3: Demonstrates the ability to communicate and work cooperatively within a group. Level 4: Demonstrates the ability to work toward a common goal as a team member. SCANS skills for Collaboration and Wellness are Responsibility, Sociability, Participates/Team, Self-Worth, and Self-Management.

Technology levels are: Level 1: Knows available technology, follows proper procedures; Level 2: Understands requirements of the task, Manipulates technology for desired results; Level 3: Analyzes task/technology relationships, proposes simple technological solutions; Level 4:
Integrates systems technology, interprets/evaluates results. Technology SCANS skills are Acquires Information, Organizes Information, Selects Technology, and Applies Technology.

**SCANS Skills**

Under the SCANS skills, performance indicators were developed to help clarify what was expected at each level. Students will be responsible for demonstrating two different SCANS skills under each of the five categories. The performance indicators dictate how these skills can be demonstrated. A sample of the performance indicators selected for use at VCSU include:

**Writing.** Students must show their performance through the use of processes (such as brainstorming, outlining, or clustering); writing concisely and clearly; adjusting for different purposes; correcting information (through checking, editing, and revising); and using appropriate form, grammar, spelling and punctuation.

**Mathematics.** Students must show consistent accuracy and the ability to make decisions and predictions using mathematical processes.

**Listening.** Students receive, interpret and respond to verbal and nonverbal cues, clarify, paraphrase, and model attentive behavior.

**Speaking.** Students understand purpose of communication and are able to identify the audience to receive communication, effectively organize ideas, clearly convey messages using verbal languages, use appropriate body language to convey messages, provide vivid and powerful detail, and respond with ease and confidence to audience reactions.

**Creative Thinking.** Students see all parts of the issue, explore a broad range of possibilities, consider possibilities from outside of the normal, consider futuristic possibilities, challenge assumptions, and take best elements from a broad range of possibilities.

**Decision Making.** Students begin with well-defined objective, set criteria for attaining objective, identify possible barriers, identify possible risks, identify probable consequences, consider multiple alternatives, and select and alternative that meets established criteria.

**Problem Solving.** Students identify the problems, examine all probable causes of problems, implement decision-making strategies, monitor progress of proposed solution, adjust alternatives when necessary, and revise plan as indicated by the findings.

**Reasoning.** Students use logic to examine issues, consider the source of information, challenge assumptions that underlie the issues, analyze the relationships, and generate theoretical conclusions based on logic.

In developing a plan for implementing the SCANS skills across campus, it was decided that a software program would be selected to help record and measure the performance of these skills. VCSU worked closely with ADVANCE Education Spectrums to develop a software package that would be user friendly and would have the ability for students to access and monitor their own progress. A software package that is capable of allowing teachers to create a learner tree with individual names or teams and the activities they must perform to demonstrate competency of a given skills was developed.

The learner has access to view the learner tree but only the instructor that created the tree has access to create milestones showing competencies. The instructor can define the number of skills that are assessed, and the date it was assessed. The learner can quickly check to see what milestones were awarded. New skills assessments can be generated if needed.

**An Example**

In Education 315, Math in the Elementary School, students are required to create their own personal Web Page. Each student includes a homepage, pictures and graphics downloaded from the Internet, a personal information page, lesson plans they have created, links discovered on the Internet, links to problem solving, place value, NCTM Standards, and information they have learned in the course. All of this information is organized in their home page with links from their table of contents. This project is designed to meet the technology ability with specific reference to the SCANS skill of organizing information.

In Education 322, Methods and Materials of Language Arts I, students are required to prepare an electronic portfolio using the presentation software PowerPoint. The portfolio includes a table of contents with buttons, scanned pictures, digitized movies of lessons taught, a personal page, and examples of what students have learned in the course.

The ability demonstrated in this project is Problem Solving. The SCANS skills included in this ability are decision making and getting information. Students provide an introduction on how they met this ability and give specific examples of how they met the SCANS skills. They include teaching examples and how they used decision making skills to determine what to include in the portfolio.

**Conclusion**

This plan is still in a very fluid state. We believe that it will always be in a fluid state. We are trying to create a culture that can and will adapt quickly to new demands and opportunities. If we were to report on this plan next year you would see many changes in it. The students have responded to the changes and the direction, for the most part, in a positive vein. An on-campus survey conducted by Dr. Kathryn Holleque reported that the majority of the students were satisfied and felt the increase in tuition was merited.

We believe that through the use of ubiquitous technology, the student will find it appealing and satisfying to take charge of their portfolio and thereby their own learning. We believe that only when the student learns to self assess and...
make personal decisions on how to improve performance
will we have students with the initiative and ability to
succeed in a world where change is a constant and life
seems to be reinvented every few years.

Val_Christensen@mail.vcsu.nodak.edu.
Established in July of 1996, the Center for Instructional Design and Delivery (CIDD) of the University of South Dakota (USD) has as its main focus the training of USD faculty and staff to optimize the application of technological resources in their daily activities. In its third semester of existence and second semester of training activity, the CIDD program has changed to better serve USD faculty needs.

Progressing from an initial situation in which the Center had to borrow facilities from the academic units of the university to deliver its training, CIDD now has a state-of-the-art facility with a broad variety of technological resources in terms of software and hardware. To deliver the training program, CIDD incorporates diverse USD internal human resources, utilizing guest speakers from various academic units. Depending upon the topic of the training, the characteristics of the trainee group, and the skills available from the pool of potential visiting experts, the guest speaker might be, representing disciplines from Arts and Sciences, Business, Education, Fine Arts, Law, and Medicine. This situation has turned out to be win-win; the trainee faculty see by the visiting scholars’ diversity that technology is widely used and widely necessary in education. The visiting scholars also derive a great deal of satisfaction from being able to contribute to the university-wide upgrading of computer skills without having to take a significant amount of time from their schedules.

For direction, curriculum development, and academic integrity, CIDD has added a half-time tenure-track faculty member whose forte is instructional design and delivery. To schedule and hold training sessions for USD faculty, staff, and students, an instructional coordinator has also been hired. At the present time, CIDD personnel number fourteen:
- Two co-directors, representing support services and academia
- Instructional design and delivery specialist (half-time)
- Instructional coordinator
- Graphics designer/multimedia production specialist
- Photographer
- Videography/digital audio/audio production specialist
- Administrative assistant/smart classrooms technician
- Electronics technician
- Senior secretary
- Four graduate assistants

There are two distinct training opportunities offered at CIDD. The first is general training sessions open to the entire campus. The second, and the focus of this paper, is daily training sessions for selected USD faculty. Each semester, the deans of each academic unit at USD indicate two teachers to be trained at CIDD. These trainee faculty have become known as the CIDD faculty and attend, in groups of a maximum of twelve per semester, a training program of ten hours per week. In order to accomplish this, faculty need release time from their normal workload. During the first semester of training sessions, CIDD faculty were released from 50% of their workload by their deans, CIDD funding half of the release time and the sponsoring academic unit assuming the other half. In this, the second semester of training, CIDD is no longer funding release time and, consequently, CIDD faculty receive only 25% relief from their normal work load.

Planning

The ten-hour-a-week training program for CIDD faculty is based on the broad goal of the CIDD training, which is to enable USD faculty and staff to optimize the application of technology in their daily professional activities. Having instructional design as unifying theme, CIDD offered, in the first semester of the 1997/98 academic year, thirteen weeks of training, each focusing on one specific technology with potential instructional application. After one week of classes on the foundations of instructional design, the weekly subjects included, among others, web page development, PowerPoint, PhotoShop, video/audio, distance learning, and multimedia production. On the first day of each new week, the instructional value and potential applications of the coming instructional technology theme were discussed.

The faculty involved were to fulfill six CIDD expectations:
1. design or modify one course during the semester,
2. serve as a liaison between the CIDD and their academic units,
3. attend training sessions offered by the CIDD,
4. present their CIDD projects to their sponsoring entity,
5. provide advice and/or assistance in the design, development, and maintenance of the CIDD home page, and
6. assist the CIDD in the pursuit of grant funding.

In order to help faculty accomplish this goal, laboratory sessions where they could get individual assistance and work on individual projects were offered in addition to the technology-oriented training sessions.

Evaluation
At the beginning of the semester, the CIDD faculty completed an attitudinal survey investigating their attitude towards the use of technology. The survey items were derived from other attitudinal survey instruments and items were added to adapt the instrument to the USD and CIDD goals. A computer program was written to allow the CIDD faculty to do the survey on-line, thus reinforcing the idea that data capture and analysis through technology is more efficient.

376 — Technology and Teacher Education Annual — 1998

382
The results of the survey show that the CIDD faculty overwhelmingly agree that using technology in their professional activities is relevant, necessary, and appealing, both for them and for their students. The only remarkable dissension from this opinion comes in the question about computer use reducing stress; by a large majority, the respondents disagreed.

In order to evaluate the work of the current semester and provide bases for future changes, the CIDD faculty members completed an evaluation form every week before starting a new theme. Seven questions were asked, once again on-line, this time formatted in a word processing template to allow more flexibility for the “essay” answers:
1. How many of the five sessions have you attended?
2. Please list the subject(s) covered.
3. What would you like to have had more of?
4. What would you like to have had less of?
5. The content covered satisfied your needs,
   a. expectations.
6. The instructor
   a. knew the subject;
   b. gave clear explanations;
   c. presented the material in an interesting way;
   d. used appropriate techniques;
   e. was fair;
7. Please make whatever additional comments you think might be helpful.

The most frequent comment/complaint was that there was too much lecture and discussion and not enough hands-on work. The participants wanted to begin producing something in the first class and pick up the theory inductively, or not at all. Perhaps because all of the participants were professional educators and had therefore already assimilated an amount of instructional theory, they objected to talking about instruction instead of creating some. Another frustration manifested by the participants was that they needed both instruction and time to complete their individual projects, and ten hours a week was not enough time to absorb the former and finish the latter.

**Replanning**

Based on analysis of the trainee faculty’s evaluation of the course, evaluation of the participating faculty members’ work, and dialogue with participants in training sessions, an evolution of the model is being implemented. CIDD has established a Technology Enrichment Grant (TEG). Any USD faculty is eligible to apply for a grant that allows the recipient to become a CIDD faculty member for one semester and pays up to $300.00 for supplies. The grant is for the design of a specific new course or the redesigning of an existing course. The target course is defined by name, proposed effect, means of evaluation, and expected date of implementation in the grant application.

The outcome of this modification will be twofold: to make CIDD instruction more hands-on and project-specific and to provide increased opportunities for participation. USD faculty may now enter the CIDD program by 1) obtaining release time from their dean or chair, 2) applying for a TEG, and 3) buying release time through a USD faculty development program grant. An important aspect of the modification is to make becoming CIDD faculty a voluntary decision of the individual faculty member rather than an administrative decision by the dean or chair.

**Summary**

The Center for Instructional Design and Delivery (CIDD) at the University of South Dakota (USD) is the result of a university initiative to direct resources into modernizing course design and delivery through technology. After two semesters of training USD faculty to incorporate technology into their teaching and research activities, CIDD is using feedback from the participants to modify the program to better satisfy both the requirements of the university and the perceived needs of the trainee faculty.

Celina Byers is an Assistant Professor in the Division of Technology for Training and Development (TTD) at the School of Education and the Instructional Technologist at the Center for Instructional Design and Delivery (CIDD), University of South Dakota, Arts and Sciences Building, (North Annex), 414 E. Clark Street, Vermillion, SD 57069. Voice: 605-677-5247, Fax: 605-677-6518. E-mail: cbyers@sundance.usd.edu.

Michael R. Hoadley is a Professor and Co-Director of the Center for Instructional Design and Delivery (CIDD), and Chair of the Division of Technology for Training and Development (TTD), University of South Dakota, 108B School Education, 414 E. Clark Street, Vermillion, SD 57069. Voice: 605-677-5839, Fax: 605-677-5438. E-mail: mhoaday@sundance.usd.edu.

William A. Byers’ diverse background includes being an English professor in Iran, a management consultant in four different countries, the co-founder and Director of Pedagogy at an ESL school in Brazil, and a member of the faculty of the Intensive English Language Institute (IELI) at the University of North Texas. Presently, he is a consultant and software developer working on educational applications. 1532 Crestview Drive, Vermillion, SD 57069. Voice: 605-624-4386, Fax: 605-624-7987. E-mail: wbyers@sundance.usd.edu.
As we move rapidly into the 21st Century, it is becoming increasingly clear that educational technology is not a classroom frill, but is indeed an integral component of effective instruction. We have moved dramatically from the lantern slides of the 1930s, to the overhead transparencies of the 50s, and the Dukane sound/filmstrip projector of the 1960s. Now elementary school children use interactive computer software to probe the digestive system of the frog, and secondary students use the Internet to research interpretations of Hamlet’s key soliloquies.

Despite these advances, some teachers are just beginning to wade, and some rather tentatively, into the mainstream of current educational technology. For these teachers, as well for those who have been surfing the net for years, in-service and graduate instruction remains essential.

Gunns engaging description of the two-year TEEM project provides an example of a positive and innovative telecommunication and multimedia in-service program involving twenty-four teachers from six different school districts in Arizona. She discusses how the TEEM project members developed a CD-ROM which houses a bibliography, lesson plans, and student-centered multimedia presentations. Using The Oregon Trail software package, Smith-Gratto and Fisher demonstrate how school curriculum standards across disciplines (language arts, social studies, and science) can effectively met. Swinsky suggests a variety of on-line resources and activities to guide novice Internet surfers. In Drivers’ Ed for Teachers Navigating the Superhighway, Owens, Magouan, Eaton, and Smith assess the effectiveness of a statewide teacher in-service program using the Internet. Out in the islands, Hochenberger describe an in-service program she uses on the Marshall Islands that may serve as a useful template for other small, and perhaps geographically isolated, schools. Brownell and Brownell present a snapshot of their six semester-hour summer experience integrating technology, problem-solving, and curriculum.

Blakeslee, Ferris, Roberts and Yoder analyze the problems they encountered with Launching an Internet-Based Master’s Degree in Technology and Education. As more institutions and agencies of higher education contemplate alternative delivery formats, such insights may help us from reinventing the wheel. Corry and Lynch provide a thoughtful five-stage plan for marketing distance education. Meadows, Aversman, and Lowery present an overview of a computer technology certification program to address new Virginia State Standards of Learning competencies.

Faculty development is often problematic. Milligan and Robinson’s thoughtful article showcases how critical faculty technology development can be implemented using technology-literate students. They report one major obstacle to success: lack of faculty time and commitment to practice skills being developed. Kajs describes how a university, through its instructional and technical resources, and through the process of collaboration between university faculty and teacher-mentors, can facilitate lifelong learning for both teacher-mentors as well as beginning teachers. Hoping to create teacher technology evangelists, Jones and Shelton provide a guide for staff development based upon the three I words: incentives, inventive, and important.

On a different note, Rice’s provocative article asks us to re-examine how we perceive others’ thoughts when they are a known anonymity; whereas, Casey re-exams early literacy and technology.
INSERVICE TO PRACTICE: A PROFESSIONAL DEVELOPMENT TECHNOLOGY PROJECT

Cathy Gunn
Northern Arizona University

A telecommunications and multimedia inservice project sponsored by the Center for Excellence in Education at Northern Arizona University and by the US West Foundation included the study of an evolving professional development venture that connected university-based preparation with ongoing education of teachers. Twenty-four teachers from six geographically diverse regions of northern Arizona—from rural Reservation to agricultural valley to mountain community—participated in the Telecommunications, Environmental Education, and Multimedia (TEEM) project. The two-year TEEM project was funded July, 1995 through June, 1997; however, the partnership between participants—K-12, university, and community—extends beyond the funding period.

The Project: A Description
A non-reader student at our school with emotional difficulties one morning wandered by my monitor as I was demonstrating some Web pages that dealt with sports....Jose came by and looked at the screen and said, 'What are they doin?' Jose began to notice that students were engaged with a computer that required reading, yet had 'cool' stuff on it. Jose then wanted to know what other stuff could I find out about on the Internet. As soon as the other children left we both sat down and began our journey. I asked Jose what interested him and what hobbies did he have. Jose told me he really liked Lowrider cars. So we punched in the word Lowrider...and found a plethora of information....We then began to download pictures and text for him to take home to read. Jose was astounded at the information that was available that concerned his culture and hobbies...Upon further exploring of the Web pages Jose stated that he could not read what was on a lot of the screen. However, Jose himself noted the importance of reading this day....Jose has just finished the fourth grade and is well on his way in becoming a reader and an expert on Lowriders. [Susan, teacher participant journal]

Project Participants: Teacher Teams
A telecommunications and multimedia inservice project sponsored by the Center for Excellence in Education (CEE) at Northern Arizona University (NAU) and by the US West Foundation included the study of an evolving professional development venture that connected university-based preparation with ongoing education of teachers. Twenty-four teachers from six geographically diverse regions of northern Arizona—from rural Reservation to agricultural valley to mountain community—participated in the Telecommunications, Environmental Education, and Multimedia (TEEM) project. All twenty-four participants were K-12 teachers, with a mix divided almost equally among elementary, middle school and high school in six different school districts in northern Arizona. A TEEM Advisory Board consisted of an NAU biology professor, a middle school principal, a high school teacher, and representatives from Wupatki National Monument, Red Rock State Park, the Museum of Northern Arizona, NAU’s Institute for Native Americans, the United States Geological Survey, The Flagstaff Arboretum, and the Audubon Society. The two-year TEEM project was funded July, 1995 through June, 1997; however, the partnership between participants—K-12, university, and community—extends beyond the funding period.

Project Content: Standards, Multimedia and Telecommunications
National standards (Appendix 1) in geography, math and the arts (music, drama and visual arts) were brought together with Arizona Department of Education environmental education (EE) guidelines (Appendix 2 & 3) in this project to address concerns that schools should be developing and using coherent integrated curriculums. State EE guidelines were chosen in an effort to increase teacher attention to promoting and maintaining a sustainable future. Integration of the content areas of geography, math and the arts fulfilled a need to integrate an area such as environmental education across diverse curriculum content. This unusual marriage of disciplines presented a real-world problem for teachers as they investigated their own practice and worked towards an integrated curriculum in their classrooms. Multimedia and telecommunications technologies were naturals in support-
ing integrated curriculum development and in supporting this developing community of teachers from diverse, rural and remote locations.

Teachers in the project were introduced to multimedia components: still video cameras, scanners, presentation software, projection devices, and the use of these components integrated into K-12 curriculum. They were also introduced to telecommunications: e-mail, LISTSERVS, the World Wide Web, creation of Web pages, Web page design, and integration of Web-based resources in K-12 classrooms.

Teacher teams developed EE lessons and instructional multimedia modules based on an environmental waste material theme. Teachers worked with instructional design specialists, programmers, artists, and content-area specialists to develop classroom lessons, activities, products, and resources. Modules were linked and have been reproduced on a CD-ROM to provide resources for participant teams for inservice purposes in their schools and in CEE’s teacher education program.

Work in Progress: A Teacher-developed CD-ROM

The CD consists of introductions to telecommunications, multimedia, curriculum integration, using one computer in a classroom, assessing student multimedia projects, on-line search strategies, background information on the change process and equity issues. National standards in math, geography, music, drama and art, as well as Arizona environmental education standards are found on the CD (Appendix 4). The CD houses an extensive bibliography, thirty-one lesson plans or activities, samples of student-created multimedia presentations, and profiles the project members. Each lesson plan or activity has links to related national or state standards and are cross-referenced throughout the CD (Appendix 5). Through search strategies or by menu, a teacher can locate lessons related to math, lessons about or using composting, or all lessons related to a specific environmental goal (or national standard). Lessons are also linked to informational resources, such as “Multimedia How-To” (Appendix 6) or “Telecommunications How-To” (Appendix 7) if there is a multimedia or telecommunications component to the lesson. Related video clips, student presentations, or background information are also available as links to lessons.

All lessons are also linked to actual Web pages which have been “whacked” with WebWhacker software through two levels to illustrate how the Web can be integrated into the teaching and learning process. For example, “Protect our Planet,” a play written by an elementary class, has links to a playwright interview, information on another environmental play, and a Web page on how to assess students in drama (Appendix 8). A middle school lesson titled “Garbage Graphing” includes links to a student-produced landfill presentation on PowerPoint software, an on-line graphing lesson, and information on solid waste management (Appendices 9-10). Because it contains a telecommunications and a multimedia component, the lesson is also linked to “Telecommunications How-To” and “Multimedia How-To” pages. The telecommunications and multimedia how-to pages include introductions to the topic in scenario format, photos of equipment, a video clip on how to scan materials for digitizing, examples of multimedia presentations, scanned student art work with accompanying audio explanations, and video clips of teachers talking about how the use of computers might enhance student learning. Lessons, standards, and text around highlighted issues can be printed for teacher use.

A World Wide Web home-page linked to resource locations has been set up as a repository for developed inservice modules. This Web page is under construction and is one method for continuing the project outcomes beyond the funding cycle.

In the second year of the project, teacher-participant teams planned and provided nine hours of professional development inservice to their peers using the CD-ROM disc to begin development of school-wide integrated environmental education plans, with inservice also emphasizing telecommunications and multimedia technology applications.

The CD-ROM disc is not just a how-to guide on integrating technology with teaching. Participants have included modeling through examples which exemplify true integration. For example, a user of the CD can choose to view a PowerPoint presentation created by a combined 2nd/3rd grade classroom of a field trip to a landfill and the process they used to collect data at the site (Appendix 11) or read a scenario which describes a multimedia-supported classroom (Appendix 12). Lessons can be accessed on the CD which are linked to state and national standards, to supporting information such as how to use multimedia or telecommunications in the lesson, and to Web sites which support the lesson. Preservice students should benefit from the integration modeling found on the CD as it is used in methods courses at the university.

The CD-ROM disc has been made available to the participating schools, to the US West Foundation, and to the Center for Excellence in Education for use in its teacher preparation program. Information from the CD is also available at the project Web site available at http://www.nau.edu/~cee/environ.html.

Attention to Process

To provide as much local support as possible, teachers were visited in their school locations several times throughout the project to tailor inservice to their specific needs. For example, an undergraduate student in NAU’s engineering program was hired to visit each school site and to engage in
a needs assessment for connectivity. This student talked with teachers, administrators, and district technology experts. He was able to provide detailed plans for connectivity when needed, and in some cases, was able to physically connect a teacher for telecommunications access. The technical project staff person also visited schools and helped them locate unused multimedia-related equipment, such as a scanner, or helped teachers and administrators determine what equipment might be purchased.

As a result of [our] participation in the project, I have seen both staff and students grow in their knowledge and experience with multimedia. What is even more exciting is that I have seen these people share their knowledge and experience with others....One of our school’s student artists produced a line drawing of a hornet, the school’s mascot, which was then scanned. The scanned image was colored with PhotoShop by our principal, who then submitted it to the architect. It is now on the newly constructed football field’s artificial turf and looks awesome. Before the project, we didn’t have the equipment, software, or know-how to do this. [Joan, teacher participant journal]

Joan’s school had purchased a scanner several years before the project, but as is typical in many schools, the person responsible for purchasing the equipment moved on and the scanner was moved to a closet. The TEEM technical staff found the scanner without software, worked with the principal on determining software needs, completed the software order, installed it, and provided training to teachers and administrators on the use of the scanner. Unintended outcomes, such as the mascot drawing above, show that the project went beyond our original plans. While not directly connected to integration, the enthusiasm generated by project participants led others, including school administrators, to begin using technical resources.

The project director met with teacher teams at their school sites after on-campus instructional workshops to apply what was learned in a university computer lab to their own individual situations.

I learned because I was given an opportunity to explore without pressure. That is how we learn, that is why I provided the same opportunities with teachers, students and parents. [Ellen, teacher participant journal]

Teacher teams met face-to-face three to four times a year on the NAU campus and met electronically through a project LISTSERV administered at NAU. Three of six participant school districts were located in remote regions in the Navajo Nation with ten out of twenty-four TEEM participants living locally. The project design included several on-campus seminars, but a majority of the work was done via e-mail and LISTSERV discussions. The Navajo Nation is approximately the size of West Virginia, with a population of 150,000-200,000. To be able to connect teachers and students within the Reservation schools, but also to extend a cultural exchange to teachers and students in communities outside of the Reservation, was an extraordinary boost to the participating teachers and their students.

Teacher participants were encouraged from the beginning to take ownership in the process. “What do you need?” was a question teachers needed to answer frequently. Planning for the CD may have been the most difficult part of the project. A mock-up of what a CD might look like was presented several times in the first six months of the project, but teachers were responsible for the content and for how the CD would look and work. This involved several brainstorming sessions with both large and small groups to work through the process. Teacher participants were not comfortable with taking the lead on the direction or content. To facilitate this, a workshop was held to address change theory and stages of concern. When teacher participants realized the CD could be called a “Work in Progress” and that they could collaborate, each with individual talents contributing to the whole (as opposed to having to become an expert in all areas), references to the project became “our project” rather than “your project.” At this point in the process, teachers began directing, forming work groups, and they took responsibility for the final product.

There was a measure of pride and humility that accompanied this experience. It was awesome to ride on the coat tails of such an accomplished group of people. [Denise, teacher participant journal]

Addressing the Change Process

An unintended outcome of this project has been the development of strategies to address the change process when teachers are introduced to technology innovations and information about change was included on the CD to help teachers address this (Appendices 13-14). A turning point six months into the project came from the use of innovation continua with teachers determining both self and group movement or change on a continuum for each innovation (Appendix 15). A continuum was developed for each innovation (i.e., telecommunications access, project LISTSERV, integration of EE standards). A continuum indicated non-use or introduction in a column on the left to a full implementation column on the right. The use of these continua throughout the project brought teachers together as a working group.

Once the innovation continua were introduced graphically and used by teachers personally to mark their progress, they began asking for other continua to be developed later in the project. For example, during a summer 1996 workshop, a group of participants developed their own continuum to show progress in developing environmental lessons for the CD-ROM. Wall size posters of project tasks and training topics (e.g., progress in learning to use presentation software, develop Web pages, conceptual design of CD-ROM) for workshops were created and used periodically to show group progress. Whole-group debriefing sessions
centered on these wall posters to guide the next day’s work. Colored post-its were used as markers and were moved by participants to indicate a group consensus of progress. Discussion established that while individuals might have moved up on levels of use, group growth reflected a definite location on the continuum with some individuals seen as outliers. Teacher participants commented on this sense of community:

Most teachers that boast of twenty years experience feel that they have mastered teaching and are experts in molding young minds. My heart and knowledge have shown me otherwise....I thought it would be fun for the children to write their poems on the computer, projecting it with the Proxima [projector] for the class to see and read together. I couldn’t get the Proxima to work...I wheeled it down...to my associate’s room...I saw frustration on her face as she tried to figure out how to use a computer program....It then dawned on me that the best resource we have in teaching is our fellow teachers. I helped my peer figure out her program and she came to my classroom and helped me teach my lesson that had failed. At the end of the lesson, one of my students summed it up for me by saying, “It’s always more fun with someone to help you.” That is what I feel the US West TEEM project is all about...teachers helping each other. [Jane, teacher participant journal]

It seemed appropriate then, that when a group of participants met to begin CD-ROM design, graphic continua were used to determine progress of design, content and programming tasks. These strategies are currently being tested in other technology innovation professional development projects.

Progress: Extensions of the Project

The project was completed formally on June 30, 1997, but activity in this area continues. Several teacher teams planned a series of on going workshops in their schools for the 1997-98 school year to continue what they started in spring 1997 workshops. An elementary team submitted a proposal and received funding for a telecommunication curriculum grant project between their urban school and a Reservation school. The grant provides computers for two teachers at each school site, on-line and telephone technical support, and virtual training seminars. The principal at the urban school has indicated that through their participation in the TEEM projects, she has seen the benefits of using technology to support instruction and is willing to pledge any financial support needed to make the extended project successful.

The CD was introduced into CEE education courses Fall 1997, ensuring that the project continues at a different level. Developing a CD for inservice use and as a reference has provided inservice teachers with a tool for both introduction to and refinement of integration of technology into K-12 curriculum. We are confident that what was begun in this project will continue with the core teachers taking a leadership role in their school.

Teachers in the project directly or indirectly affected more than 125 teachers and over 3,000 students in the integration of multimedia and telecommunications during the two-year project. But possibly more importantly, the teachers in the project went through a two-year journey of finding what it is like to be learners in a constructivist learning environment.

My perceptions of a teacher-led process...has gone through several stages of transformation, kind of like an insect going through the stages of metamorphosis. When we started I wanted...wee little assignments and [a facilitator] to tell us exactly what we should be doing. Instead we were treated as professionals and given the license to do what we were best at doing....At first, this process was frustrating to me, I wasn’t sure where my place was in this process. However...the group seemed to have fallen into step and we were off and running....I felt like we became an interactive team, pulling in the same direction to reach our goal—the CD-ROM. I don’t remember anyone saying to me, you do this! ....Allowing this to be a teacher-led process was scary at first, however...it feels gratifying and empowering. This is an experience [constructivist environment] I want to bring into my classroom for my students. [Denise, teacher participant journal]

The teachers themselves were encouraged to provide direction for the project content and the final product. Each workshop was planned around teacher concerns and supported their evolving “control” over the project. This journey was long and arduous, but through reflection (journals, evaluations and surveys, focus groups, small and whole group conversations) most teachers left the project with a new or renewed sense of the effect of creating active and constructivist learning environments for and by the learner. Teacher comments indicate that their K-12 classrooms will never be the same.

Institutional Systemic Change

The Center for Excellence in Education has encouraged systemic change through various ways, with this project serving as one example. K-12 school and university partnerships in technology have centered around long-term instruction and support to teachers in the field. This includes working with inservice teachers both in state-of-the-art technology classrooms on campus and in the real-world classrooms found in K-12 schools. We feel this provides support to teachers on what can be done with what is available, but also what is possible. The networks of people created from this project and similar telecommunication projects have proved invaluable in continuing a project beyond its funding cycle. For example, three teachers involved in this project (two local, the other on the Navajo reservation) had participated in previous telecommunica-
tions projects sponsored by CEE and had already begun their own network for collaboration on curriculum. During the project, boundaries between participating school teams blurred as a teacher in a reservation high school collaborated with an elementary class hundreds of miles away on a telecommunications project unrelated to the TEEM project. Since then, several middle school and elementary teams have also formed collaborative groups that are in place today. We are looking towards simultaneous change; this project exemplifies the combination of preservice and inservice support for technology integration to make systemic change.

Appendices
All of the appendices listed in this paper can be found on the SITE 98 CD-ROM version of the 1998 Annual.

Cathy Gunn is an Associate Professor of Educational Technology in the Center for Excellence in Education, Box 5774 - Eastburn Education Building, Northern Arizona University, Flagstaff, AZ 86011-5774. Phone/Voice: 520.523.9507, Fax: 520.523.1929. E-mail: cathy.gunn@nau.edu.
One of the most difficult transitions to using technology within the curriculum is the question of how to use it to help students meet the curricular requirements. Early software left a lot to be desired (Hasselbring, 1986; Hunter, 1989; & Jonassen, 1990). Teachers tried some of the programs and found that many did not live up to expectations. Many teachers felt technology in education fell short of the claims. Partly due to these experiences, integration of the technology has been slow in coming.

In addition, some teachers view the computer as an additional area to cover, rather than a means to further the curricular requirements (Smith-Gratto and Blackburn, 1997). Handley and Sheingold (1993) suggest that teachers need to use the technology to meet curricular objectives rather than as a separate content area. We agree that the technology is best used to further the curriculum and suggest that in addition to the development and use of models recommended by Ehley (1992), templates or prototypes be developed to provide examples for teachers. Prototypes are commonly used in education. We are all familiar with the books that can be purchased in teacher supply stores which provide a variety of activities based upon a particular content or theme. These books contain a variety of activities and ways to use different types of educational aids which teachers use directly as written or adjusted for their curriculum objectives and students. It would simplify computer integration if examples of computer activities were combined with other classroom activities for teachers to use in the same way as the activity books.

The example of the type of prototypes needed will use the software, “Oregon Trail,” since it is available in a large number of schools. We used the Guildford County Schools Curriculum Guide (1996) to provide a full example which incorporates content integration. Many of the activities address more than one area at a time. For convenience, the objectives are numbered so that it is clear which activities address each objective.

### Objective s Addressed through Activities

(all are taken from the *Guildford County Schools Curriculum Guide, 1996*)

**Language Arts**

1. “Use print and electronic resource materials such as dictionaries, encyclopedias, and atlases.” (p. 17)
2. “Revise by refining beginning and ending paragraphs.” (p. 17)
3. “Write literary, informational, and practical texts to convey meaning, to learn, and to clarify thinking.” (p. 17)
4. “Write descriptions that have a coherent, logical, and organized structure.” (p. 17)
5. “Edit for errors in sentence formation - fragments and run-ons.” (p. 17)
6. “Edit for errors in usage - subject/verb agreement, pronoun case, double negatives, and use of apostrophies.” (p. 17)
7. “Edit for patterns of mispellings.” (p. 17)

**Mathematics**

8. “Explain the kinds of decisions that need to be made in constructing graphs.” (p. 18)
9. “Systematically collect, organize, appropriately display and interpret data both orally and in writing using information from many content areas.” (p. 18)
10. “Explore increasingly complex displays of data including multiple sets of data on the same graph, computer applications, and Venn Diagrams.” (p. 18)
11. “Compute averages within a context, using a calculator if appropriate.” (p. 18)
Science
12. “Explain and illustrate layers of the earth.” (P. 19)
13. “Explain natural processes that change the earth such as volcanoes, earthquakes, and weathering.” (p. 19)
14. “Compare and contrast weather and climate emphasizing concepts such as temperature, atmospheric pressure, clouds and land features.” (p. 19).

Social Studies
15. “Describe the absolute and relative location of major landforms, bodies of water, and natural resources in the United States, Canada, and Latin America.” (p.19)

Activities
1. Discuss the program “Oregon Trail” with students. Many will have already used the program and will be able to describe the things that happen during the simulation. Have students discuss the choices they will have to make (choosing supplies within a budget, trading, hunting, crossing rivers, amount of food to eat, and travel speed).
2. Explain that students will be using the information they collect for other activities. Put students in groups of two to complete the program. One student should act as a recorder, while the other inputs his or her responses to the simulation into the computer. Students can take turns being the recorder. Students should record the following information while they work on the program.
   A. Enter the date you begin your journey and end your journey and whether you reached Oregon.
   B. Enter the speed at which you plan to travel and each time you change your speed and the distance traveled each day.
   C. Enter the major landmarks, including rivers that you pass on your way.
   D. Enter the type of weather experienced each day of travel.
3. After completing the simulations, some time should be devoted to discussing what the students experienced during the use of the program. This discussion can then lead into the differences in the dates groups chose to start, when they finished, and whether they reached Oregon. Next, the teacher should ask the students how they can pictorially represent data. The students should be guided towards the production of graphs to represent the data. In their teams, have students write what information is needed to construct a graph showing start dates and with successful completion of the journey and a graph showing start dates which ended in unsuccessful trips. Once students make a list of needed information, the information will be put on the chalkboard. Each group is provided with graph paper and makes a line graph with the information, which has one color for the completed journeys and dates and another color for the dates the incomplete journeys were made. The teacher should then ask questions such as: “Are there dates that show a higher success rate than others?” and “Are there dates which indicate that the trip is likely to fail?” Depending on the data collected, the teacher should construct other questions which probe the students’ understanding of the graphs. Using a word processing program, students can then be asked to write a short essay about what date they would choose to leave and why, based on the information in the graphs. The draft essays are then printed out, and students are placed in groups of four for editing. Once the editing is completed, students return to the word processing program and enter the changes. (Objectives: 2, 3, 5, 6, 7, 8, 9, and 10)
4. As a follow-up activity to Activity 3, students would plan and create a graph using the speed and mileage recorded during use of the simulation. Students would use a spreadsheet with graphing capabilities and a word processing program. As they plan how to use the data, students should be told to take notes, stating how they are using the data and why the data is being used in that manner. After making the notes, students would then create a spreadsheet and a graph. At this time they would make notes on any problems encountered with the data and how they made adjustments and why. Students then print out the completed spreadsheet and graph. Once the spreadsheet and graphs are completed, students would write a description of their planning and any problems they encountered using the word processing program. The descriptions would then be printed out, and students would edit the descriptions, make corrections on the word processor, and print out the completed description. As a whole class activity, students could discuss their planning process, the problems they encountered, and how they handled the problems. Data about distances traveled by each group would be placed on the chalkboard. Students can be asked what the average speed for each group was. The averages can be computed by hand, calculator, or a spreadsheet program. If students have more time, additional activities could include distance and speed problems related to the route traveled using other types of transportation such as cars, trains, and jets to create other graphs. (Objectives: 2, 3, 4, 5, 6, 7, 8, 9, 10, 11)
5. After instruction on how the earth’s features are formed geologically, students are given a blank map of North America. On the first map students will enter the natural landmarks and rivers encountered during their journey. Students will use resources such as atlases and encyclopedias (both print and electronic) to obtain those locations. As they use the resources, students should be asked to enter any other natural landmarks they find in North America. The teacher should then put students in groups and assign each group a natural landmark

Graduate & Inservice Education — 385
found in North America (the Rocky Mountains, Great Salt Lake, Grand Canyon, the Great Lakes, etc.). Using reference resources, students will prepare a Hyperstudio report on how each of these features were formed geologically. (Objectives: 1, 4, 12, 13, 15)

6. After discussions on how climate and weather are related, students would use the data about the weather encountered on the trip to create a graph which uses the dates and weather encountered on those dates. Next, students would use CD encyclopedias and the World Wide Web to research the climates and weather patterns encountered in the areas traveled through during the simulation. Students would compare their graph with the information gathered in their research and discuss how that may affect the results encountered in Activity 1. Students would then create a database with categories that students believe are important in determining climatic areas. Next, students would compare what categories they felt were important and why. After discussions, students would refine and change their databases and enter any new information. Once students have completed the database, the teacher would give students characteristics of areas which resemble some of the data that students collected and have students determine what climate the examples are. As an extension, students can research climate types not encountered and enter their characteristics. (8, 9, 10, 11, 14)

Conclusion

In this paper, we have given a brief example of a prototype that could be used by teachers to help guide their integration of computer use into the existing curriculum. While in complete prototypes, more detailed descriptions of the activities and alternative activities would be provided, it is hoped that the brief example given here indicates what the prototype can contribute to solving the problem of computer integration. As can be seen, the prototype incorporates a tangential software program (“Oregon Trail”) and the use of application software to forward the objectives within the curriculum. Since teachers often use prototypes to add variety to their class activities, it is believed that they can be used to assist teachers in the movement toward integrating computer activities and the curriculum.

USING THE INTERNET TO INTEGRATE THE CURRICULUM WITH TECHNOLOGY

Carol Siwinski
Germantown Academy

The Internet has the potential to be the catalyst for technology integration. It will infuse our lesson plans with technology through its communicating, publishing, presenting and resource gathering tools. It naturally leads to the use of many of the technology tools our students need to be productive citizens of the 21st century. Full implementation of technology into our curriculum, through using the Internet, will also help us attain other instructional reforms as it transforms our classroom from a passive environment to a more student centered, engaged, purposeful learning environment. This paper will present suggestions for integrating the Internet with classroom instruction.

Listserv: Educators Rest Stop

The Internet and its resources can be daunting. I found it no different when I started working with it in 1992. I decided not to be overwhelmed by the mountains of information it offered, but to use it as a natural extension for my student’s telecommunication activities. Instead of our projects taking place on closed bulletin boards, the whole world could now participate through the use of listservs. Because of my success in using on-line projects, I designed and maintain the Educators Rest Stop (http://www.forum.swarthmore.edu/~carol/rest_stop.html) to answer some of the questions other educators may have as they explore integration through collaborative on-line projects. The site offers tips for finding and becoming involved with Internet based projects, along with lists of successful projects.

Many projects can be found on the Internet through either e-mail or the World Wide Web. For e-mail based projects you must subscribe to the list. As the messages come in everyday to your mailbox, you will see exchanges being made to projects in progress and you will receive Calls for Collaboration. A Call for Collaboration is the way to announce a new project to the Internet community. A good Call for Collaboration will contain a summary, timeline, curriculum area, grade level, and registration information. My listserv address (also found at http://www.forum.swarthmore.edu/~carol/listserv.html) contains a list of some of the listservs that I have used, along with instructions for subscribing. You will find them full with many interesting and diverse projects.

If you would like to know more about the listserv and the projects the list runs, visit its web site. The web site will usually give you a chronological listing of its most successful projects over the past year, along with information about each project. If you find a project that interests you and the information is from last year, don’t despair. Write to the moderator concerning the project’s status. Most projects are run annually. Take a minute to browse my web site (found at http://www.forum.swarthmore.edu/~carol/web.html) for additional information.

Where to Start: Websites

Internet based projects are a wonderful way to integrate technology into curriculum and to introduce students to the culture and diversity of the world through global dialogue. However, I have found that educators new to telecommunication and the Internet are very hesitant to get involved. Most educators new to the Internet are uncomfortable with the collaborative effort required from on-line projects since they are unsure of their Internet skills. They need time to polish their e-mail techniques - sending, receiving and replying to messages without the burden of handling the extra volume of mail associated with listserv membership and the constriction of a project timeline.

The easiest place to start for most educators is sharing a favorite lesson plan with the global community. Most of us have a favorite lesson plan that we hone each year, adding and subtracting ideas to make it better. Posting these lesson plans with supporting handouts and student work to the web is a very non-threatening place for educators to start. Because they’re comfortable with the lesson and proud of the student outcomes, they’re more than willing to share it with colleagues. With the help of WYSIWYG, page authoring programs such as PageMill and Claris Home Page, I have had success not only with teachers, but also with students as young as second grade becoming web publishers. Web Sites, which successfully use this model to present their methodology and pedagogy to the global...
community along with student outcomes, are included in the reference section.

**WebQuest**

Once educators test the waters of publishing on the web they are more than ready for the next step of designing lessons that incorporate the presenting and resource gathering tools of the Internet. Dodge (1997) gave a name to these integrated activities - WebQuest. A WebQuest presents the students with a task or problem to solve. It provides all the resources they will need to explore and solve the problem. Then it typically asks the students to synthesize their learning in a summarizing act such as a web page presentation, newspaper, e-mail exchange, or a power point presentation for their peers. It also defines in detail the process the students should follow to successfully accomplish the task, along with assessment criteria. The following full WebQuest designed by the faculty of Germantown Academy are a good example of how a variety of culminating activities can incorporate various technology tools:

- **Forensic WebQuest** [http://www.ga.k12.pa.us/curtech/physiol/guest.htm](http://www.ga.k12.pa.us/curtech/physiol/guest.htm)
- **Mexican WebQuest** [http://www.ga.k12.pa.us/curtech/modlang/spanish/spmexqu.htm](http://www.ga.k12.pa.us/curtech/modlang/spanish/spmexqu.htm)
- **Spanish Cooperative Learning/Writing Project** [http://www.ga.k12.pa.us/curtech/modlang/spanish/spquest.htm](http://www.ga.k12.pa.us/curtech/modlang/spanish/spquest.htm)
- **Forum Romanum** [http://www.ga.k12.pa.us/academics/MS/8th/romanhis/indexrom.htm](http://www.ga.k12.pa.us/academics/MS/8th/romanhis/indexrom.htm)

If you have only three to five class periods to complete an integrated task, a short-term WebQuest such as Sampler, Scrapbook or Treasure Hunt may be helpful. Faculty at Germantown Academy designed modified quest for a variety of disciplines:

- **Movies in Madrid** [http://www.ga.k12.pa.us/academics/MS/8th/Mersky/spanish/spmovie.htm](http://www.ga.k12.pa.us/academics/MS/8th/Mersky/spanish/spmovie.htm) is sample of Treasure Hunt where the students are asked to answer a variety of questions.
- **¡Hola! ¡Bienvenidos a la Florida!** [http://www.ga.k12.pa.us/academics/MS/7th/florida/florintr.htm](http://www.ga.k12.pa.us/academics/MS/7th/florida/florintr.htm) is an example of a Scrapbook quest where students are asked to put together a page of scrapes on a specific topic.
- **Art Sites Search** [http://www.ga.k12.pa.us/academics/MS/7th/Osterwei/explain.htm](http://www.ga.k12.pa.us/academics/MS/7th/Osterwei/explain.htm) is an example of a Sampler where students are asked to evaluate Art sites from a personal perspective.

Carol Siwinski is the Curricular Technology Specialist at Germantown Academy. She can be reached at csisw@ga.k-12.pa.us
To evaluate the success of this program, the participants have been given a survey that includes both objective and open-ended questions. This paper will present a summary of the responses for the three identified groups.

**Group I:** The trained and practiced group. Teachers who have completed both a year of training and a year of implementation in the classroom.

**Group II:** The trained but no practice group. Teachers who have completed a year of training and have just returned to the classroom.

**Group III:** The group that has no training or practice. Teachers who have just begun the training phase.

Because Group III has just begun the program, there are limited responses to the open-ended questions from this group. At the time of the survey, Group II had yet to put the program to practice, but many have examined how they will incorporate technology into their curriculum during the new academic year, and these thoughts have been reflected in their open-ended responses. As a whole, an overwhelmingly positive attitude toward the program has been expressed by majority of the participants.

**Introduction**

The essence of the “Driver’s Ed. for Teachers Navigating the Information Super Highway” is a plan to address the problem of training and retraining of classroom teachers (trainers) who will then train and retrain their colleagues and students to utilize the Internet in order to expand and enrich their educational experience. The project has been made feasible because the State of Louisiana established a statewide network, LANET, in December 1992. By December, 1993, provisions were made for all public and private colleges and universities in Louisiana to be connected to LANET and, consequently, to the Internet. The State instituted a master plan calling for all K12 schools to gain access to LANET starting in 1994. The missing link has been a comprehensive training program for educators that will stimulate the application of Internet resources in the classroom and the continued growth of teachers.

When it is completed in 1998, this three year project will have provided these school districts with a cadre of well trained resource persons and the support necessary to benefit from electronic networking. This project will, in the space of three years, have prepared 60 teachers in fifteen school districts to successfully use Internet technology, effectively integrate resources on the Internet with state mandated curriculum guides, translate the technology into daily classroom activities, and train their colleagues.

Personal networking and electronic communication channels will have been established so that these teachers will have continuing access to sources of expert assistance in their teaching endeavors at all times. Based on the survey responses, it can be concluded that the training that has been provided by this program has had an overall positive effect, thus benefiting the fifteen participating local school districts.

The survey was looking mainly at what impact, if any, technology is having on the participant and his or her
students as a direct result of being a part of the “Driver’s Ed. for Teachers” Program. Open-ended questions were designed to investigate changes, if any, in teaching methodology and to what extent these changes were impacted by the implementation of State and National Standards for mathematics, science, and technology. Also targeted were changes in teaching style as a direct result of using computer activities and how these changes have affected classroom procedures. The results of the survey are also being used to help determine the direction that the “Driver’s Ed. for Teachers’ Program should take before resubmitting for a future program of this type. The survey collected information about the participants such as: teaching background, demographic information about school and school district, and professional enrichment and training activities. We feel that these issues have a direct impact on the participants and cannot be ignored when viewing the survey results.

A total of 27 participants responded to the survey. Replies from the survey reflect a sample from each of the three groups, with over half of the responses from Group I because they were attending classes at the university when the survey was taken. Although the numbers were small for Group I and II, they reflect a 33.3% and 36.8% respectively, while Group III had a 66.7% of returned surveys from the participants for the three years program. Participants from all three groups represent a sample from each grade level.

The three groups were categorized by the level of their participation in the program, with Group III starting the program, while Group I and Group II having completed the intensive course work that included an on site practicum. This practicum was conducted in their parish as a computer technology liaison and Internet trainer. Through workshops, seminars and demonstrations, they provided faculty and staff the opportunities to examine and exchange viewpoints about the role of technology in education.

The first section of the survey asked the teachers questions about their teaching experience. Information on how many years of teaching experience, grade level of experience and subject matter that each had taught was summarized. In analyzing Question one, Group II and Group I teachers reflected averages of 18.7 and 20 years of classroom experience respectively. These numbers alone would lead one to think that both groups had equally experienced teachers. However, the minimum and maximum numbers for Group I were 14 years to 24 years, while Group II had nine years to 24 years. Group III displayed the least teaching experience with an average of 13 years of teaching experience with a minimum of seven years and a maximum of 18 years. This observation was interesting because it was the seasoned teacher who first became involved with a program that emphasized technology rather than the teacher with less classroom experience.

Responses to Question two illustrate the grade level for teaching experience of the participants. The results show that the background of Group I participants represented school types of K-12, elementary, and middle schools; Group II represented a sample from each of the school types of the survey; and Group III dominated elementary, middle school and high school levels. This indicates that on completion of the three-year program there will be a base of experience and expertise available for each grade level of K-12 on the utilization of the Internet for the participating districts.

The results from Questions four and five demonstrate that the participants represent every grade level of school and a wide area of subject matter that is being enhanced by the participation of the teacher. As stated in the introduction, the thrust of this project was to train K-12 teachers in the utilization of Internet with emphasis on integrating its resources in teaching methodology across the curriculum by using the State and National Standards for mathematics and science as a model.

State and National Standards for mathematics, science and technology stress that instructional materials and equipment can increase students’ interest and improve achievement. Students should have access to materials and equipment and be offered opportunities to learn to use them effectively. It is essential that classroom teachers have the necessary non-consumable and consumable material and equipment and that they have means to maintain and/or replenish these as needed. With this in mind, the survey directed Questions five through nineteen to investigate the school and school district profile of each participant.

In accessing these responses, we found that there is a critical need for more classrooms that are equipped with computers and Internet connections. For reform to occur in the classroom, it is imperative that hands-on teaching is included in the curriculum. It is recommended by the National Council of Teachers of Mathematics and Science that classrooms should keep current with the state-of-the-art technology appropriate for the grade level being taught.

The results of our survey show that schools and school districts have projected an increase in their spending for technology for the 1997-98 school year. We feel certain that this is a direct impact of the new technology plan that was implemented this year at the state level. Millions of dollars were earmarked to enhance technology at the K-12 grade level by the state legislators. In personal interviews of several of the participants of this program, many have played key roles in authoring and researching information for their parish technology plans that were submitted this past July to compete for these funds. Group I and Group II have also had several of their participants taking on new jobs as technology coordinator for their districts.

Professional enrichment and training are the thrust of the program to prepare the participants to return to their school.
and district as a trainer of Internet for others. This program has provided opportunity and encouragement for the participants to attend state and national meetings in their disciplines and to become involved with the technology plans in their own districts. It has opened the door of opportunity to many as they have returned to their districts as the technology coordinator and Internet trainer. For some, these skills take them beyond the schools and into the community through training for local businesses, organizations, and churches. This effort has help build an infrastructure and technical support for not only education facilities but the entire community.

State and National Standards require the integration of technology into the curriculum. The participants were asked: to what extent have State and National Standards for mathematics, science, and technology affected the participants teaching of the curriculum? Having been exposed to these standards, many of the Group I teachers have stated that changes have been made in the classroom to reflect those standards. Following the lead of the national standards, new benchmarks have been mandated by the state. At least one of the local parishes has also developed a technology plan and is presenting it to the state for approval. Another teacher commented: “My curriculum was affected drastically in that I teach math only. The Standards are very well planned and it is easy to find Internet access to sites that are in conjunction [with the standards].” Group II teachers anticipate that they will be using more discovery techniques with more observation (as opposed to test) evaluation. As a result of the State and National Standards, the instructional methods of Group I and II teachers will be geared more to application rather than rote memorization.

What part of teaching with computers is viewed by the teachers as the most difficult? Responding to this question, numerous comments have been made. A great deal of planning and organizing has to be done in order to use computers in the classroom. This was the consensus of Groups I and II. Accommodating students who do not have many computer skills and are not secure in the new environment is of major concern of one of the Group I teachers. In other words, each student must be brought to a common point of understanding. Most are either very knowledgeable or have no experience at all. Another issue of difficulty that the participants have addressed is the shortage of computers for effective instruction and the money needed to upgrade and connect to the Internet. Members of Group II foresee many of the same difficulties. They also have noted the need to plan for failed access to the Internet. One respondent has revealed that backup activities might be needed, or activities should be planned that can be done while waiting for the downloading of links during heavy use times. While there are difficulties with the utilization of computers in the classroom, being aware of the challenges allows these teachers to prepare for them.

Participants were asked to describe how the program has been beneficial to their professional development. Groups I and II have conveyed that the program has been very beneficial to their professional development. The teachers of both groups have acquired expertise in the area of incorporating the Internet into the curriculum. These participants are now able to train others, and they themselves have grown professionally and simultaneously have received “beneficial exposure.” Additionally through this program, some Group I and Group II teachers have been able to attend NECC and LACUE conferences, work towards masters plus 30, and attain certification in Computer Science and Computer Literacy. Another Group I teacher notes that this program has delivered a new excitement about teaching. It has been expressed by a Group I participant that these teachers have been provided with an opportunity and the time to explore a medium that, at the beginning of the program, they knew nothing about. Group II members note that at this point they have become more aware of changes in technology and how to integrate it into instruction. They have revealed that they are excited that, through the workshops they have taught, these teachers have been able to transfer their new found knowledge and excitement to other teachers in their own school systems. It can easily be concluded from these enthusiastic responses that the “Driver’s Ed. for Teachers Navigating the Information Super Highway” program has indeed been beneficial to these teachers’ professional development in a multitude of ways.

The participants were also asked: Overall how was your participation in the program beneficial to your students? “Whenever a teacher is excited about something new, the children know it and when that knowledge is shared, they grow! My students have blossomed! They enjoy the computer, the Internet, and they enjoy being successful! If children do not learn the way we teach them, we must change and teach them the way they learn. Computers enable us to do that and so does this program!” replied a Group I teacher. Furthermore, another Group I participant responded that students are learning skills which will help them get a job. Additionally, a Group II member observed that when students are “playing” on the computer, more retention has been observed and interest is increased. Taking these responses into consideration, it can be concluded that while the program has been beneficial to the professional development of the participants, it has also positively impacted the current and future students of these teachers.

Is the “Driver’s Ed. for Teachers Navigating the Information Super Highway” program also beneficial to the teachers’ home schools? In response to this question, a Group I educator notes: “I gained training expertise. I am able to go out and train others, and I am able to use the knowledge I have gained to grow professionally, and also secure grants for the school.” Teachers are now trained and
can provide staff development training in Basic Computer Terminology and the Internet. It has been reported that a Group I teacher’s home school was even been selected as a pilot school for their Parish Technology project in Spring of 1997 and that many of the participants have been able to have their schools connected to the Internet. Group II participants have also had similar experiences. Teachers have also aided their schools in writing technology plans. Based on the responses, it can be concluded that the home schools of the participants do indeed benefit from the “Driver’s Ed. for Teachers” Internet program as well.

The respondents were then asked: “Overall how was your participation in the program beneficial to your school district?” When examining the program’s benefits to the school districts, responses have revealed that these educators have been able to extensively train other teachers in the school systems with Internet as well as receiving training themselves. Others feel it has helped move their schools forward. It has also been noted that among teachers, a positive attitude is growing toward technology. One respondent states “Hopefully my participation and the other teachers’ participation will inspire funding and commitment to technology.” Group II respondents also have made very positive statements. One teacher has announced, “I have had great support. My district is willing to try all forms of technology. We are striving to put a computer in every classroom. We did a tremendous amount of training all summer.” These teachers will now be able to help their districts meet their goal of producing productive, technologically literate citizens. Participants of the “Driver’s Ed. for Teachers Navigating the Information Super Highway” program have indicated that they have even helped to write the parish technology plans which will aid in receiving technology funding from the state. Participating school districts will therefore become more competitive in the “technology race” because of the “Driver’s Ed. For Teachers” Internet program and will better prepare their students for future career success.

Enthusiastic responses abounded when teachers were asked: What do you most enjoy about teaching using computer activities? “Everything! It is magic in the classroom. The kids love it!” responded a Group I educator. Others have noted that it is motivating for the students and, as a result, the instructor. It offers versatility and peaks students interests. Respondents from Group II foresee that having up to the minute information available will be an asset. Evaluating these responses, it is apparent that the utilization of computer activities in the classroom have increased the teachers’ enjoyment of teaching.

Let us look at the focus of this paper: Is the “Driver’s Ed. for Teachers Navigating the Information Super Highway” program meeting its goal? Reviewing the responses of the participants of Group I, while it is preliminary, it is apparent that the program is achieving its goal thus far and will continue to do so for the remaining two groups. Attitudes towards the program are very positive and the results are beneficial on not only the personal but the student, school and district levels as well. The visions that Group II express reveal their enthusiasm towards technology in the classroom. It is this enthusiasm that radiates and thus creates desires within others in their school systems to pursue the benefits of technology. Based on the plethora of benefits cited by the participants of Groups I and II, it can be assumed that Group III will, after receiving training and implementing this training, express similar positive attitudes and benefits of the “Driver’s Ed. for Teachers Navigating the Information Super Highway” program.
Kwajalein Schools, located on the island of Kwajalein in the Republic of the Marshall Islands, is a private school system organized on the American school model, and it is NCA accredited. Located 2300 miles southwest of Hawaii, the schools serve 465 students in grades K - 12. The students include dependents of US Army personnel and government contract employees stationed on Kwajalein as well as approximately 85 Marshallese students. The school employs 47 faculty and staff who teach on two campuses.

**Preceding Events**

New hardware received in the Kwajalein Schools during the '96-97 school year included 120 new Pentium computers with at least 16MB RAM and a 1GB hard drive, 17" inch monitors, a 21" monitor for each building, 42 HP DeskJet 870cxi color printers and 6 HP laser printers.

Half the computers were installed in 4 labs. A computer and color printer were placed in each classroom, and the remainder were located in two libraries and school offices. During the summer of 1997, 10 TV Converters also arrived.

Software on each computer included Windows 95, MSOffice 95 and a grading program site license which many teachers were already using. Other software was available, but many programs were not compatible with the new hardware.

**Problem**

Our problem was to provide a productive inservice at the beginning of the 97-98 school year which would enable the staff to utilize the new computer equipment and compatible software. Five inservice days were scheduled in August for training of faculty and staff as well as classroom preparation. The staff had various levels of expertise. One teacher had used the Internet and Journey North in her 6th grade classroom during the 96-97 school year, while another had not even turned on the machine.

The location of the school is not conducive to bringing in outside instructors. We have done this in the past, but many ideas and applications have not been effective in our isolated location. Distance from the mainland, unreliable international phone service, time zone and date line differences all make communication with prospective workshop leaders difficult.

**Solution**

In May of 1997, the staff was surveyed for interest in either a beginner computer class or sessions specific to MSOffice 95. Based on the survey, a two day session was offered for beginner computer users to familiarize them with Windows 95 and Microsoft Word. Others requested specific MSOffice sessions in Excel, Word and Power Point or use of additional available software and technology hardware.

**Beginner Class**

For those interested in a beginner computer class, a one semester hour of credit was offered through the University of Maryland. I was the instructor and familiar with the levels of those enrolled.

**Course Description.** This course was designed for teachers with little or no experience with a microcomputer. The course was specific to Windows 95, a limited use of Microsoft Word 7.0, and software which was available at the time on classroom machines.

**Prerequisite.** None

**Course Objectives.**

- Be aware of rapid and relevant changes in technology.
- Be familiar with hardware requirements and specifications of classroom computers.
- Be able to use Windows 95 and maneuver around in My Computer.
- Be able to create a document in Word and save to the hard or floppy drive.
- Be familiar with care and use of floppy and CD-ROM disks.
- Be able to use the printer attached to their classroom machine.
- Become comfortable and less intimidated using the computer.

**Grading.** Grading was based on active participation. After the initial instruction, participants had time to use the machines in their classrooms. The course used a pass/fail grading system.
Fifteen teachers chose to take the beginning course. Eleven enrolled for one semester hour of credit. Of the fifteen, twelve had worked with Windows 3.11 or had some exposure to Windows 95. Those remaining had little to no experience on a computer. The class met in the elementary computer lab on the second and third day after school began.

**Day One, Morning Session.** The entire time was spent working with Windows 95. I wrote my own handouts beginning with a list of computer terms and their meanings. Other handouts included Turning On the Computer and Starting to Work on the Desktop, Working With My Computer, and Switching Applications. The handouts were used in a Power Point presentation. Participants read through the handouts as I demonstrated to them what was to be done on the computer. Then, they chose a computer in the lab and completed the handout on their own. Participants assisted each other as they encountered problems working through the handouts. I was available to assist those who were having additional difficulty.

**Day One, Afternoon Session.** I introduced word processing beginning with WordPad. I have found that WordPad is simpler than Word 7.0 and does not have as many confusing icons, toolbars and key combinations. Participants were taught how to create a document and keyed in a letter concerning a job opening. They carefully checked for misspelled words—as there is no spell check in WordPad—and printed a hard copy. I then gave them a copy of the same letter to which I had made changes. They were to make their document look like my example. Participants learned to center, bold, underline, bullet, insert and delete selected text, change text color, font and size, and print a color copy of the edited letter. By the end of this session, they were ready to move to Word 7.0.

**Day Two, Morning Session.** Class began with formatting a floppy disk, creating folders on the floppy, keying in four short documents using Word 7.0 and saving these to their floppy disk. I demonstrated how to change margins in Page Setup and also within a document. Participants were now ready to try a document on their own. The remainder of the morning was spent keying in, saving and printing beginning-of-the-year letters to parents, class rules, schedules or any other task for which the software could be used. It was now time to start the first 4 sessions at IMD’s computer lab. I led session 5 as I was familiar with the additional hardware and software available to the schools.

Staff members were required to attend at least two sessions, but were permitted to attend as many as they desired. The remainder of the inservice time was devoted to organizational building meetings and classroom preparation.

**Results**

The response to the inservice has been overwhelmingly positive. The entire staff learned new and/or different skills during the inservice. Teachers said this was the best inservice we had ever had. Faculty and staff began the school year excited about using their classroom computers and technology. They no longer feared the hardware or software. Teachers have continued to use ideas presented in their sessions and share results with each other. They have requested that similar sessions be offered for our spring 98 inservice.

Since the inservice, I have offered after- or before-school mini-sessions, lasting less than one hour, on additional MSOffice tips, shortcut key combinations in Word, understanding and using the network and the Internet. Many teachers have access to the Internet at home so I have made handouts available. One addressed URLs, which they could access to give them practice surfing the Internet. Another explained different search engines and how to use each. Individual classroom teachers are also sharing their expertise in using specific software. Examples of such sharing include an after-school session on using Microsoft Bookshelf for teachers of grades 4-6, presented by a teacher comfortable using the software. Another session demonstrated the use of a word processing program which incorporates graphics to create reports or stories. Each first, second, and third grade classroom has its own CD-ROM to use with this software program and a knowledgeable third grade teacher presented this after-school session.
Conclusion

As teachers, we face the challenge of continued rapid change in technology. How do we stay abreast of all that is happening? One person cannot do it. It needs to be an educational team effort. Inservice can build a solid foundation of training, and also pull the team together. We must then continue to help and support each other. At Kwajalein, we have had a great beginning. We know our task is not complete, since new and additional hardware and software will continue to become available and be installed. We will continue to provide staff inservice and support to each other in the field of ever-changing technology.
Throughout the 1980's and 1990's a number of factors have led to the creation of formal undergraduate and graduate experiences in technology and education for preservice and inservice teachers, so that they may better serve K - 12 students. Such factors include: various reports critical of current practice in education and offering ideas for reform (Gardner, 1983); research on computer competence nationally (Martinez & Mead, 1988); technology as seen as a means of school restructuring (Bruder, 1992; O'Brien, 1991; Papert, 1980; Papert, 1993); and a growing concern that students need facility with technology as preparation for further education and for the world of work (Marshall & Banon; 1988, Naron & Estes, 1986; Gilder, 1993). One such response (Brownell, Haney & Sternberg, 1997) is a 33 semester-hour Master of Education in Classroom Technology program at Bowling Green State University which was designed with careful attention toward national guidelines in computer education for teachers as developed by the International Society for Technology in Education and adopted by the National Council for Accreditation of Teacher Education (ISTE, 1992; NCATE, 1992, Thomas, 1993).

This brief paper will present a snapshot of information about a six semester-hour experience taken by students during their second summer of coursework, as hours 13 through 18 in their program (EDCI 611 - The Curriculum, and EDCI 635 - Technology, Problem Solving and the Curriculum). The courses were taught back to back (with a lunch break between) for 3 hours and 10 minutes each and met twice a week for six weeks.

**Importance of Curriculum Studies and Developing Problem Solving Skills**

It is vitally important that educators understand the field of curriculum studies (Tanner & Tanner, 1995; Eisner, 1994). Topics such as curriculum design, development, implementation and evaluation; philosophical and psychological bases of curriculum; societal influences on curriculum decisions; history of curriculum; and instructional methodology as it relates to the curriculum are standard in a course such as EDCI 611. For teachers and administrators interested in technology and education, this understanding of curriculum becomes even more important because of the many ways technology may influence almost all of these topics. It is further important because technology adoption and integration may either be driven by informed educational decisions made with regard to curriculum and instructional practice, or technology adoption may drive educational choices made on the basis of technology availability without regard to educational (pedagogical) considerations. It is our position that informed educational decisions should drive technology adoption—that technology should be used in service to education. We do not believe that technology should dictate the form education should take, simply because the technology exists. Indeed, few educators would adopt the latter position.

**Course Descriptions, Texts, Goals and Assignments**

Below, we present the description, required text(s), goals and assignments for each course. Please note that the final project, at the end of this section, was completed to fulfill requirements for both courses, in an attempt to bridge the content of both courses in a practical way. Also, please note the second required text in EDCI 611 (The Connected Family, Papert, 1996). This allowed us to address many relevant curriculum and technology issues from the viewpoint of societal (family) involvement and with an emphasis on technology and technological fluency.

**EDCI 611**

Description: EDCI 611 - The Curriculum (3) - Sources of curriculum: foundational bases for contemporary curriculum; forces that shape design and development of curriculum; and factors relating to implementing, modifying, and evaluating curriculum.

Texts used in the course:
Goals - each student will:

- Understand the components of the field of curriculum studies and the components of curriculum development.
- Understand influences (both historical and contemporary) that affect the development of the curriculum and affect the development of instructional practice.
- Identify ways the components of the field of curriculum studies and curriculum development affect teachers and students daily activities;
- Understand ways various implementations of technology may affect the curriculum and instructional practices.
- Investigate resources available for curriculum studies, and curriculum development, implementation and evaluation.
- Investigate and understand the role technology plays in the culture, the family unit and in schooling and education, with regard to the curriculum and instructional practice.
- Understand the concept of Media Literacy and identify and discuss one or more examples of video-based objects of study for a Media Literacy curriculum.
- Identify a specific curriculum or portion of a curriculum, analyze its underlying theoretical principles, and introduce the use of technology into the curriculum using either constructivist or behaviorist principles.
- Identify possible changes in the learning environment over the next two decades due to advances in technology.
- Understand the current problem-based learning activities that are part of SchoolNet, and what they might mean regarding curriculum and instructional practice in Ohio.

Assignments for the EDCI 611 course:
- Round Table listserv—participation by each student in an ongoing discussion of topics from both courses.
- Group (formal) presentation to class of assigned chapter in Eisner
- Group (formal) presentation to class of assigned chapter in Papert
- Group curriculum studies/curriculum development resources investigation and informal presentation
- Group investigation, discussion, and informal presentation of assigned web site/CD resource
- Media Literacy (individual) - taping/in-class discussion & informal presentation
- Final Project

EDCI 635

Description: EDCI 635 - Technology, Problem Solving and the Curriculum (3) - Investigation of technology as a means to teach problem solving in the curriculum. Coverage of Logo and extensions of Logo, as well as other software to develop problem solving skills. Emphasis on a constructivist approach to using technology to develop students' problem solving abilities. Prerequisite: EDCI 633 - Hypermedia for Educators I.

Multiple additional readings were assigned in class.

Goals - each student will:

- Learn fundamental problem solving skills in relation to structured programming and structured design.
- Apply top-down design skills by successfully writing programs utilizing superprocedures, procedures, and subprocedures.
- Learn a subset of Logo commands related to the turtle graphics environment.
- Learn a subset of Logo commands and techniques for handling list processing in Logo.
- Investigate the use of Logo as computational geometry and understand what curriculum implications that entails.
- Become acquainted with and able to use various extensions of Logo.
- Explore and use a variety of software packages designed to teach problem solving in the schools.
- Read about, understand, analyze and critique various models and theories for teaching problem solving in the schools, especially in relation to using classroom technology.
- Cite, analyze and discuss different forms of assessment regarding the learning of problem solving.
- Understand the current state of research regarding teaching of problem solving in the classroom, especially as this relates to the use of classroom technology.
- Demonstrate the ability to design learning experiences that use technology to teach problem solving and the ability to integrate those experiences into the curriculum.
- Compare and contrast a constructivist versus a behaviorist approach to the learning of problem solving in the schools, especially as this relates to the use of classroom technology.
- Become familiar with various methods for teaching problem solving in the classroom especially with relation to the use of classroom technology.

Assignments for the EDCI 635 course:
- Round Table listserv (same project as EDCI 611).
- Logo Exercises.
- Software Evaluation—Written evaluation of one or more problem-solving programs, submitted for inclusion on class web pages.
Final Project: EDCI 611/EDCI 635

The final project is a major project through which students demonstrate and apply knowledge, skills, and concepts learned in both courses. It involves the integration of problem solving and technology into the curriculum. Students submit proposals for projects that demonstrate and make practical use of what they have learned, complete the projects, and present them to the class.

Options given for projects include:
- writing a unit involving use of technology for problem solving;
- creating, for use by students or teachers, a program, hypermedia product, or MicroWorlds product that involves problem solving;
- developing a problem-solving curriculum for your school, grade level, or class, that includes the use of technology;
- modifying the existing curriculum, including addition of problem solving and problem solving with technology;
- any instructor approved project that meets the students needs and the course requirements.

Within the project written justifications are included for choices made in the project. The justifications should relate to both problem solving concepts and curriculum studies and development and should demonstrate student understanding of information and concepts covered in both courses.

In terms of curriculum, the justifications should address the following questions:
- What influences are manifest in what you did?
- What curriculum ideologies?
- What are implications in terms of implicit, explicit, and null curricula?
- What type of evaluation/assessment is present or implied?
- How do you categorize the use of technology in relation to Papert’s views?
- What are implications in terms of instructional practice?
- What are implications for implementation?
- What are implications for faculty education/training?

In addition, the justifications should address the following questions with regard to choices made about problem solving:
- What types/heuristics/strategies of problem solving are involved and why did you choose those over others?
- What benefits/results/transfer/outcomes can be expected with relation to problem solving and thinking skills?
- What assessment strategies/issues related to problem solving are involved?
- What purpose does technology use (related to problem solving) serve and how does it impact the project?
- What practical issues (related to problem solving aspects of the project) need to be addressed during implementation?

Reflection and Future Directions: We’re All in This Together

Overall, the experience was a success. Several areas we will revise in the future include the coverage of Logo in the EDCI 635 course. There may be better ways in EDCI 635 to present the ideas about problem solving we are currently covering through Logo. Also, coverage of Logo itself may be better suited to a different course in the program. The listserv provided a lively forum for outside-of-class discussion on the topics in the courses, as well as fuel for in-class discussions. The final project was a great success, as students made major contributions to their schools and districts and used the vocabulary and concepts developed in both courses to express and defend the choices they made. Projects ranged from inservice professional development for whole districts to insightful integration of technology in many different (existing) curriculum areas to the development of new curriculum in conjunction with a statewide technology integration project.

As with any “first-time-through” experience there are areas, both on the problem-solving and the curriculum sides, that we will deepen prior to the next offering. Resources are always a problem, and we were fortunate to start with a good base of software, but by next summer we will be able to increase availability of problem solving software for review and classroom use. In the curriculum course, we will introduce better coverage of the “reconceptualization” of the curriculum field and how that relates to the life of the teacher. As Pinar (1995) points out, many courses such as EDCI 611 are still taught on a curriculum development model that has been replaced (or at least challenged) by a curriculum understanding model due to the reconceptualization of the field that began in the 1970’s.

One main concern of this endeavor was how to make course topics relevant. Teachers sometimes view topics from the curriculum course, in particular, as impractical in regard to their daily activity. This is not a unique problem, but one that needed to be proactively addressed by both the nature of the work in the courses and as a topic of discus-
sion within each course. With our approach, we strove to establish lasting, meaningful relationships with course participants, and actively engaged participants in discussions regarding the scope of the course, value of the content, place of the course in their program, etc. As one student positively observed, "We feel like we’re all in this together." Given this basis for facilitation, it was possible to explore relevant topics against a backdrop of practical use and develop ideas and views that teachers rarely have time to explore, given the current structure of schools. In this way, each participant (graduate student and instructor alike) was seen as having something unique to bring to the learning experience, and that uniqueness was highly valued, shared and developed.

**Conclusion**

As technology integration in the schools proceeds there are many areas of opportunity for teacher educators with an interest and background in technology to explore that, we believe, can further aid the process of that integration. As educators interested in technology, we all have a story to tell. It is obvious that those stories can be told from the perspective of technology. It is not as obvious that we can also tell those stories from other perspectives. For instance, our stories can be told from the perspective of a curriculum course, or a foundations course, or any one of the methods courses, etc. By doing so we can offer course participants a fresh perspective, open new perspectives and possibilities for ourselves, and further enhance the integration of technology into education. Experiences such as the one cited here are an attempt to do that.

LAUNCHING AN INTERNET-BASED MASTER'S DEGREE IN TECHNOLOGY IN EDUCATION

George Blakeslee  
Lesley College

Angeline Ferris  
Lesley College

Nancy Roberts  
Lesley College

Maureen Yoder  
Lesley College

In the fall of 1995, the Lesley College Technology in Education faculty decided to begin offering its graduate courses online, in addition to its traditional on-campus semester format, and off-campus intensive weekend format. By the fall of 1996, we realized that to reach a different audience than our two current formats allowed, we would have to offer all 11 courses that composed the master's degree. We developed a proposal to our dean, including a budget indicating the cost for supporting such an endeavor. The funds we requested were for course release time for converting our syllabi for online delivery, for short courses for the faculty to enable us to teach on both the Macintosh and PC platform, for books and software, and for the evaluation of the first cohort’s experiences. The proposal was fully funded.

An online “Readiness Survey” (www.lesley.edu), created by another group within the school, was used to give potential students a guide for determining the program’s appropriateness for them. The survey has two sections: “Technical Readiness” and “Disposition Readiness”. In the technical readiness section we indicate the minimal computer configuration required for the program and ask questions about their use of key software and hardware tools. In the disposition section we ask questions such as access to a computer, ability to work alone and remain motivated, and willingness to persist in a technologically challenging environment.

The college’s Office of Information Technology is very supportive of our efforts, having wired the campus last year with a state-of-the-art network. The Technology in Education faculty received networked Mac PowerPCs and PCs running Windows '95. The school acquired an Internet-based threaded discussion software, NetThread, which currently seems adequate for our needs. The college’s president has made integrating technology into campus life one of her primary goals.

Pilot Courses

A sabbatical and a grant from the Sloan Foundation enabled us to pilot, and thoroughly evaluate, two graduate courses in the two years prior to launching the entire master’s degree program online. An independent evaluator supported by the Sloan Foundation grant looked at both online courses, and, for the grant supported course, comparable sections being offered in the traditional semester format and intensive weekend format. The evaluation process included student interviews, review of email correspondence, a comparison of students’ final projects, pre- and post-course surveys, and classroom observations. Technology: Impact on Society and Schools (ECOMP 6101) is a deliberative course based on reading and reflection. Teaching and Learning with Multimedia (ECOMP 5016) is a methods course which considers the effective application of technical multimedia skills.

Both online courses were structured as 14-week semester classes. The syllabus specified a weekly set of technical tasks and/or readings. Texts and readings were sent to the students ahead of time. For the multimedia course they also received software and video tutorials on its installation and use. The students corresponded with the instructor about the weekly tasks via email, and any assigned work was submitted via FTP to a college server for examination and evaluation. Discussion of educational concepts, experiences, methods, and issues followed the syllabus topics and was conducted on the course internet discussion forum.

The courses required a technical infrastructure, both by the college and by the students, to support the offerings. For the college this consisted of computer servers for web pages, email, and discussion forums. It also required support personnel to maintain the computer servers and services, and a knowledgeable instructor who could troubleshoot student technical problems. The technical requirements for students included a suitable computer and...
peripherals and an internet account with web browser and email. The technical knowledge needed by the instructor included a variety of web browsers, email programs, internet service providers, FTP applications, online discussion forums, and word processors.

The students enrolled in the courses for many reasons. All students were matriculated in the Technology in Education Master’s degree program. They represented all regions of the United States, as well as on-campus students. The most common reasons for enrolling in the online courses were “flexibility of scheduling, ability to accelerate study, and need to learn how to conduct online learning.” (Peake, p. 5; Moon & Peake, p. 10).

The students reported a number of benefits received from learning in the online mode. These included “flexibility of scheduling and pace, technology learning by doing, ability to work independently, equal participation by all, convenience, and learning style fit.” (Peake, p.5) The reported challenges were “dependence on technology, lack of immediate interaction [these were asynchronous courses], volume of email, dependence on text material, and sense of progress.” (Peake, p.6; Moon & Peake, pp. 24-29)

Online learning is different from other “classroom” environments. When asked to assess the differences, online students responded that the courses “had less intense interactions, more responsibility on the learner to attain content, more conducive to reflection, more access to instructor, more equal participation by all, more time consuming - but at one’s own schedule.” (Peake, p.6; Moon & Peake, p.37-42)

The evaluation analysis suggests that the online students “achieved the same level of competence” (Moon & Peake, p.43) as the students in the two more traditional courses. Moreover, the independent learning environment clearly suited the students who chose the online format. However, there was an indication of some feelings of isolation and a difficulty in creating a collaborative learning environment to support discussions and group work. “For while we know there is the technical capacity to deliver courses in an online format, the issues surrounding pedagogy and challenge of building virtual learning communities are formidable.” (Moon, p. 7)

**Online Master's Degree in Technology in Education**

The online master’s degree in Technology in Education is designed for students who are interested in learning about technology and ways technology supports education. Founded in 1979, Lesley’s Technology in Education program has been developed by faculty, all with K-12 and college level teaching experience. The requirements for the degree, in any format, are identical. Class size, also standardized throughout the program variations, ranges between 20 and 24 students. Required courses include:

<table>
<thead>
<tr>
<th>Course Title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computers, Technology, and Education</td>
</tr>
<tr>
<td>Telecommunications: Curriculum in a Global Context</td>
</tr>
<tr>
<td>Teaching and Learning with Multimedia</td>
</tr>
<tr>
<td>Integrating Technology into the School Curriculum</td>
</tr>
<tr>
<td>Fundamentals of Computer Structure</td>
</tr>
<tr>
<td>Technology and Special Needs</td>
</tr>
<tr>
<td>Microworlds, Models, and Simulations</td>
</tr>
<tr>
<td>Technology: Impact on Society and the Schools</td>
</tr>
</tbody>
</table>

Elective courses, of which three are chosen, include:

- Technology in the Mathematics Curriculum
- Technology in the Language Arts Curriculum
- Creating an Educational Environment with Logo
- Creating a Multimedia Curriculum using Authoring Languages
- Video as Educational Technology

**Recruitment of Students**

Recruitment of online students differs from traditional recruitment in two important ways. First, we strive to reach an audience that otherwise would not be able to take our courses. Although we have off-campus courses in many states across the country, our online courses can be taken by students in any state or country in the world. Also, students whose life styles or physical challenges prevent them from traveling, can participate in our courses from their homes. Access to the appropriate technology is more important than geographical location or physical mobility. Second, attracting students can be accomplished without a mass mailing of a printed brochure. No mailing list includes as thorough a list of potential students as the audience of the millions of people using the Internet.

Face to face information meetings are not required to answer questions from potential students. Many of our potential students hear about our program electronically, by visiting our Web Page. Others are still responding to a simple, one page flyer sent to a small selection of international schools. Almost exclusively, email is the chosen method of communication when potential students need additional information. Questions are answered individually, usually leading to the registration and application process. One important step in the process is the online Readiness Survey at our Web site. Here interested individuals assess their potential for success in an online program by taking an honest look at their learning style and technological skills. If they consider themselves good candidates for the program and want to enroll, students can register for courses using a form on our Web Page. Application for matriculation in the master’s program must be done using traditional mail because of the security required for transcripts and references. Administrative information about future courses, deadlines for registration, and other program related issues are posted on a Web page.
Management of Program

Once a course begins, materials are sent to students in a variety of ways. Our students live as far away as Asia and as close as the next town. When materials include papers and software, local students pick them up at Lesley College. United States students are sent materials by traditional mail. A costlier, international courier service is used to mail materials to our students living outside the U. S. Some courses do not require materials to be mailed. Readings and assignments are accessed through faculty Web pages.

Throughout the courses, electronic mail is a primary source of communication and a method of sending assignments and clarifying course objectives. In some courses, students are required to send weekly journals and progress reports. Class discussions take place using NetThread, an asynchronous discussion software that the college supports. Discussions are password protected and students participate in a variety of ways. Formal dialog takes place following a question posted by the instructor or one of the students. Topics include reaction to reading assignments or a discussion of a controversial topic in the news that relates to the class. The discussion area is sometimes used as a bulletin board where student reports are posted to share research. Informal dialog takes place anytime on any topic that a student or the instructor posts.

Video conferences, using public domain software and inexpensive cameras have taken place several times, with subsets of a class visiting a public or private reflector site. Students can see each other in small windows on their computer screens and communicate with each other by typing messages or through their microphones.

Comments on student work and assessment of student projects are done by email or traditional mail. Grades for courses can be sent by email but an official grade report will be sent by traditional mail after the course. The management and administration of the online program is different from a traditional setting but the access to email, Web pages, conferencing, and traditional mail combine to support communication between and among students and faculty as well as the sharing of materials.

The online program is being offered on a year-round calendar. Students study two courses in each of three academic terms—fall, spring, and summer. The first two courses, offered in the fall of 1997, are Computers, Technology, and Education and Telecommunications: Curriculum in a Global Context. In the spring of 1998 we offer Integrating Technology into the School Curriculum and Teaching and Learning with Multimedia, and so on throughout the degree. If the students continue at this pace, the first cohort will finish in the summer of 1999. However, students do not need to travel through as a cohort. Our first group consists of students from the U. S., Mexico, Malaysia, and Kuwait. Because of the number of inquiries for the online program, we are beginning a second round of courses in the spring semester. We plan to look carefully at the amount of growth we can sustain as we proceed.

Based on the findings of the evaluation from our pilot courses, the faculty teaching the first two courses are making a special effort to: make our syllabi very clear; intentionally require online discussion; and intentionally require some assignments, such as a software evaluation, to be done collaboratively. In addition, we are trying to identify as many resources, such as online readings and software demonstrations, to eliminate copying and mailings and encourage our students to develop a comfort exploring the Internet.

What we have learned

Learning began before the first class. One of the courses required that a package of materials be mailed to the students. Due to last minute registrations, we were sending out packages until a few days before the class began. To get the materials to the students on time, we had to use courier services thus increasing our mailing costs. In the future we plan to have registration end several weeks prior to the start of classes. Also, whenever possible, we plan to design the first week of the course to be free of special materials.

Both courses were developed in great detail. The syllabus for one course was an ever-expanding web page, while the syllabus for the second was a lengthy printed handout. We are finding that assignments, in particular, require great specificity. Students in our traditional classes ask many clarifying questions. Online students ask questions too. They want both further explanation of assignments and more clarity on grading criteria.

We realize that downloadable online readings are vital to the program. Online readings avoid the copyright issues of duplicating articles and they have no cost to the College. In the course, Computers, Technology, and Education we used many online readings. There were problems. Readings disappeared between August and October. In one case the web site disappeared and in another case the reading was no longer available to download. To minimize the problems, we are working with a librarian to find good sources of online material. The telecommunications class had success ordering books from amazon.com, the large online bookstore.

In the telecommunications class, students were required to send weekly journals. Many assignments involved reading and exploration, and did not result in a product, such as a paper or program. The journals were the only method of assessment. The more thoroughly the journal related to the task, the more positively the instructor evaluated the student work. When the instructor did not “hear” from a student for more than a week, the instructor questioned the student’s effort. In fact, there were times when servers malfunctioned and the student’s email did not get through. We learned not to rush to a judgment when students are out of touch. Silence can be misinterpreted.
In *Computers, Technology, and Education* students submit a variety of assignments with one due each Monday. Since this is a survey course the assignments range from making a timeline, to writing a newspaper, to creating a database, to programming in Logo MicroWorlds. In most cases students submit their work as attachments. It takes a few weeks for all the students to learn how to send attachments. Some students work on Macs and some on PCs. They also use a variety of email and word processing programs. We learned a lot sorting out the different file types. One student project consisted of twelve files! Putting projects in a format suitable for grading is incredibly time consuming.

In the telecommunications class, most of the students were able to solve their own technical problems. They found local resources in the form of other people, manuals, and customer support numbers. Though encouraged to post problems publicly in the class conference area, they rarely did. Some admitted that they were embarrassed to confess to having trouble. They were more likely to post their questions on a large, public newsgroup. Both classes consist of self-sufficient, independent learners. The students solve most of their own problems. We are aware that subsets of each class emailed back and forth and help each other. In only one case, did large numbers of students post their problems for their classmates to see. Faced with programming in Logo, students posted their questions to the class via email. What happened was wonderful. Classmates responded; they answered the questions in great detail. The feedback provided was quicker than the feedback from the instructors. All the students learned from the questions and they put the information to use in their own programs.

We want to develop more meaningful ways for students to work together. Both classes have group projects. In general the projects work well. However, we realize we need to develop methods to facilitate online group work. We also have to develop techniques to handle situations when groups are not functioning and the participants are angry with one another. Naively, we never considered that students would become angry with each other. Both courses use NetThread to facilitate online discussions. The students use this system to complete assignments. We need to work towards more fluid NetThread discussions. All courses in the eleven-course sequence require collaborative work and online discussions.

Most of all we have learned that teaching in this manner can work. The framework the faculty lays out for a course is critical. After the course begins, the faculty becomes a guide, a resource, and an assessor. Teaching in this manner is extremely time consuming. We are very conscious of the additional time it takes to develop the syllabus, identify online resources, and respond to students’ email. We estimate this to be about twice that associated with a traditional course offering. Thus far the involved faculty find the experience of teaching online both exciting and rewarding. We are carefully evaluating this first online cohort to insure the academic quality of the program.

As distance education becomes more prevalent in society, training programs, educational programs, schools, and universities have the opportunity to offer instruction to students throughout the world. With the increased use of the Internet, distance education is becoming an international activity. This is one of the benefits of distance education that has appealed to many educational leaders. Matriculated students are no longer limited to those who can physically be present in the classroom. This opens the door to many new opportunities for educational institutions to provide instruction to an international body.

However, the fact that an educational institution offers distance education courses does not mean that they will automatically have increased enrollment. For this to happen, it is crucial that a well conceived marketing plan be established in coordination with the delivery of the distance education instruction. The development of a well conceived marketing plan for distance education courses is the basis of this paper.

A Distance Education Program
The authors currently serve as faculty in the Educational Technology Leadership Master's Degree program delivered entirely via distance education at George Washington University. This program is designed for individuals who want to lead the way in improving teaching and learning in education and training settings through the application of educational technology theory and practice. The program makes use of many technologies including satellite television, video, e-mail, World Wide Web, and NetForum software.

Students can choose to take individual courses or enroll as degree students. The course credits and degree are no different than those awarded to on-campus students. The program has an enrollment of approximately 270 students. Most of the students have full-time jobs as teachers, educational administrators, media coordinators, instructional developers, active duty military, or training specialists. The program has been in existence for eight years. The program Web site can be seen at: http://www.gwu.edu/~etl

A General Overview of Marketing
Marketing is one of the essential ingredients utilized by organizations in their never-ending search for survival and growth. In most cases, marketing attempts to generate profits from the sale of goods and services to fill customer needs. Most basic marketing systems contain three components: 1) an organization, 2) a delivery channel, and 3) a customer (Dalrymple and Parsons, 1983). Additionally, at the root of every market-driven economy there are four central ideas:

1. Individuals strive for rewarding experiences.
2. Individual choice determines what is rewarding.
3. It is through free and competitive exchange that individuals and the organization they deal with will best realize their objectives.
4. The mechanisms of the market economy are based on the principle of individual freedom, and more particularly on the principle of consumer sovereignty (Lambin, 1993).

With all of this in mind, Lambin (1993) defines marketing as a "social process, geared toward satisfying the needs and wants of individuals and organizations, through the creation of free competitive exchange of products and services that generate values to the buyer" (p. 5).

For distance education, we have modified the previous definition slightly to better incorporate the instructional environment. We see distance education marketing as a "social process, geared toward satisfying the needs and wants of the learner, through the creation of free competitive exchange of instruction that generates values to the learner."

A Five Stage Plan
As we have gone through the marketing process for our own distance education program, we have developed a five stage plan for implementing our marketing goals (see figure 1). This plan is very iterative in nature. As the distance education arena, our program, and technology in general change, the plan is re-evaluated and revised if necessary.

Stage One - Identifying Demographics
The first stage in developing the marketing plan is to identify the demographics of your proposed student population. This includes their background and experiences, future goals (i.e., why do they want to take the courses you
offer), and their geographic location. This stage must be completed first, because each of the other four stages are dependent upon it.

A good avenue for collecting this type of information is to do a survey to determine the demographics of your current students. This information will provide you with a good starting point if you attempt to advertise to students similar in background to your current student population or if you attempt to advertise to a new demographic group.

**Stage Two - Identifying Key Information-Providing Resources**

Once the demographics of the proposed student population have been developed, the next stage is to identify the key information-providing resources for those students. These resources could include newspapers, magazines, journals, special publications, online (Internet-based) advertising, radio, and catalogues of distance education courses.

Again, a good starting point to collect this type of information is your current students. You can conduct a survey to see when and where they get their information. After these key resources are identified, the approximate advertising cost for each resource needs to be obtained. Many times, a discount can be arranged by working through the marketing representative for the educational institution.

![Figure 1. A Five Stage Marketing Plan for Distance Education](image)

**Stage Three - Evaluate the Options**

After the key information-providing resources and their costs have been collected, the next stage is to evaluate each option. This stage will vary depending of the available budget of the educational institution. After reviewing the budget, sometimes the more costly advertising options can automatically be eliminated. The remaining options can be evaluated using data from the advertising resource themselves. For example, newspapers can provide an estimated number of daily readers and World Wide Web sites can tell you how many hits they have had in the past on a particular page.

Advertisers can also tell you what type of person is exposed to their advertising. For example, a business-oriented publication would be better than a cooking publication if you are interested in advertising to potential students interested in enrolling in business courses. This data can be used to determine which of the advertising options will best fit the needs of the educational institution.

Another important issue at this stage is how much of your budget you want to commit at one time. Do you want to advertise throughout the year or only during specific times (e.g., the month before registration)? Do you want to spend most of your budget on one particular advertising option (e.g., television) or do you want to spend it on several less costly alternatives?

**Stage Four - Prepare and Run the Ads**

Once the best information providing resources have been identified for the educational institution, the next stage is to prepare and run the ads. The placement of the ad and its appearance can have a profound impact on the reader’s response. Therefore, it is important to work with a professional when preparing the ad. Many times the educational institution will have a marketing representative who can assist in this area. It is also important to verify that the ad is run when and where specified.

In conjunction with this stage, you need to make sure that you are prepared for the response to your ads. If your ads are successful, your point of contact may be overwhelmed by telephone calls, e-mail, faxes, and mail. You need to make plans in advance for this issue. Options could include hiring and training a part-time employee to handle the inquiries or installing a second phone line. Finally, make sure the content of the ad is correct (incorrect contact information can be very costly).

**Stage Five - Collect Feedback and Revise**

The last stage of the marketing plan is to collect feedback and revise the plan. The purpose of collecting feedback is to determine where the matriculating students are finding out about the distance education course or program. The best way to collect feedback is to ask the student this question at one of three possible times: 1) when they first contact you, 2) when they register for the course, or 3) on the first day they participate in the course.

The feedback that is collected serves as the ultimate evaluation of the marketing plan. It may turn out that one of the information-providing resources is much better or much worse than anticipated. Once this data is collected and reviewed, it is then important to revise the overall marketing plan to reflect this information. Marketing coordinators for the educational institution can then go back to stage two or three to incorporate these changes.
Conclusion

In general, marketing is an important tool that educational institutions and others offering distance education courses can use to attract students from an international body. Whether a marketing plan is successful or not can have a tremendous impact on the growth and survival of a distance education program. Therefore, it is important that a well developed marketing plan be implemented early and followed.

This paper reports on a five stage marketing plan that has been developed based on the experiences in our own distance education program. The five stage plan can serve as a starting point from which successful marketing can be implemented. Marketing plans should be periodically evaluated and revised based on the ever-changing distance education arena and technology in general.

As enthusiasm for the educational use of the Internet and the WWW in education grows, educators would do well to re-examine the current status of the computer in the classroom. Just as the Internet and the WWW are now seen, computers were often promoted as a “silver bullet” which would transform education. Tens of millions of dollars were invested in efforts to bring computers into the classroom, often utilizing funds meant for the more fundamental but less glamorous resources such as textbooks, library materials, and school maintenance. As the enthusiasm for “on-line schools” grows, a number of authors have begun to re-assess the impact of computers on education.

Mergendoller (1996) noted that the most common uses for computers are “drill and practice in elementary schools and word processing in secondary schools” (p. 43). Jonassen (1996) reported the results of surveys showing that almost 85% of software in use in schools is for drill and practice or for “tutorial software that was designed to support rote learning” (p. 15). Mergendoller further suggested that these are the uses which fit most closely with existing teaching and curricular practices, indicating that computers have not transformed the classroom, but have been “transformed” to fit existing school practice.

Stoll (1995), in his popular work, Silicon Snake Oil, saw possible causes for this problem as: a lack of good educational software, problems with the technological aspects of computers, rapid development in technology making machines outdated within a year, and the lack of teacher training. A recent survey by the U.S. Department of Education reported that only 15% of the nation’s teachers had nine or more hours of instruction in the use of educational technology. The survey also noted that the need for computer training is especially critical among veteran teachers, certified before computers became common in classrooms (Free Lance-Star, 1997).

Audet and Abegg (1996) suggested that “introduction of technologies into schools often follows a linear path from invention of the software to formation of educational applications” and that:

Curriculum materials and instructional approaches elaborated before suppositions about the relationships between students, computers, [software], learning tasks, and instructional styles are tested may suffer fundamental flaws. Ideally these concerns should be addressed before [their emphasis] the technology is in place (p. 22).

As new computer-based technology, such as the World Wide Web, appears in the classroom, the issue of developing a meaningful educational role for the computer will become more critical. It should be obvious that any such development must take place in cooperation with classroom teachers who will be using the technology in their classroom, and it must occur in that same classroom environment. Just as obvious should be the realization that worthwhile use of these resources does not involve “classroom business as usual, but the enactment of a complex new managerial and instructional role (Mergendoller, 1996).” Owston (1997) states the issue clearly: “[T]he days of frivolous experimentation in schools have long passed. Before we introduce any new technology into our classroom we must be able to justify its contribution. The public expects no less of us” (p. 33).

Technology Standards

In a number of school districts and states, the issue of developing meaningful educational applications of technology has been forced by the adoption of standards of learning. The Virginia State Board of Education has developed such technology standards as part of the State Standards of Learning, which will be in force as of July, 1998. These technology standards list the computer competencies which are to be met by students at the end of grades five and eight.

These competencies include: (1) the use of application software such as spreadsheets, databases, desktop publishing, and word processing, to produce reports and documents, (2) the ability to communicate through networks and telecommunication, (3) the ability to create “home page” documents that can be accessed by worldwide networks,
and (4) the ability to store, process, retrieve, and access electronic information.

If educators are to help their students achieve the levels stated by the standards, then it is obvious that these educators must possess an equal or higher level of skill than their students in order to provide instruction in areas. The State Board of Education recognized that fact and proposed corresponding Standards for Instructional Personnel that described the technical proficiencies required for licensure in the Commonwealth of Virginia. School districts are being directed to incorporate the use of technology into staff development programs, and to consider applicants’ abilities to use these skills as new staff members are hired. In addition to the skills listed in the student standards, instructional personnel must be able to: (1) plan and implement lessons and strategies that integrate technology to meet the diverse needs of learners in a variety of educational settings, and (2) demonstrate knowledge of ethical and legal issues relating to the use of technology.

**Description of the Program**

The Computer/Technology Certificate Program was developed by the School for Continuing and Graduate Education at Mary Washington College, with participation of personnel from area school districts and Mary Washington College, in response to these new State Technology Standards. The program was designed for Virginia educators, including teachers, administrators, media specialists, and technical support staff, who feel that they either do not possess the skills mandated by the standards or do not possess them in sufficient degree.

The program consists of a sequence of five, one-credit courses. Four of the courses are “core courses”, addressing specific technology standards. The fifth course is an elective which teaches a technology skill not directly stated in the Standards, but which is still of value to any educator working with computers in the school. The four core courses are:

1. Implementing the Computer/Technology Standards - a discussion of the State Computer/Technology Standards and an overview of the Certificate Program,
2. Introduction to the Internet and World Wide Web (WWW) for Educators - an overview of the educational resources available on the Internet and the WWW,
3. Introduction to Desktop Publishing and Multimedia for Educators - an overview of specific applications using Desktop Publishing and Multimedia software and associated hardware, and
4. Implementing Technology into Instructional Programs - provides participants with a basic understanding of the instructional applications of modern technology.

The two electives currently offered are:

5. Implementing a Technology Plan for School, Department, or Grade Level - provides a basic understanding of computer technology, including research and selection of appropriate and software for the classroom and/or department, and
6. PC/Software Maintenance and Troubleshooting Techniques - provides participants with a strong, non-threatening approach to basic troubleshooting techniques and preventive maintenance procedures for hardware and software.

The program has recently added an additional course, Basic Computer Skills, as a supplement to the program rather than as a requirement. Many teachers wished to participate in the program, but were unable to meet the minimum requirements: experience in completing tasks such as finding, opening, copying, and saving files, using floppy disks, and familiarity with a word processor.

While teaching the skills needed to make use of the different types of software and hardware associated with these courses is important, if we were to avoid some of the problems reviewed in the introductory section of this paper, the program developers felt that it was critical that the skills be taught with an emphasis on integrating these tools into the teachers’ daily classroom instruction. Classroom teachers participating in the program are asked to bring a frequently used unit or lesson plan to the first course, administrators a plan for technological development, media specialists a survey of current technology uses, and technical support staff a training program or equipment “wish-list”. The participants then enhance this unit or plan throughout the sequence of courses, making use of Internet and WWW resources and contacts, utilizing desktop publishing software and hardware to better present their plan, and then bringing all resources and skills together in the final course to produce a technologically “enhanced” unit, program, or plan.

Close collaboration with local school districts has led to the development of specifically designed training schedules for many teachers. The Fredericksburg (Virginia) Public School district has arranged to have at least 75 teachers take part in the certification program, providing a cadre of 25 trained teachers in each of the 3 district schools. These teachers will take the courses, as a group, both during spring semester courses and in intensive summer training sessions.

**Program Assessment**

Several research questions have guided this study. They are: (1) What are the levels of background computing experiences that K-12 teachers have as they enter the certificate program?, (2) What are K-12 teachers’ perceptions of, and opinions of, the individual courses as they complete them?, and (3) What are the experiences, and resulting changes in perceptions and attitudes, of these K-12 teachers as they complete the certificate requirements?
While a small number of courses have already been taught, one entire sequence of courses will not have been completed until January, 1998. We have found that offering a “staggered” schedule, with several sessions of the first few courses provided each month, seems to better fit educators’ schedules. Data collection, analyses, and interpretations from the first group of participants will be completed by January, 1998. While our presentation will report on the results of one entire sequence of coursework, this paper will describe our methodology.

Participants

While the program is open to all Virginia educators, the majority of our participants have been classroom teachers from the surrounding school districts: Fredericksburg city, Spotsylvania, Stafford, Caroline, and King George counties. There has been a balance, up to this point, of elementary and secondary teachers. No trends in terms of subject area have been noted, with roughly equal numbers of science, math, and humanities teachers represented.

Data Sources

Data currently being collected, analyzed, and interpreted consist of: (a) surveys of perceived computing skill levels, collected at the beginning of the initial course, at the beginning of the third course, and at the conclusion of the sequence; (b) course evaluations and comments; and, (c) focus group interviews with participants. Initial results seem to indicate that participants are highly satisfied with the program’s approach to teaching skills in an educational context and believe that their skill levels do increase.

The survey of perceived computing skills asks the participant to rank order their knowledge, using a 0 - 7 Likert scale, of various computer applications. Areas examined include their knowledge of hypermedia software, spreadsheet software, web browsers, and e-mail. They are also asked to respond to short answer questions regarding their years of computing experience and types of computer used. After completing the computer experience survey, participants are also asked to complete a survey of Attitudes Toward Using Computers. This survey consists of 35 statements, all ranked in terms of agreement using a 0 - 7 Likert scale, with 0 indicating “Not true of me now” and 7 “Very true of me now”.

A course evaluation form is provided to participants at the end of each workshop. This instrument addresses the following areas: course instructor, course activities, handouts and other documents, hardware and software used, and classroom use and links to the state Standards of Learning. There are 17 such statements on the form, each answered by a 1 - 6 ranking on a Likert scale. One question requests an overall course rating, with choices ranging from Very Poor to Excellent. Participants are also asked to provide comments and suggestions on the back of the evaluation form.

Participants in focus group interviews will be identified based upon varying degrees of background computing experience and their levels of satisfaction with the course. We hope to discuss several issues with participants who are highly experienced and with those who are relatively inexperienced with computers, as well as with some individuals who are highly satisfied and with those who might be less satisfied with the course. The issues addressed in the groups will include perceptions of usefulness of the hardware and software used during the program, issues regarding classroom integration, and relevance to the state Standards of Learning.

Analysis of the Data

Background computing experience. Self-report information will be descriptively analyzed to describe the participants. A primary purpose of this data collection is to establish a baseline from which future comparisons can be made. For example, if teachers are coming to the courses with increasing levels of word processing experience, this aspect of the course could be downplayed to allow more time for “high-end” technologies to be explored. Course revisions such as these will be required to maintain current content. We've set 18 months as the window that K-12 teachers have for completing the series of courses leading to the certificate.

Course evaluations. The results from the course evaluations will be quantitatively described using summary statistics, charts, and graphs. By examining the results from the course evaluation forms, we will be able to determine which aspects of our program are perceived as being most effective and which are least effective. This information might also provide some ideas as to where teachers might most often see “problems” in using computers: hardware, software, or classroom integration. The course evaluations will also provide a “real-time” monitoring function, enabling course developers to learn from each course experience, and make modifications as they are required.

Focus Groups. Transcripts from the focus group interviews will be reviewed and examined for emerging concepts and themes.

Our Presentation

Due to the fact that we are still collecting data, and will be for the next few months, this paper will differ in some ways from our presentation. In this paper we have attempted to provide a rationale for our project, and a description of our approach to solving a well-known problem: the meaningful use of computers in education. Our presentation will consist of (a) providing an overview of the courses within the program, (b) the rationale for selecting the courses and the project-based approach that we are using, and (c) some examples of student projects from the first few courses that have been completed. Research results will also be shared through our presentation.

---

410 — Technology and Teacher Education Annual — 1998
Computers offer a promise of change to our educational system much the same as the book changed education, by allowing storage of information over time and place (Moursund, 1992). They have impacted almost every aspect of society. However, schools today remain much the same as they were forty years ago, little changed by the possibilities provided by the technology (David, 1991; Ingram, 1994).

According to Cuban (1986) the teacher is the gatekeeper of innovation, for it is the teacher who must implement the innovation. The teacher is the key factor in using technology to bring about positive change. But how do teachers become the innovator? Teacher education must provide the skills, knowledge, attitudes, and models for teachers. Teacher education programs are the catalyst for change (Ingram, 1994).

Teacher education institutions have a unique opportunity to prepare teachers to use technology in ways that bring about positive change. The International Society for Technology in Education (ISTE) has developed a set of standards for preservice teachers. These standards include goals in three major areas: basic knowledge of computer operations and concepts, personal and professional use of technology, and integration of technology in instruction.

If preservice teacher education is to make a difference in how teachers use technology then teacher educators must model effective technology use. As seen in several models of faculty development at teacher education institutions, faculty can integrate computerized lessons and presentation software into existing curricula; use e-mail to communicate with students, colleagues, and professional organizations; utilize application software for preparing student materials, recording student progress, and calculating grades; and integrate the Internet into class resources (Ennis & Ennis, 1996; Topp, 1995).

According to the Office of Technology Assessment (OTA) report Teachers and Technology (1995), too few faculty are modeling instructional methods that integrate computer technology into teacher education courses. As indicated by Ingram (1994), the missing ingredient is a college and university teacher education faculty that is sufficiently technologically literate to accomplish these goals. However, faculty are reluctant to use computers in preparation and delivery of courses (Ennis & Ennis, 1996).

Several barriers to faculty development are identified in the literature: lack of access to adequate hardware and software, lack of active support from administration, time constraints, limited recognition of the potential of technology in education, and faculty who are uninterested or unwilling to take the risk and make the commitment (Roberts & Ferris, 1994; Staman, 1990; Wetzel, 1995). Other barriers to the integration of technology in teacher education courses are found within the K-12 education community. These include the lack of a clear, generally accepted vision for the role of technology in education, lack of enough technology in the schools for it to make a difference, and lack of adequate teachers to be role models for student teachers (Roberts & Ferris, 1994).

Faculty resistance may also stem from insecurity and fear. Replacement of teachers with machines was a concern from the early days of technology development. However, change may be more threatening than replacement.

The threat from technology may, in fact, result more from an anticipated role change than from the fear of being replaced. The effective use of technology within the organization of schools may require changes in the curriculum, the way in which teachers transmit the curriculum, the way in which students learn, and the way in which schools operate. And each of these changes implies a change in how teachers do their work. A sense of efficacy comes from work well done. To change the way professionals are expected to do their work threatens their sense of efficacy. This may make individuals particularly resistive to change (Harrington, 1991, p. 50).

There are several strategies that have proven successful in effecting changes in the use of technology in education. At the University of Nebraska at Omaha a model for faculty development for technology integration was built upon three key elements: availability of equipment, faculty training, and expectations of utilization of technology in
academic activities (Topp, Mortenson, & Grandgenett, 1995). Faculty training focused on awareness, experience, and integration and was provided through overview and summer immersion sessions, brown bag lunch presentations by other faculty, focused sessions with follow-up coaching and encouragement, and experiences in “supportive and comfortable hands-on environment” with knowledgeable individuals available for assistance” (p. 13).

Team teaching courses in which professors of subject area methods courses were paired with technology faculty or teaching assistants with strong technology backgrounds is one effective strategy (Roberts & Ferris, 1994, Robinson & Milligan, 1997). At Lesley College Graduate School of Education the computers-in-education faculty developed a program to integrate technology into teacher education by team teaching. Similarly, at the University of Tennessee a course was developed and taught by a mathematics education professor and an educational technology graduate student (Robinson & Milligan, 1997). Benefits for the faculty member included increased skill in the use of networks and web-based materials. Benefits for the graduate student included developing relationships with faculty, learning how to teach by coaching rather than lecturing, and developing confidence and experience in team teaching skills.

Other successful models that include mentoring and one-to-one tutoring have been used as part of on-going faculty development both in K-12 and higher education settings (Beisser, Kurth, & Reinhart, 1997; Farley, 1992; Gonzales, Hill, Leon, Orrantia, Saztin, & Sujo de Montes, 1997; MacArthur et al., 1997; O’ Bannon, 1997; Pryor & Bitter, 1995-96). In the “Learning Technologies Program” (Gonzales et al., 1997), masters and doctoral students mentor faculty members two hours a week after setting specific goals. Since equipment availability is often a barrier, this program has made available a multimedia teaching classroom and near-by labs with Mac and IBM platforms. The program benefits both the faculty and the students. Students gain experience through interactions with different faculty members, who share expertise and model effective behaviors of faculty activities.

Zachariades and Roberts (1995) describe the process and the benefits of a collaborative effort between a graduate student in instructional technology and a language arts faculty member. The graduate student was enrolled in a seminar-type course in which one assignment was to help faculty integrate technology into their content area. Together they designed a plan of action that began with awareness and comfort, moved to experience, then integration and modeling of technology use in the course. The success was due to the individualized nature and self-paced workload, focusing on the specific needs of the faculty member.

Undergraduate students can also be effective mentors of technology skills. Beisser, Kurth, & Reinhart (1997) describe a single student-single faculty situation in which the team met for one hour each week focusing on the integration of technology into a specific course. Communication was maintained through interviews, observations, journals, and e-mails.

Ennis and Ennis (1996) outline 12 ways to motivate technology use that includes elements similar to the programs described here. These include the use of peer coaching, avoiding the one shot approach, basing the development on the faculty member’s own needs and choices, and providing technical support at the time that it is needed. Individualization of plans and availability of support are critical to success.

As emphasized in these models and others, the key elements of mentoring relationships include effective needs assessment and advanced planning, positive reinforcement, attention to personal goals, and communication (Beisser et al., 1997; Pryor & Bitter, 1995-96). The purpose of this project is to meet a critical staff development need at Carson-Newman College for technology training. Our goal is to develop, implement, and evaluate a faculty development model that makes the use of the best elements of these models and strategies. Following is a discussion of the design, description, and implementation of this mentoring project. The project is directed by two teacher education faculty, one is an educational technology specialist at Carson-Newman College and one is a subject area specialist at the University of Tennessee, Knoxville. This team approach provides a view from the inside and outside and a focus from a technology specialist mentor and a faculty mentee.

Description of Project

The faculty development model that we designed sought to formalize the key elements of mentoring relationships. Faculty members will be able to have individual help in their own offices on skills they want to learn. Students will work with faculty individually to develop teaching and mentoring skills. They will also develop new technical skills as they help the faculty member.

As the mentoring relationship develops, the student technology mentors will have the opportunity to observe the faculty member use their newly developed technology skills to do their job. From this mentoring relationship, they will observe first hand what it means to be a teacher. The experienced faculty member then becomes a mentor to the student as he/she develops an understanding of teaching as a profession.

A key element of the project is a formal commitment to the mentoring relationship on the parts of both the faculty and the student. For the faculty member this means signing a formal agreement to work with a technology student mentor.
had taken the educational technology course required for all project. These students were selected from students who interviewed about their experiences in the project. During the semester break the faculty will meet, serve as a major means of formative evaluation of the project. The purpose of the meetings are as follows: two meetings at the beginning of the semester to get the project underway, one in the middle to discuss their mentorship experiences, and one at the end of the semester to evaluate the project. These requirements, especially the journals and mentors meetings, serve as a major means of formative evaluation of the project. During the semester break the faculty will be interviewed about their experiences in the project.

**Implementation**

Five students participated in the first semester of the project. These students were selected from students who had taken the educational technology course required for all education majors and from education students who regularly used the department computer lab. The on-site project director teaches this course and manages the computer lab. Four of the students were undergraduates majoring in education. One was a graduate student in the Masters of Arts in Teaching program, a program designed for students with an undergraduate degree in a field outside of education to receive a license to teach as a part of the degree. There are 11 full-time faculty members in the teacher education department at Carson-Newman. All faculty members, except one were able to participate in the project. Due to scheduling difficulties, one faculty member was unable to begin participation in the project until after mid-term.

The students and the on-site project director examined the ISTE goals and several technology skills checklists for educators. On the basis of this examination, each student mentor developed a list of interview questions and chose a faculty member to interview. They also completed a journal entry in which they evaluated their own technology skills in light of these technology goals. After the initial needs assessment interviews were conducted, the mentors met to determine how the mentors and faculty were to be paired. As it turned out the students worked with the faculty members they interviewed. Initially students were concerned they would not have the technical skills they needed to mentor faculty. After the interviews they felt more confident that they did possess these skills necessary. Each mentor worked with two faculty members.

The student journals have become an important tool in implementing the project. Since all of the students were familiar and had ready access to e-mail, the journals were sent to the on-site project director via campus e-mail. Students e-mailed questions they had as they worked with their faculty member. They reported their successes as well as their frustrations. In addition to the students’ e-mail journals, the on-site project director sent e-mails to the faculty asking them to describe their experiences. This was not a part of the original assessment plan, but was initiated during the semester as a way of encouraging faculty members to reflect on their experiences.

The mid-term mentors meeting served as a time for mentors to share their experiences as well as discuss problems encountered so far. A central aspect of the meeting was the syllabus requirement of the learning plan that was to be developed. None of the mentors had turned in a plan for the semester, even though they had outlined in their journals what they would cover the next time they met with their faculty member. They suggested that it was very difficult to write a formal plan because they did not know what to expect. Their prior experience of planning consisted mostly of writing single lesson plans for class assignments. They suggested that a structured format would be helpful in writing a long range plan.

The final course evaluation will take place at the end of the semester. It will begin with a meeting of the project.
directors and mentors. The evaluation session will be conducted as a focus group led by the off-site project director. Questions to be discussed in the session include:

What did you gain from participating in the project?
Do you feel that you have met your planned goals with your faculty mentor?
What are your overall impressions of the project?
What would you change about the project?
Would you do it again?
What would help prepare you for participating in this project?
How did the on-site project directors’ model of mentoring help you be a mentor?

At the request of the student mentors the participating faculty members will be asked to join the group discussion. They will be asked to share their perspectives as mentees, provide feedback on the benefits they have gained, and offer suggestions for the upcoming semester.

Next Steps

Based upon the formative evaluation available, preparations for the continuation of the project contain some changes in the course requirements. The course requirement concerning the development of a learning plan will need to be restructured. Some type of format will be provided to aid the students in developing the plan. There will be an increase in the number of mentor meetings. A critical problem that still needs to be addressed is the student’s frustration with lack of faculty time and commitment to practice skills being developed. The formal evaluations conducted at the close of the first semester will be crucial in identifying some ways to deal with the issues of faculty time and commitment.

Another important change next semester will involve expanding the project to faculty outside the department of education and Carson-Newman College. New student mentors will have to be identified. Public school elementary teachers at a local school have also been identified who are interested in having a mentor. A mentorship agreement, similar to the faculty agreement, will have to be developed. Experiences gained from this semester and findings from research will continue to help us improve this mentor relationship.

The opportunity of teacher education institutions to prepare teachers to use technology to effect change is also the challenge for teacher education institutions. As projects are designed and implemented to assist in this endeavor, the ideas and results must be shared with others in order to continue the process in a positive direction. This discussion is one contribution to that effort, to that challenge, to that opportunity.

References

Teacher-mentors are needed to assist first-year teachers with the common problems/issues beginning teachers encounter (Martin & Reynolds, 1993; Niebrand, Horn, and Holmes, 1992). Mentors, serving as a professional colleague and friend, have the responsibilities of modeling successful pedagogical techniques to new teachers, assessing beginning teachers’ instructional practices, and discussing strategies to improve classroom teaching. Moreover, teacher-mentors as adult learners want professional programs to meet their specific, lifelong educational needs for both professional and personal growth (Chickering, 1994; Cross, 1991). Lifelong learning serves as means for self-renewal in an ever-changing world (Collinson and Others, 1994). Consequently, public school and higher education officials need to collaborate in preparing teacher-mentors to serve as successful models and guides for beginning teachers, as well as to meet mentors’ own professional needs (Rodriguez, Alaniz, Kajs, & Lira, 1993).

A critical component of this mentor-teacher preparation program is familiarity with technology, especially with its usage in the classroom setting. "Technology expertise can serve as a vehicle for educators to creatively explore with parents and community members ways to develop independent thinking, collaborative problem-solving, risk-taking, and multicultural sensitivity among elementary students" (Regional Collaborative Center for Professional Development and Technology Proposal, 1992, p. 4B-5). University instructors ensure that mentors demonstrate competencies based on the International Society for Technology in Education (ISTE) guidelines. Components of the guidelines include the ability to utilize computer/technology-based software/materials in a successful manner, to use computers to facilitate instruction, to demonstrate proficiency with word processing, spreadsheets, and print/graphics for both professional and personal use, to access information using computer-based technologies, and to practice reflective thinking about the application of current technologies in the instructional process (Regional Collaborative Center for Professional Development and Technology Proposal, 1992).

Assumptions in Developing the Teacher-Mentor Program

In developing a syllabus for the professional program for teacher-mentors, assumptions were made based on guidelines established for mentors by the certifying agency and on past experience working with teacher-mentors. First, participants were teachers serving as mentors for the first time or teachers who had not served as mentors within the past five years. The consequence of this was that teachers had never participated in a formal mentor education program or had not enrolled in a mentoring program within the past five years. Second, mentors would possess a diversity of instructional background and varying levels of proficiency with personal computers and related technologies. Third, teacher-mentors may or may not have computer technology available in their classroom and/or schools. Fourth, since the program would be delivered in late afternoon after teaching six or seven hours in the classroom, mentors could arrive fatigued for the mentoring program, thus influencing motivation levels. Moreover, attendance at the program could require long distances of travel by some mentors. The recommendation of weekend classes to address the issues of fatigue and distance was not an option due to the unavailability of human resources. Fifth, mentors may miss technology sessions due to campus obligations. Lastly, because of the availability of computers at the university, the computer education component of the professional program required the use of Macintosh computers. It was explained that while mentors may have IBM-compatible computers in their schools/classrooms/homes, participants could transfer Macintosh software experiences, e.g., E-mail, Internet to their IBM-compatible computers.

Teacher-Mentor Input in Developing the Professional Program

In light of the assumptions and the value of collaboration to meet professional needs of teachers, the professor solicited teacher-mentor input for the construction of the
syllabus. Mentors completed a questionnaire that requested
teacher mentor input regarding their backgrounds and experiences
with computers and computer-related technology. The
background information included the teacher-mentor’s
name, campus, district, and number of years as a teacher, grade level or specialization, and number of years as a
mentor. The computer and technology-related information
included the type of experience with personal computers; the
number of computers in their classroom; the number of
hours per week that teacher-mentors used personal comput-
ers; the accessibility to computers in the classroom and/or
school and to the kinds of software used; and their previous
attendance at mentoring courses or workshops, and if so,
when. The questionnaire also asked mentors to respond
whether they needed experience (i.e., NE) or had experience
(i.e., E) with various computer programs/technologies. The
list was based on the use of Macintosh computers because
of their availability as stated earlier. The list included
Macintosh Operating System, computer files and folders, E-
mail, Internet, and TENET (Texas Education Network), word
processing, spreadsheets, grade sheets, and database, Kid
Pix/Kid Works, CD-ROMs, and Hyperstudio. The question-
aire also asked mentors to list any other computer-related
issues they wanted discussed or practiced. The results of
the survey guided the professor in developing the computer
and technology-related lessons for the classes.

Technology-Related Software Utilized

In presenting technology sessions to teacher-mentors,
the professor utilized a variety of software applications
including Netscape Navigator by Netscape Communications
Corporation, Eudora by QUALCOMM Incorporated,
ClarisWorks 4.0 by Claris Corporation, Kid Pix by Craig
Hickman and Broderbund Software Inc., Kid Works by The
Davidson Company, The Writing Center by The Learning
Company, SuperPrint by Bruce Ballard, US Atlas and
HyperStudio by Roger Wagner Publishing, Incorporated.

Teacher-mentors were introduced to a number of CD
ROMs available from the university for classroom use
including Preschool Parade, Reader Rabbit 1, Reader
Rabbit 2, Reader Rabbit 3, Sammy’s Science House,
Treasure Cove, Treasure Mountain, Scary Poems for Rotten
Kids, The Tale of Peter Rabbit, The Velveteen Rabbit, The
Adventures of Pinocchio, Ocean Life, Cinderella, Spell-
bound, Rainforest Explorer, Weather Science
Explorer, Counting on Frank, and Reading Develop-
ment 1 and 2. The Living Books Series included Mud
Puddle, Heather Hits Her First Home Run, Just Grandma
and Me, and Moving Gives Me a Stomach Ache.

References Used in Preparing
Technology Sessions

In preparation for the computer and technology-related
sessions for mentors, the professor used various references
as background information and as a guide to facilitate
teacher-mentor learning. These references included Brown,
Ann C., Visual QuickStart Guide ClarisWorks 4 for
Macintosh, Peachpit Press, Berkeley, CA, 1996; Crabb, Don,
Guide to Macintosh System 7.5, Hayden Books, Indianapo-
lis, IN, 1994; Fraase, Michael, The Mac Internet Tour Guide:

New York, 1996; and Williams, Robin, The Mac is not a

Issues/Dilemmas that Arose during the
Professional Program

Although the majority of mentors were neophytes with
the basic use of computer technology and computer
software, a few mentors demonstrated extensive experience
with some of the software programs. When teacher-mentors
encountered a lesson familiar to them, they used the time to
assist colleagues with computer technology and to develop
their knowledge of programs less familiar to them, e.g.,
Internet. While the instructional pace was appropriate for the
teacher-mentors, at times, a few mentors had difficulty with
certain steps of the software programs. To handle this
dilemma, colleagues assisted one another in a cooperative
learning format, and a computer-literate person worked
individually with mentors. While most teacher-mentors had
accessibility to computers in their classrooms or schools in
order to practice, a few did not. These mentors were invited
to use the university computer lab or the computers in the
university library to practice computer technology learned
during the classes.

Implications of the Professional Program

The teacher-mentor professional program in technology
served two major purposes: First, mentors developed a
knowledge base of computer and related technologies to
guide and assess beginning teachers’ use of technology
during instruction. They acquired familiarity with the
technical terms of technology and the types of software
programs and CD-ROMs available for instructional use.

Secondly, the professional program provided mentors’
continuing education to assist them in meeting lifelong
learning objectives as well as to provide opportunities for
self-learning using technology. For many of the mentors this
was the first professional development program in computer
technology. This learning experience helped them “become
effective agents for their own lifelong learning and personal development," a process of self-discovery (Chickering, 1994, p. 3). Teachers became more intentional about their specific personal and professional needs. The professional program provided an opportunity for teachers to ask questions in a non-threatening atmosphere and to learn with and from colleagues. Mentors discussed common concerns about the availability of computers and related technologies, and their use in the instructional process. The ability to access and “surf” the Internet serves as a demonstrable example of the teacher-mentors’ development of self-learning. Before and after the Internet session, participants would regularly search for pertinent information to accompany instructional materials, especially for thematic units. The ability to use E-mail provided one teacher-mentor the opportunity to communicate with her son stationed 1500 miles away at a military base. At the end of the program, each teacher-mentor presented a portfolio, which included weekly self-reflections, that documented their professional and personal growth.

Conclusion

The university’s instructional and technical resources, and the process of collaboration between university faculty and teacher-mentors in determining educators’ lifelong learning needs, precipitated a renaissance in adult learning (Cross, 1991). A joint educational responsibility exists in which higher education assists classroom practitioners with the knowledge and guidance in current technology for a changing world (Cross, 1995). And, in turn, the technology-proficient mentor-teachers assist beginning teachers as well as their own classroom students to prepare for a technology-driven environment, demonstrating a positive ripple effect in lifelong learning in preparation for the 21st Century.

Training That Makes Teachers Technology Evangelists

Mary Jones  
Fort Worth Independent  
School District

Marla Shelton  
Fort Worth Independent  
School District

Fort Worth Independent School District’s Instructional Technology Department can show you how to make your technology staff development training so effective that participants will get excited and spread the word. Your training will become so sought after that teachers will eagerly apply for the classes and routinely fill waiting lists hoping to get in. Just follow these simple steps based on three “I-” words: Incentives, Inventive, and Important.

Offer Incentives

Incentives can be big as in our Technology Bootcamp, TECHS Seminar or Teacher Technologist Institute where upon completion of training, teachers get a computer, printer, and software for their classrooms. Training programs for which teachers get a computer include a minimum of forty hours and are focused on teachers with specific skill levels. The following table provides additional information.

Table 1.
Technology Training Programs - Fort Worth ISD

<table>
<thead>
<tr>
<th>Course and Extension Program</th>
<th>Hours</th>
<th>Skill Leveling</th>
<th>Incentives</th>
<th>Following Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technology Bootcamp - Selected by committee from standard applications</td>
<td>60</td>
<td>Skills</td>
<td>computer, printer, and software for the classroom</td>
<td>Contributing to class-tested technology-based lesson plan to the district during the next school year</td>
</tr>
<tr>
<td>TECHS Seminar - Selected by committee from program applications designed to highlight starting technology skills</td>
<td>40</td>
<td>Some experience</td>
<td>computer and software for their classroom</td>
<td>Developing and share a multimedia project which addresses a housing objective in their grade level or subject area</td>
</tr>
<tr>
<td>Teacher Technologist Institute - Selected by principal using guideline criteria</td>
<td>65</td>
<td>Some experience, used processing, skills required</td>
<td>computer, printer, and software for their classroom</td>
<td>Receive 30 hours of technology training to support their classroom and complete one class-tested technology-based lesson plan to database</td>
</tr>
</tbody>
</table>

Incentives can be small. Our Take the Class - Get the Software sessions allow teachers to receive training and get software to use with their students the next day. For these classes, we select software for specific grade levels and subject areas that reinforce our district’s objectives. To take the class, teachers must teach the appropriate level and have a computer in the classroom or regular access to a computer that will run the software. For example, if the software is specified for grades K-2, Macintosh format and comes on a CD, the teacher must teach one of those grades and have that type of computer with a CD-ROM drive to take the class. This method of training has placed a lot of good software into immediate use by our students and has given teachers another way to present or reinforce an objective.

Incentives can cost nothing at all. Valuable opportunities can be made available to your participants without additional cost. For example, training can be tailored to meet specific needs that teachers must address. In the fall of 1998, all Texas teachers must integrate the Texas Essential Knowledge and Skills (TEKS) into their curriculum. Some teachers would consider our class offering Training and Lesson Plans for Integrating the TEKS for Technology into your K-5 Curriculum vital without further incentive. Training can also address specific groups such as this class offering: Using Technology to Address Learning Styles and Special Needs of Students in Alternative Schools. If the teacher knows that the training will meet a particular or individual need, that is often incentive enough.

Be Inventive

Not all teachers will jump into technology use just because their students love it or because technology would make some things easier for them. Offering classes that use technology in unusual ways may be just the hook to reek in an otherwise reluctant teacher. We offer a whole series on Technology and Textiles with the hope that teachers who enjoy these classes will be encouraged to use technology in their instruction. The series includes computer quilt design, how to make cloth books, computer pattern customization, and computer conversion of scanned images to cross stitch designs. We even demonstrate the use of sewing machines with computer chips that will sew your computer-entered image. Along a similar line, we offer T-Shirt Design and Print where teachers use a computer to create a design, then use our commercial press to put it onto a T-shirt. That same press or our special laminator can create name badges. Mouse pads, refrigerator magnets, bound books, and much more can be computer-created and finished on our special equipment. Even our more conventional classes are focused on empowering students and teachers with technology, not just using technology. For example, a class concerning laserdiscs emphasizes repurposing the laserdisc to fit the

Graduate & Inservice Education — 419
teacher's objectives rather than just how to use laserdisc
technology.

**Important Resource**

Your trained teachers are *Important* to your training
network. Value and support them as they use technology.
The majority of teachers we train are asked to contribute
something to our technology training program. For many
teachers it is a technology-based lesson plan that is
presented to other technology-using teachers at a meeting
following their training. These lesson plans are added to a
database that is given to all contributing teachers and made
available to all district teachers through our preview lab.
Other teachers contribute a multimedia project that is begun
during their training and presented during the following
semester. These projects are written to CD and made
available as well. Some teachers contribute training for other
teachers in trade for their specialized training.

Our most ardent technology evangelists volunteer for
high-end training such as PhotoShop, Premiere, and video
editing and become the district's training specialists for
those applications.

**Continued Support.** Every teacher who takes our
training is recognized and supported in some way. Trained
teachers receive our newsletter which highlights teachers
using technology, provides tips for computers, printers,
operating systems, and some common software; announces
contests, grant opportunities, and conferences, and includes
a calendar of our scheduled training classes. The next step
of training is offered regularly for teachers at all skill levels.
*Bootcamp Booster* classes help beginners to take their skills
to a higher level. Since both word processing and using a
database are addressed in Technology Bootcamp, one
Bootcamp Booster topic is *How to Do a Mail Merge* which
uses both previous topics. Teacher Technologist Institute
graduates can move to Teacher Technologist Level II and
Teacher Technologist Level III by completing training
requirements from previous levels and taking advanced
training.

**Stand-Alone Training.** TECHS Seminar and *Take the
Class - Get the Software* participants may take more stand-
one training in everything from *Scanners, Cameras, and
Video Capture* to *Using Presentation Software*. The more
technically oriented may take classes like *Operating a
School BBS* and *Build Your Own Computer*. Of course,
*Integrating the Internet Into Your Curriculum* is in demand
right now as we finally have Internet access in all our school
libraries. Teachers whose subject areas have electronic
textbook adoptions receive training in using that special
equipment and in teaching strategies that take advantage of
the technology.

**Recognize Achievement.** We have an annual *Celebrate
Teaching with Technology Teacher Awards Program* that
spotlights exciting uses of technology in instruction. The
prizes for this program were chosen by a committee of
teachers to be sure that what we offered would be desired by
the entrants. Of course, the top prize is a computer, printer,
and software for the classroom. The first year of the
program, wiring for a classroom Internet connection was also
included in the top prize. There are winners in each contest
category as well as an overall winner. Categories are divided
by grade level so a Kindergarten teacher is not competing
against a High School teacher.

**Funding.** The scope of training incentives we can offer
is enhanced by the Texas Technology Allotment. Our
school district receives funds from the state according to
enrollment. This money may only be spent on hardware,
software, and technology staff development.

**Evangelistic Spirit.** When all is said and done, teachers
who take our training tend to spread the word. That's why
we say our Technology Training Makes Teachers Technol-
yogy Evangelists.

When teaching strategies for classes with writing are reexamined through the methods and contexts of computer teach-nology strategies, both practices (re)become refreshingly effective. This student and teacher reflection on learning and practice promotes lifelong metacognition, offers educational empowerment, and enables reconciliation between content and method through building on the known and creating exciting avenues for the new.

Computer Assisted Teaching Strategies as High-Impact Classroom Strategies

Many secondary and post-secondary students are becoming quite familiar with the benefits of anonymity and the elimination of time and space when communicating through email for purposes outside academe. However, they may still struggle with fluency and voice in their "academic" writing. By reflecting on this medium’s relationship to the writer, the text, and the audience—as a class—and by examining such related issues as fluency and voice by sending (virtual) email inside the classroom without computers (passing notes), the opportunity for students to empower their writing becomes immediately apparent. For example, ask each student in a class to write one sentence on a specific issue and pass it to another student in the class. The new recipient can then write an agreeing or rebutting position and either pass the note back to the originator (the known participant), or to a third person in the class. After a few iterations, ask students to reflect on the differences between responding to positions that agree and responding to positions that rebut the perspectives raised by known participants then, examine differences in responding to known participants versus responding to perspectives of the semi-anonymous (positions from unidentified students in the class). How do varying audiences affect the rhetorical stance of the writer and the text? How does the writer invent the audience or how does the audience invent the text (Ede & Lunsford, 1984)? Ask students to reflect on how it might be different to respond to perspectives of people who are “completely” anonymous (outside of the class). How does what’s known about the writer shape the significance of the text or the audience’s relation to the text? While these questions are not new, by metacognizing the electronic medium in terms of the paper-based model, by passing notes as virtual email, content learning is enhanced.

This same metacognitive reflection can be adapted to other activities in our classroom instruction. Is it possible, for instance, to simulate freewriting on a computer through paper-based methods? Perhaps not, but the attempt to do so will demonstrate the recursive nature of writing. Freewriting is a process-oriented approach to allow writers to engage in expression with as little critical mediation as possible. When freewriting with pen and paper, however, because most writers must look at their writing hand when composing, immediate visual and mental recursion takes place. Writers can think about and see what they are writing, as they write it (Perl, 1980). When typing on a computer, however, writers do not need to worry about penmanship and, if familiar with the keyboard, do not need to watch their hands or the screen. It would seem in this case that recursion exists solely in the mind (Berthoff, 1981). How does this different process of writing change the rhetorical triangle? Does the writer on the processor “embrace the typo” or does the practiced right-hand pinky of the typist instinctively reach for the Backspace-Key? Further, how do the sounds of the typewriter—or the imagined echoes of their plucking—affect one’s writing? What about the sound of other keyboards flapping about in the classroom? Does the accelerated pace of familiar key combinations move freewriting in different directions? What about the need to save one’s work? If a writer is comfortable with her handwriting will her fluency be more confident than a writer whose courier typeface is annoying? Does re-processing a draft on a computer or on hardcopy promote more re-visioning or more product-based editing? Applicable inquiries on traditional teaching theory moves students to question their own process of writing. Reading...
as well as writing and thinking develops into a truly interactive process. Students and teachers can energize traditional strategies of learning and teaching if the medium and content are reconciled, and if class inquiry is rooted in known practices.

"Known-Anonymity": The Known-New Contract in Synchronous Strategies

This reflective, known-new contract can be applied to collaborative, synchronous activities as well. Reflective learning involves being wholehearted to the project at hand, sincere and open-minded to each perspective, and responsible to the hidden curriculums or ideologies that present (Woolfolk, 1995). A writer’s voice becomes more wholehearted and sincere if her confidence isn’t checked by an unfriendly conception of audience. It doesn’t take long for teachers who use chat rooms on the Internet or synchronous communication programs to discover that student voice may be wholehearted and sincere in these environments but often lacks a sense of responsibility. The newly found freedom that this malleable audience and “flexible text” promotes can often be counter-productive (Zeitz, 1992). Students often move too quickly: not from the known to the new but from the known to the unimaginable. It seems that for the student, the unimaginable demands no responsibility. There are, however, methods of harnessing virtual anonymity which offer the freedom effect and encourage voice and fluency yet inherently demand responsibility. Simply put, writers who consistently interact with the same “anonymous” audience over a period of time are more apt to become reflective learners. Students realize how the unimaginable can possess an (implied) image, and begin to engage in “known-anonymity,” the virtual (you) understood.

Teachers need to be taught and learn strategies which build on the known to get to the new. These strategies, however, must be rooted in the students’ consciousness and embrace reflective lifelong learning that includes responsibility as well as wholeheartedness and sincerity. Exploring the use of electronic synchronous chat programs in multi-geographic collaborative learning groups can offer a metacognitive reflection model that makes use of known-anonymity to encourage such responsible learning habits. These strategies, when examined in terms of classroom-based practices, much like virtual email, (re)simulate for students and teachers responsibility in collaborative learning groups.

Known-Anonymity Through First Class Client and Other Environments

Modeling has often been viewed as the most effective teaching strategy that can be employed. Through modeling a successful synchronous chat with students inside the classroom, without computers, students are encouraged to participate in electronic chats much more reflectively. An asynchronous, synchronous chat with computers can also be modeled. For instance, ask students to write on a computer, switch seats, and continue the chat asynchronously. Further, reflecting on how students in a class come to know one another encourages the productive development of the unimaginable to be known-anonymously (this encourages open-mindedness toward subcultures). That is, while there exists in electronic chat the opportunity to express ideas freely without some of the nonverbal intimidation that a walled classroom might hold, the community of learners in multi-geographic, synchronous communication strengthens each time these necessarily-responsible “anonymous” collaborators reconvene. Students build a sense of free-responsibility in their particular anonymous groups, responsibility that is intrinsically chosen and not demanded by a teacher. But why use collaborative groups with participants from other communities?

Multi-geographic conferencing does encourage open-mindedness and a sense of “respectable” responsibility. These chats, rooted in the interests of the students, also create natural bridges outside the academy which serve as models for classroom inquiry about community and subcultures. Students use their own experience as foundations to interact with the perspectives of others students. One ongoing set of courses can serve as a model.

What happens when a student from Oregon, a student from Indiana, and a student from New Hampshire regularly meet in synchronous chat as a peer-response group? While the students remain relatively anonymous to one another, the social distances between each student and their relative academic communities are (re)explored in terms of geographically-inspired distances between each student in the group. That is, because each student in the group has some reference to institutional marginality in common with each geographically-distant peer, the students discover this common link which bridges social and geographic distance. Further, differences between the teachers of these students and their discourse communities are (re)explored. This is the practical teaching of reflection rethinking.

As we strive to rethink technology in teaching from the less instrumental to the more substantive, real techniques on how to integrate technology into our teaching practices need to be examined. The theoretical hypothesis of the power of known-anonymity in electronic collaboration can be investigated through many different computer programs. One set of environments which has helped students discover the usefulness of peer-collaboration through known-anonymity includes the use of FirstClass® (FC) and a web-page learning system. FC is an Intranet Client that has been an environment that is easy to explain to distance learning students. FC offers our students seamless remote access to a series of user-friendly folders and conferences, electronic mail, and synchronous chat, all in one package. More information about this program can be found through
http://www.softarc.com. Although FC does incorporate web-pages, we’ve built a set outside FC at http://www.bsu.edu/classes/newbold/104. Known-anonymity has played a key role in the development and practice of this course.

Because many of our current students are from previous sections of computer assisted writing courses, and because this is distance learning, our students begin the course with some knowledge and experience of working in networked environments. A sense of community develops within groups and then between groups in FC and we ask them to share their work and their community with other students outside of class. We move from the known to the set of web-pages outside FC. These pages serve as jump-off points to other synchronous mediums such as LinguaMOO at http://lingua.utdallas.edu; to other Online Writing Labs such as Washington State University’s http://owl.wsu.edu; and to other class web-page learning systems where students introduce themselves to students at programs from three different states.

Using FC, students in our distance learning sections begin their journey through our class folder (see fig. 1):

Informal writing assignments which require process-oriented, asynchronous dialogue with the class readings, as well as synchronous conferencing within each group, are offered each week. Formal writing projects which explore various student-centered themes in the course, such as “The Writing Process,” “Time, Space, Relativity, and Reliability,” and “Mirrors and Labyrinths,” are also scheduled. A mailbox flag notifies each student their account has received new information to explore. Once the information has been reviewed and interacted with, the new information becomes the known.

Each group member shares the process of their thinking within their own group community and then offers to the other groups particular synchronous chats in the form of “Public Chats.” Each group has their own set of folders to store their recorded chats, their peer responses, their essay drafts, and their dialogue journals. Each of these process-oriented tasks are reviewed by the instructors as well as each group member throughout the course (see fig. 2).

Thus, a student has the opportunity to gain the confidence necessary to share his or her voice with others outside his or her immediate community through a series of known-new contracts. The reflective known-new contract is extended to the reflective known-anonymous contract through the class web-page learning system; carrying with it the hidden curriculum that responsibility as well as sincerity and wholeheartedness is a lifelong endeavor (see fig. 3). Through synchronous and asynchronous process-writing curriculums, teachers in Oregon, Indiana, and New Hampshire have pooled their learning communities together to foster a rich collaborative tool. Interacting courses do not necessarily have to be distance learning courses: while it is difficult, scheduling online conferencing between three different courses in three different states in three different time-zones can be done.

Perhaps the most effective teaching strategies are those which are useful tools and provoke a special kind of response from the faces of students: something that says “coolness.” Exploring known-anonymity through FC, and reflectively extending this process to other communities through multi-geographic learning groups, has created an inhabitable hyperspace which has offered a shared sense of metacognitive “coolness.” As teachers strive to make the “Information Age” the “Interactive Age,” exploring such teaching and learning strategies as “known-anonymity” is
not only useful to promote lifelong learning in the transitioning times we live in, it is absolutely necessary.

As literate adults we listen, speak, write, read and use technology to problem solve and accomplish the tasks of daily living. Schooling needs to be a mirror of the society a child will need to function in. Integrating reading, writing and spelling in the curriculum have been shown to be effective means to this goal. This paper will present two approaches to the integration of reading, writing, and spelling with technology for early literacy.

Research

Brain research (Sylwester, 1995) supports the finding that the brain learns holistically and in an integrated fashion. Isolated teaching that expects the learner to make the connections between various subject areas is complicating the task for the brain. The learner often does not see the connection between this type of learning and the real world in which they live. Through integrated reading and writing lessons and language experience activities aligned with science, social studies, math, and other subject areas, children learn that reading and writing are not just for learning how to read and write; they are for life (Jensen & Rosen, 1987). During the early years of schooling, both reading and writing serve a variety of child-generated pragmatic functions, ranging from letter and message writing to thank-you notes to list making, story making and research report writing. Clearly, the teaching of reading and writing must not be separated (Heller, 1991).

Simi Star Project

Children in six school districts, twenty-four classrooms, were presented with an integrated writing, reading and spelling program supported by the computer as a tool for producing their work. Evaluations of over 2,000 writings of these children showed that they were writing and reading two levels higher then their peers in classrooms without technology support (Casey, 1994). Five years later a visit was made to observe the students who had started with computers integrated into their classrooms. These students had access to networked computers in the classroom as a tool to write and problem solve for from kindergarten to sixth grade. What differences had this made in their learning? As sixth graders they had been winning the district writing contests every year, and they wrote research reports of high quality way beyond what would be expected for a twelve-year-old. They had formed a WorldWide Web club and were designing their own WEB pages. Most of them had global penpals they communicated with daily from the classroom. Several were involved in global on-line science projects. They used Powerpoint in creating their science and social studies reports as well as HyperStudio for designing multi-media presentations. Using the computer as a daily communication tool was as common to them as a pencil has been to past students.

In interviews, they reported that they had influenced their parents to purchase a home computer and gotten their parents on-line. They reported that they felt a part of the technological job force they would one day enter. Several of them had ideas for improved technology that they were e-mailing to Bill Gates at Microsoft; there seemed to be no limit to their enthusiasm and creativity using the technology. Most impressive was the way that various students used the computer to highlight their own personal strengths. Some were already fantastic graphic artists and electronic animators; others wrote the poems and stories that won the writing contests and still others were focused on global on-line communications and projects. The school WEB page was the pride of the entire class since all were involved in constantly adding videos, personal information and photos to keep it lively and up-to-date.

Writing to Read and Young Children

Writing to Read (WTR) is an early literacy program developed in the early 80's by Dr. John Henry Martin, an educator with 35 years experience in elementary education. Writing to Read 2000 has been helping kindergarten and first grade students across the nation write and read in their own natural language. As recently as 1988, over 1 million preschoolers, kindergartners, and first graders had already experienced WTR in over 5,000 labs and classrooms in schools throughout the U.S. (Grimm, 1988).

A vital component of the Writing to Read 2000, program is the creation of a literacy rich environment which provides numerous opportunities for writing, reading, speaking, and
listening. Using a multiple learning-center approach, the Writing to Read 2000 environment provides opportunities for the engagement of multiple modalities-visual, auditory, tactile and kinesthetic. The purpose of this program is to enable children to write and ready by using their own natural language. The major focus of the program is on children's daily writing of their experiences on the talking word processor, but at the same time computer software introduces the alphabetic principle, or the idea that the words of our language can be constructed with sounds, or phonemes, which are represented by letters or combinations of letters (Martin 1986).

**Language Processing**

Today with the sophisticated word processor replacing the pencil as the writing tool of choice, learners can put their own thoughts and ideas directly into the computer and see what they wrote, hear what they wrote and print out a professional copy of their words and ideas immediately for their enjoyment and to be read to all interested parties and as proof of their ongoing literacy development. I have called this new process of converting our language experience stories to print via word processing, Language Processing. Writing to Read 2000 and similar early literacy programs using technology and learning centers in the classroom can provide students with language processing support throughout the day in all curriculum areas. One hour a week visits to a computer lab are not sufficient to allow the power of this writing, learning tool to have any lasting effect on learners. This is a tool that must be as available as a pen or a pencil. Writing must be practiced daily in conjunction with reading good literature and classroom discussions and explorations of topics students need to know and are interested in learning.

**Qualitative and quantitative evaluation of Writing to Read**

In an effort to demonstrate to the educational community and test for themselves the effectiveness or lack of effectiveness of the Writing to Read program, six major California School districts joined in a partnership with IBM to get the computer equipment and then hired me as an outside educational consultant to write a detailed qualitative evaluation plan and then conduct a major two year evaluation study. Having done a significant qualitative evaluation of school reading programs for the ABC Unified school district in 1984 I had experience in this research methodology (Casey 1984). In fact the qualitative evaluation plan gave a much more accurate picture of what the innovation had accomplished. Over 1,000 writing portfolios were collected from K-1 students representing 29 classrooms in 6 school districts. Included in the population were several Spanish-language classrooms, ESL classrooms, and classrooms with learning handicapped students. All students in the experimental Writing to Read program averaged at least two writing levels higher than those in the control classrooms.

The experimental group had a significantly higher positive reading attitude than the control group. Students identified as ESL, LD, ADD achieved the same benefits from the program as did the other students.

**Riordan Foundation**

In 1987, lawyer and philanthropist Richard Riordan visited a Writing to Read site and was impressed with the early literacy development of the young children he saw there accomplished through the use of technology. Convinced that early learning and early intervention was essential to bring literacy to all of the students of Los Angeles Riordan formed a foundation to help provide computer equipment to schools that were willing to pilot these new programs and provide training and implementation for their teachers. He was dedicated to giving all students this early literacy environment. The Los Angeles Roman Catholic Archdiocese was one of the first groups that Riordan made his generous offer too. The Los Angeles Archdiocese is the largest in the United States, both in terms of territory and population. It spans Santa Barbara, Ventura, and Los Angeles counties. Several of its schools contain large pockets of Hispanic and South East Asian (Korean, Vietnamese, and Cambodian) cultural minorities. At first their response was rather cool, perhaps the sentiment being..."if God had wanted us to have computers, he would have mentioned it in the Bible." However they were all fine educators dedicated to the early learning of their students and willing to give it a try. Once their computers arrived in their schools and they had the opportunity to witness the empowerment of the young children they served, they rapidly became converts to this new technology. One of the very same sisters who reluctantly agreed to try the program in the beginning, when I phoned her a year later to find out the progress and ask if she would like to return the lab, she said, "absolutely not, why it is a miracle!"

Now nine years later 160 out of the 320 Archdiocese schools have computers in the classrooms. Sister Agnes Jean Vieno is the enthusiastic and capable Writing to Read Coordinator. She proudly told me, "all our children can write and read at five. Teachers see what happens when the children are interested, involved and empowered by the computer and get very excited. Success of the children makes believers of the teachers. Now the teachers from all the other grades want computers in their classrooms.

Sister Agnes Jean strongly believes that computer technology belongs in elementary schools. "We live in a technology-oriented age. Our society is permeated with computers," she says. "We're all turned on by media. It's natural for little kids to sit down without any fear at all in front of technological components of any kind, including computers, and go ahead and use them as tools. It would be a wasted opportunity if schools did not capitalize on the attraction youngsters feel for computers.
Unlike television or videocassette players there's something magical about computers suggests Sister Agnes Jean. To get a computer to work, you have to do more than simply turn it on. "With a computer you have functions to perform," she explains. "How you use those functions is going to change that piece of media. Either we teach our youngsters to use it well or we're cheating them. Children's ability to get and hold a job in the future is completely dependent upon whether they are computerize. "One of the most important results of the program," suggests Sister Agnes Jean, "is the aspect of self-image, the improvement in most important results of the program." A recent study in a computerized learning program for over eight years were asked to give their response was the self-esteem of the child and the belief or attitude that they can be a success at writing and reading, so important for any beginning learner. Next they mentioned that the computer whether in labs or in the classroom offered students the opportunity to be completely independent at managing a lot of their own learning.

Mary Odell is the director of the Riordan Foundation and she told me that they have been involved in state-wide implementations of Writing to Read in the states of Mississippi, Rhode Island, West Virginia, Alabama, and Vermont as well as the many California Schools. To date the Riordan Foundation has participated in funding approximately 1600 Writing to Read projects in 36 states. To those who comment that schools cannot afford this type program, she points out innovative educators like those in the state of Illinois who have found resources by decreasing the thousands of dollars previously used for large textbook buys and freeing up funds for technology. Children have been shown to be much more avid readers of the stories they have written and literature books they have selected then any basal stories.

Now fourteen years after the beginning of this technology innovation for early literacy, I attended a Focus meeting of the Riordan Foundation, formed eight years ago by the Mayor of Los Angeles, Richard Riordan, this foundation has given 8 million dollars to date to support technology for early literacy in our schools nationwide. I listen to the success stories from the Los Angeles Unified School District and wonder what it will take for us to finally give all our children this opportunity. The labs in L.A. Unified never sit empty, after school and on Saturdays, pre-schoolers and illiterate parents work as a team on joint family literacy projects.

When the leaders of school districts who had used this program for over eight years were asked to give their summary of the most powerful aspect of WTR, their first response was the self-esteem of the child and the belief or attitude that they can be a success at writing and reading, so important for any beginning learner. Next they mentioned that the computer whether in labs or in the classroom offered students the opportunity to be completely independent at manipulating and using the technology by themselves. They felt this independence and ability to create their own pace and literacy acquisition was a key to success.

Summary
Summarizing seventeen years of global research on the use of technology for early literacy, the proof is undeniable, using computers in the primary classrooms has been proven to have the following benefits:

- Provides students with tools to build bridges from the spoken to written languages
- Enables students to write what they can say and read what they have written
- Utilizes the students' natural language base
- Uses integrated multi-sensory instructional methods
- Teaches students to be responsible for their own learning
- Takes advantage of advances in computer technology
- Technology has been shown to have an enormous positive effect on early literacy development for the children of the world, all of our classrooms now need to be equipped to support their learning.

There has been a tremendous increase in the use of technology in today's classroom. With major technological changes occurring at unprecedented rates, it is often difficult for teachers and educators to remain current on software and hardware advances. As software and hardware vendors compete for market share leads and innovation, and as the technological advances continue, the gap between the use of technology and the teacher increases. Everyday teachers are already bombarded with school, district, state, and federal mandates, it is now become almost impossible to keep educators abreast of such changes. Solutions to this ever-evolving problem must be provided and applied to our current situation.

During teacher education programs pre-service teachers are trained in uses of technology, application of various software programs, and taught ways to involve computing power into their classrooms. This little time spent during pre-service programs by no means presents a thorough training of the array of applications found in the classroom. In addition, by the time a student finishes his/her program, the technology has changed. These rapid revisions never give new teachers the opportunity to stay current with the most recent innovations.

Due to the numerous responsibilities a school-teacher must perform, in addition to rapid technological changes, current educators find it difficult to keep current on the most recent advances in educational technology. In-service training programs are trying to combat such occurrences, but have to balances other district needs, financial considerations, and various state stipulations. These issues are addressed by the poster session presented at the 1998 Society for Information Technology and Teacher Education (SITE) conference in Washington, D.C.

Issues of focus for the poster session include providing approaches to solve two major issues: (1) how to keep teachers current with today's technological advances, and (2) identifying what types in-service programs school districts can perform to keep their teachers on the cutting edge of technology.

Technology is continuing to develop at an accelerated rate, bringing new opportunities for teacher educators to share new skills and information. As the field of instructional technology develops, the need for strong instructional design increases. Instructional design is a process in which instructional problems are addressed by a systematic analysis of the conditions needed for learning. Though many design models exist, twelve authors impart their perspectives and address these design aspects as they impact their educational experiences.

Ahern, Mize, and Burleson begins this section discussing issues in design regarding the implementation of technology in today’s classroom. They address the need for task and technology matching while focusing on factors in design.

This section progresses with Jin and Willis’ article which focuses on the creation of an instructional package. Their package uses technology to introduce pre-service and in-service teachers to theory, practical teaching and learning implications of constructivism. The creation of their web site, The Constructivist Educator’s Page, was developed using the Recursive, Reflective, Design, and Development instructional design model. This model is the scheme that guides their process of design and development while meeting their educational goal.

Lohr’s article addresses an alternative instructional model, the ADDIE model. She uses this model in the implementation of her Web-based instruction. In her paper, she challenges instructional designers with the dual task of designing good instruction while providing clear directions for access and use of information.

The fourth article is Cormer and Geissler’s. In their paper, they propose a methodology for evaluating instructional software. This method is designed to acquire software effectiveness in the classroom setting. Cormer and Geissler’s writing also address issues a novice evaluator may need to consider when evaluating software applications.

Abramson’s paper continues with evaluation by addressing computer-supported learning. This process involved a study which was used to learn about the various elements that contribute to successful, computer-supported learning. Abramson also identifies recommendations from home-users and teachers in the conclusion of her article.

Schoeny and Strang follow by using LearningLinks for the construction and evaluation of content modules in teaching. Their program is designed to provide guidance to users while they construct self-directed learning modules. LearningLinks is demonstrated as a well suited application for achieving outcomes such as learning definitions, spatial orientations, and interrelationships between content elements. Faculty at other postsecondary institutions are invited to cooperate.

Carlson’s article moves from evaluation to addressing courseware. In her paper, she reflects on her own experiences in the development of two courseware projects. Even though her projects were not modeled after one other, both used a holistic design paradigm. Carlson identifies the effects of this holistic design, discusses the classroom assessment and teacher input aspect of the development process. Her article concludes by stressing the critical role played by formative evaluation in the development process.

The next article in this section addresses the development and utilization of software to analyze teaching performance. In their article, Stranbrough and Stinson, show how software programs can be used to facilitate the collection, analysis, and reporting of observable teaching behaviors. Their program, called The Evaluator, is based on researched teaching behaviors which have been shown to influence student learning. Effectiveness of the reports generated by The Evaluator may lead to positive behavior changes in classroom teachers.

Jackson and Brent address, POLIS, a web course construction kit in their article. They discuss POLIS in terms of attempting to meet the demands of faculty and administrators who want innovative instructional support tools. In their article, they identify the major purpose of
this developmental software for building teaching materials as well as for the dissemination of information over the World Wide Web. Jackson and Brent emphasize the need for making this process as easy as possible.

The next paper moves to a case study approach where the authors, Graves, Barnett, Gamble, and Kolak present the use of this forum to teach about instruction design. In particular, they focus on addressing the needs of a teacher education program at the University of Houston. Their case study involves implementation of instructional design into teachers education at the graduate level.

Gibson, Sebastian, Herber, and Mayhew, in response to the needs of American Indian students of Utah, designed a group of collaborative multimedia courses. They identify the need of these courses as a way to prepare teachers to work more effectively with American Indian students. The development of these courses as well as the theory used to design these courses are identified in their writing.

This section concludes with Last, O'Donnell, and Kelly exploring the influences of student's prior knowledge and desired goals on the benefits and dilemmas while using hypertext. The authors used student interviews to understand and examine the pathway taken through a hypertext system. The experiences of the authors in this section will help the development of instruction across many areas of teacher education.

Emerging Technology Factors in Design

Terence C. Ahern
Texas Tech University

Charles Mize
West Texas A & M University

Kathy Burleson
Texas Tech University

Current computer technology has given us faster machines with more raw power than was imaginable just five years ago. It has been said most computers have a half-life of about 3 months. As soon as you purchase the equipment the new models are starting to roll down the assembly line. Given such a rate of change, educational computing is struggling to keep up. This is not a new problem as Taylor wrote in 1980 that “the application of computing to education encompasses a range of complex activity, formidable in its apparent diversity” (p. 2) and can be confusing for even sophisticated users of computer technology. His observation is even truer today.

Schools are pressured to use not only the more traditional technology but to embrace the more exotic of the new communication tools such as the Internet and the World Wide Web (WWW). Schools are expected to purchase the latest and greatest technological marvels for the classroom. Teachers are also faced with enormous pressures to implement technology, which according to the media and pundits, will revolutionize teaching and learning. The major problem for teachers besides access is how to effectively choose from a myriad of innovations which one is most appropriate given the instructional task.

Teachers are caught between two views of technology. The transparent view, in large part championed by Clark sees the instructional outcome as paramount. According to Clark (1983) the technology used to reach the goal is unimportant as long as the goal is reached. Consider fixing a loose bolt. The goal is to tighten the nut which can be accomplished with a variety of tools: a pliers, an open-end wrench, a socket wrench etc. If we tighten the nut, then it really does not matter which tool was used as long as the goal was accomplished. Technology is only a means to an end. If the technology works it becomes transparent to the user as a result.

The revolutionary view, in contrast sees technology as an end in itself. In this view the technology revolutionizes the way we do things such as how we teach, learn, interact etc. These powerful technologies by themselves are able to transform schools instantly not only in how teachers teach but also in how students learn.

Technology is not transparent nor is it all powerful. There is a reciprocal relationship between the user and the tool. If a pliers was always the best way to tighten a loose nut, there would be no reason to invent a socket or adjustable wrench. In the same way technology is not revolutionary but evolutionary. The favorite example is the printing press that is touted as revolutionizing the printed word. On closer scrutiny this just not the case. It took over 200 hundred years to evolve what we have come to understand as the book. The older technologies of the script and pen were still utilized. In fact, even today, we still teach handwriting as not only a worthwhile but as an essential skill to know.

The problem with either these approaches stems from a lack of understanding of the nature and use of technology. According to Simon (1996), the goal is not simply to accomplish the task but to seek the most optimal solution. If we could, we would make our tools fit precisely each task thereby maximizing the possibility of an optimal solution. Given the real world, however we settle for something less than the optimal which Simon calls satisficing. For example, a pliers is not a very good choice for tightening a loose nut; a better choice would be an adjustable wrench. An even better choice would be an open-head wrench and finally the best choice, given the nature of the task, would be a boxend or socket wrench. If we do not possess or have available the correct wrench, we will satisfice by using the pliers to do the job. If the technology is truly transparent or revolutionary, then there would be no reason to improve or invent new and more effective technologies.

These view of technology demand that our teachers always satisfice. First by contending that technology is transparent and it does not really matter which technology you use. Secondly, the revolutionary approach says that old technology is irrelevant and that teachers will always need the newest technology to be effective. What we need is a different approach that attempts to match the inherent characteristics of technologies with the inherent demands of the task.

Mize (1996) considers the underlying argument between task and technology as unified and reciprocal. Educators can begin with either the task or with the technology and arrive at the goal of improved instruction. A variety of tasks can be accomplished with a variety of
different technologies, because they are intertwined in such away that any change in either will require re-evaluation of the other. This linked relationship allows educators to begin with either the task or with the technology and arrive at the goal of improved instruction. For example a teacher may find a new computer in the classroom who can start with this one machine and discover what it can do. In contrast, another teacher may have an insight concerning an instructional task and then seek out help in applying the appropriate technology. With the infinity model (Figure 1) teachers can start improving instruction from either perspective because of the reciprocal nature of task to technology.

Infinity model

Figure 1. Infinity Model (Mize, 1996).

The infinity model allows teachers to start where they are comfortable. To effectively implement the Infinity model teachers need a filter mechanism (Figure 2) that will help them match the best technology for a given instructional task.

Factors in Design

There are six factors (Figure 3) that influence the design and the delivery of instruction: time, context, interaction, task type, content, teaching method. Each of these factors is highly interrelated so that making adjustments in one factor will have a profound impact on many of the others.

Figures 2 and 3: Factors in Design

In this way a teacher can create an optimal design for the delivery of instruction.

Factors in design

Time is a very important factor because it not only determines how much contact the students will have with the knowledge or skill, but it greatly impacts the design of the instruction. For a designer a 14-week course provides an opportunity to either delve deep into a particular topic or to provide the learners with sufficient breath. In contrast a 3-hour lecture poses problems for the designer.

Context determines the environmental channel in which instruction will take place, ranging from the classroom to a course delivered over the Internet. The context also indicates the available or necessary resources in order to deliver the instruction.

The interaction factor describes how the students and instructor will interact not only with the material but also with each other. This factor describes the style of the interaction. A teacher giving a lecture is a one-to-many style of discourse. There are other forms such as many-to-many in case of a small group discussion or focus group.

The factor of task defines the nature of the instructional problem. Essentially there are two kinds of tasks, well defined and ill defined.

Well defined. Well-defined tasks usually have a clearly understood solution or can be solved through a systematic process of problem decomposition to axiomatic propositions. For example, finding the name of the city where the capitol is located for each of the 50 states is well defined task, which has a single solution. This type of outcome is well suited for novices and factual information, which can be presented directly and is easily acquired.

Ill-defined. In contrast an ill-defined task does not have an axiomatic solution. An ill-defined goal state is equivocal and normally requires multiple input that can lead to different solutions as well as perspectives. For example, trying to understand the reason that Lee lost at Gettysburg is ill-defined, because there is no one single answer. There are a lot of factors, input and different perspectives that provide a range of solutions.

Content is the state of the knowledge or the skill to be delivered in the instruction. Content can be dynamic such as HTML script, which is currently rapidly changing. Whereas high school physics is relatively static and has not changed much over the last 20 years.
The final factor is the selection of a teaching strategy, behavioral, cognitive or social. The interesting facet of this element of the design phase is that it is a dynamic process. If a designer is given a particular content, they must analyze the content and determine the best environment, the type of interaction, how much time and so on. Each step is intertwined with every other step.

Each of the six factors discussed above will impact the decisions of an instructional designer and one change in one factor will influence the other five factors. Consider a classroom teacher who is doing a lesson that is typically well defined. However she wants to instill in her students more creativity so decides to do more ill-defined problems. The research indicates that collaborative interaction, or teams will do better on ill-defined type problems. Consequently it takes more time to do group interaction. In addition, the teaching model requires a more social approach.

The instructional designer must consider each factor and how that factor influences the entirety of the design. The goal is to achieve a balance between each of the factors in achieving the optimal design. In this way we will have effective and appropriate instruction.

An Example

Using the factors for design allows teachers to integrate technology from whatever perspective that makes them comfortable. Remember our classroom teachers who want to instill more creativity into her students. At that time we did not even consider any technology. Given that she wants her students to engage in more collaborative problem solving technology could have an appropriate place. A simple place to start would be to have the student’s pairs up around a single computer and run a simple spreadsheet and then discuss the results with their partner. This does not require much in the way of altering the way the teacher typically did things, but notice it does require consideration of the environmental context in which she would conduct her class.

However, our teacher finds out about the Internet and wants to improve her lesson using the Internet. She wants to create an opportunity to make homework more collaborative and effective by creating a peer-to-peer problem solving system.

By first understanding the factors that constrain her from reaching her instructional goal she is in a much better position to choose the best technology. Time for this teacher is really not much of an issue because her goal permeates the entire course. Interaction, however, does play a central role in this design because the teacher wants a high level of peer-to-peer interaction. This is necessary because she has created a task type that is ill defined. The high level of interaction is necessary because all of the information necessary to solve the problem is not contained within the problem statement. The lesson content is fairly stable and is not undergoing any radical transformation. Finally the teaching method is transformed from direct instruction to a more social or discovery model in which the students must decide together what the best course of action will be.

Integrating technology into such a lesson requires a similar type of evaluation to choose an appropriate delivery media. Desktop video (DTV) appears to be a good choice because an ill-defined problem requires a high amount of interaction and collaboration. With (DTV) the students can see each other and interact in real time. Currently, most teachers around the country probably do not have access to DTV. Consequently, our teacher would have to redesign her task to fit the available technology. However, given our framework, the teacher is able to select a more appropriate and effective delivery media, abet somewhat less exotic. Looking at our task and matching the technology to the task, e-mail appears to be a better choice.

The teacher probably has access to e-mail. E-mail’s characteristics provide for one-to-one interaction, asynchronous connectivity, a static artifact and a private social structure. Connectivity is easier. The students can log on whenever it is convenient, and it provides for peer-to-peer interaction and support. Further, e-mail is a text based medium, so that the artifact of the previous interactions are available. Students could review the various discussions in time for a test or exam. By understanding the task characteristics the teacher can create an optimal match with the appropriate technology.

Discussion

A variety of implications result from using the six factors as a filtering mechanism for instructional technology. The first implication is old technology can provide an optimal solution. Further, teachers are not limited by the technology or by what they are required to teach. What remains constant is the design. Finally teachers will no longer have to abdicate their responsibility in using technology. Technology is not inevitable but is due to the quest for an optimal solution to a particular problem. By exploring and maybe even designing better software, teachers can create the optimal instructional solution thereby providing an effective and appropriate instructional experience.

A WEB-BASED INSTRUCTIONAL RESOURCE FOR TEACHER EDUCATION: CONSTRUCTIVIST APPROACH

Seung H. Jin  
University of Houston

Jerry Willis  
Iowa State University

Over the past ten years, there has been dramatically increasing interest in the use of technology to support student-centered/constructivist learning. However, in spite of the great benefits of technology for constructivist learning, the majority of teachers have little or no experience using technology in the classroom. That applies to constructivist as well as more traditional uses of technology. The problem appears to begin with the preparation teachers receive in their preservice programs. A number of recent studies and reports in the area of technology and teacher education (Willis & Mehlinger, 1996; OTA, 1995; Thompson & Schmidt, 1994) have indicated that preservice teacher education has failed to prepare teachers adequately. Even the teaching materials used in preservice teacher education have been questioned. Several reviews of instructional materials used for computing courses in teacher education programs have indicated that the content or structure of textbooks or instructional packages is inadequate (Padron, 1992). In fact, the lack of well designed, appropriate instructional materials that support the integration of technology into teacher education may be one of the major barriers to wider, more effective integration.

Writing a “better” textbook on the constructive use of technology is one way to address the problem of instructional resources. Another way would be to take advantage of the available technology and create an electronic resource. The work reported here focused on the creation of an Internet-based resource for preservice and inservice teachers. In this study a web-based instructional resource was developed by a participatory team comprised of subject area and instructional design experts as well as potential users including preservice and inservice teachers. The Recursive, Reflective, Design, and Development (R2D2) instructional design model developed by Willis (1995) guided the design and development process.

Product Overview

The Constructivist Educator’s Page is a web page temporarily located at http://www.cite.uh.edu/seung/frame.html. It includes three general types of material: a database of information and resources, an area for discussion, and a collaborative project area. The entire site, including the home page, uses two different frames: a small left frame for main buttons which can be clicked to jump wherever the user wants to go in the site and a larger right frame that displays material selected by the users (see Figure 1). The database area, which is the largest area on the site, includes four units: i) constructivist learning theory, ii) lesson ideas, iii) cases, and iv) references. The discussion area allows users to select a thread by clicking a topic in the content frame. The project area provides annotated links to some ongoing projects as well as centers around the world where constructivist teaching is a major focus. Each area in the site contains a different type of information about constructivist teaching and learning. This web site is open to everyone who has access to the Internet.

Figure 1. Home page on Constructivist Teaching

The Design and Development Process

The instructional design model used in this study, R2D2, is based on three guiding concepts: participatory

Instructional Design — 435
design, recursive or iterative design, and reflection. Each of these foundational concepts supports the idea of gradually shaping a vague idea into a more precise and more fully formed product. The entire design and development process was iterative and occurred in a non-linear fashion. There was no linear set of steps, but it does include two focal points: a) the definition focus, and b) the design and development focus.

The Definition Focus

The definition focus included 1) front-end analysis that investigates whether there is a need for the type of alternative instructional material, 2) the creation of a participatory team that includes both experts and potential users, and 3) establishment of a progressive problem-solution focus that begins with a vague idea of what is to be developed and progresses through more and more detailed and complete versions of the material.

Front-end Analysis. The front-end analysis was conducted via a review of the literature on technology and teacher education programs, interviews with teacher educators and teacher education students, and observations of courses about technology in teacher education programs. Through the front-end analysis, several problems in technology and teacher education programs were identified: 1) Instructional strategies in teacher education programs are heavily based on behaviorist approaches. 2) Preservice teacher education students do not see modeled, or learn to use, a wide range of instructional strategies that support incorporating technology into classroom teaching. 3) While teacher educators and preservice teacher education students have positive attitudes toward constructivist approaches, instructional materials based on constructivist approach are not widely available. These findings formed part of the basis for creating the prototype of the instructional material developed in this study.

Creation of the Participatory Team. In this study the development team consisted of several teacher educators who teach methods courses for preservice teacher education students, educators who are knowledgeable about constructivist uses of technology, instructional design specialists, and instructors and students in preservice and inservice educational computing courses. The members of the development team helped develop the concept for the instructional resource, participated in the development of the prototype, and provided input and feedback on everything from instructional goals and topics to be covered to instructional strategies and user interface.

Progressive Problem-Solving Focus. In the R2D2 instructional development model both the problem and the solution are progressively defined throughout the interaction of the development team members. This study used several techniques such as semi-structured interviews, individual and small group tryouts, observations, and open-ended questionnaires to encourage participation in the development process. Subgroups of the team also occasionally met together to discuss the current status of the project and make decisions about changes.

The Design and Development Focus

The design and development processes were combined into one focus instead of separating design from development and requiring a linear “design first” “then develop” sequence. That is, members of the team worked on components of, and versions of, the package and made changes continuously. Some ideas were selected and developed across the process, but some were initially selected but later abandoned as the team elected to take the development in a different direction.

Preparation Tasks. The preparation tasks included a) selection of a development environment, b) selection of the instructional media, and c) selection of the format and instructional strategies. The preparation tasks were performed by discussion with experts and examination of contexts in teacher education programs.

a) Selection of a Development Environment - The development environment for this project includes a number of different software products such as Adobe Photoshop, Microsoft Image Composer, and PowerPoint but was centered on the creation of a multimedia/hypermedia Web document. Most pages in the site were created in Microsoft FrontPage and modified by hand coding.

b) Media Selection - The medium of instruction was interactive, Internet-based, hypermedia using World Wide Web (WWW) technology. The WWW is a powerful navigational tool, providing access to virtually limitless Internet resources. The instructional material developed on the Center for Information Technology in Education (CITE) server at the University of Houston was delivered via the Internet.

c) Format and Instructional Strategies Selection - The material developed in the study was created in a number of different formats, such as hypertext documents, instead of a traditional textbook format. Different units had different formats, called for different types of interaction on the part of students, and supported different types content. For example, the discussion area supported a range of communication alternatives. These alternatives included threaded discussion groups where topics can be raised by any participant (see Figure 2).

Creation Tasks. The creation tasks category includes the procedures for developing the product. These procedures of design and development were divided into five major types: a) beginning concepts and ideas, b) component development, c) single path prototype, d) alpha version, and e) beta version. Progress through these creation tasks was not, however, strictly linear. Some component creation was the beginning point, but components were revised, changed, or redone throughout the
process as the participatory team worked on improving the product. Throughout the process, feedback and participation from both experts and potential end users provided information used by the designer to make changes and revisions to the product.

Figure 2. Interactive Discussion Area.

a) Beginning Concepts and Ideas - The beginning work started with the general idea of developing a web site that was an organized, but non-linear information resource on constructivist learning environments. Some of this content would be original, created specifically for the site, and some would be available via links to other sites. The conceptual outline of this web site was developed through semi-structured interviews with stakeholders like the instructor who had suggested the creation of this project. Interviews with four stakeholders were conducted to identify the needs of users. They suggested that effective materials for teacher education are needed to provide more information about instructional strategies based on constructivist approaches and various uses of technology in constructivist learning environments.

b) Creation of Components - During the design and development process for individual components, the home page was much more carefully developed than many other pages because the components of other pages in the site depended on the home page. After the home page was developed, a graphic design expert suggested that a consistent, integrative design relating the major units of the web site to the icons on the home page would help users identify their position while navigating the information resources. Most titles on the site were created in tones of green or yellow to make them consistent with the “Forest” icons that were used as a metaphor of the site’s information landscape home page. In addition, one important goal of the design and development process was the creation of a user-friendly interface that would make it easy for novice teachers to navigate the web site.

c) Single Path Prototype - A single path prototype is a limited version of the product that allows users to explore all major aspects of the package if they “stay on one path.” The purpose of creating a single path prototype was to obtain feedback or suggestions about all aspects of a working model before the development team created a version of the entire program. Eight stakeholders, two graduate students in instructional technology, three undergraduate students in teacher education, and three experts in instructional technology and constructivist learning theory, were involved in the evaluation of the single path prototype. This single path prototype was revised many times.

There were several major recommendations about the single path prototype from experts and students. For example, the theory unit was well organized with the emphasis on constructivist theory related to classroom teaching and some of the more esoteric links to constructivist philosophy were eliminated. In addition, all the links to other web sites were annotated with a brief explanation of the link (see Figure 3).

Figure 3. Constructivist Learning Theory Page in a Revision.

Experts and students who worked through the single path prototype were very positive about the site. According to them, the graphics were attractive and the layout was very clean and consistent. Also, they felt the content on the web site helped teachers understand constructivist theory and teaching.

d) Alpha Versions - When revisions in the single path prototype warranted no more significant changes, the alpha version, a full rough version of the product, was developed. The alpha version included all paths and options in the three areas of the site: database, discussion, and project. All components in the product were essentially functional though some areas still had rough graphics and tentative content. The alpha version was evaluated by experts and potential end-users including novice users who were not familiar with the content or web technology.

Instructional Design — 437
Three subject matter experts and five preservice teacher education students explored and evaluated all areas of the Constructivist Educator’s Page. They were generally very positive about the overall content, data structure and user interface. Experts also made many suggestions about other resources that could be added to the site, including links to other web sites that described constructivist projects. Expert comments resulted in two major changes to the alpha version. The first major change was related to the content included in the lesson ideas area. In a revision several additional types of instructional strategies/learning environments were added including information banks, symbol pads, construction kits, phenomenaria, task managers, and microworlds (see Figure 4).

![Figure 4. Lesson Ideas Area in the Alpha Version.](image)

The second major revision was also related to paths through the database. One constructivist teacher educator suggested that instructional strategies and learning environments might be combined in one path and that another path for exploring lesson ideas by grade level should be added. Therefore the lesson ideas area (see Figure 4) was divided into three different paths: grade levels, learning environments or instructional strategies, and subject areas. A number of students who evaluated the alpha version also contributed lesson plans or ideas of their own. For example, the lesson idea called the Best Building was contributed by a student who was a second grade teacher in a bilingual classroom.

e) Beta Versions – When suggestions for revisions to the alpha version were made, the resulting the beta version was uploaded to the Center for Information Technology in Education (CITE) server at the University of Houston and was delivered via the Internet. Until that point components and versions of the material had been run locally from a Zip disk or hard drive. Users could access the Constructivist Educator’s Page at http://www.cite.uh.edu/seung/frame.html. All components in the beta version were fully functional and all graphic design components were finished (tentatively). The beta version was evaluated by eight potential end-users through a survey questionnaire, by observations of use, and by informal interviews while students were using the product. Most evaluators felt the Constructivist Educator’s Page was interesting and motivating. They liked the screen design including the use of color and text, and they found the navigation options easy to use and functional. They could navigate without any difficulty in the database area and project area.

There were a few suggestions for changes or revisions. For example, some users wanted to see more examples in their particular areas. Another comment was about background color. Two users suggested using a different, distinctive background color for each page, but this suggestion was not implemented. When asked, several other students said they did not want the color or background graphics to change from page to page because of additional time required to navigate the site. When all the revisions to the beta version were made, the product was considered to be Version 1.0. The Constructivist Educator’s Page was then ready for general use in preservice and inservice teacher education.

**Discussion and Conclusions**

This study was a development project that used an alternative instructional methodology. While traditional studies emphasize objective methods of data collection, this study depended on subjective data obtained via interviews, discussions, observations, and questionnaires. The design and development work was performed in a flexible, iterative format that encouraged input from a range of stakeholders. Most decisions were made through negotiation among members in the collaborative group. Across the design and development process there were hundreds of revisions, some large, some small, but all a result of input from experts or end users.

Based on the comments of experts and end users, the Constructivist Educator’s Page seems to have several advantages over traditional instructional materials. One of the advantages is that it supports a user-centered learning environment through a non-linear information landscape. Second, the web site is not a static entity. This web site can be a dynamic, changing entity in ways that are simply not possible with traditional printed material. Third, the Constructivist Educator’s Page provides preservice and inservice teachers with not only a variety of lesson ideas but also accessible information on the basic concepts of constructivist learning theory. The Constructivist Educator’s Page includes practical and useful resources relevant to constructivist teaching on one web site as well as links to many other useful sites. Fourth, with Internet connectivity, the Constructivist Educator’s Page can be
accessed from anywhere there is an Internet connection by anyone who has access to relatively basic computer equipment, an Internet connection, and suitable browser software. There is no additional cost to access the resource. At the end of study, the Constructivist Educator's Page was judged by experts and potential end-users to be a valuable and useful site for educators seeking information on both the theories of constructivism and the practical professional implications of the theory. However, this ongoing project will be expanded and revised continuously through the active participation of preservice and inservice teachers.

Creating instruction for the World Wide Web is a complex task requiring multiple levels of design effort and skill. Accustomed to traditional face-to-face instruction, many learner's struggle in training settings like the Web which require self-direction. Since teachers are not readily available to answer questions as they arise, learners in Web environments often need an additional layer of instruction: instruction on how to take part in instruction. The instructional designer is challenged with the dual task of designing good instruction and clear directions for accessing and using the instruction.

The phenomenon of distance between the teacher and the learner in Web-learning environments requires optimizing a learner's sense of autonomy (Moore and Kearsley, 1996). Where in the past designers focused on designer-controlled events (the pursuit of the perfect mix of objectives and strategies for the maximum number of learners), designers in Web-environments focus on creating learner-controlled events (embedding strategies to increase the self-direction of the learner.)

While most instructional designers have considerable skill and experience in designing content, few have experience in designing optimal learner-control environments. The designer must create obvious ways for learners to interact with training by chunking content into menu/sub-menu structures, providing navigation tools, embedding instructions on how to go about learning in a Web-environment, designing feedback mechanisms such as LISTSERVS and Web chat rooms, to name a few. In short, the designer must proactively address many of the tasks innately performed by a teacher.

Criteria for designing learner-control are not well-defined and many instructional designers lack confidence when confronted with the task; in large part because few designers have the knowledge, skills, or experience in the design of graphical user interfaces (GUI.) A graphical user interface is defined as the form of communication between users and computers that facilitates interaction (Mok, 1997). GUI for Web-based training encompasses all interactions between a learner and the Web-based learning environment. Design for Web-based GUI includes creating all of the visual elements on the Web-based computer screen that help learners perform the task of learning.

Designing a Web-based GUI is a daunting task. Limited screen real-estate (space for communication,) the "lost in space" phenomenon of hypertext (Jonassen, 1991), anticipation all of the design and technical problems learners can encounter in a virtual classroom (receiving instructions, motivation, participation issues, etc.), are just some of the challenges of Web-based design. As stated above, to accommodate these issues requires the designer to embed many of the functions of a teacher into the interface.

Modeling the functions of a teacher in a computer interface is not a new practice. Most computer applications today employ electronic performance support systems (EPSS) such as online help, wizards, coaches, and even some forms of artificial intelligence (such as Microsoft's personal assistant feature) that perform many of the functions of a teacher. The design and development skills required to produce EPSS fall into many domains outside education. Skills in graphic design, message design, human factors, advertising, cognitive engineering, and computer science are just some of the disciplines involved in the development of EPSS. Rarely is one person, or disciplinary field, skilled in all areas of design required (Mok, 1997). Until EPSS development tools are easier for the typical instructional designer to manipulate and use, embedding teacher functions into a learning environment will need to take a less sophisticated form. This paper presents easy-to-implement strategies for increasing learner autonomy by embedding teacher functions within the graphical user interface.

The embedded teacher (ET) model proposed in this paper is similar to the butler model (Hoekema, 1984) which describes a good interface as performing many of the roles of a good butler. A good butler help a person enter, exit, and move from room to room within a house. Additionally, a good butler learns the preferences of visitors, bringing them beverages they like, and learning to small-talk about the visitor's interests. A good butler however, doesn't interact with visitors on a learning level. A butler isn't typically trained to assess where the learner is, where the learner needs to go, and the best strategy for getting the learner where they need to be.
Schwier and Misunchuk (1993) address interaction on the learning-level, by identifying the need for core and complementary instructional zones in an instructional interface, as well as the need for interactive feedback. Core information zones refer to a consistent placement of key instructional information. Complementary zones refer to consistent placement of instructional elaboration, if needed. An example of core information might be descriptive information about a task, such as changing a bicycle tire. An example of complementary information might be a drag and drop computer environment that would allow a learner to practice changing the tire by dragging and dropping the appropriate objects in a correct sequence.

The ET model combines the butler model (Hoekema, 1984) with Schwier and Misunchuk’s (1993) core and complementary information zones by recommending four overall teacher functions be embedded into a GUI: 1) Orienting the learner, 2) Providing navigational assistance, 3) Providing instructional strategies (core and complementary information zones), and 4) Providing interactive feedback. Altogether these four elements work to perform the essential tasks of a “live” teacher. Table 1 below lists anticipated questions for each of the four teacher functions. By addressing each of these questions, a designer is able to embed the supportive roles played by a good teacher.

The Embedded Teacher (ET) model (Table 2) presented uses the framework of the ADDIE design model. ADDIE is the acronym for the Analysis, Design, Development, Implementation and Evaluation phases of the instructional design process. The following section describes how each stage of the ADDIE model was used to address the ET model when creating a GUI for a university course teaching Corporate Course Design.

</tbody>
</table>

The Analysis Stage

During analysis the designer identifies learner, content and delivery needs. The designer’s goal is to match the form and content of training with learner needs and preferences. The designer becomes familiar with the format of content at a high-level and is able to address...
thematic elements of the instructional interface. The designer arranges content into a presentational sequence and establishes “the lay of the land.”

Analysis Questions
“What is the instructional topic?” is addressed for the Corporate Course Design class by placing the topic in a prominent location (see letter A in Figure 1) and by using an image of corporate architecture. “What is the breadth of the course?” is addressed by providing an overview of the entire course in the left section of the GUI. Project numbers and semester dates show course scope (see letter B in Figure 1). “How do I get started?” is addressed by the words “Start Here” accompanied by a prominently displayed arrow. Project numbers identify a sequence for learners to follow (see letter C in Figure 1). “What is the instructional climate?” is addressed using corporate look and feel (see letter D in Figure 1).

Navigation Questions
“What is the depth of this environment?” is addressed (see letter E in Figure 2) using a flowchart structure to represent submenu sections. Each element on the flowchart represents a major task/lesson. “Where am I in the process? Can I mark where I am?” The large arrow (see letter F in Figure 2) marks the learner’s location in the lesson, serving as a You are here reminder. Learners, however, cannot mark where they have been in the program. It’s up to the learner to remember which sections of the program they have completed. “What do I do now, next? How do I back up?” The flowchart metaphor (see letter G in Figure 2) guides learners to complete the highest element on the flowchart before completing lower elements. Learners can click on previous sections to back up. “How do I get out of this?” Clicking the home button (see letter H in Figure 2) allows learners to exit.

The Design Stage
During design, the designer uses information from the analysis stage to create instructional strategies which address the instructional goals and objectives. These strategies are shaped into core, complementary and interactive feedback information zones. Core information zones are used for the presentation of key instructional content. Complementary information zones are used to provide learner practice and elaboration. Interactive feedback zones are used to provide learner assessment and remedial feedback. For the Corporate Course Design course, these zones were established using a teacher icon and a conference room icon (see Figure 3) for presentation of core information, and a drafting table icon for complementary information. Interactive feedback was implemented using the briefcase icon and the teacher icon. The teacher and conference room icons branch to pages which present background information and requirements. The drafting table icon provides instructions and space for learners to practice what they have learned. The briefcase icon allowed learners to submit work. The teacher icon in subsequent sections of the lesson responds to learner’s work by making suggestions, addressing weaknesses and strengths (interactive feedback).

Instructional Strategy Questions
“How do I interact with this instructional strategy?” Numbers next to the teacher, conference room, drafting table and briefcase icons (see letter I in Figure 3) indicate a sequential order for the learner. Instructions next to numbers describe in general terms what the learner is to do. “Can I get more/less information? Can I skip information?” is addressed by putting all of the tasks the learner must perform in the same visual space (see letter J in Figure 3). Learners control the amount of information they receive by clicking or not clicking. Because all relevant information is contained in the same visual space, learners see the “big picture” and understand the context of what they are choosing to explore or skip.

Interactive Feedback Questions
“Am I doing the right thing? Should I be doing something differently?” is addressed using the teacher icon.
The words "Good work" let the learner know that they are on track. Suggestions for improvement and space for learner dialog are provided with the text box that has a LISTSERV function.

Figure 3. Instructional Strategy Functions Identified During Design.

Figure 4. Interactive Feedback Functions Identified During Design.

**Implementation and Evaluation Stages**

User-testing of design, following recommended formative evaluation methodology (Flagg, 1990), will conclude the ADDIE process of GUI design for the Corporate Course Design class. User-testing will involve a series of one-on-one tests of the materials. Individual users will be asked to think aloud while working through the Corporate Course Design interface. Prompts to address each of the questions embedded into the interface will stimulate learner response if necessary. User responses will be used to modify the design and to identify additional questions needed by the ET model. After one-on-one testing, small groups of two or three individuals will test the interface. Again, user comments will be addressed by modification of the ET model and interface. The final pilot test of the product will be conducted in future semester sections of Corporate Course Design.

**Future Studies**

Several questions guide future evaluation and design of the ET model. One obvious set of questions must be asked: "Do the embedded teacher functions work?; Are learners able to direct themselves through instruction without the intervention of a live teacher?" To address these questions, a control group using an interface not implementing the ET model could be tested. Another question, "How direct (realistic) do teacher functions need to be?" can be addressed by comparing the interface presented in this paper with interfaces that are both more and less direct/realistic. Do users need to see the lay of the land to know where they are in a program? How much detail is needed to help users see the lay of the land? Does a separate syllabus need to be included into the interface, or can the syllabus be embedded into the interface? Until sophisticated technology that allows a simulated teacher (similar to Microsoft's personal assistant) to be easily integrated into Web courses, these and other questions can direct efforts in designing optimal learner control environments for Web learners.

Linda Lohr is an Assistant Professor at the University of Northern Colorado in the Educational Technology Department of the College of Education, Greeley, Colorado 80631. Office (970) 351-2513. E-mail llohr@edtech.unco.edu.
When attempting to evaluate software for education, the goals of the learners and the instructors need to be explicitly stated from the outset. For example, considering a specific piece of software adequate simply because it is labeled ‘multimedia’ is not acceptable. As pointed out by Nyns (1989), a teacher’s starting point in using Computer Assisted Language Learning (CALL) should not be “what can I do with my PC?” but rather “which medium is best suited to teach such and such a skill?” (p. 36). To which we would add - to these students, in this school, and on this type of computer system.

Evaluators must make a series of decisions about which characteristics and interests of the given learner population.

a. Cognitive Characteristics. (i.e. Development level (such as Piaget’s levels of cognitive development), Reading level)

b. Psychosocial Characteristics. (i.e. Interests, Motivations, Anxiety level)

c. Physiological Characteristics. (i.e. Sensory perception (visual and auditory acuity), Age)

Identify Instructor and the Learning environment

This step is important to ensure that if a purchase is made, the product will be given a positive reception and some environmental support is in place to secure its effective use in the classroom (Smith & Ragan, 1993, p. 31).

Issues that are important to examine because they directly address the needs of the teacher and therefore inform the software evaluation are:

• Feelings towards computers in education - What are the educator’s attitudes and opinions? If teachers are reluctant or negative then the mere introduction of software — regardless of its quality — may be a waste of time and money. Administrative support or training may be helpful.

• Interests and preferences of teacher - What are her interests outside the content matter? Some software may be more intrinsically motivating due to its relevance to her interests and teaching styles.

• Experience level of teacher - How much experience does she have with the content, learners, media and teaching in general?

• Curricular/instructional goals - What are the specific goals that should be addressed by the product?
Identify Technical Needs
This may be the most simple and straightforward aspect of the instructional context analysis (depending upon the technical knowledge of the evaluator). The purpose of this stage is to explicitly state the maximum and minimum requirements of the physical resources on which software will be used.

- **Who?** The best sources for the information one requires are the people who purchased, installed and maintain the system. The issues to consider when speaking to these informants are:
  - **What?** Type of computer - Determine operating system; processor speed; size of hard drive, RAM; monitor type (color?) and size; multimedia capabilities (sound, video and CD-ROM speed); modem speed; and networking capabilities.
  - **What else?** Peripheral devices - What other kinds of devices are attached to the computers? Printers, scanners, mice, microphones, removable media drives or projection systems.
  - **Where?** Number and configuration - How many computers are there? Are they in a lab or in classrooms? Are they connected by a network and if so, what kind? Do they have Internet access?

Instructional Goal Analysis
"Ask not what a computer can do to students, but what students can do with a computer." David Thornberg (as quoted in Ryan, 1997)

The next step is to determine the instructional goal that the software should fulfill. This goal will give context to the ultimate question “What is the best software?”. It will contain the pertinent information about the learner; teacher and learning environment; and technical needs. It will also include a statement related to the functionality and/or type of software desired; and the instructor’s beliefs about the learning process.

The terms which help define this statement depend upon some philosophical issues that the evaluator needs to consider:

**View of software**
Software that will be used in the classroom comes in many forms. Taylor (1980) created a distinction among software - tutor, tool and tutee (e.g. Romeiser & Yerem, 1994). A tutor can be seen as a surrogate teacher, a tool takes student input and generates output which is used by the student in a task, and software that students use to ‘teach’ the computer are considered tutees. Software that is not instructional in nature would not fit into these categories. For example, Taylor’s taxonomy (1980) cannot properly deal with Internet browsers which are not instructional but have the potential to become standard applications in many classrooms.

More importantly, it may be argued that these classifications look at the question of computers in education only from a technological point of view (what can the computer do?) and hardly consider what many would feel is the most integral part of the instructional context - the learner (what can the student do with the computer?).

Using Dewey’s (1943) ‘Natural impulses of the learner’, Bruce & Levin (in press) suggest that software be classified by how the learner can use it in meeting these impulses — thus the categories media for inquiry, media for communication, media for construction and media for expression emerge. This change from the ‘technocentric’ to a more learner centered point of view fundamentally changes how one phrases the statement of the instructional goal.

For example, if one asks “What kinds of games teach punctuation in an English as a Second Language (ESL) classroom?”, an assumption has already been made that a game — a category that is becoming more difficult to define — is the appropriate option. The exploration of possible software titles has been needlessly limited. However, if one looks from the learner's perspective, the question becomes something like: “With what media can a student examine (media for inquiry) and practice punctuation in an ESL classroom?”. This question, in turn, may be answered with a punctuation game, concordance application, grammar checker and the traditional ‘paper and pencil’ workbook. The scope of possible applications has been greatly expanded beyond those that the category ‘game’ could yield.

**Theory of Learning**
Software developers have beliefs about how people learn and interact in different environments. By critically examining and comparing computer applications, often these beliefs can be deduced. In the same way, teachers have strong beliefs about how best certain content or concepts can be taught to different learners.

If an evaluator wants to find appropriate software that will be used to fulfill a particular instructional goal, then the learning theory which was used in the program’s development must reflect the teacher’s tacit theories of learning and instruction.

As a consequence, during this process, “software may be found inappropriate rather than ineffective” (Miller &
Burnett, 1986, p. 159). With reference to the previous example, if the teacher believes strongly that students can best examine punctuation inductively and then practice it by writing compositions then a 'behavioristic' game would not be appropriate and probably would never be used in that classroom.

Therefore, at this stage the evaluator would ask the question "What does the teacher believe is the best way for the instructional goal to be met?" and then ensure that possible software choices reflect this. With this information, the evaluator will have once again narrowed the focus of the search and made the selection process more efficient and, possibly, more successful.

Issues to consider when developing a personalized software evaluation checklist

**Content**

- **Quality**
  - Learners
    - Appropriate vocabulary and subject matter for target audience
    - Well written and grammatically correct texts
    - Variety of explanations and examples
  - Teacher
    - Features which take advantage of the computer
    - Easy procedure for modifying, adding or updating content
    - Clearly stated objectives
    - Outlines, summaries and reviews

- **Depth**
  - Learner
    - Versatility
    - Numerous and 'just in time' explanations, examples, and illustrations
    - Presents 'correct' examples, non-examples and mistakes most commonly made by learners.
    - Situates the examples within a context
  - Teacher
    - Applicable in a variety of teaching/learning situations
    - Meets the instructional goals

- **Tests**
  - Teacher
    - Systematic review of learned materials
    - Coincide with objectives
    - Presented appropriately

**Navigation**

- Technical
  - Timing is self-paced and flexible
  - Ways to go back one step or go back to the main menu, etc.
  - Help or hint options
  - Exit and review instructions
  - Text or images that are hyperlinks should be clearly indicated
  - The 'granularity' (number of links to other screens) should be level appropriate
  - The cursor should not appear if it is not possible to use it

**Text Quality**

- Learner
  - Font is large enough
  - Clear and easy to read (including text inside buttons)
  - Glossed, with pop-up references
  - Symbols and icons should be obvious or, if tried once, easy to remember

- Graphics
  - Learner
    - Style and graphics are suitable
    - Graphics clarify or enhance the points being made
    - Familiar objects should be included in illustrations
    - Illustrations are clearly labeled and as close as possible to the text to which they refer
  - Technical
    - Graphics would improve the program
    - Still images do not interfere with the text
    - Consistent use of symbols
    - Overall quality and clarity of displays
    - "Current video standard (QuickTime)"

**Sound**

- Learner
  - Voices are intelligible

- Technical
  - Sound constitutes an essential or integral part of the program
  - Appropriate use of voice over music
  - Quality recording and playback features

**Interactivity**

- Feedback
  - Learner
    - Helpful messages to aid in the correction of errors.
    - Types of feedback
    - Immediate
    - Delayed
    - Summative
    - Types of branching feedback
    - Review
    - Remedial Audio
    - Single/Multiple Remediation
    - Unpredictable patterns
Technical Processing time
Sequence
Learner
- Linear or fixed sequence
- User directed
- Hyperlinks
- 'Open' in that there is no predetermined sequences
- Avoids putting learners in infinite loops or sending them
to dead ends
Teacher
- The instructor can order the topics for presentation
Technical
- Acceptable time delays
Questions
Learner
- Those asked by learner
- Questions of clarification
- Key word searches
- Complete sentences
- Those asked of learner
- Categories of questions
- Appropriate to the audience
- Related to the content
- Randomized
Classroom related issues
Entry Level / Technical Requirements
Learner & Teacher
- Entry level skills and knowledge (keyboarding, mouse,
  navigation)
- Amount of basic or remedial training required
- Level of computer literacy skills
Technical
- Compatibility of the system's requirements and the
  minimum requirements
- The availability of site and distribution licenses
- Total cost
Motivation
Learner
- Motivating and challenging as a whole
- Novelty (vs. lasting) effect
Backwash
Teacher
- Provides teacher with information/insight into students'
  strengths and weaknesses
- Provides teacher with ideas for instruction
- Structure/content mirrors classroom activities
- Allows teacher to 'offload' some tasks
Management
Learner
- Creates a 'history' of the path taken through the
  program
- Allows one to save one's work/position
- Multiple-user profiles
Teacher
- Ease of implementation
- Audit Trails
- Diagnosis of difficulties
Support
On-Line Help
Student
- Key word / topic searching
- Glossary / Index
- Pop-up menus
- Tutorials
- Ability to annotate
Teacher
- Ability to annotate student help
Technical
- Unambiguous on-screen options
- Uses 'help' key
- Other on-line help
Off-Line Help
Student
- Pre-Printed workbooks and guides
- Print-outs of help topics and/or annotations
- Lists of suggestions for study, resources or
  bibliographies
Teacher
- Clear instructions on how to operate the program
- Instructor's guide
Technical
- Clarity in its documentation
- Telephone support and fax-back services

Using LearningLinks to Construct and Evaluate Content Modules

Zahl G. Schoeny
University of Virginia

Harold R. Strang
University of Virginia

Instructional applications of technology are rapidly expanding, but their utility is often diminished by limited flexibility and low user-friendliness. Furthermore, most content-based instructional software fails to provide immediate relevant feedback either to the learner or to the teacher who uses it. This paper describes a tool that is designed to meet these challenges. LearningLinks (Strang & Schoeny, 1997) is a Windows-based instructional tool designed to create self-directed learning modules. Currently modules are being developed for post-secondary applications. This Visual Basic software tool allows teachers to develop interactive lessons that can be used by students in self-directed study. Lessons can be developed in any instructional area that involves a link between pictorial and textual content. This teaching vehicle is well suited to achieve direct instruction outcomes such as learning definitions, spatial orientations, and interrelationships among content elements. It can also be used to promote higher level problem-solving outcomes. Once authored, lessons are self-administered by students via a stand-alone runtime module.

LearningLinks can be used to implement direct instructional objectives such as learning definitions, spatial orientations, and interrelationships among specific content elements. It can also be used to promote higher-level learning that includes exploratory and problem solving activities. The program’s instruction and testing functions center on a student’s interaction with a series of frames, each containing several layers of information and cues pertaining to the instructional unit. Student learning is maximized through LearningLinks’ application of powerful principles such as prompting, feedback, reinforcement, and practice (Strang, Badt, & Kauffman; 1987 Strang, 1997).

Even with minimal computer literacy, instructors quickly learn to combine text and graphical materials to create highly individualized instructional or testing experiences for their students. In turn, students quickly learn to navigate these instructor-authored modules. A key component of LearningLinks allows instructors to easily develop a variety of feedback reports that clearly define both specific and global aspects of student performance during instructional or testing experiences. These reports can be used by the instructor for assessment and/or can be shared with students during debriefings. The data used for the feedback reports can be used to research the quality of the content modules developed for student learning.

Encouraging results defined by both student learning and participant enthusiasm have been obtained from two pilot applications. In an Audiology course, an instructor-authored module helped students to comprehend the spatial organization of the structures in the human temporal bone, and in a child development course, another module helped students understand both similarities and differences among key psychological concepts.

Lesson Development Options

This section focuses on LearningLinks lesson development capabilities. An actual authoring session will be used to illustrate the key aspects of each of the four lesson-planning phases listed on the Utility Menu (see Figure 1). A summary of the major features of each of these phases follows.

LearningLinks

Utility Menu

- Develop Content
- Develop Unit Structure
- Develop Lesson
- Generate Feedback
- Exit Utility

Figure 1. Initial screen for the LearningLinks Development Utility.
Content Development

During this phase, the module’s basic content elements are gathered and integrated. These components may consist of a series of text blocks and/or graphical structures that will be integrated into the instructional or testing frames. A 'Vocabulary Builder' module facilitates the generation of text blocks. Since the vocabulary files that house these blocks are simple ASCII files, word processing software can also be used to develop these files. When a word processor is used, however, "glo." must always be the extension in the file name.

Unit Structure Development

During this phase, the unit title, frame titles, and frame subtitles (if desired) are first defined. Next, the basic content elements developed in the first phase are used to construct the unit’s basic frames. During this authoring, as many as 12 separate hotspots can be individually sized and imbedded in each frame. Finally, As many as 10 frames can be serially linked.

Lesson Development

This phase allows the author to use the unit structure developed in the previous phase to construct either an instructional unit or a test. During the development of an instructional unit, the on-off setting for each of the unit’s 10 navigational buttons is determined. During the development of a testing unit, specific frame sequences are selected, test items and testing types within frames are chosen, and post response feedback is determined.

Feedback Generation

This phase offers the following three options: a) the first allows for creating a data file that houses pertinent information on the performance of each student that completes the current lesson; b) the second allows the printing of individual student test results, and c) the third allows for printing two different reports of collective student performance results relating to the instructional lessons. The Navigation Record gives a complete history of student movement through a lesson, clearly documenting each decision and its temporal benchmark. The Learning Pattern Report lists quantitative measures of lesson performance in six major areas ranging from basic lesson navigation to the frequency and content of student-initiated note taking activities.

E-mail: hrs9j@virginia.edu
For twenty years, educational technology literature has maintained that most educational software does not meet its promise. There are, however, some excellent programs that enhance teaching and learning. In addition, many programs contain laudable features that are worthy of notice. Eighty-one graduate students reviewed state-of-the-art hypermedia/multimedia software, across the grades and subjects, in search of indicators of good software learning tools. The objectives of this experience were to identify both good ideas to replicate and bad ideas to avoid, in order to shorten the software development learning curve and to develop model, prototype products. A serendipitous outcome of the analyses was a heightened awareness of valuable indicators that assist in the selection of software materials for learning and training.

This presentation discusses elements that contribute to successful, computer-supported learning. Within the paper are ideas organized into two major categories, the learning environment and person-machine communication, i.e., the software.

Learning Environment

This section addresses conditions relevant to a positive environment for learning. Papert (1980) described a student-and-computer system as a place called microworlds where certain kinds of learning could hatch and grow. Let us extend Papert’s metaphor to encompass the immediate universe experienced by the program user, i.e., the setting in which the computing use is done. Today’s hardware is a multimedia, networked computer. Settings include one remote learner with a computer, a one-computer classroom, a classroom with shared computers, and/or a classroom with individual computers. In terms of software, some programs are tutorial materials that provide instruction; others review and reinforce instruction, drill-and-practice; still others are tools for experimentation and construction. Whatever the combination of hardware, software, and learners, together they constitute a microworld, an environment where learning may take place. Following are observations and recommendations about building the environments not necessarily in any sequence.

General recommendation from the users to the developers:

- Challenge provides motivation.
- Learning, at all levels, may be fun.
- Elements of surprise (pleasant, not scary) are pleasant.
- When sections of a courseware program may be used independently, provide a map that highlights (or otherwise indicates) successfully completed sections.
- A boring program will be abandoned.
- Prepare a “how to use this product” video. Make it available with a hyperlink on the splash screen.
- Bookmarks allow users to continue from previous sessions’ stop points.
- A new version of a program should be a well-debugged improvement.
- Always look to see whether computer is the medium of choice for product.
- Users should control pacing. Timed “reminders” may be used to tweak inactive users.
- Transmitting information does not equal instruction.

General recommendations from teachers to developers:

- Provide learning objectives and never lose sight of them.
- Product should meet the conditions of learning (Gagne, Briggs, & Wager, 1992).
- Lists of ancillary material help integrate the technology into the learning process.
- A good teacher with appropriate resources will envision novel ways to use a program.
- A product may be reviewed by an experienced teacher (or trainer or librarian) but really needs to be tested by target users for best decision-making.
- Observing the target population using the software for the very first time is very instructional for design and for purchase decisions.
Provide pointers for teachers in obtaining subject expertise.

Unless a program is totally intuitive, time must be borrowed to learn to use it.

This time is not easy to replace.

Individualize instruction by providing problems based upon performance.

Some subjects must be learned in linear fashion.

**Recommendations specific to pre-school computing:**

- Development should be based upon principles of pedagogy – the science of teaching to children.
- Older children happily mentor younger ones during initial experiences with a program.
- Some early childhood software is really child-with-older-person experience.
- Parents/teachers who will be working with young children appreciate “models of intended use” videos.
- Children who use programs without supervision are likely to miss some of the best features.
- Children expect screen objects to be hot spots.

**Recommendations specific to adult computing:**

- Development should be based upon principles of andragogy – the science of facilitating adult learning (Bullard, Brewer, Gaubas, Gibson, Hyland, & Sample, 1994).
- Most good programs have narrowly defined target audiences.
- Novice, computer-using adults are more likely to persist if patient human support is available.
- Wizards, magicians, and agents are often welcome on-screen guides.
- A truly intuitive program should not require a help feature.
- Label icons. Adults do not recognize “rebuses” as readily as do children.
- Provide varying methods for learner self-evaluation.
- Begin with clearly defined learning objectives. “In this lesson, you will ...”
- The computer experience may guide a real-life one. Instruction in cooking, wine tasting, and playing of musical instruments calls for off-screen activity.

**Person-Machine Communication**

The field of endeavor that examines the communications processes between the program and the user is called Human-Computer Interface/Interaction (Shneiderman, 1998). By definition, a well-designed program interfaces successfully. All instructional design issues must be tested for their ability to communicate well. This section addresses different aspects of the design and implementation processes. Which of the alternative suggestions is best depends on the subject, the learners, and the objectives of the program.

**Links, buttons, and icons:**

- Make icon (button, link) large enough so that poor-mouser is not frustrated.
- Keep icon areas sufficiently apart so that accidental clicks do not occur.
- An inconspicuous “teacher” icon could call up suggestions for further learning.
- Simulations that mirror reality should feature invisible icons.
- Provide enrichment accessed with an “extras” icon.
- When mouse passes over icon, label should pop up.
- Use a voice icon to bring up audio help.
- Use a document icon to bring up printed help.
- Provide a “What do I do next?” icon.
- To help users extend their vocabularies, make new words hotspots that bring up definitions and/or images.
- An index icon on the navigation panel allows for true self-directed learning assuming all indexed items are hyperlinks.
- Avoid moving buttons that need to be clicked on.
- Always make links “dynamic”; the shape of the mouse should change when it passes over a link.

**Internet links:**

- Internet links greatly expand learning resources.
- Internet links usually allow the user to link elsewhere making it easy for the user to become irretrievably lost.
- Using simulated links (resources that are contained within the program) solve the “getting lost” problem.
- Programs with simulated links must be upgraded often to avoid “staleness”.

**Sound, voice, music:**

- Where oral pronunciation is an issue, use a microphone to capture user’s voice. Play back voice. Let user compare own voice with computer-tutor’s rendition.
- Evaluate user’s pronunciation with speech recognition software.
- Synchronize voice output and on-screen lip movements.
- Keep music on a toggle (on/off) switch.
- Consider using “snippets” of music as rewards.
- After a while, the camera shutter click grows annoying.

**Feedback, rewards:**

- Feedback should be immediate, relevant, and useful.
- Feedback should be provided often in an interactive experience.
- Inform learner when answer is wrong. Do not repeat original phrasing.
- Feedback should address why answer is wrong.
Looking for an exact match in an answer may cause an essentially correct response to be evaluated as incorrect. Solution: multiple choice answers.

After two wrong tries, provide user with correct response. Never trap user in failure cycle.

Do not put learner through identical process repeatedly. That is punishment.

Easy-to-program rewards include praise words, happy sounds, award ribbons, animation.

Reward should be appropriate for activity. Winning is a reward.

Rewards may be cumulative if the program is used over time.

Images:
- Decide on a metaphor to give the program cohesion.
- List all possible artifacts that would typically be found in that universe and use them as hotspot objects.
- Images must be clear and relevant to the content.
- A well-placed picture is often better than explanatory text.

Text:
- Define all terms that will be used in the instructional process.
- Keep instructions visible or retrievable with toggle switch.
- Bold, black lettering on white background is easy to read.
- Limit the number of words on a screen at any given time.
- Always allow the user to read at own pace.

Content:
- Content must be micro-checked for correct spelling, grammar, sentence structure and factual accuracy.
- Always use multiple resources to ensure accuracy of facts.
- Choice of materials for inclusion should embrace expert opinions.
- Have the computer generate progress reports periodically.
- Provide enrichment opportunities.
- Provide suggestions for improving performance.

Conclusion
There is no end to how much may be learned through analysis. Teachers who develop software or who guide their students in the development of software projects, experience virtual field experiences when reviewing a sampling of current offerings in a given subject and age/ability range. Examining products created with commercial budgets provides insights into today’s technology potentials and opens doors into an existing universe.

In this paper, I reflect on my participation in two government-sponsored courseware development projects. Though neither project was modeled on the other, both used a holistic design paradigm in which classroom formative assessment and teacher input played a critical role in the development process. The two projects were —

- **R-WISE (Reading and Writing in a Supportive Environment)** — a learning environment to teach writing at the 9th and 10th grade level. The project was a timely collaboration among the military, business/industry, and the educational community to address one of the most pressing challenges facing our nation: teaching the thinking skills necessary to participate in a complex, modern society. R-WISE was developed by the Air Force’s Armstrong Laboratory in partnership with MacArthur High School in San Antonio, TX. Over the course of the project (1990-1995), the software was implemented in several different states and used by thousands of students (Carlson, Hitzfelder, Hudson, & Redmon, 1996).

- **BioBLAST (Better Learning through Adventure, Simulations, and Telecommunication)** — a content-rich learning environment that mirrors research being carried out at several NASA centers. The project (1995-present) consists of simulations, microworlds, and interactive multimedia based on NASA’s Controlled Ecological Life Support Systems (CELSS). Sustaining humans in colonies beyond earth’s environment requires a balance among components and systems. Focal points of research include: (1) plant production, (2) human requirements, and (3) resource recovery. The target audience is 9th and 10th grade biology. Using the “tools,” laboratory activities, and collaborative interaction, student teams design and balance a closed biosphere to support a crew of six, living on the lunar surface (Carlson, Ruberg, Johnson, Kraus, & Sowd, in process).

In each of these projects, high school teachers were part of the design team from the beginning, and both alpha and beta versions were field-tested in classrooms, representing adequate numbers and diversity to make the feedback useful. But more than these similarities, in each project the “development team” was as a multi-talented collaboration involving domain experts, instructional designers, software engineers, curriculum writers, and classroom instructors. The teachers were regarded as fully-vested members in the process.

**Educational Software — Promise and Puzzlement**

Increasingly, K-12 educational technology has come to mean some form of computer-mediated product. More affordable hardware, increasing awareness of new media (information technology in general), and the combined push from reform mandates and the pull of marketing for new media all contribute to an environment of rapid change.

Yet, reports both from the workplace and from higher education indicate that meaningful integration of advanced information technologies is not a matter of simply making the hardware/software available. For example, Geoghegan (1994) estimates that of all the educational technologies implemented in higher education, no more than five percent of instructors use computers as anything more than high-tech substitutes for the blackboard and the overhead projector.

On the K-12 level, many multimedia educational products available today are conceived of as “super-books.” They present students with multi-modal representations of materials and explanations, but their “pedagogy” is primarily didactic and their assumptions about learning are fairly static. Increasingly, we are seeing a backlash in the popular press against advanced educational technologies. The claims center on charges that most software engages only at a superficial level and — over time — both “deskills” the student and “disenfranchises” the teacher.

In general, educational software has not reached its potential for a variety of reasons. I suggest that these inhibitors can be clustered under four categories:

- **Lack of meaningful formative evaluation** — While change is in the offing, the current-traditional design methods for courseware/educational software do not include adequate feedback loops. Although this may be typical for an “immature” industry, it is to be hoped.
that developers of educational technologies will at some point have as much regard for product design and end-user needs as does the automobile industry.

- Emphasis on the student as end-user — Certainly, the learner (primarily, the learner’s measurable achievement) drive much of today’s concern for educational reform. However, a technology-enabled curriculum should be conceptualized as a dynamic partnership among three agents: the student, the teacher, and the computer-mediated learning tools.

- Lack of a robust new paradigm for technology in education — Education’s recent history contains several examples in which a new entity emerged in a glow of promise but never reached fruition. We seem to be at that awkward transition point for computer-mediated learning — one in which the old methods are falling away, but the new paradigm, enabled by advanced information technologies, is not apparent.

- Overemphasis on teachers as technophobic — Too often, the teacher’s role in technology adoption has been characterized as inhibiting and conservative. While advanced technologies may be a threat to some instructors, dwelling on negative “attitude” and on the need to “educate” teachers on hardware and software operation misses the real strengths teachers can bring to the process.

Collaborations for Progress

Figure 1 accounts for a spectrum of features in the “ecology” of education. This model suggests systematic and defensible design/evaluation of software / courseware in situ to promote “best teaching practices.” Furthermore, the model implies consideration of a range of issues including integration of information technologies into existing curricula (easing the transition from traditional to innovative), establishing creative partnerships among students, technologies, and teachers, as well as selecting courseware /software for specific needs.

![Figure 1: The Ecology of Educational Technologies.](image)

As indicated in this schema, the teacher is the nexus for many issues of integration / implementation, administrative policy, assessment, and educational reform. The remainder of this paper extracts from the teacher commentary in both BioBLAST and R-WISE a set of characteris-

Software that Allows Teachers to Become Mentors and Facilitators

For this section, I will look specifically at the BioBLAST project, and focus on how this content-rich learning environment embodies emerging changes in science education. The radical shift away from lectures, decontextualized experimentation, and textbooks demands a great deal from the teacher. The move to authentic, situated, and project-based learning mandates that teachers drop their authoritarian mantel and assume a master-apprentice relationship with the learners.

All of the BioBLAST teacher-leaders are accomplished educators who have enthusiastically adopted the new role for teachers of science. They were selected to work with the project through a nation-wide competitive application process. Their specific charge in the first fielding (1996 - 1997) of the BioBLAST CD-ROM was two-fold. First, as classroom experts, they were asked to comment on the appropriateness of the materials for their situation. Second, as skilled practitioners of the new pedagogy, they were asked to facilitate the “weaving” of patterns of effective usage from the many available activities. In essence, teachers were asked to serve as “sherpas” in finding paths of learning through the rich and intensive environment.

During the academic year of 1996 - 1997, teacher-leaders adapted the components of the program to their individual situation, providing feedback on their experiences and adaptations. I summarize here three specific software features driven by the teachers’ remarks.

Developing Bridging Activities for Clarifying and Reinforcing Concepts

Students — even the most enthusiastic of learners — have few mature strategies for constructing meaning from even the most well-planned of classroom activities. Thus, the BioBLAST teachers underscored the need for devising software activities that model complex concepts or behaviors in small or more familiar domains of experience.

For example, most classes approach BioBLAST as a long-term, project-based activity within which to examine important biological concepts. The overall theme of the photosynthesis / respiration cycle between humans, plants, and the external environment lends itself to “energy usage” as a starting point, with progressively more complex examination of basic processes occurring as additional cycles (carbon, nitrogen, water, decomposition, respiration, and combustion) are added.
Using "Artifacts" to Foster Learning

Active learning is both product and process based. Ideally, constructing one level of "knowledge product" (or artifact) feeds into the process of attaining yet a higher level of understanding. For example, collected data can be analyzed for patterns and trends, from which the student may be asked to draw cause-and-effect inferences or formulate predictions or generalizations about future behaviors of the elements under study. The very richness of the BioBLAST domain challenged teachers to work through iterative cycles of process fostering a product which then initiated yet another process.

This "spiralizing" upward from concrete to abstract was used well by a teacher who started her class' BioBLAST experience by having each team construct a "quart-jar ecology" (snails, plants, bacteria, and the like). The classes also constructed a 5 by 9 foot human cell and investigated components and relationships. As the course progressed, these "microcosms" became analogs for the more complex and sophisticated macrocosms of Advanced Life Support (ALS) and other controlled ecologies. Additionally, these classes used hands-on experiments (mirroring actual NASA research interests as indicated in the software) to be particularly engaging. They posed questions and formed partnerships with NASA scientists for extending their investigations. For example, students will grow control plantings for an experiment in plant reproduction to be conducted on the space shuttle.

Sustaining the Sense of a "Community" for Scientific Inquiry

Meaningful implementations of collaborative learning require sustaining the intellectual rigor of scientific inquiry while at the same time nurturing the socio-cultural dimensions of group activities that foster respect for individuals and mutual dependencies among students and teacher for learning.

Many of our teacher-leaders insisted upon an open-ended quality for BioBLAST in order to foster collaboration between students and teacher in deciding upon evaluation standards. Discussing possible outcomes and constructing rubrics as a class activity lowers student anxieties and increases motivation. Promoting a constructivist approach to learning, teachers used guided-inductive techniques to help students define issues, determine problems to be solved, and exchange ideas in a series of positive interactions. BioBLAST also helps students establish communities beyond their local situation. Intra-school sharing of data on common experiments marked the "pilot" year. The 1997-1998 implementation has a "newsgroup" feature for students to share both data and reflections. Also, the program contains new opportunities for student to contribute to distributed research and to participate in NASA-sponsored student projects.

In essence, our teacher-leaders recommended that BioBLAST incorporate project-based and inquiry-driven learning, using both content and delivery mechanisms featuring an engaging context from which learners can generate authentic questions for in-depth inquiry. They further suggested that these student-defined investigations be carried out in a community of inquiry where classmates and teachers collaborate to complete complex activities and to produce artifacts available for meaningful assessment. Based on these recommendations, educational technologies (especially advanced media) should be "situated" and should foster collaboration and active learning.

Software that Encourages Students to Become Active Participants in Problem-Based Learning

For this section, I will look specifically at the R-WISE project, and focus on how this "cognitive tool" encourages students to view writing as a critical thinking activity. The past three decades of inquiry into the writing process have yielded a greater understanding of prose composition as a cognitive act. Specifically, Bereiter and Scardamalia (1987) draw upon years of empirical research to extract the notion of "intentional instruction," or explicitly teaching writing as a process of setting goals and achieving those goals through schema-driven strategies and metacognitive awareness.

R-WISE is based on the theories of Bereiter and Scardamalia. As a learning environment, the software provides scaffolding and visual algorithms that gently guide the writer through multi-staged intellectual activities. The software encourages students to practice powerful strategies for composing in a computer-mediated environment that fosters guided-inductive learning and ensures mindful engagement in the task. The entire R-WISE suite is made up of three sets of adaptive workspaces, each mediating the entire writing process but focusing on the strategies and self-regulative awareness characteristic of one of three domains: (1) finding ideas, (2) transforming ideas into prose, and (3) refining both ideas and text into final documents.

Modern pedagogy for teaching composition envisions dramatic changes for the role of the student. However, learners who have grown accustomed to the "traditional" pedagogy which places heavy emphasis on lecture, textbook, and drill may initially flounder when this structure is removed. Certainly, it is unrealistic to think that "little experts" will spontaneously emerge when confronted with an open-ended problem — no matter how intriguing the presentation. Nevertheless, with the guidance of our teacher-leaders, we were able to design software that produced advancements in students' participation in the process and understanding of the content.
Below, I summarize three specific goals that the teacher-leaders identified as crucial to a computer-mediated writing environment.

**Improved Strategies for Inquiry**

Modern pedagogy emphasize inquiry over lecture and demo. Certainly, the ability to write is engendered through intellectual curiosity coupled with reasoning and patience. R-WISE teachers asked that the embedded pedagogy emphasize improved problem-solving and enhanced critical thinking (asking “why” rather than “how”) among students. A second common request was that the software help students to take on larger “chunks” of the process of composing and that students become more self-directed and capable of self-sustaining a high level of effort.

In response to these observations, R-WISE contains a series of “thinking frames” that mediate the transition from “novice” to “expert” behavior in composing. These “cognition amplifiers” ease demands on short-term memory and help to focus the student’s attention on strategically important aspects of writing. Additionally, these visual algorithms help the student to self-initiate higher-order processes (metacognition) which the novice writing is unlikely to activate without prompting.

**Enhanced Communication and “Publishing” Competencies**

Authentic tasks in writing education take students through a “critical path” of asking a question, doing an investigation, answering the question, and communicating the results to others. All teachers mentioned the need for an “invention” workspace in the software suite — both for idea collection and for reflection. Equally important was the ability to share drafts and finished products with classmates. Teachers wanted a vehicle for increased sharing among students which would also enhance students’ ability to communicate with peers in collaborative work efforts — for example, in providing commentary and accepting constructive criticism. Most teachers reported that the software suite improved abilities to draw inferences and to develop a synthesis out of multiple sources or perspectives and increased tolerance for uncertainty. Students became more adept at pulling things together and “reporting” for a range of audience, purpose, and forms.

**Increased Understanding of Relationship between Information Manipulation and Concept Formation**

Understanding the “process” of writing means knowing how to extract higher-order meaning from carefully collected data and objectively recorded observations. Teachers helped to author many quantitative and qualitative activities in R-WISE to encourage students to see the meaningful trends observations and to use this information for such sophisticated cognition as prediction, explanatory generalization, or decision-making.

As a direct result of our teachers’ advice, R-WISE was given interfaces that model explicit, strategic intellectual processes so that the fledgling student avoids what Collins and Gentner (1980) have termed “downsliding,” or becoming increasingly entangled in lower and lower levels of mental actions, finally concentrating all attention on such things as spelling, grammar, and sentence construction to the exclusion of larger concerns in the process. Additionally, adaptive instructional statements within the context of a workspace mediate transitions from thoughts to symbolic representations. Students are helped with such mature cognitive activities as discerning patterns in bodies of information, decision-making, staged problem solving, analysis, synthesis, and inferencing.

**Using Classrooms as Testbeds for Educational Software**

The development cycle for BioBLAST and R-WISE emphasized feedback from teachers. I have reported here on the development cycle and initial field-testing of a pre-release versions of two large software projects. At well-defined intervals, “lessons learned” were incorporated into the next release. This overarching commitment to iterative design and formative evaluation has many benefits:

- **Integrating Advanced Media into the Curriculum:** Software supplements for teaching/learning cannot be treated as “self-driving” or as “stand alone”: advanced technologies must gracefully partner with the aims of the teacher and abilities of the students in order to enhance education. Each of the teacher-leaders in both groups is highly adept at fostering both content and concept learning through skillfully orchestrated classroom practices. The creative ways in which each teacher integrated various components of the software into a meaningful “whole” gave the development staff insights in two categories. First, we made valuable observations on the larger pedagogical issues of embedding advanced media in education. Second, we learned much about the more local issues of bundling the tools, activities, and informational support into engaging, day-to-day lessons.

- **Accommodating Self-Directed Learners:** As valuable as teacher creativity was in using the software, student usage told us much about mediating learning in a problem-based environment. Of the approximately 12,000 students participating in the R-WISE development and the approximately 800 working with BioBLAST, the majority were intrigued by the subject matter and the approach. (Analysis of data — including results from a pre- and post-test have been reported elsewhere). Observation by teachers and from site visits by the development staff point toward increased student engagement.
Developing new approaches to advanced educational applications always involves a risk. These two projects were especially demanding because of the complexity of the domain, the richness of the items included, and the freedom of choice offered both teacher and student in exploring content and performing tasks. However, through the efforts of a multi-talented team, field testing of both R-WISE and BioBLAST demonstrated the fundamental soundness not only of the software but also of the collaborative approach through which they were built.

Teachers learn a great deal through trial and error. Yet, as we continue to teach, it becomes obvious that planning, organization, student characteristics, progression of skills, social dynamics and other variables are prominent elements in our teaching performance. We must not only be visionary but also analytical in what creates an effective learning environment.

Teachers need to subject themselves not only to periodic self-evaluation, but also to the scrutiny of peers, superiors, and to their students as well. Subjective ratings, anecdotal records, and comments from others are an important part of evaluating teaching effectiveness. However, many of these methods may lack reliability and may not be easily transformed into solutions for a problem area. Systematic evaluations are objective. The objective data created from observation of frequency of events (such as positive feedback or using student names) and duration of activity (such as time on task or opportunities for correct skill practice) contributes a great deal of information about what is actually going on.

**Rationale For Developing Customized Software**

There are a variety of pencil and paper assessment instruments available for analyzing and evaluating teaching performance. The instructors wanted to share with the students a variety of educational technologies. Therefore, a search for software which facilitates collecting, analyzing, and reporting of observable teaching behaviors was instigated. The advantages of such a computer software program that utilizes objective criteria such as time and frequency enables a person with minimal training to conduct an evaluation of someone’s teaching performance. Computerized screen presentations and graphical printouts of a teaching performance would create an immediate and informative awareness of one’s teaching behaviors. Simultaneous situations recordings such as time on task and frequency of behaviors could be tracked and transcribed more easily through software technology than by a manual paper-pencil and stop watch operation.

The current software packages available did not address all of our needs. The decision was made to develop our software in a Windows environment. The Windows interface would make the computer program more user friendly than MS-DOS based software available. Our goal was to develop customized teaching analysis software that would accurately measure any recorded various teaching behaviors and communicate useful results quickly to the observed teacher with the goal of improving teacher performance.

**Development of The Evaluator**

Our objective was accomplished by developing a PC computer software program, *The Evaluator* (Henry and Hubbard, 1997), that uses a Windows interface programmed in Visual Basic language. It was designed to effectively measure time on task behaviors as well as frequency of teacher related behaviors. *The Evaluator* allows collection of data for any observable behavior that can be timed, counted or commented on. Specific behaviors to be measured can be determined by the observer prior to actual observation.

Figure 1 shows the opening format. The window has four sections. Each section contains a help portion to assist in performing the functions of that section.
**Evaluation forms.** Creates, modifies, and prints evaluation forms.

**Online Evaluation.** Evaluation data is entered while observing using a developed online copy of an evaluation form.

**Evaluation Data.** Evaluation data is entered from a printed hard copy of an evaluation form or to modify existing data.

**Reports.** View and print reports generated from evaluation data in statistical and graphical representation.

Figure 2 shows a form that has been designed in advance to record the specific observations of a teacher's lesson performance.

![Figure 2. The Evaluator Evaluation Form.](image)

This software program can be used with a PC or laptop computer input directly in the classroom/gymnasium or in conjunction with paper/pencil recording with later transfer to the software program using an online form such as figure 2. The program is designed to print reports, charts and graphs for immediate feedback. Figure 3 is an example of a completed evaluation of a teacher's performance. This report was instantly processed and displayed for immediate feedback to that teacher.

![Figure 3. The Evaluator Online Completed Evaluation Form.](image)

In addition, figure 4 is a graphical representation of observations recorded in that lesson. Graphics can help a teacher get a better "picture" of how the lesson progressed.

![Figure 4. The Evaluator Graphic Report.](image)

The advantages of a computer software program that utilizes objective criteria such as time and frequency are obvious. An individual possessing minimal training can conduct an evaluation of another person's performance. The computerized screen presentation and/or printout with a graphical display of a performance are immediate and informative devices which give someone immediate awareness of their teaching behaviors. Simultaneous situations (such as time on task, definitive portions of a lesson - introduction, review, etc.) as well as the time span of those situations can be tracked more easily through the software's technology rather than manually through a person's paper/pencil and stop watch procedures.

**Final Thoughts**

Evaluators using *The Evaluator* are able to use their time more efficiently, primarily after the evaluation is complete for counseling the individuals. The work is virtually done after the evaluation. All of the reports are generated automatically and immediately by *The Evaluator*. The reports can be graphically demonstrated to allow better understanding. Immediate feedback is the major contributor to behavior change. The immediate feedback of *The Evaluator*'s reports increases the likelihood that an evaluation will result in positive behavioral changes. *The Evaluator* can identify specific areas for improvement of individuals being evaluated. The objective accuracy of *The Evaluator* means more confidence in the results and the more likely they will be accepted. As the performance of a person being evaluated improves through the use of *The Evaluator*, the performance levels of others will also improve. *The Evaluator* can also be used to measure time on task and other learning behaviors of teachers. The same benefits of evaluation, immediate feedback and positive behavior change that applies to teachers can also be applied to students. A demonstration version and infor-
Information on the computer software program *The Evaluator*, may be obtained at web site: http://www2.southwind.net/~guerilla or by contacting Guerrilla Software, 6826 East Odessa Ct., Wichita, KS 67226.

Supporting Planful Teaching: Embedding Instructional Design in Ongoing Assessment

Sally Jackson
University of Arizona

Wayne Brent
University of Arizona

Starting about four years ago, the University of Arizona began a major initiative to try to reform teaching practice and to rebuild serious scholarly interest in teaching. The central component of this initiative was reform of the general education curriculum, which has now been completed. But an important offshoot of the initiative was a re-examination of teaching and its importance relative to other areas of faculty responsibility. Tenure and post-tenure review procedures were rewritten to weight teaching more heavily in evaluation and to require more documentation of teaching effectiveness and more explicit defense of teaching choices. Workshops and symposia were offered on such instructional designs as cooperative and collaborative learning. Study groups were formed to try to figure out how the university could become more ‘student-centered.’ Grants were awarded across campus for competitively selected instructional innovation projects. Gradually, the idea spread that there might be a need for change in our routine teaching practices, and much interest began to center on the possibilities presented by the Worldwide Web and other electronic media.

In this changed institutional environment, faculty are becoming much more planful about their teaching but also much more demanding of credible advice about teaching. Urged by instructional designers and information technology specialists to experiment with educational use of the Worldwide Web, faculty raise challenging questions about the value of new technology and about the balance between effort and return. They want to know whether investing in development of materials for the Web will pay off in any sense: whether it will improve learning, and if so, whether the improvement will be substantial enough to compensate for the time invested in development and for resistance from students. Many have heard from colleagues of the frustrations of building elaborate websites for classes that students never visit or, worse, visit but regard as useless.

Even faculty who are intent on improvement are often leery of change. This paper documents an effort to respond to the sometimes paradoxical demands faculty make in these circumstances: demands for tools that make it easy to do new things, and demands that these tools be accompanied by documentation of their effectiveness that can only be obtained after the tools are put to use. Our main strategy has been to try to try to build a learning community among faculty, using an online instructional support system both as a platform for dissemination of new ideas about teaching and learning and as a device for continuous collection of data on strategies and outcomes.

The Support System: POLIS

POLIS stands for “Project for On-Line Instructional Support,” and the current version of the system is available on the Worldwide Web both as a production site for University of Arizona courses and as a demonstration site for public use (Jackson, 1996). POLIS is a web course construction kit that lets instructors build a course on the Worldwide Web in any subject, for immediate delivery to students over the Worldwide Web. No special training is required to use POLIS. 75 distinct courses were mounted on POLIS for Fall 1997, despite a complete absence of training programs or advertising. Instructors found the tools through word of mouth, search of the University’s website, or direction to POLIS from the University Teaching Center. Most instructors never need assistance of any kind in using the system.

To build a course, the instructor visits a certain website and creates interactive web pages using POLIS resources. The resources include things like student-built bibliography and webiography, support tools for student study groups and student project teams, and several varieties of discussions. Instructors can also upload their own hypertext or multimedia content and link or embed these in POLIS resources, or they can use POLIS tools from within an independently maintained website. Although there is considerable flexibility within POLIS, a beginner can create an entire course without dealing with any of the complexities normally associated with web publishing.
The ease with which POLIS can be used is an important design feature of the system, but it is not the most important feature of POLIS. The most important feature of POLIS is that it allows for creation of highly sophisticated interactive dialogues on any topic, again without requiring any web programming skills. All resources in POLIS, but especially the interactive dialogues, aim for “significant” interaction requiring thought and effort (Milheim, 1995-96), mostly in the form of free verbal resource to questions and arguments.

At present, POLIS offers four well-defined dialogue types (in addition to a general-purpose threaded discussion format). Known as “POLIS lesson protocols,” these dialogue types are online simulations of interaction sequences known from prior research to be effective in traditional classroom settings. Each online protocol can be described as a sequence of display and response elements (Jackson & Madison, 1997).

One-Minute Essay. In traditional classroom settings, the one-minute essay involves simply having students write for a very short time on a topic covered in the lecture or discussion, sometimes as a way to develop materials prior to discussion and sometimes to summarize, integrate, or reflect on materials already covered (refs). The online version has two required elements (a prompt and a student response) that can be elaborated with an optional display of student writings, shown before or after the student’s own submission. As compared with the inclass version, the online version has two potential advantages: its adaptability for asynchronous interaction and its automatic archiving and publication of student writings.

Recitation. A standard recitation is a question/answer/assessment sequence. Although this familiar protocol has fallen out of favor as constructivist ideas have taken hold, it remains a popular tutorial sequence. The POLIS online recitation has four elements: the question, the student’s answer, a “model answer” to which the student’s own answer can be compared, and a self-assessment. Like the One-Minute Essay, the Recitation protocol can include optional elements such as display of any amount of background information in text or multimedia, and it can include display of other students’ writings at any point in the response sequence. As compared with an inclass recitation, the online version has the advantages mentioned above, plus the advantage of allowing every student to give an independent answer to every question in a set of exercises.

Adversary. Responding to many recent calls for an increased reliance on argumentation in learning, especially in the sciences (Kuhn, 1993; Kuhn, Shaw, & Felton, 1997; Pontecorvo, 1993; Meyer & Woodruff, 1997; Zeidler, 1997), POLIS offers a simulated online debate protocol in which students are invited to stake out positions and defend them against counterarguments written by the instructor or selected from other students’ writings. The Adversary protocol’s elements are as follows: description of a controversy; student selection of a standpoint and preliminary defense of that standpoint; presentation of an opposing argument; student reaction to opposing argument; and student reconsideration of standpoint and explanation for changing standpoints or standing pat. Any number of opposing arguments can be presented for the student’s reaction. The next revision of this protocol will also allow for review of other students’ arguments on either side of the issue.

Virtual Peer. Based on Mazur’s (1997) ConceptTest protocol, the Virtual Peer is an alternative format for incorporation of argumentation into courses in any subject. Mazur’s protocol, as used in traditional classroom settings, has 6 distinct elements: presentation of a problem with a set of candidate answers; silent reflection by students; commitment by each individual student to one of the candidate answers; argumentation among pairs of students trying to convince one another of the correctness of their answers; reconsideration of candidate answers; discussion of the correct solution and reasons why other candidate answers are incorrect. The online version presents the problem with a set of candidate answers; asks for the reasoning leading to the selected answer; presents contradictory reasoning favoring each unchosen alternative and asks how the student would respond to a classmate reasoning in this way; presents the candidate answers for reconsideration and asks for reasoning supporting the student’s new answer; and finally presents the correct solution. The online version sacrifices live interaction with peers, but improves on the live version by assuring that every student will have to respond to reasoning that differs from his or her own and by assuring that this reasoning will present significant intellectual challenges.

How POLIS Disseminates Advice About Teaching

When instructors open their lesson composer in POLIS, they are presented with choices among four supported protocols, and along with structural descriptions of each protocol they see a short passage containing “Recommendations.” The recommendations give a very short summary of the research basis for the protocol, explaining its origination and whether it has been shown to enhance learning. For example, the recommendations accompanying the Virtual Peer protocol read as follows: “No-tech inclass version has been shown to be very effective in teaching both science concepts and problem-solving. Online version allows for close control over the ‘peer’ contributions to learning.” The recommendations accompanying the One-Minute Essay protocol point out that the contributions of routine writing to learning do not depend on whether an instructor grades each piece of writing.

Instructors come to POLIS as an easy way to create interactive course materials on the web. However, their
actual engagement with POLIS has the potential for more profound and pervasive change in teaching practice, and this potential follows as much from the design of the authoring tools as from the design of the protocols themselves. Two features of the design of the authoring system are significant for the present discussion.

First, the display of four distinct protocols, each described in terms of its display and response elements, draws attention to a more abstract process of lesson planning. The four protocols do not exhaust all of the possible teaching/learning dialogues that can be composed once an instructor begins thinking strategically about forms of interactional engagement. The recommendations draw attention explicitly to the features of each protocol, and more importantly, they draw attention to the possibility of using these protocols in traditional classroom settings as well as in online applications. So the lesson construction tool is not just an authoring tool, but also a learning environment for teachers, a place where they are introduced to a relatively unfamiliar way of thinking about lesson planning that can be assimilated into practice in many ways.

Second, the recommendations emphasize the theoretical and empirical justification for each protocol. The recommendations explain what grounds there are for believing that these protocols will produce effective lessons. The inclusion of a protocol in the POLIS lesson composer is a sort of institutional stamp of approval for the use of these kinds of interactions in teaching. Protocols that have produced negative results in research (Marttunen, 1992) are not supported within POLIS. However, even for protocols that have been included, the stamp of approval is clearly provisional, subject to revision as experience with the online protocols either confirms or contradicts experience using similar protocols in traditional classroom settings. The design of the authoring environment is meant to emphasize that planful teaching has grounding in research and reflection.

POLIS is officially a support system for online instruction, meant to assist instructors in moving coursework onto the web. It should be obvious, however, that the support tools and the learning environment they create have the potential to alter the way instructors plan for face-to-face meetings with their students.

**How POLIS Gathers Data on Teaching and Learning**

We mentioned earlier that POLIS does not simply disseminate what is currently known about teaching and learning, but also allows us to continuously accumulate data on these processes. Most POLIS data collection is completely unobtrusive. When teachers use the POLIS tools, their activity leaves records in the form of specific objects built for their classes, such as lessons. When students work within POLIS, their activity creates responses archived within the course directory. Both instructors and students generate logs of use and of movements from page to page within a site. Additionally, new quiz and survey tools built within a related system (tentatively known as WILBUR) allow us to gather self-report data of any sort from students and instructors.

The lessons constructed by POLIS instructors and the choices they reflect can be analyzed both quantitatively and qualitatively at any point in time. A search tool designed to allow instructors to locate relevant examples of each dialogue type also allows us to determine how frequently each lesson protocol is being chosen. These can be cross-classified with the type of subject being taught to build knowledge about the fit between protocols and subject matter. For example, the Virtual Peer is modelled explicitly after a protocol developed for the teaching of physics, but it is by no means limited to that field and has yet to be used in a science course at the University of Arizona. It has, on the other hand, been used extensively in social science courses, and it could be adapted to courses in any area. We can also examine the content of the protocols for internal evidence that instructors are attempting to appropriate the structures for other than their intended purposes. We found early on that instructors in some fields were using the One-Minute Essay framework to post announcements and assignments, setting the number of prompts to "0" to suppress the production of a student response page. In effect, this means that instructors chose to make their web resources noninteractive. To discourage this way of using the protocols, we added separate tools for posting assignments and announcements, but we have not yet been successful in getting instructors in math and science fields to use online writing to support learning.

Student responses and logs function similarly as sources of data. By examining and content analyzing student writings, we can recover surprising information on how students orient to the various features of the protocols. For example, we have discovered simply by examining automatically generated archives and logs that our original design for the Recitation protocol has the unintended effect of making the "model answer" seem to be the point of the lesson. Stripped down to its structural minimum, a recitation has three required elements: a question, a candidate answer, and an evaluation. Our online implementation of the recitation originally consisted of these three elements, with the answer taken as open-ended essay and the evaluation offered as a "model answer" returned when the students submitted their answers. In many situations, getting the "right" answer is of relatively little importance compared with having a chance to compare a candidate answer with an expert model.

Unfortunately, we have found through examination of logs generated as byproducts of the students' activity that they routinely skip to the model answer before giving their
own answer. Checking input to be sure the student has made an answer is useless, since students can simply enter a nonsense string. Adding a fourth step to the protocol in which students are asked for their reaction to the comparison of their own answer to the model has also done nothing to fix this defect: students who have simply copied the model answer into the response space will assert proudly that their answers were “exactly right,” since they matched the model exactly. The lesson they are learning is “exactly wrong,” of course, and knowing this, we can tinker with the protocol to try to prevent it.

Although surprising amounts of information can be recovered unobtrusively, from records generated automatically as byproducts of teaching and learning, we do also gather data systematically and overtly using online surveys and questionnaires.

POLIS went into production in Fall 1996. By Spring 1997 we had an end-of-semester questionnaire for instructors to complete, reporting on their experience with POLIS. Unfortunately, the number of courses using the system was still rather small, and among these the response rate to the survey was low. Consequently, we learned relatively little from these questionnaires compared to what we learned from the unobtrusive data. Much of what we learned from the questionnaire data could have been learned from direct examination of usage data: for example, instructors gravitated first to the information tools (weblogiography and bibliography), overlooking entirely the powerful interactive capabilities of POLIS. Not surprisingly, instructors found it easiest to adopt the “stage one” tools that closely resemble their prior teaching practices than the “stage two” tools that attempt to induce new practices (Hall, 1993). Survey data from Fall 1997 are not available at this time, but even without survey data a trend toward increasing use of the dialogue and discussion tools is evident.

Assessment and database tools being introduced for Spring 1998 as part of the WILBUR initiative will greatly expand our ability to evaluate impact on student outcomes. These tools will enrich the authoring environment by adding the capability of building quizzes, tests, and surveys for courses and other uses, and by linking data drawn from responses to these instruments to POLIS archives and to other information systems. As with the current data sources in POLIS, these assessment tools will generate data as byproducts of teaching and learning. For example, a quiz used to assess a student’s comprehension of the material contained in an online lesson will serve secondarily to help us evaluate the effectiveness of the lesson design.

Conclusion

POLIS was designed to make teaching on the web as easy as possible and to work well within the ordinary preparation and planning practices of teachers. The authoring tools are available to instructors 24 hours a day from any point of access to the Internet, and they make instructors completely autonomous web publishers, independent of consultants, network administrators, programmers, or other support staff. Ease of use and ubiquitous availability to the instructor is crucial to the usefulness of the system as a platform for disseminating current knowledge about teaching and learning and as a device for gathering new data on what works.

Instructors come to POLIS for the authoring tools; but in using the tools they learn about new teaching strategies and they contribute information automatically that helps refine our knowledge about teaching practice and learner outcomes. Students come to POLIS for the lessons and other resources; but in doing their work they too contribute data that we use for evaluation of the tools themselves. This interweaving of instructional support and instructional assessment allows us to build a self-correcting system whose development directions emerge constantly from examination of teaching practices and learning outcomes.

Before the design process could begin it was imperative that the group set goals and define its own purpose for composing a case study. The group’s intent was to write a case study to aid graduate students’ understanding of the purposes and use of a needs analysis. Students were to use the case study to enhance their understanding of instructional design. Because the case study was for an IT class, it was decided that a web presence would be the best way to deliver the project. As a group, it was determined that a case study would provide the best medium to help students develop a better understanding of the steps involved in designing, analyzing and implementing an effective needs analysis. The case would involve real events at a fictitious company. The process of gaining insight into the characters and company would help facilitate the students’ ability to process classroom lecture and text. It was thought that the case study would affirm the progress of the students as they formulated answers to given case materials. It was expected that active participation with the case study would create an extension of classroom learning.

It was envisioned that the students would combine classroom knowledge of their disciplines and connect this information with the subject of study: the fictional company WeSaySo Oil and Gas. This case study was designed to facilitate the transfer of conceptual knowledge to concrete concerns. The use of the case scenario was designed to provide the student with an opportunity to become a constructive problem solver.

**Basic Components**

The case study was facilitated through a web site, e-mail and a listserv; however, the web site was the primary information source. The listserv and e-mail were used primarily to communicate the discussions of fictitious characters in the case study. Additionally, students were encouraged to join in discussions with the characters. Each team member in the case study took on a persona, so there were three employees of WeSaySo and one training consultant.

The web page consisted of six primary web pages with secondary pages linked to the Case Study page. The Welcome page and the Why a Case Study page were designed to give the instructional design student more information about the rationale for a case study and how to use the WeSaySo case study (screen capture 1). The primary source of information for the case study was found in the biographical information about the individual characters. Work history, education and other pieces of information helped to define the case study environment (screen capture 2). Additionally, performance appraisals and sound clips helped to add further definition to the environment (screen capture 3).

Once the students were acquainted with the characters, company and problems, the listserv was used to facilitate discussion between the training consultant and employees. An interview process was used to gather information for the need’s analysis. Students in the instructional design class were invited to join the discussion (screen capture 4). After allowing ample time for discussion, the need’s analysis went up; this was followed by further discussion, and a final product went up two weeks later (screen capture 5).

In addition to the actual case study, a link page provided other sources of case studies, a timetable page provided a summary of weekly input and progress of the case study, and a contributors page gave information about the participants.
Group Dynamics

The four members of the case study preparation group are pursuing masters degrees in Instructional Technology at the University of Houston. We were able to share our classroom learning, unique talents, and work experiences on the project. The combination of our formal learning and work experiences enabled us to develop a fictional case study based on real-life for instructional design.

To facilitate this project we needed to establish parameters for communication. We decided to meet face to face as needed to brainstorm ideas and deliverables as well as discuss our roles and responsibilities to the team. To supplement these meetings we chose to use e-mail as our mode for information and data sharing.

With any group communication can become a problem. For example, e-mail service is unpredictable and information may be misinterpreted. Overall our group was able to take communication mishaps in stride and continue working together to accomplish our goal.
At the initial meeting we were debriefed individually about the case study project. No clear objectives were established, resulting in part of the learning process becoming the creation of learning objectives. At times the group became frustrated. We did not know where to start, what was expected of us, how the final product was to be used, and what was the scope of the project. The scope of the endeavor was overwhelming at the start, yet we were also excited about the opportunity to display our instructional design competencies, develop new competencies and share our experiences with fellow students.

In the early meetings we brainstormed ideas about what was to be accomplished and developed a plan of action. The first concept was to develop two case studies: a business model and an educational model. Two case studies would enable the project to appeal to all the learners in the classroom and demonstrate differences in the instructional design process. We developed individual roles and responsibilities and set out to gather information to share about the case studies. Our initial plan was to take the students through the development of a needs analysis for a business model and continue with the development of a finished product in an educational setting.

Midway through the project some team-member’s enthusiasm for the project began to wane. Other factors such as work, school, and personal obstacles intruded on the project. There was also a renewed sense of frustration in trying to complete what had become a broader undertaking than we had first conceived. As a group, we decided to revisit our original vision and modify it to fit the students’ needs and our own time constraints. The new vision was to follow through the whole instructional design process using the business model. With our new vision in mind, we set off to accomplish the task with increased excitement.

As the project drew to a close, we discussed housekeeping tasks that needed to be accomplished. These responsibilities included student and instructor evaluations of the project, assessment of the web page, appraisal of the use of the listserv, release of the final deliverables, discussion of what worked well with the project and how could it be improved in the future.

For all of us this was the first time we worked in a group framework that extended over a long period of time. Most of us were familiar with working in a single group for short projects but never over a sixteen week course with everyone depending on each other to accomplish the tasks. There were some communication breakdowns, misinformation, and technology problems encountered throughout the process. However, as group we worked through these and it made us stronger. We all feel that next time we work in a group that will extended over a long period of time we will be better group members.

### Benefits to the Class

Using one or more case studies in the curriculum design class has advantages and disadvantages. Several modes of learning were made available to the class, including role-playing, debate, game design, lecture and demonstration, individual and group research, and the online case study. As one of several methods of instruction, the case study could become an important part of the course.

The case study addressed here was a business model involving an accounting department, a situation with which most students in this class would normally be unfamiliar. The advantage of using an unknown circumstance is that this is a position in which a professional training consultant or course designer likely will find himself at some point. It also frees the class from digressing into a discussion of how things are done currently in their own schools or businesses and focuses the class attention on the problems at hand in the case study and how to solve them.

A case study with the writers of the study available for online discussions has exciting possibilities for being a dynamic instructional instrument. Student interaction with the “characters” of the case can increase student interest, allow deeper understanding of curriculum elements, and cause the case study to be different every time it is used. The characters can engage the students in debate, discussion, and allow student comments to alter outcomes. The disadvantages of the use of case studies revolve around the same issues as the advantages. An unfamiliar situation may cause students to have decreased interest in the project due to lack of appeal of the application. If the case does not directly affect a student’s particular situation, current or desired, he may have little motivation to examine the ramifications of the case. The online discussion and interactivity with the characters causes the case to have to be developed in “real time” with the class, leading to deadlines being unmet and frustration on the part of the class itself, as well as those working on the case study.

As the curriculum design course is intended as preparation for employment in some kind of training capacity, the use of case studies, both real and fictional, are important parts of the course. A selection of cases already prepared and “in the can,” so to speak, may be a solution to the disadvantages enumerated above. The course instructor could select an appropriate case study for a class, and have a group of students who have previously taken the course assume the roles of the characters online. Continued use of case studies will define and refine its role as part of the curriculum design course.

### What the Team Learned

In designing a case study it is easier to construct a situation about something which the authors have explicit knowledge and awareness. However, the team agreed that
the instructional design class would benefit more from a study that was distinctly different from their comfort zone of the classroom. The team chose a business model hoping that it would challenge the instructional design class to think outside their world the classroom. However, this decision created additional problems that had not been anticipated.

First, the team had a difficult time constructing a real-world study because it was dealing with accounting concepts within a business model. The model for the case study was an oil and gas company with problems in an accounting department. It was very difficult to construct the case study so that the model was real and credible. The team simply did not have an awareness of the business to make it “feel real.” The team enlisted the services of an accountant to help with some of the details; this helped some. A case study can be written about a situation that is foreign to its authors and users; however, it takes extra research into the situation and an awareness that the situation will need to be even more rigorously researched and developed. In the case study of WeSaySo memos, dialogues, charts and even a company prospectus could have been used to make WeSaySo more realistic. The biographies, sound bites, and performance appraisals that were developed helped to create the context for the case study, but more could have been done.

The team soon came to an awareness that the personalities, experiences, and goals of each team-member were important to the successful completion of the project. The opportunities and challenges of working as a self-directed team helped each of the team members to grow in an understanding of the dynamics of cooperative learning. The members also came to a better understanding of what it is like to be part of a project-team. One team member remarked at the end of the project that this was the first experience that she had ever had in being part of a team.

As part of this team-effort, the four students came to understand that each individual was on the project for different reasons. Different reasons imply different levels of commitment to certain components of the project. These different levels of commitment resulted in a perceived inequity in the sharing of the workload. The four team members discussed this perception of inequity and agreed that the most important result was that the job got done in a professional manner while allowing all members to make a significant contribution. The four members agreed at the project’s completion that this was accomplished. However, the team also agreed that many of the problems could have been precluded with better pre-planning and clearer member guidelines.

More lucid guidelines and better planning could mean several things. First, a more formal time schedule with strict rules for adherence should have been considered. Individual goals and team goals could have been discussed and agreed to. Personal contracts between the team members could have been written. Consequences for failing to meet deadlines could have been implemented. Several things could have been done to establish the parameters of personal and group conduct, but it is uncertain that they would have been effective. Because the class was only a three-hour class, and because each student had different personal goals and responsibilities, it may have been difficult to get a group consensus as to what to expect. It would have been even more difficult to enforce the guidelines. Nevertheless, the group still agreed that some form of accountability should have been built into the project plan.

Designing the case study was not an easy task, yet the time spent working through the issues of instructional design helped the team-members to understand the steps of instructional design as well as the steps that go into designing curriculum as a team.

The Final Report of the Indian Nations At Risk Task Force states that, “Our schools have failed to nurture the intellectual development and academic performance of many Native children, as is evident from their high dropout rates and negative attitudes towards school” (U.S. Department of Education 1991, p. 1). Data gathered as a result of this report identified multiple issues regarding the training of teachers, cultural differences in the non-verbal regulation of classroom interaction, culturally appropriate curriculum, and psychoeducational assessment measures and practices (Baer & Bennett, 1987; Gundersen, 1986; Littlebear, 1993; McShane, 1983; Wald, 1996; Wells, 1991). In response to this report and the growing concern in Utah for the educational needs of American Indian students, the Department of Special Education at the University of Utah developed, with the assistance of federal grants, a graduate program designed to prepare teachers to work more effectively with these students.

The graduate program, with a specialization in teaching American Indian students with disabilities, included four graduate level courses offered during summer quarter sessions on the campus of University of Utah. Personnel from Special Education, Educational Studies, Educational Psychology, and Ethnic Studies within the Graduate School of Education at the University of Utah collaborated on conceptualizing the model, defining the components, and operationalizing the priorities into a unified graduate program of study. Faculty involved represented several minority groups, including individuals from two American Indian nations. This collaboration from different educational and cultural perspectives provided essential input and relevancy to the project. As an extension of this project, developers decided to offer a portion of the specialization content via distance education in an effort to reach educators working with Indian students throughout the state. The purpose of this paper is to describe the process of designing a multimedia distance education course entitled Culture and School Success: Teaching American Indians.

Building Support

Project developers applied for and received funding for a curriculum development effort sponsored by the Utah System of Higher Education under a Technology and Distance Education Initiative. Two major outcomes for this project were identified: (1) to educate a minimum of 350 educational professionals per year in their home communities in “best practice interventions” for American Indian children and youth in Utah, and (2) to develop and test an innovative technology enhanced model for curriculum development and distance delivery which included cost effectiveness, longevity, and flexibility in its use.

The course to be developed “Culture and School Success: Teaching American Indians” was conceptualized as a graduate level course that would be available in both pre-service and in-service contexts to educators in both urban and rural/remote parts of Utah. The course content was distilled from the four existing federal grant funded classes that were taught previously by four professors and offered only on campus. The challenge of developing such an inclusive and flexible course to address the needs of American Indian children and youth at risk in Utah was formidable. The circle was chosen as the culturally relevant metaphor for the multimedia course. In many American Indian cultures, the circle represents the balance of life, as all things important to maintaining life fit somewhere on the circle. By touching one part of the circle, all parts are included. It was found that the metaphor used to address the issues of the course also applied to the development process in creating the distance education course. (Herbert, Mayhew, Sebastian, in press).

In the initial proposal it was clear that the project would need extensive technical assistance. Therefore,
support from an instructional design team and resources for multimedia development were built into the proposal. The four faculty members who serve as content specialists were provided with either released time from other course assignments or stipend support. A graduate assistant was selected to help obtain and organize course support materials. Two additional faculty members, also responsible for distance teacher education in the department, completed the project development team.

Together, there are ten individuals with very different backgrounds and experiences directly involved in the development and production of the course. Each person has a different role, responsibility and expertise to contribute to the process. Roles include: distant education specialist, syllabus designer, video producer, world wide web consultant, copyright research specialist and content specialists in the fields of Indian education, special education, educational psychology, and ethnic studies. Coordinating the activities of the design team, particularly at the beginning of the project, became one of the greatest challenges of this project.

Course Design Theory

Multimedia development is an interdisciplinary effort focused around producing the most effective instructional episode for the learner. Media is defined as a means for effecting, conveying or communicating something. By that definition anything used to effect a learners instructional experience is a medium. A multimedia course uses several different types of media to communicate the instructional message.

The various media examples shown in the model (Figure 1) have distinctive advantages and disadvantages in the instructional episode because each appeals to different learning styles. By combining different media we reach a wider variety of learners creating a rich blend of sensory perceptions. The decision on which medium to use comes from answering the question, “which method makes it most clear what is to be learned, and which does it most interestingly and most economically of time, space, and money” (MacMillan, 1930, p.338)

To effectively decide which medium should convey what message, developers must first start by defining the message. If the instruction only consists of one medium, for example the professor communicating to the students, then chances are the design process for that course could be relatively simple and direct. But when the design involves a team of developers the process becomes more complex.

Participants who come to the multimedia development process come from different cultures, and therefore have different world-views and perspectives in terms of the design, development, production and implementation process. By involving development stakeholders in the design process needs, frustrations and alternative solutions can be addressed. (Carr, 1997). The team needs to come together to develop a shared language to be able to communicate with one another about all aspects of the project. “The design effort must be interdisciplinary in nature. No one person is likely to be a specialist in all media and content areas to be covered in the process of developing a successful course” (DeBloois 1983, cited in Romiszowski, 1986). In order to successfully communicate and produce what you set out to produce, it is essential that the development have a shared vision of the finished product.

**Instructional Multimedia Team Design Model**

![Collaborative Design Model](image)

Unfortunately, many content experts are resistant to this idea, and for good reason. The faculty culture places a high emphasis on ownership for intellectual property, student credit hours and revenues from the completed course. These issues must be answered before the project begins. Regardless of the political landscape for development, the most important pre-requisite for faculty involvement must be the motivation to create an effective instructional environment for the learner. With this as a common denominator among all team members, all other logistical problems are more likely to be solved through effective communication.

The tool for communication in this production process is the instructional design; therefore, it should also be developed collaboratively. Team members’ experiences, revelations, and enthusiasm for the project need to mix together through time in order to find solutions to instructional challenges. The successful process allows for that design time. It provides for breathing moments, reflection, and review. It should be a flexible process that always keeps as its focus the ultimate beneficiary, the learner.
However, this process needs to be examined within the context of production timelines, grant funding periods, and academic calendars. Instruction can only benefit the learner if it is implemented; therefore, the team does have to accomplish stages of design, development, and production in a timely manner. To insure that no step is left undone, instructional design systematizes the process but it should not take the creativity and flexibility away from the design team. The process should give the team freedom for creativity by taking away the stresses that comes from last minute production issues.

To assist the design process an instructional designer facilitated a series of large group brainstorming sessions. This person utilized a systematic approach to the design process (Gustafson, Branch, 1997: Romiszowski, 1986) to insure all aspects of the project were thoroughly thought out before the production process could begin. Four stages or levels of design were addressed in designing the course.

**Level 1 - Course Parameters**

There are potentially as many solutions to a given problem as participants in the design, especially if there is not a clearly defined direction from the start. The first stage of development outlines all of the influencing factors in the course as well as the overall course goal. This helps give the team a common vocabulary to describe the problem and the solutions:

- Who will be taking this course?
- Where will it be taught?
- What technical limitations will the students have?
- Can the material developed for this course be used in any other ways? If so, what ways?
- Why are we offering this course?
- In what specific way will this course meet the challenge?
- How much money do we have to work with?
- When will the course be implemented?

This kind of analysis helps in making the tough decisions of what to include and what to leave out. Many of the issues discussed at this stage are often overlooked because team members assume everyone is starting from the same understanding of the project. However, with such a diverse group of people it is risky to make such assumptions. What may seem trivial now could become a major production problem down the road.

**Level 2 - Content**

This stage outlines the knowledge, skills and attitudes needed by the learners in order to achieve the overall goal. This includes the assumptions the faculty has about the learners' pre-requisite knowledge and attitudes. The ultimate goal at this level is to define the knowledge gaps between where the students are now and where they need to be after instruction. The definition is stated in the form of learner outcomes. Taken as a whole these outcomes should address all aspects of the ultimate goal of the course.

**Level 3 - Scaffolding**

At this point the team strategizes the best way to meet the learner outcomes defined at level 2. The goal is to chunk the concepts in a way that builds a scaffold of superordinate and subordinate concepts linking prior knowledge to new knowledge. (Peters, 1996: Pressley, McCormick, 1995) Then the team needs to decide what is the most effective way to achieve those outcomes by deciding which medium will best address the concept while keeping the learner engaged and motivated in the process. This is done by reviewing the strengths and weaknesses of the media choices.

Another factor influencing media selection is the possibility of re-purposing the developed media for other projects. Production costs can be expensive. If a product can be used in different ways, the impact of the product is increased and the relative production cost is more efficient. By exploring other possible uses at this early stage, copyright clearances and agreements can be obtained.

**Level 4 - Media Element Design**

Once the team has developed a more specific list of its media production needs, it becomes easier to determine what already exists and what needs to be produced. Complete segments may already exist thus saving valuable production time and money. This production outline also facilitates more involvement from the community in finding resources for the production. At this stage the team sets realistic expectations about production time line and costs. The team also identifies subject matter experts for each produced element and assigns those elements to a faculty member who will serve as the production team's contact point. However, it is important for one faculty member to be the point person or project leader as faculty is more likely to accept direction from another faculty member.

**Course Design Practice**

While the process can be viewed in stages it is by no means linear. With a diverse team, it is important to take a more iterative approach to the process, allowing the team to construct and deconstruct the design. In developing "Culture and School Success", the faculty team met first without the rest of the design team to flesh out the content areas that needed to be addressed within the course. The request for proposal process helped to define many of the issues addressed at level one.

When the design team met, the instructional design facilitator took each of the chunks of content brainstormed by the faculty and worked with the entire team to develop the knowledge, skills, attitudes, pre-requisite knowledge...
and assumptions about the learners. From this point the team arrived at the outcomes for the course.

The course content chunks were also pulled into a sequence by the team. In order to illustrate these sequences, lists were put up on walls to help the group visualize the structure of the course. As outcomes were developed, the sequence was reorganized in a manner that best met the scaffolding needs of the instruction. This scaffolding had to fit within the confines of the University imposed semester system, 15 two-hour sessions.

Within each session, the team decided to mix the media based on which medium would best communicate the desired message to the learner. The team wanted to develop an interactive structure that presented a concept or event via video and then utilize break out activities to engage the learner. The purpose of break out activities is to allow the learner to create meaningful concrete experiences for him or herself about the abstract concept covered in the video module. This design follows the “Professor Plus” model extensively used in the rural, distance education program of the Department of Special Education at the University of Utah. (Sebastian, Egan, Welch, &Page, 1996). Enrichment activities, readings and other outside the class events are designed to reinforce the instruction.

Themes developed during this process transcend the individual outcomes. These themes were used in each session to guide the class design. The themes include:

- Historical Context - to set the information in a framework and to call attention to the purpose of the session.
- Self-reflection - to personalize the material, bringing it into the students lives to increase relevancy.
- Student designed solutions - to put a positive slant on the material, helping the students build confidence in developing class based solutions.
- Evaluation - to provide opportunities to track student performance and reward successful achievement.

These themes also have the added benefit of following the ARCS model of attention, relevance, confidence and satisfaction, a method developed by John Keller for improving the motivational appeal of instructional materials (Keller, 1987).

The design was developed over a period of two months for a total of eight all day meetings. Because of outside commitments, not all of the design team participated in each meeting. This meant that throughout the process the team would go back and evaluate what happened at the last session, deconstructing and reconstructing the work. This was especially true when the team started developing the design for individual class sessions. Often members of the team would want to go back to review the content or to the learner analysis when starting a new session design. It was sometimes difficult for the faculty to let go of a specific content area to move on in the course. By keeping the work done to date visible to the team via white boards and paper post-ups, the faculty could be reminded of content already covered which helped to keep the team on track.

The end result was an outline (Table 1) that lists the elements to be covered in each session. Each element includes the amount of time allowed for the element, the presentation style, and the content to be covered, and which faculty members will serve as the subject matter expert for that element.

**Total instruction time:** 110 minutes

**The next step**

This account only describes phase one of the long involved process of multimedia course design, but arguably it is the most important step. From here the
various development teams will produce the video elements, develop the print materials, research the enrichment activities, train the facilitators, explore possible world wide web interactions, and design the student activities and projects.

It is at this point that the design team took advantage of the vast community resources available. Given the fact that the course being developed addresses the needs of an under-represented segment of the community it was seen as particularly important to solicit community involvement. An advisory board made up of leaders in the field of American Indian education, school district personnel, families, and tribal representatives was identified to provide additional assistance with the course content and help in the identification of resources. The design team felt very strongly that regular interaction with the advisory board would also be important for the quality and integrity of the course. Because the needs and expectations of the project have been articulated through the design process, the team has been able to solicit input on the specific research needs from this advisory board.

### Lessons Learned

There are several lessons the team either brought to the process or picked up along the way. These include:

- Complete the design process before you start the production process.
- Take advantage of the community and culture around you as information resources.
- Formatively and summatively evaluate the project based on the design.
- Look for possible re-purposing opportunities before production starts.
- Be flexible.
- Don’t assume anything.
- Provide food at group meeting sessions. (If you feed them, they will come.)
- Faculty who are intrinsically motivated to develop a more effective instructional product will more likely to stick with the entire development process.

The goal of “Culture and School Success” is to promote cultural pluralism in the classroom. Multimedia course development also merges vastly different cultures in an interdependent process that crosses several disciplines. Our final lessons, therefore, have been adapted from the outcomes of the course:

- Celebrate the diversity that comes from different fields of expertise.
- Respect all members of the development team.
- Allow yourself to think outside the box when it comes to changing the way you approach course development.
- Believe and trust in yourself and in your teammates.
- Above all, approach the process from the perspective of what’s best for the learner not the development team.

Instructional Design — 475
The study reported here was an interview study of low and high prior knowledge students with strong or weak goals exploring a hypertext stack. We examined the influences of a student’s prior knowledge and desired goal on the difficulties and benefits associated with using hypertext. In-depth interviews were conducted with students who participated in the study.

A commonly recognized difficulty with hypertext is the possibility of getting lost or disoriented (Conlin, 1987; Edwards & Hardman, 1989; Hammond & Allison, 1989). This kind of disorientation often occurs when a user suffers from cognitive overload as a result of being confronted with a mass of links through which to navigate with little structural support (Giril & Luk, 1992).

Akanabi and Dwyer (1989) noted the importance of prior knowledge over text structure as students with varying levels of prior knowledge benefited from different types of text structure. Students with high prior knowledge profited most from a less structured, inductive learning environment while low prior knowledge students benefited most from a more structured, deductive environment. Similar results were found by Pazzini (1991) who showed that the rate of concept learning was affected more by students’ prior knowledge than by a text’s content structure. In general, prior knowledge can determine how well a learner acquires information from hypertext since it can supply a mental framework, providing both perspective and context for new and inter-connected concepts, allowing a learner to fill in gaps in knowledge. Prior knowledge allows a learner to focus more directly on information presented by reducing the amount of overhead associated with the task of navigating through hypertext. Without some kind of mental map of the material already in place, working memory can become overloaded as a user tries to understand all the information presented and how it is structured.

Alexander, Kulikowich, and Jetton (1994) concluded that it is important to consider how additional factors other than prior knowledge affect learners. One such factor is the goals that learners have. With many options available in a hypertext structure and all possible avenues equally available, students’ goals must play an important part in the ease and effectiveness with which hypertext is used.

In an ideal constructivist environment, hypermedia users would search for complex information to meet their own goals (Jonassen & Wang, 1993). However, external goals are often imposed on learners and even when the learners accept such goals, they may not have appropriate strategies available to them to attain the goals.

While goals and prior knowledge have been shown to affect linear text processing, very little research has been conducted on how these factors affect learners in a hypermedia environment. Because these factors have not been carefully considered in relation to hypermedia learning, research is still at the stage where rich descriptions are necessary in order to identify and explore relevant factors. Utilizing a qualitative methodology and small sample size, this study examined the influences of a user’s prior knowledge and desired goal on the difficulties and benefits associated with hypermedia.

Method

Participants. Twelve subjects from an undergraduate course in Educational Psychology were recruited to participate in the study. Eight were female and four were male.

Materials. The study utilized a hierarchically structured hypermedia system, SKEIM, developed by A. Kelly (Kelly, 1993; Kelly & O’Donnell, 1994) which runs on the Macintosh platform and was developed using HyperCard Software. The program’s content, organized by A. O’Donnell, contains material based on an undergraduate course in educational psychology on the subject of tests and measurement. Concepts were characterized using the sets of relationships identified by Dansereau and his colleagues (e.g., Holley & Dansereau, 1984). This classification of concepts was instantiated within SKEIM and was meant to provide an extra measure of structure and support for hypertext users. Students’ performance while using the system was automatically collected by the program in the
form of a trace. The data collected in the trace recorded the student’s review strategies by choice of theme, concepts searched, level of detail of the information accessed, and relationships among concepts. Traces contained data on theme, card name, level of depth for card, and time spent on card. Material in SKEIM is linked together in a hierarchical structure, which can help users avoid some of the navigational issues associated with hypertext (Girill & Luk, 1992). Using SKEIM requires a user to begin at the highest level of detail for a theme, and through the use of pop-up menus, browse through several levels of detail about the theme; the deeper a student browses, the more detail about the topic is encountered. For example, if a user decided to explore the topic of frequency distribution, she would be presented with a pop-up menu and would then have to choose one of the following: Example, Characteristic, Leads to, Analogy, Part of, Type of, or Definition. In all, SKEIM contained 5 themes and 82 subtopics distributed through nine levels of depth.

Procedure. Participants varied in prior knowledge of the program’s content and were assigned to either the low or high prior knowledge category. Within the high and low prior knowledge groups, subjects were randomly separated into two sub-groups: strong and weak accomplishment goals. Students in the strong goal group were given a specific task to complete. They were required to fill in partially completed sentences found in the hypertext database. Students in the weak goal group were given a non-specific task. They were asked to review the material in the system, and told they would be asked questions about the material when they where done.

Each student was shown how to use the program and then given his/her specific or non-specific goal to accomplish. Students were allowed to browse through the SKEIM program uninterrupted for approximately forty minutes. After the student completed the task, he/she was interviewed for approximately forty-five minutes. In order to gain insight into the students’ thought processes while using the system, the researcher interviewed students using an interview guide approach.

The first part of the interview involved questions related to the subjects’ feelings about use of the program in general: In what ways was navigation difficult or simple, what kind of strategy did they use, etc. Students were then shown every step they made during their use of SKEIM; this was reenacted by the program in a sort of slide show shown every step they made during their use of SKEIM; and students had the opportunity to reflect on their activity. At branching points which represented a shift in topics, the researcher asked questions to try and gain understanding about the student’s immediate goal or purpose, if any, as well as any reflections on cognitive and met-cognitive activity relating to the branching decision.

Results

Prior Knowledge

Students falling in the low prior knowledge category tended to find the system difficult to use. The most common complaint was in terms of navigation, especially in reference to getting lost in the system. Several students claimed that the farther they went into the program, the more they felt lost; the more details they encountered, the harder it was to maintain a navigational model. Students with prior knowledge were comfortable in navigating. Several students wanted a faster, more efficient way to navigate and none complained about feeling lost or in need of assistance while using the program. Whereas the low prior knowledge students complained about the structure of the content being different from their own, the high prior knowledge students all reported that the material was exactly what they expected; none felt their prior knowledge interfered with searching but rather made navigation simple. In response to questions about navigation, almost all felt they were able to find what they wanted easily and keep a model of the program in mind.

One seemingly beneficial aspect of a hypermedia system such as SKEIM is the presentation of a highly structured and organized set of information. For the high prior knowledge students, this characteristic was always helpful since these students already had mental models of the content but not to low prior knowledge students. Several students reported conflicts between their understanding of the content and that presented in the program. In describing her strategy during a certain part of her trace, Laurie noted:

When I thought I knew what to expect, it usually turned out different than I expected – and that threw me off. I had preconceived notions about the grades topic – I expected material about “A’s, B’s, and C’s” but instead found information about frequency distributions, mean, and mode instead.

Another possible problem with providing a highly structured learning environment is that there is less incentive for students to organize material on their own. Students who do not actively participate in learning activities will not benefit as much as those who do (Phye, 1997). Benny felt that the content is SKEIM was: “…organized in a way that made it seem structured – I didn’t have to structure it myself. I actually would rather have created my own structure since I wanted the material organized differently.”

Goals and Prior Knowledge

Students with little prior knowledge and weak goals were extremely frustrated and anxious. They followed the structure of the stack but were unsure of their actions. When low prior knowledge students had strong goals, they could not find the information they needed as they were
lacking in a conceptual model. High prior knowledge students had little difficulty and in the weak goal condition, they meandered at will in a somewhat random manner. Students in the strong goal group experienced more navigational problems. Students with little familiarity of the material found the task extremely difficult, used poorly defined strategies, and became quite frustrated. Students with higher prior knowledge were better able to perform the task, had only slightly better strategies, and were much less likely to become frustrated.

Low prior knowledge students tended to go through the material methodically, in the order it was presented. This was especially true of those students who had weak goals. High prior knowledge tended to bounce around looking to fill in gaps in their knowledge.

If I was seeing something for the first time, I didn’t go too deep into detail but tried to get a more general idea. I was afraid that if I went too deep I would lose sight of what I had just learned. [Laurie]

Laurie’s methodical strategy is illustrated in Table 1 which contains a list of all possible nodes in the Test Scores theme, the depth for each node, and the relative order that Laurie traversed the nodes. Laurie claimed that she was extremely unfamiliar with the test scores topic, and as Table 1 reveals, she visited most of the cards in that theme and navigated basically in the order presented by the system.

Unlike the novice students, the high prior knowledge group performed the weak goal task in a fairly non-methodical manner. Their strategy, although not haphazard, was much more unpredictable. The students tended to search out of order looking for material that was either new or of interest. This tactic, however, only pertained to material that was familiar. When the students discovered new material, their strategy changed, appearing similar to the novice users’ as they searched in an orderly and thorough fashion:

I usually tried to start with a topic less familiar and then went through it carefully. I realized I knew most of the material in the program so I tried to find topics I hadn’t already seen. [Cory]

The trace data in Table 2, a section of the Test Types theme, reveals some of the behavior described by the students. Both Cory and Jamie visited nodes sporadically and out of order, revisiting a few nodes after exploring other topics. Danielle’s behavior in this section does not match the expected high prior knowledge strategy displayed by Cory and Jamie but rather is more indicative of a low prior knowledge student; she visited the nodes in this section basically in order and thoroughly.

In general, subjects with high prior knowledge were better able to take advantage of the program’s assets since for most topics, they were not learning the subject for the first time. They were able to search for new and interesting information without the fear of navigational difficulties and generally seemed more enthusiastic and encouraged by their experiences.

When questioned as to why they followed such a thorough strategy, the students explained in terms of their low prior knowledge; they generally had poor cognitive models of the material and as a result followed the model or structure presented to them by the program. This strategy was adaptive since by following the program’s model, there was less cognitive overhead related to navigational factors therefore reducing the risk of getting lost.

### Discussion

The study considered the influences of prior knowledge and goal specificity, focusing on students’ search strategies and navigation styles but also considering students’ affect toward the hypertext learning experience. The ability to trace students’ search behavior can provide valuable information about the learning process. By conducting in-depth interviews, we were able to investigate some of the affective as well as cognitive reactions to non-linear text processing. Results show that students tended to have more than just a cognitive reaction when learning from hypertext. High levels of anxiety were common for the low prior knowledge students especially when they were required to perform a specific learning task. The implications to these findings are that hypermedia design aspects, which in interaction with specific individual characteristics
such as prior knowledge and goals, can promote negative affect which is known to be non-productive for learning.

This study contributes to the previous literature by considering how learning goals affect hypermedia users. The results of this study suggest a relationship between subjects’ level of prior knowledge and desired goal. This relationship was most noticeable in relation to students’ search strategies and navigational styles. The low prior knowledge students performing the strong goal task had complaints about navigation and generally stated that they would have benefited from the use of a navigational aid. In general, they were unsuccessful at their task, suffering more seriously as a result of cognitive overload, frustration, and poor ability to navigate than did those novices simply wandering through the system. The high prior knowledge students suffered much less from negative affect and were somewhat more successful at completing the strong goal task. The task was easier for these students since they already had a mental model of the content and had some idea where to look for an answer.

These findings suggest that developers of educational software should seriously consider features of the audience before committing to a method of instructional delivery. A system designed to teach novices might be more effective if it used techniques geared toward introducing students to a subject rather than a hypertext format. In general, hypermedia systems should be designed to accommodate users of different levels of prior knowledge. A hypermedia system designed for an audience varying in subject expertise should provide as many resources as possible, since novices will probably require them and experts might benefit from their presence.

The Instructional Design Network Project was an Educate America Act Grant for $158,000 designed to support local school improvement initiatives in Kansas through utilizing technology to assist in developing instruction design specialists. The grant was aimed at meeting goal 4 of the Educate America Act, "...helping the Nation’s teaching force have access to programs for the continued improvement of their professional skills and the opportunity to acquire the knowledge and skills needed to instruct and prepare all American students for the next century."

Approximately 41 personnel from 14 school districts were involved along with 11 academy staff members. The project involved three two-day workshops, contact via an electronic mail listserv, newsletters, and a project webpage. The focus was on utilizing technology in the instructional design process and each team was also given skills to enable them to work with staff development at a district level.

Need
The districts selected for the project already had strong academic governance programs regarding curricular instruction. However, there was a great need for training in the systematic design of instruction that aligns with curricular outcomes. There was also a high degree of need to both include technology in the new high performance outcomes and in utilizing technology in developing the program. It was also found that school districts needed instruction in utilizing authentic assessment with school curricula. Thus, the project centered on supporting local school initiatives through using technology to design effective instructional curricula.

Goal
The goal of the project was to create a school/university/business partnership and system for developing and improving the skills of public school teachers in designing and executing performance based instruction.

Objectives
Specific objectives of the project were to: 1) create cadres of instructional design specialists in a network of schools districts located in all regions of Kansas, 2) create a field academy for instructional design at Emporia State University, 3) use the academy to train and support the instructional design specialists in both curricular reform and utilizing technology, 4) provide a means for specialists to work closely with their district or school’s academic program governance unit, and 5) provide a means for specialists to work closely with designated businesses in their communities to address business interests and cooperate on community resources.

Activities
Training activities employed strategies that ranged from peer coaching to comprehensive workshops. The workshops focused on 1) academic decision making, the design down system for preparing, implementing and managing curriculum and instruction, 3) the development and use of print and electronic media including writing web pages and development of electronic portfolios for assessment, 4) recommended uses of interactive media, including interactive TV and the Internet, 5) planning and conducting faculty development programs within a district, 6) the relationship between clear instructional design media and acquired funding from business and other potentially supportive organizations, and 8) establishing a national network, primarily through the Internet.

To facilitate the implementation of the grant the IDN Project Council was formed. The council consisted of 13 members, 11 participants and 2 additional district personnel. The Project Council provided continual input to the Academy Staff and had a major role in meeting overall school district needs. An Executive Council was also created with 5 members who approved budgetary items and set major policy for the project. Both Councils met separately from the Academies and most meetings were held in Salina, Kansas.

Three Instructional Design Network Academies were held on two weekends as well as three full days in June when schools were out of session. The academies focused on design considerations, technology, and train the trainer. All of the Academies were held in Visser Hall, the primary
home of the Teachers College at Emporia State University, Emporia, Kansas. Three of the computer laboratories in the Teachers College were used almost continually during the Academies, further evidence of the integration of technology into the curriculum design process.

**Academy Staff and Participants**

The staff consisted of personnel with considerable expertise in curriculum design, staff development, curriculum leadership, K-12 subject areas, and instructional technology. Of the 11 staff members, 6 were professors with doctorates who were employed at Emporia State University and 6 were affiliated with the Curriculum Leadership Institute. The 41 participants were from 13 public school districts and 1 parochial school, the Catholic Diocese of Wichita. The school districts were from widely scattered counties in the North, West, and East Central areas in the state as shown in Figure 1. The participants were selected from full time teachers, professional support persons, or administrators. They were curriculum leaders and were to possess skills in educational technology.

![Image of School District Counties on Kansas map](image)

**Technology Components**

An early assessment of each district's Internet capability found that only three districts had access, and of those, two had connections only in the library. While few districts had access, most were "working on it." However, of the academy personnel, each already had an individual electronic mail account and full Internet access. Thus, while some technology was available in each district, most had only read about the capabilities of worldwide communications and the easy access to information for both teachers and students.

At the very first Academy participants were paired and were given minimal instruction in using Netscape Navigator before being assigned to accomplish a student-level objective. The teams then used the Internet to obtain information, synthesize the results, and then report their findings. The assignment quickly showed the participants the importance of technology to students and also that many teachers and administrators needed additional skills in this area.

The class "Internet Resources and Tools for Educators" is regularly offered by Emporia State University entirely through the world wide web by the author. To enhance the project participants expertise in the Internet, they were offered the opportunity to take the class without paying a fee. While only one person elected this route, 7 went ahead and paid the university fee so that they could obtain graduate credit for the course.

Another technology tool used was establishing a listserv, IDNGRANT@LIST.EMPORIA.EDU. They were then instructed in both using electronic mail and subscribing to a listserv. The listserv was very useful for communications between participants and the Academy Staff. However, since many participants were not comfortable with electronic mail it proved to be of most use to the staff.

A webpage was constructed for the project and many participants had the opportunity to distribute material via the webpage. Participants were also given the chance to learn basic web construction using Netscape Navigator Gold. Additional training was provided in Microsoft PowerPoint, and it proved to be most popular among the software tools. Indeed, when groups from the districts presented their District Action Plan, almost everyone had either transparencies created with PowerPoint or used a video projector and a computer in their presentation.

**Outcomes**

The primary outcome of the project was to develop or improve the skills of inservice teachers in designing and executing performance and technology based instruction. This would include all teachers in participating districts and on selected surrounding districts. The second outcome was to develop stronger relationships between the local educational and business communities.

**Conclusions**

The project evaluators felt that the major goals of the project were met. Instructional Design Specialists were developed for each participating school district. However, there was some evidence that the project tried to do "too much," and it was also felt that each component could have had more depth. Many participants wanted considerably more skill development in using technology, especially with the advent of the Internet and its many implications to curriculum at all levels.

Armand Seguin is Associate Professor of Instructional Design and Technology in the Teachers College, Emporia State University, Emporia, KS 66801. Office: 314-441-5627, Fax: 314-341-5785, Home: 314-343-2699. E-mail: seguinar@emporia.edu.
Science has been changing rapidly over the last decade. Like everything else around us it seems to be in a turmoil of altering, mutating, or disappearing. Most likely the idea of change is a cultural phenomenon, and could be seen as a side effect of the ‘strange attraction’ the media have invoked upon us. Chaos and all of the modern self organizing hocus pocus are splattered all over popular interpretations of phenomena too complex to talk about.

How Hard is the Science?

One of the distinguishing factors in all this may be the evolution of computer science, realizing its potentiality of calculation, representation, and symbolization. This goes beyond the mere superficial digitalization of all scientific data, of the analyses programs, and the evaluation and the dissemination of results. Suddenly a bunch of people grew weary with the way things were going, they strapped together a couple of simple hypotheses and started to advocate controversial views to quintessential theories. Some 20 years ago, it was obvious that interdisciplinarity as a mission had failed, but at the very same time it became apparent that the traditional pillars of academic wisdom were cracked and that previously well defined disciplinary domains were merging, to the horror of many. Only one element was hampering the demolition of the dusty temple: the lack of a common methodology, a collective vocabulary, a general theory that could function as a fertile ground for the postulation of even wilder things to come. And suddenly the words were all over the place: chaos & order, complexity, artificial life, cellular automata, self-organization, virtuality, smart materials, fuzzy logic, dynamical patterns, adaptive systems, ... The palace revolution had started and the punks took over the security guards. Some older guys who previously had been pushed into the peripheries, headed the gang. Paul Davies, Richard Dawkins, Brian Goodwin, Stephen Jay Gould, Daniel Hillis, Douglas Hofstadter, Stuart Kauffman, Christopher Langton, Marvin Minsky, Dan Norman, Roger Penrose, ... are now considered the intellectual barometers of this time, and get the status of pop stars with equal broadcasting time.

From the beginning on, that new frame of analysis and research was not restricted to the hard sciences like genetics, physics, biology, or to deviant groups within artificial intelligence and logics. No, there was a strong belief that whatever was to be discovered or disputed could be of interest to any denomination within the social and human sciences, and arts as well. In an introduction to Ilya Prigogine’s ‘Order out of Chaos’ Alvin Toffler suggested this as early as 1984.

Ever since, most areas have been tuning in: recent publications from sociology, philosophy, anthropology, and also communication theory use perspectives drawn from this ‘scientific revolution’. Though the unresolved question remains: how can we look and at what exactly, and how can we represent all this? But there is a new authoritative certainty - whether right or wrong is not at stake here - that former views just yield a less complete picture of the world. Furthermore, the idea is out that we have to live with a lot of contradictory, heterogeneous theories applied with less certainty than what we have put to use in the past.

How Human are the Arts?

Now, turning to the human sciences - the field where for centuries content, cultural and social values, aesthetics and the interplay between them have been debated - we find a strong sense of isolation and stagnation. Not only has critique been paralyzed by an overrated historical consciousness, blind for the schism caused by the new scientific revolution’s paradigms, there is also a strong luddite affiliation. This purely emotional aversion from automation of activities, as if it would obstruct the free thinking wet being called man, even founded a new subsection, knit together by anti-technological quotes from this and that renowned philosopher: technology assessment! Over the last 20 years the arts seem to have forgotten it has always been also a field for experimentation with media, content, and ideas. And finally, after missing the boat completely and over and over again, under strong instigation of the other sciences mentioned above, the arts are reformulating their position towards interdisciplinarity.
In this rescue operation, it obviously has lost its sovereignty within the academic world. This is not a trivial issue, at least not for the field of education. The cultural literacy debate may be considered one of the last outrages of a dying world. It is the desperate attempt of a couple of old men to put traditional knowledge and methodological revisionism back in the saddle. The whole discussion was politically driven by conservative governments but backed up by either center and left. Of course it had nothing to do with politics, but with the way a changing world was imposing its demands on society itself.

**How Literate are Martians?**

Hirsch’s statement conformed to the American tradition in which lists are the representation of the facts behind the curriculum. Cultural Literacy. What Every American Needs To Know (1991) claimed to be built on research and learning theories, and concluded with an extensive list of names, dates, items, words. It advocated a common knowledge as a solution for dropout and failure. Roger Schank, in his Engines for Education (1995), dismissed the position as inappropriate. He extensively showed Hirsch’s fundamental misconceptions of current research, communication models, and learning theories. Back to the real world. About 20 years ago in school I had to learn by heart all the states of America and their capitals. Now there is a company who sends out a demo package for computers to do speech recognition. Your computer is a quiz-master and you have to reply the capital for the given state. To my embarrassment I did not know anymore what the capital of California was. So much for my schooled mind of course. So much for the list-approach and common knowledge myth, I guess, because you cannot force a background and situation on someone, which leaves room for speculations about more essential questions. How do we organize a dynamic curriculum based on different and common styles of learning, dependent on the individuals involved, and how do we introduce temporal changes. Secondly how do we assess learning, and how do we feed the results - if any - back into the curriculum. Thirdly, how do we provide schools and individuals with the necessary equipment, tutors, and finances to safeguard a long-term organization of learning with different collaborative and individual units.

All these questions are addressed frequently nowadays, but somehow it seems that the cultural division between old and new still obstructs a common view, on how to act effectively in this society, knowing that there is only a soup out there, a loose collection of disparate knowledge. Reformulating this for instance from the point of view of art: How are you going to deal with culture and art in a world where literature, video, film & music, and other arts become indistinguishable from each other?

The traditional historical method is to a certain extent useless, since it leaves out the crossovers to save the disciplines. To my own astonishment, most people lack the necessary background in 20th century art to use it satisfactorily: when most of the constructivist academics have never heard of the Russian constructivist movement at the beginning of this century, when engineers robotics have never read (even about) Capek or Asimov, when multimedia designers has never seen any dadaist film experiment from the thirties ... My judgment is that they won’t necessarily be bad theorists, scientists, teachers, artists. The only conclusion we can draw here is that the humanities have failed tremendously in conveying creative models for dealing with necessary activities nowadays: whether you talk about cognitive, cultural, or educational things.

Another answer was supposed to be found in the works of the current fashionable breed of French Postmodern philosophers like Jean Baudrillard, Gilles Deleuze, and Felix Guattari, Bruno Latour ... Nowadays fiction and technology seem to merge, in a sense that the everyday use of electronic money, digital sound and images, cybercommunications, etc. trashes most of the utopian science fiction predictions from let’s say a decade ago. Philosophy, like we already mentioned above, hasn’t been too inventive lately. Apart from the inefficiency of technology assessment to act as an ‘ethical’ filter and controller in the proliferation of the digital era, the critical distancing techniques formerly used to comment and reflect on socio-cultural change proved to be totally inadequate dealing with media technology. Baudrillard, Deleuze and Guattari and others can try to formulate insights and theoretical foundations, due to the quantification and commodification of the media. They try but they are not heard at all, and therefore are irrelevant in the media debate. One of the reasons for this could be that the languages within the media - natural and artificial - conflict radically. To give one trivial example one size of course doesn’t fit all. In the philosophical essay “rhizome” our famous and over-quoted friends bullshit away for as long as 65 pages to describe what is generally referred to as a network, and the metaphors it could allude to. In fact when they describe a rhizome it takes them approx. 15 pages of incomprehensible and abstract jabber to explain nothing else than what Ted Nelson and others were talking about, in much clearer and more influential language, some 20 years before.

Now Deleuze and Guattari do the story over with metaphors, mystifications, and doubtful analogies. But that is not the major problem. By doing so, they don’t add anything to the picture we already have, constructed by our individual use of cultural and technological artifacts. So, this form of abstraction leads not to a better understanding of innovations in society, a cognitive change, or a cultural dynamic. On the contrary, it is in essence a centralist move.
- rather in the spirit of the former literacy debate - to save the boundaries of the discipline by declaring it open and well-suited for creative use.

Not only is the language itself unsatisfactory (incomprehensible as we labeled it, but call me an idiot if you understand it and you explain it better to me), also the form in which the language occurs is totally ineffective to acknowledge the position it claims: debate is out there on the network itself and not in the printed medium. Furthermore, the definition of the networks and the cultural artifacts related to it are dynamically created on the network and by the users (including industry), but not in the mind of some chic philosophers, or in a series of publications after the fact.

And so the last text by Felix Guattari before he died, Remaking social practices, got merciless slashed to pieces on the nettime-list recently. So much for the inadequacy to mix, and trash, and clash. (I know, endurance exists only in the printed world.). Latour already warned against what he called the 'disillusioned rationalists'. Maybe the sterilizing effect this kind of discourse has on our culture in general, can also be comprehended looking at the art world.

Characteristic is the choice of the curator of the last Documenta, Catherine David, to expose existing works: there is no new productive message to be launched, no creative task to set out but expose what already has been done. There wasn’t any Documenta before so drenched in discourse: more lectures than artworks were presented to the audience. The catalogs mentioned good old Roland Barthes, Jacques Lacan, Louis Althusser, Michel Foucault and Jürgen Habermas as if they were still alive.

And I guess we expect more in these neo-postmodern years. There is more happening than just global economy and a monolith capitalist system. The commodification of research and development throughout the dependency on machines and software (from text processors through organizers and mail programs) is also chaperoned by a whole set of new conducts and practices. So it is not enough to say: “look people, the picture is fuzzy” or shout out “chaos-theory”, whether we talk about media, culture or education. It is not enough to shout “simulation” to reality, and indulge into an ultimate reformulation, ironization and redoubling of theories and practices. And finally it is not enough to denounce ‘Mickey Mouse’ culture and hide into cultural and political protectionism.

We have to take seriously into account the present activity-shift, the job-hopping happening at the other end of the fashionable debates, in order to realize the potential behind the new tools we use, even if they will prove to be the emperor’s clothes later on. There is an obvious split occurring, one that no-one wants to stop, because the promise at the other side of the hill is much more rewarding, maybe out of selfish curiosity or crazy trendyness, but much more because there is bread in it in the first place.

From Data to Wisdom, Will the Real Hologram Stand Up?

Now the discussion we have been conducting so far may seem far-fetched or only for a crowd of insiders. But it serves as an illustration of how our disciplines fight to persist, despite a radically different and alternative construction that encircles them, threatening certain authorities, and constructing new ones. In a way it predicts the end of traditional epistemology and philosophical/critical discourse, and it embodies the slow germination of elements, which could - but not necessarily - breed a new genre of academic and socio-cultural practice, maybe an educational one.

We want to portray the difference between what we jokingly call (in true post-neo-startrek style, I know) “the battle analogs vs. digitals”. It comments on the growing schism apparently occurring throughout the use of those specific media, called new media (to separate them from pre-80s technologies), and the reconstruction of a new kind of discourse springing from that digital fountainhead. Finally it illustrates the complexity of attitudes, or beliefs, towards information and knowledge.

At both ends of the continuum we can identify different sensibilities that position themselves paradoxically and antagonistically against each other. On one end there is a belief in abstraction as the representation of many phenomena occurring in reality. The belief is that generating new abstractions can lead to a better insight in reality. The other end does not recognize this as a plausible method, and only validates inferences derived from concrete data. This results in a new form of behaviorism, visible in the new developments in machine vision, software agents, ...

Another characteristic belief can be described with the terms involvement and participation. Whereas the traditional brand of academics still believes in ‘distance’ as a condition for formulating critique, others emerge who claim ‘involvement’ as essential. That this difference is not merely a generational or technological discrepancy is illustrated by Clifford Geertz’s After the Fact in which he looks back on his career as an anthropologist, claiming that there is no general truth and a singular history, while reflecting on his personal fieldwork and relating it to some developments within human sciences.

This leads us to a third paradigmatic difference: ‘situatedness’. It is the tip-top where anti-abstraction and involvement meet, and takes into account the environment in which the network is situated, with its almost tangible users/participants. It is the dynamic attitude of recognizing the incapability of escaping the social construction which constitutes the artifacts that surround us. A well-known example is Donald Norman’s The Psychology of Everyday Things, one of the publications that contributed to the change of cognitivism as well as the start of a new direction in interface design.
There are many different views possible, and worth mentioning, only to get rid of the false dualist representation in the former paragraphs. Manuel Castells talks about transformists, continuists and structuralists, to indicate the different attitudes and views in the information technology debate. Transformists believe in the major transformation of everyday life due to the exposure of new information and new ways of dealing with that information. Continuists see the information revolution rather as an evolution from previous stages of communication systems, and are skeptical about the value of that apparent change. Finally structuralists believe that information technologies don’t change the nature of the industrial society, and don’t believe in a new social order emerging from it. Of importance in the debate is the rate at which institutions like schools, banks and public spheres change, and to what extent.

This reminds us of the old Piagetian paradigm: assimilation-accumulation. Papert states that the traditional school system doesn’t change through accumulation but assimilation. Schools only accept what secures the persistence of the existing situation. Therefore - according to Papert - the first waves of technology did not change the organization of learning and teaching and was driven to its own bankruptcy, since computers were only adopted as add-ons to emphasize existing methods and organizations. OK, that was back in the 80s but do we have reasons to believe that the situation is different now? Can the new computers and network technologies reinforce the necessary innovations to educational systems?

From Wisdom to Creativity, Can I Have Another Piece of Teacher?

We believe that during the last decade the world has changed profoundly due to the proliferation of hybrid networks of computers and human beings, in an admixture not existing before (think where Castells would classify us!). Discourse in general has changed because the participants and the subjects have changed. Though there remains much more work to be made of real research into the use of multimedia and network media, instead of the bulk of justifications we often rely on. It is clear that current technologies are able to change the nature of information (the format) together with the cultural settings in which it is handled (the context and use).

The multitude of communication means allow us to think, express ourselves, and gather information in quite different ways than before: e-mail, listservs, news groups, chatting, video conferencing, the different wwww-implementations via javascript, java and cgi’s...

In a couple of years’ time the idea of the Net, the Web or any other cozy name you give to it, has changed because of the activities that are deployed on it. Kids do it, elderly people do it, professionals and unemployed do it, morons get spammed. Obviously, design is perceived through the innumerable graphics, movies, and animations that form an indispensable part of the experience of getting through data, downloading programs, and submitting a request for more information. But the real value of the ‘design’ is present in the simplicity of the format of the html-page, and the triviality of uploading that to a remote server. Anyone can do it; free tutorials and tools are abundant on the medium itself; and what is more, they are widely used!

To be honest, most people, including teachers and students of any age or gender, learn it quickly without taking traditional classes. They don’t cling to the idea that you need a certificate to work with it, contrary to most other technological activities like driving cars or installing air conditioning. To our own astonishment two years ago, we could guide a bunch of language teachers through online resources and then stimulate them to make their own homepages, in only three evening sessions! They had never had any previous experience on the web but in the end some even had frames and animated gifs in their pages. Whether afterwards they could put it into further use or not, is beside the point here of course. Well, it takes more effort to become a good instructional designer, but on the other hand, we could argue that with such a transparent medium, some simple tools, and good common sense one could get far. And has not the teacher with or without technology always been some sort of designer without proper training, rather developing his/her experience in the field? So if we would be able to give a necessary introduction in technology, and get the message of innovation and change across ... but, many have said this before and I guess that would be too easy for teacher trainers ...

Within the school environment, the difficult factor has always been access to equipment, for teachers and students alike. But recently, most of our governments and school managers have made a great effort in getting computers there, a tendency that is unlikely to stop (long live commodification?). What we grew more concerned with at the same time, however, was the ineffective use of information technology in the classroom and the fact that it proved difficult to integrate within traditional curriculum settings. Of course we are convinced that integration is very important, if only to comply with Seymour Papert’s notions of successful implementation. But shouldn’t we broaden our view in the light of what authentic activities on the net consist of, and allow the participants to change the classroom? There are various reasons why constructivism, open and distance education are badly understood and implemented in the field. In fact the whole of educational innovation with ICT has by many been perceived as a threat, where it should have been acquired as a benefit and convenience. But that is the exact point where we started this paper.

Instructional Design — 485
It seems hard to achieve innovation, because it requires more than good courses in new technologies, because what we really want is attitudes and proficiencies, even buildings and institutions, to change. That can only be brought about when the participants are immersed in authentic practices in which change seems evident, unconstrained, and intelligible. One way could be to enlarge our view of integration to the broader diversions in which students participate. Let us forget classroom borders, and design information, activities, and resources for a cultural setting in which school is no longer a singularity. Obviously we have to include the technological activities at home, at work, whatever they are, and relate them to the construction of expressions and models of knowledge that constitute learning. Now we see a lot of learning happening already out there on the web that is not always recognized by teachers, because they find it hard to assess. I think of the participation in list discussions and news groups, browsing, searching, saving local files for later use, playing games, making html-pages, animations, and the like.

I have seen more peer learning, coaching, and facilitating on the net only during the last year, than ever before in any classroom. Also, the subjects were not exclusively related to the medium itself, but included references to publications and resources outside the web. Thus, we cannot but take new ways of communicating seriously, because they modify our way of perceiving the world and alter our ways of thinking/learning. David Jay Bolter, in Wired 5.01, talks about the infamous Myst and Doom games as subverting the values of print because they supersede the book and, along with it, traditional verbal identity. The only ones who experience it as a threat are those whose values were formed in and by the age of print. He ends asserting that if the Supreme Court Justices would recognize this, they wouldn’t worry about banning pornography, but they would ban “inexpensive digital cameras, graphic accelerator boards, 3-D rendering software, and, above all, the freedom to merge your point of view with that of a raindrop.” And doesn’t that last statement come very close to what we expect the learner to do?

Panic Design and Positive Breakdown

The educational digital designer from a constructivist point of view has to deal with the construction of knowledge and at the same time the construction of models to deal with that knowledge, as Jonassen pointed out long ago. But after a deep breath, and before he has jotted down his first tag, s/he already runs into huge problems. Due to the nature of the web, its users, and its applications, the participation of learner and teacher in a collaborative and culturally suited situation, is not a big issue. But what should be made of non-linear sequencing, the different media constraints, the status of the teacher, and designer or the quality assessment. By now, the teacher and most of the students are driven to despair as well. The more we try to get them involved in this uncertain learning/teaching situation with the use of ICT, the more we seem to push everyone and everything over the edge. So, maybe we have to turn to areas where the global wave of innovation and virtualisation progressed better, and learn from experiments that have succeeded. Even if they require a more radical point of view, we have to try to adopt them, instead of concentrating on the remediation of the growing mismatch of social and educational implementations.

Karamjit Gill, in the first chapter of his Human Machine Symbiosis, The Foundations of Human-centered System Design, extensively comments on methodological issues and combines dialogue, action research, and other collaborative techniques. Reminiscent of Terry Winograd and Paul Adler’s Usability, Turning Technologies into Tools, traditional design is challenged. Drawing from the work of Polanyi The tacit dimension, the concept of “tacit knowledge” is elaborated in recent research. Also, some fundamental concepts for human-centered design like usability, breakdown, tool perspective, and language approaches are introduced. Especially the concept of breakdown is seen as a fundamental aspect of dialogue, reflection in practice, and mediation - all central concepts for educational design.

“While it is desirable to situate tools and systems within existing traditions and practice, breakdowns are also essential elements of innovation, creativity and designing for the future. This is the essence of participatory and cooperative design within the tradition of human-centeredness” (p 28)

Finally the concept of “user-involved” design, a set of cooperative and participation techniques, seems adequate to cope with current field problems in education, from the organizational, technological, and socio-cultural point of view. It can bridge a gap in a rather traditional and static environment, and realize part of the (social) constructivist agenda on a very immediate level, by involving the user directly in the development of interactive content (for learning). The designer is adopting a new role, but not by imposing solutions out of the blue - faintly hoping it will benefit users’ skills. Designer becomes Mediator, using new strategies more appropriate to sustain the dynamic process of learning, in which novice gradually transforms into creative expert through dialogue with content and tools.

That sounds encouraging, doesn’t it? But now back to the bench where the computer is waiting.

Open That Can of Software, Waiter

We try to implement these ideas in several cultural and educational projects, using different media and targeting different kinds of users. In each case we hope that the initial concepts, formulated as a task for us, can evolve
into the creation of a collaborative product, and can help the people involved to take on similar projects in the future. In 1991 we started with the development of a collection of contemporary references to several classical European literary works. We wanted to trace the corrections to the traditional canon, and reconstruct a debate through several representations in media and arts. The first outcome was an electronic book on disk on Cervantes’ Don Quixote. The material was used for presentation of the research project and documentation on the subject. The second collection, on Defoe’s Robinson Crusoe was done in 1992 and was transferred to www in 1993. The idea we had at that time, reflected a naive belief that very soon others would add to the collection and even, eventually take it over, to the benefit of education and culture. We contacted teachers from different disciplines to collaborate. Some came, some even proposed ideas, but most of them nodded and looked away. Most of them did not have the time, equipment, or desire to collaborate with an experiment. They also were very diffident about networks and after a while we moved to another project.

We were asked to document a governmental initiative about curriculum development and attainment goals for art education in Flanders. The idea was to “hyper-edit” the document with multimedia examples from classroom practice. The first change we proposed was the idea to mount it on a server instead of producing a CD-ROM. Secondly, we asked some organizations involved in art and children to try to document their projects for further linking. We hoped they would learn how to ‘publish’ on the web and maintain this service later on by themselves. Finally we went out to document good and useful practice. The first project documents the development of a CD-ROM about multicultural childcare. It was conducted by the department of Psychology at the University of Ghent in collaboration with several partners from France, England, and Ireland. Each partner finally submitted a scenario for an interactive part, including all material (photos and video, graphics, sound) and a description of interactives. The CD-ROM was introduced at a conference in October 1997, and made a tour through Flanders on a so-called “technology bus”. Recently the project team decided to switch to a non-involved method.

The second project describes our participation in the development of a “virtual center” on the web, for a European project called T3 (Telematics for Teacher Training). Our involvement started late in the project, and had to cope immediately with a very confused and complex situation. Due to circumstances, the so-called ‘T3-centrum’ was virtually non-existent, and separate www-environments had been developed by several partners. The first task was to coordinate a group of art students who were proposing a concept for the virtual centre in December 1997. Depending on that, a strategy for implementation, development and collaboration among the partners was introduced.

The third project is the creation of a www-course on cultural literacy at University of Ghent. The basic material has been selected, but since we believe that only through participation the environment can become binding, we are looking into a number of ways of involving students. The task is to go beyond the constraints of the traditional setting in which academic learning takes place, due to limitations of infrastructure, access, attitude, and assessment. We have already named the project secretly ‘the conflict zone’, and we hope it mixes down well with the imploding territories and blurring borders as they are explored and documented.

As information technology draws us all closer together I am sometimes surprised that every section of this annual is not entitled “International this” or “International that.” This year a much greater number of papers that several years ago would have been labeled “International” have been placed in other sections. Too, the majority of the papers in this section could have been categorized under different headings. During the sorting process I looked covetously at those from distant parts of the world that have become the provenance of other section editors.

Each year as the papers come in to me, with exotic stamps and far-flung return addresses, I am once again a young girl on a dusty Texas farm, dreaming with the world atlas in my lap, traveling the world, but now with the added threads to other teacher educators, and through them, to the children of the world. For all these vicarious trips I thank the authors is this section.

While we are all drawing closer together I ever delight in the differences that languages and cultures impart to this whole teacher education and information technology communication process. As editor of this section I feel a heavy responsibility to present each of the papers in a manner true to the intent of the author or authors. At times that means that I must sometimes take words that have been translated into the authors’ second or third language and make them sound like standard English without loosing the essence of their thoughts, their works, their philosophies. It is a heavy responsibility, but it is also a joy.

Part of the joy each year is planning a trip to visit each of the authors. This provides a convenient way organize this section, a ‘braid’ of coherence; strand one is teacher education; strand two is information technology (IT); and strand three is proximity, if South America can be considered a near neighbor to Australia. I also think it important to start from a different continent each year so I begin our journey in South America. [See Figure 1 for the starred focus locations.]

The first paper is a collaborative effort by Martinez, Astiz, Medina, Montero, and Pedrosa, of the National University of Mar del Plata, Argentina, who report on teachers’ positive opinions of IT integration but lack of its actual use in their classrooms. Crossing the south Pacific to the University of Sidney, Caitlin Cronin and David Reid address a similar problem with suggestions for overcoming the status quo through focusing on pedagogy rather than technology. Sail north to Malaysia where Ab. Rahim Bakar and Shamsiah Mohamed explore perceived IT roles of vocational and technology teachers.

Continuing north Greg Lee and Cheng-Chih Wu at National Taiwan Normal University share their design and implementation of a computer education course that combines computer literacy with practical pedagogical issues. Leaving Asia, across the Indian Ocean to Africa, find several papers deal with IT and teacher education in a very different culture. Paul West, Technikon Southern Africa, addresses a number of difficulties related to IT integration in Africa and puts forward a suggestions for solutions. Next, Mari Peté, Technikon Natal, provides follow-up research on the “KwaZulu Concept Burger” [see SITE97] with some interesting data on the continued use (or lack thereof) of materials produced in differing media. Peté with Parivash Khalili then consider the implications of the post-apartheid national educational policies and the changing roles of lecturers that will result.

The next paper comes from the east African coast via several professors from Texas Southern University, Claudette Ligons and Wren Bump, who describe a Fulbright Project that took them and others to Tanzania for a five-week immersion in the culture. This experience was later integrated into their teacher education program through a Web and other media.

Leaving Africa the road leads north to Kiev. Yuri Demchenko describes the experiences of the past two years as the Ukraine struggles to implement cooperative and contributive learning models and IT in the midst of economic restructuring that would daunt most of us. Turning to the west the reader will see that there are many universals in IT integration in teacher education. We cannot consider this process without looking at what our various governments are doing, pro and con. Along this line, Baron and Bruillard
provide an eloquent view of France's new national plan and its implications for teacher education.

Across the English Channel to London Hughes and Sasse describe a project that involved teachers in the design of their own instructional media with the ultimate goal of putting them more in charge of IT. Northwest of London at Keele University, Staffordshire, Dunning describes an IT and motivation study of direct practical significance to teacher educators. Westward across the Irish Sea are two such educators, FitzGibbon and Oldham, of Trinity College Dublin, who report on their preservice teachers readiness to integrate IT and they offer a case study of a system in transition.

Turning back east to the Open University of the Netherlands, Kirschner, Hermans, van den Boom, and Münstermann are doing similar work on inservice teachers. They look at ways teachers may be retrained for educational innovation and IT. Clayton Keller, University of Minnesota, Duluth, and Ragnar Thygensen, Norwegian University of Science and Technology, move back and forth across the Atlantic through videoconferencing. Their paper shares the technical, logistical, and educational issues they faced over two academic years as they connected faculty and students at their two universities for lectures and discussions.

Moving west from Norway to Canada, Christina Dehler of Concordia University also investigates the benefits of using IT to move across international boundaries to expand our cross-cultural understanding. Heading south the final paper in this section provides an excellent example of what Dehler has suggested. Deborah Pulliam describes how one college, Missouri Southern State, infused their entire curricula with a campus-wide China theme that involved extensive use of IT.

While this vicarious trip has brought me back to the central USA (Missouri is just south of Iowa), the final paper has shown how IT can provide multiple windows on the world. All the papers give me a feeling shared humanity and purpose among the IT teacher educators around the world. We face so many of the same challenges, some we have met and conquered; some we have yet to meet; and some we are still struggling with. Just knowing that others are dealing with similar conditions is strengthening. Also, too, is this Annual as a resource for locating others who may have answers to our questions.

Figure 1. Locations of IT focus.

This paper reports work on the process of incorporation of the computer as a pedagogic tool for school activity, in the Basic General Education (BGE), at the County of General Pueyrredon, Province of Buenos Aires, and its area of influence. Argentine schooling, that is undergoing a process of reformation, currently presents general characteristics of encyclopedic and memorization type learning, with low development of critical thought and little contribution of technology to the classroom work. These conditions are reflected in the habits of current teachers and are implicitly recognized in official documents. These documents emphasize the need for training teachers so they can assimilate the innovations taking place in educational policies as well as in the pedagogic field of their respective specialties. The Continuous Educational Formative Federal Network is an articulated system that includes objectives for the planning for training of inservice teachers. In a previous research work (Martinez, Astiz, Medina, Montero, & Pedrosa, 1997), we explored the feasibility of implementing computer supported learning environments. This was done by means of analysis of school equipment with regard to hardware and software, the degree of usage of these materials, the attitudes of teachers towards the incorporation of computers into school activities, and the government attitude and policies. Even though the survey on attitudes of teachers had given positive results, it was necessary to deepen and extend the inquiries in order to determine how well teachers were able to utilize the computer as a tool of support for the active process of building knowledge and developing activities.

Training

Training, set up for the official group of teachers in service from the BGE, included both distance education components and presentional components, i.e., components delivered locally. In the distance education stage each teacher received a set of modules on diverse general aspects and of contents of the educational reformation in the Province of Buenos Aires, following the outlines defined in the Federal Law of Education (GDCE, 1995).

The stage of presentional training, on the pedagogic utilization of the computer, was developed within the framework of the Continuous Educational Formative Federal Network and by agreements between the National University of Mar del Plata and the Direction of Culture and Education of the Province of Buenos Aires. It consisted of a three-module course, twenty hours each, using Microsoft Works for practical and operative purposes. Once the teachers had their three modules approved, they then had to present a proposal related to the pedagogic usage of computers in their schools, using the studied technological resource. They were given several weeks for the elaboration of this and the proposal had to be evaluated and approved in order to successfully complete the course.

For the purposes of this research, it is interesting to note some critical objectives of the educational reformulation and its appearance in the corresponding sections of diverse branches of thought. As a matter of fact, each one of them appears in a chapter dedicated to describing a set of attitudinal contents leading to the building of a critical thought (FCCE, 1995; GDCE, 1995). Of this set, we consider as outstanding the following:

• Confidence in their abilities to pose and solve problems.
• Pleasure in generating personal strategies for solving problems.
• Interest in the utilization of a logical, creative, and strategic reasoning.
• Critical and reflexive position facing the results obtained.

Therefore, it was to be expected that the classroom proposals developed by the teachers would reflect, although imperfectly, those attitudinal contents.

Hypothesis

The following are two crucial factors for the implantation of computer-supported teaching and learning environments that encourage the development of a critical thought:

• the attitudes of teachers towards the incorporation of computers to their classroom activities.
• the possibilities of overcoming their old working habits in order to assume a different role, as a facilitator of the teaching and learning process within a creative atmosphere, sustained by the computer.

Objectives

• To determine the attitudes of teachers toward the computer with regard to the following dimensions: anxiety, confidence, and liking.
• To learn teachers opinions about the different modalities on the usage of the computer in teaching activities.
• To determine the degree of modification of their habits required in relation to the making didactic activities to adapt themselves to the new educational needs.
• To associate the three preceding points.

Method

Subjects

Ninety-two inservice teachers were selected at random from official schools at the end of the training courses about the pedagogic utilization of the computer. Of that set, there were 50 rural teachers and 42 urban teachers. The population from which the sample was taken was composed of teachers belonging to the BGE who had no previous experience whatsoever in the usage of computers for instructional purposes and who were required to complete the course at this stage of training.

Instruments

a) In order to determine the attitudes of teachers, a five points Likert scale (1 = strongly disagree, 2 = disagree, 3 = not sure, 4 = agree, 5 = strongly agree) survey was used. Just for this, an adaptation of the “Computer Attitude Scale” (Gressard & Loyd, 1986) was made, which consists of 30 items that measure the following dimensions: anxiety, confidence, and liking.

b) To determine the appraisal opinion of teachers about the different forms of educational usage of the computer and implications, a 20-question survey was made, with a five points Likert scale. The opinion items referred to the teaching activities to be developed using the computer in different ways. The activities over which teachers had to give their views could be divided into four big groups, namely:

• activities with the computer's controlled tutelage;
• usual activities with the computer as a tool;
• activities in which the computer is employed profitably to exercise the critical thought and the solving of problems, and
• the social implication of computers on education.

Note: In both surveys half of the items were framed in an affirmative way and the other half in a negative way; then, a random presentation order was established. All answers were codified so that the highest mark corresponds to a more positive attitude with respect to the usage of computers (attitude survey) or to a greater coincidence with the item, had it been worded affirmatively (opinion survey).

c) To determine up to what point teachers adapted their didactic proposals to some critical aspects of the new contents within the reformation, and that were mentioned in section “Training”, a protocol for the analysis of those proposals was designed. The analysis protocol discriminates whether the works teachers present for the integration of the computer in some educational activity, take into account or not the following activities:

• searching for information,
• gathering of information,
• organization of information,
• representation of information,
• storage of information,
• writing of reports, utilization of text processors,
• usage of data base administrators,
• usage of spreadsheets, text comprehension,
• interpretation of graphics, setting up relations,
• making comparisons, and
• doing inferences.

Techniques of Analysis

a) Alpha coefficients were calculated to measure the reliability of both surveys using BMDP software (Dixon, 1992).

b) The same software was used to investigate the dimensionality of the survey over the scale of attitudes. These studies were carried out by means of a principal components analysis, followed by a varimax rotation and a maximum likelihood factor analysis.

c) Attitudes of rural teachers were compared to those of urban teachers, in the three main dimensions considered, using a BMDP software. A comparison of similar characteristics was performed with the opinion survey on ways of usage and implications.
d) The didactic proposals presented by teachers were analyzed by means of the aforementioned protocol and, as indicated, it details the activities to be done by the pupils in the presented proposals.

Results

Reliability

- For the Survey of Attitudes, a general reliability coefficient of 0.91 was obtained; for each sub-scale the results were: Anxiety: 0.94; Confidence: 0.90 and Liking: 0.90.
- For the Survey of Opinions on the educational uses of the computer and implications, a reliability coefficient of 0.62 was obtained.

Factor Analysis

The analysis of the dimensionality of the scale of the Survey of Attitudes was performed over a data correlation matrix of the 30 items of the instrument. From the analysis, five factors arose that were coincident for the principal components analysis as well as for the varimax rotation factor analysis and the maximum likelihood factor analysis. Considering these factors, the first three can be reasonably identified as anxiety, confidence and liking, while the other two, with much less relative loadings, such as self-esteem and interest for complex actions.

Attitudes of Teachers

From the computation of the attitude survey, completed by each one of the teachers, the values below mentioned were obtained. The following table shows the mean and standard deviation of the data obtained in each one of the three main dimensions, differentiated in rural and urban teachers.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Rural Mean</th>
<th>Rural St.Dev.</th>
<th>Urban Mean</th>
<th>Urban St. Dev.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anxiety</td>
<td>4.09</td>
<td>0.18</td>
<td>4.17</td>
<td>0.21</td>
</tr>
<tr>
<td>Confidence</td>
<td>3.31</td>
<td>0.50</td>
<td>3.67</td>
<td>0.41</td>
</tr>
<tr>
<td>Liking</td>
<td>3.68</td>
<td>0.27</td>
<td>3.93</td>
<td>0.18</td>
</tr>
</tbody>
</table>

Differences between Rural and Urban

A comparative analysis between the mean of urban teachers (U) and the mean of rural teachers (R) in each sub-scale was carried out, with the aim of determining whether significant differences in favor of the first ones existed or not. Because of that, for each of the dimensions under treatment the following null hypothesis and alternative hypothesis were proposed:

\[ H_0 = U - R \leq 0 \] and \[ H_1 = U - R > 0 \]

Let us consider each case

- Anxiety. The estimation of the statistics for the \( t \)-Student distribution yields a value of 0.48; it follows, the null hypothesis must be accepted and, therefore, there are no significant differences in favor of urban teachers, even considering a level of significance as high as 0.25.
- Confidence. The estimated statistics value is \( t = 1.85 \). If we fix a 0.05 level of significance, we conclude that the null hypothesis must be rejected and, consequently, it should be accepted that at the indicated level of significance the mean for urban teachers exceeds that for rural teachers.
- Liking. The estimated statistics value is \( t = 2.42 \). At a 0.025 fixed level of significance, it can be deduced that the null hypothesis must be rejected and, consequently, it must be accepted that, in this dimension at the indicated level of significance, the mean for urban teachers exceeds that for rural teachers.

Opinions of Teachers

From the computation of the opinion survey, the below mentioned results were obtained. Just for this, we have constructed a four row table, each corresponding to the four thematic groups in which questions had been divided. The four groups and their identification are the following: Group A) activities with the computer's controlled tutelage; Group B) usual activities with the computer as a tool; Group C) activities in which the computer is employed profitably to exercise the critical thought and the solving of problems; and Group D) social implications of computers in education. The following table shows the mean and standard deviations of the obtained data in each of the four groups, differentiated whether they belong to urban or rural teachers:

<table>
<thead>
<tr>
<th>Group</th>
<th>Rural Mean</th>
<th>Rural St.Dev.</th>
<th>Urban Mean</th>
<th>Urban StDev.</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>2.03</td>
<td>0.28</td>
<td>1.97</td>
<td>0.24</td>
</tr>
<tr>
<td>B</td>
<td>3.28</td>
<td>0.43</td>
<td>3.41</td>
<td>0.51</td>
</tr>
<tr>
<td>C</td>
<td>4.21</td>
<td>0.19</td>
<td>4.13</td>
<td>0.22</td>
</tr>
<tr>
<td>D</td>
<td>3.28</td>
<td>0.42</td>
<td>3.19</td>
<td>0.38</td>
</tr>
</tbody>
</table>

The comparative statistical analysis between the mean of urban teachers (U) and the mean of rural teachers (R) found no differences in any of the four groups, considering reasonable levels of significance.

Analysis of Didactic Proposals

Of a total of 92 works presented on the utilization of the computer in the educational setting, 25 referred to administrative activities of the teaching task, such as keeping records of the students' marks, holding a data base.
with general information about pupils, etc.; since these are not classroom activities, those works were excluded from the analysis. The remaining works amounted to a total of 67, of which 35 belonged to rural teachers and 32 to urban teachers.

**Areas of Knowledge**

The works comprised the following areas: Language (L), Mathematics (M), Natural Sciences (NS), Societies and Geographical Spaces (SGS), Human Activities and Social Organization (HASO), Technology (T) and Physical Education (PE). The amount of works affected to each area, together with its rural or urban discrimination, are shown in the following table.

<table>
<thead>
<tr>
<th></th>
<th>L</th>
<th>M</th>
<th>NS</th>
<th>SGS</th>
<th>HASO</th>
<th>T</th>
<th>PE</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rural</td>
<td>3</td>
<td>4</td>
<td>2</td>
<td>16</td>
<td>8</td>
<td>1</td>
<td>1</td>
<td>35</td>
</tr>
<tr>
<td>Urban</td>
<td>4</td>
<td>5</td>
<td>4</td>
<td>7</td>
<td>8</td>
<td>2</td>
<td>2</td>
<td>32</td>
</tr>
</tbody>
</table>

**Amount of Activity Types**

Each proposed work implied the execution of a set of different types of activity, which were discriminated in the analysis protocol. The average activity types per work are indicated below.

<table>
<thead>
<tr>
<th></th>
<th>Average</th>
<th>Activities Type per Work</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>General</td>
<td>7.15</td>
</tr>
<tr>
<td></td>
<td>Rural</td>
<td>6.74</td>
</tr>
<tr>
<td></td>
<td>Urban</td>
<td>7.59</td>
</tr>
</tbody>
</table>

**The Most Frequent Activity Types**

The five most required activity types, and the only ones that were incorporated to more than fifty percent of the works are the following.

<table>
<thead>
<tr>
<th>Activity</th>
<th>Percent of the Works</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage of Spreadsheets</td>
<td>93%</td>
</tr>
<tr>
<td>Storage of Information</td>
<td>87%</td>
</tr>
<tr>
<td>Representation of Information</td>
<td>76%</td>
</tr>
<tr>
<td>Interpretation of Graphics</td>
<td>66%</td>
</tr>
<tr>
<td>Utilization of Text Processors</td>
<td>64%</td>
</tr>
</tbody>
</table>

**Activities of Searching, Comprehension, and Organization**

The activities of searching information, text comprehension and organization of the information affected the following work percentages.

<table>
<thead>
<tr>
<th>Activity</th>
<th>Rural</th>
<th>Urban</th>
<th>General</th>
</tr>
</thead>
<tbody>
<tr>
<td>Searching</td>
<td>34%</td>
<td>37.5%</td>
<td>36%</td>
</tr>
<tr>
<td>Comprehension</td>
<td>40%</td>
<td>59%</td>
<td>49%</td>
</tr>
<tr>
<td>Organization</td>
<td>43%</td>
<td>50%</td>
<td>46%</td>
</tr>
</tbody>
</table>

**Activities of Setting up Relations, Making Comparisons, and Doing Inferences**

These activities have the most importance for, in a sense, they are demonstrative of the type of deductions and reasoning implied in the works.

<table>
<thead>
<tr>
<th>Activity</th>
<th>Rural</th>
<th>Urban</th>
<th>General</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relations</td>
<td>2.9%</td>
<td>8.6%</td>
<td>6%</td>
</tr>
<tr>
<td>Comparisons</td>
<td>11.4%</td>
<td>15.6%</td>
<td>13%</td>
</tr>
<tr>
<td>Inferences</td>
<td>17.1%</td>
<td>25%</td>
<td>21%</td>
</tr>
</tbody>
</table>

**Analysis of the Results**

**Attitudes of Teachers**

**Anxiety.** According to the obtained mean values, 4.09 for the rural teachers and 4.17 for the urban ones, it is deduced that teachers have a favorable attitude towards computers and that anxiety represents no problem. The analysis of mean differences reveals that there are no significant differences between the two groups of teachers.

**Confidence.** Mean values of 3.31 for rural teachers and 3.67 for urban teachers reveal a moderate confidence about their interaction with the computer. The statistical study of mean differences indicates a greater confidence on behalf of urban teachers. This difference could perhaps be due to the fact that urban teachers have a general knowledge of computers somewhat greater and that this situation might influence their favorable attitudes (Rodriguez Feijoo & Stefani, 1990).

**Liking.** Mean values of 3.68 and 3.93 for rural and urban teachers, respectively, indicate a moderately favorable attitude in this dimension. The difference detected in the statistical study of the means could perhaps be attributed to the reasons mentioned above in the previous item.
Opinions of Teachers

Let us proceed now to analyzing the opinions of teachers in each of the four groups in which the total of the consulted items were divided. Beforehand, we must remember the groups: Group A) activities with the computer’s controlled tutelage; Group B) usual activities with the computer as a tool; Group C) activities in which the computer is employed profitably to exercise the critical thought and the solving of problems; and Group D) social implications of computers on education.

Group A. The opinions with respect to the computer’s controlled tutelage were unfavorable: 2.03 for rural teachers and 1.97 for urban teachers. These facts could be attributed to diverse factors, among which are worth to mention the articles written by constructivist educators, who severely criticize this type of activity, and to affective reasons, for this type of learning is commonly related to a “dehumanization of teaching”.

Group B. The opinions on this group of activities were moderately favorable: 3.37 for rural teachers and 3.61 for urban teachers. These results could be attributed to the fact that teachers, in the instruction of the course, were able to observe some advantages that the computer could bring, as a utilitarian tool, to the classes they are teaching.

Group C. The opinions on this type of activities were openly favorable: 4.21 for rural teachers and 4.13 for urban teachers. This opinion, with respect to the computer as a cognitive tool, could be sustained on the considered view that at a scholarly level, and in the society as a whole, that computers are tools for activities of reasoning, reflection, development of strategies, solution of problems, etc., even though their use in this manner is not reflected in the daily practice.

Group D. The opinions over the social implications of the computer on education were moderately favorable: 3.28 for rural teachers and 3.19 for urban teachers. This moderate opinion is the balance of favorable opinions, e.g. that students could know and use this type of technology, that its dissemination contributes to improved productive efficiency, and of unfavorable opinions in which technology is seen as causing the reduction of job opportunities.

The Didactic Proposals

As indicated in the section on results, of a total of 92 works presented, 25 of them referred to administrative activities of teaching; from that, it follows, that 27% of the teachers presented no activity for the classroom labor, and therefore, they become excluded from this analysis. From the analysis of the 67 didactic proposals we can do the following observations:

Areas of Knowledge. Comparing the amount of proposals that rural and urban teachers produced, a homogeneity is observed between both groups, with the exception made with respect to the theme “Societies and Geographic Spaces”, that had a marked preference among rural teachers, which is attributed to the environment where they carry out their activities.

Over a general total of 67 works, there are 39 that belong to the Social Sciences area (Societies and Geographic Spaces and Human Activities and Social Organization), meaning 58.2% of the general total of the works presented. This demonstrates a marked asymmetry in the utilization of the computer and points out the necessity of helping teachers in the development of didactic proposals in areas less considered.

Type of Activities. The amount of variety of activities presented in the proposals is reasonable, with a general average near seven different activities per work.

When the most frequent type of activities are analyzed, it is observed that they are generally of a routine type, except for the activities “Representation of Information,” i.e., whether information is to be represented in a graphical way or in a written manner, and in which format. Also, “Interpretation of Graphics,” consists of the interpretation of simple graphics (bar diagrams, graphical representations of linear functions, etc.).
