Activities of Searching, Comprehension, and Organization. These activities require the students searching for sources of information, selecting and studying with comprehension the information, and, afterwards, organizing the information according to objectives they must reach. The general averages for “Searching” (36%), “Comprehension” (49%) and “Organization” (46%) are not bad, above all if one remembers that not all tasks require developing these types of activities. However, it deserves to be pointed out that rural teachers have lower averages than urban teachers do. This probably arises from the diverse limitations that the rural environment offers them.

Activities of Setting up Relations, Making Comparisons, and Doing Inferences. The percentages obtained for these activities are the most worrying of all, keeping in mind that they are indicative of the deductions and reasoning implied in the works. In effect, the activity of “Setting Up Relations” appears only in 6% of the proposals (2.9% in rural teachers and 8.5% in urban teachers), the activity of “Making Comparisons” is being practiced in only 13% of the works (with values of 11.4% for rural teachers and of 15.6% for urban teachers), and last, the activity of “Doing Inferences” is included only in 21% of the proposals (17.1% for the rural ambit and 25% for the urban one). It is necessary to point out that those activities referred to the establishing of relationships, making comparisons, and doing simple inferences.

Conclusions

The main conclusions of this research indicate that teachers have a good attitude towards the incorporation of computers into schools and that they consider positively
creative and the independent thought stimulating activities. However, by analysis of their didactic proposals, it is possible to observe an ample gap between what they claim to prefer and their presentations for classroom work. This seems to be the result of habits deeply-rooted, that are not easy to remove. An additional cause might be lack of renovation of knowledge, methodology, and content that would allow them to perform a different role, thus developing the type of activities they report to value. To synthesize, a set of encouraging expressions is observed, but these expressions are not always transferred to the labor with students. From the above mentioned, some recommendations are inferred:

- to accompany the instruction on technology for inservice teachers with a methodological and content actualization in their areas of work;
- to provide teachers with a supportive structure and a permanent counsel to aid their continued progress once they have finished the training courses; and
- to facilitate the interaction of the inservice teachers with researchers in order to construct and evaluate innovative learning and teaching environments.

496 — Technology and Teacher Education Annual — 1998
"Computer Proficiency for Teachers": Moving A
Government Report into Practice

Caitlin Cronin
University of Sydney
David Reid
University of Sydney

In June 1997 the Ministerial Advisory Council on the Quality of Teaching (henceforth MACQT) of New South Wales, Australia issued a report entitled “Computer Proficiency for Teachers” (henceforth CPT). The report addressed how teachers should use education technology to support instruction and learning. In order to make the most of the computer, teachers and schools will have to adjust their approach to classroom curriculum, assessment and management structures as they currently exist. The report drew its conclusions based on existing literature, school visits, and surveys of current practice in schools and universities. Previous documents have addressed the use of computers in schools from a curricular or administrative viewpoint, but this report attempted to address the process rather than the content of teacher practice.

The computer competencies considered fundamental were broadly defined in the report as: basic operations, information technology, evaluation of software, pedagogical issues, and values and ethics (Sections 2.1-2.5). Basic operations includes the ability to understand the primary components of a computer, how to use software packages such as word processing, databases, and spreadsheets, as well as using the computer for drill and practice, desktop publishing and obtaining information. Beginning teachers should also have information technology skills such as using email, the Internet, presentation software and interactive demonstration to display their ability to find, choose, synthesise and exhibit information. They should also be comfortable with various software packages including the ability to evaluate and integrate software in the classroom setting. Pedagogical issues to be learned include possessing the “flexibility” necessary to shift instruction to a student-centred format. And finally, and perhaps most challenging and interesting for those who educate teachers, the report suggests that beginning teachers must have an understanding of the values and ethics associated with technology. This includes issues of plagiarism, intellectual property, censorship and quality control, as well maintaining a level of respect for colleagues without technology skills.

Of the nine report recommendations, three directly impact preservice training. The report recommends that by 2000 universities provide outgoing students with the skills outlined above and “that the transfer of these skills into practice be part of the supervision of the practicum component” (7.3). The desired skills and their application in classroom practice would thus need to be overtly demonstrated and recorded prior to graduation. Preservice training is also addressed by the recommendation that students receive a form of transcript providing evidence of technological astuteness as suggested in “Desirable Attributes for Beginning Teachers “ (7.8-7.9). Unfortunately, even if the students do gain the skills needed to demonstrate technological aptness in a particular classroom situation that does not mean they will be placed in a school possessing the technology they have mastered. Neither might they be asked to teach the subject area or grade levels that they have practiced upon.

Critiques of the CPT

Although this report mandates change by threatening current students’ future employability, it does not provide best practice models to guide teacher educators. The report also overemphasises the technology of today rather than its potential by requiring specific skills such as using a CD-ROM instead of outlining a direction for the more important issues like pedagogical and curricular integration. Undue and unnecessary concern is directed towards what might be considered generic people skills rather than technology specific skills such as exuding a respectful attitude towards those teachers without technological training (2.5). There are also concerns that the visited schools representing current practice were an inadequate sample.

What is particularly challenging about this report is that it encourages teaching styles and modes of curricular integration. Past ministerial reports have addressed specific issues such as special education, aboriginal education, gender awareness or multiculturalism. By addressing a tool rather than a perspective the report imposes a challenge in that it seeks to change what schools do instead of trying to
add another layer or dimension to the existing structure. Although the report’s goal is to change the way school instruction is delivered, one danger is that teachers may learn the skills but not the ability to apply them. However, a teacher who has some technical understanding may then have the capacity to challenge what competencies are necessary and what skills are peripheral to the central goals of instruction. This baseline understanding may enable the teacher to ask sensible questions and challenge the technology to contribute to education rather than be simply and superficially dazzled. It is the teacher who stands between the technology and the child and must be able to mediate this relationship for educational goals to be achieved.

Despite the above critiques, one important consideration is the notion that beginning teachers are just that — novices and not polished professionals. While it would be criminal to graduate them into schools without technical ability, they may need to learn integration as they perfect a variety of styles and methods of instruction. The report should perhaps have struck a balance between what beginning teacher’s need and what incentives should be developed to enhance inservice training through postgraduate courses or general staff development.

**Current Practice for Preservice Technology Training**

The following sections examine how the Faculty of Education at the University of Sydney plans to adjust to the MACQT mandate. It may prove useful to outline the evolution of preservice education technology training at the Faculty of Education to understand current internal practice as well as external relations with the Department of Schools Education. The Faculty of Education merged with the Sydney Institute of Education (SIE) when the universities as part of the Dawkins reforms absorbed the Colleges of Advanced Education (CAE’s) across Australia in the late 1980’s. Since the SIE conducted a much greater volume of teacher training, we will discuss their programs prior to the merger. In the 1970’s the bulk of education technology training concerned the use of audio-visual equipment including television, film, and graphics although as microcomputers arrived on the scene they were brought into the curriculum. The Educational Technology Centre (ETC) was staffed by five academics, three technicians, a photographer and an administrative officer to serve approximately 1500 students and 240 faculty. Although there were no government mandates to offer compulsory technology courses, SIE education students took one mandatory course and had several option courses available.

In the 1980’s as personal computers became more prevalent and affordable in offices, schools, and homes; they gained more space in the ETC at the expense of the audio-visual components. Students were not allotted additional time to accommodate the new technology so it had to overlay existing technology courses. The mandatory program now emphasised basic Apple applications for word processing, databases, spreadsheets as well as gaining some software evaluation skills. There was also some programming instruction available but this was in the realm of the mathematics instruction. Staffing remained at the same level as it had in the 1970’s.

It is crucial to understand that during this time that there was a quite different connection between the state-level Department of Schools Education (DSE) and the CAE’s that handled the bulk of teacher training. There were very close connections between those who trained and those who hired teachers. Almost all CAE lecturers had taught at DSE schools as well. Courses at the CAE were externally evaluated and assessed by the DSE. Additionally staff and students received income from the DSE. Thus the CAE’s had little difficulty responding to the needs of the DSE as they adjusted their expectations of what skills a beginning teacher should possess. The tight coupling between these two components of teachers’ careers allowed teacher training institutes to react to changing needs in a cooperative manner. The close linkage and cross-fertilisation between the sectors allowed for greater personal and substantive professional contact. Overt and underlying assessment was possible without formal intervention or mandates. Because of the size and scope of the SIE changes to the curriculum could be made quite quickly whereas now within a university structure changes or the formation of new courses can take up to two years to accommodate.

Currently teacher training is located in university structures that rely on far greater levels of internal assessment, management and governance. Students only encounter the DSE towards the end of their teacher training since they receive financial support from the Commonwealth government and staff rarely move back and forth between sectors. The DSE cannot influence staff and student preference through day to day financial incentives but they can induce skills output through connecting hiring and promotion structures to their curricular and pedagogical preferences. When change is mandated from outside the structure such as when the DSE alters their expectations of beginning teachers, staff who train teachers are now liable to two systems. They must work within their university structure that may hold different or contradictory expectations to the organisation whose mandate must be respected as well. Thus the CPT report was released in a more decisive and less personal manner than would have occurred in the 1970 or 1980’s. Meanwhile the teacher education institutions now have less flexibility to respond to its demands.

Alongside the merger between the SIE and the existing Faculty of Education, the climate in the 1990’s also saw increasing pressure from parents, the media and the DSE to
increase the use of computer technology in the classroom. The ETC shifted the focus of its required courses almost entirely away from audio-visual skills to the computer skills that had been introduced in the 1980’s as well as the use of on-line resources such as email, the World Wide Web and bibliographic resources. Staffing levels now stand at four academics, three technicians, and one attendant to serve approximately 1250 students and 120 faculty. All students must enroll in a 12-hour introductory course that covers word processing, databases, spreadsheets, graphics and on-line resources such as the Web or ERIC. Students who undertake the B. Ed undergraduate course must also take a mandatory second year course that covers small scale television production, basic web page design, and rudimentary AV presentation skills as well as revisiting the skills emphasised in the first year course. They have the option of taking a course during their third year that exposes them to presentation software, more web design and some design tools such as Authorware. The students in the MTeach two-year postgraduate program may choose from four options after the initial twelve hour course that include computers and communication, desktop publishing, video production for classroom use.

The mandatory and optional courses address generic skills that are intentionally content-free. Students may also gain exposure to educational technology in their subject methodology courses such as project-oriented work in Technical and Applied Studies or software evaluation in Maths and Sciences. Students will only randomly be exposed to technology integrated into their subject content courses areas throughout the university. This is especially true in the humanities although the use of on-line resources for academic communication, teaching, research and collaboration and the growing provision of presentation facilities is altering traditional practice.

Adherence to the CPT by the Faculty of Education

Table 1.

</tr>
</tbody>
</table>

Although many of the required CPT competencies are currently addressed in the Faculty of Education curriculum, how students learn, practice and apply technology is not entirely integrated. Students take courses in general education (foundations, curriculum, and pedagogy) subject methodology and subject content. The Faculty of Education has no control over the way the Maths or English departments teach their classes or whether a student will see their literature lecturer use technology in the classroom. It may then come as no great surprise that the student does not see the value of retaining the technology skills to apply in their own literature class several years from now.

Although academic policy of the University of Sydney states the value of information skills (Section 5.a, May 1997), it does not specify how technology must be integrated in instruction, learning and assessment across the curriculum. An integrated approach amongst as well as within the faculties is crucial — although highly unlikely — for achieving objectives in cross-disciplinary study. Students will encounter campus wide computing facilities as well as information technology support through the library system but that does not guarantee that they will actually see technology used for instruction. Additionally the university is considering developing two-day modules of technology instruction delivery for all entering students. Although this is still being developed the Faculty of Education may opt to retain its current structure to teach basic technology skills.

Directions and Response of the Faculty of Education

The Faculty of Education had already enrolled, and provided one semester of instruction, to its undergraduate class of 2000 by the time the report was released. In order to accommodate the mandates, students may have to take a bridging course at the end of their degree. Since the masters class of 2000 has not been admitted yet, there is some flexibility to adjust an already dense program to accommodate the changes.

Most undergraduates begin the BEd and their mandatory computer training within months of finishing high school. It may be more appropriate to teach them self-centred rather than classroom-centred computer skills (i.e. how to electronically research an essay rather than how to use a spreadsheet to make a grade book) in order for them to become familiar and adept with technology. One model of providing, reinforcing, and updating skills during their university degree would be to provide word processing and on-line research skills in Year One; graphics, scanning and multimedia use in the second; spreadsheets, databases and software evaluation in the third; and web design and construction in the fourth and final year. These would be mandatory twelve hour courses and students would have the option of electives that delve into presentation software technology.
and the myriad of computer resources available to assist honours research. While these changes may accommodate the alterations necessary to adhere to the CPT recommendations, a bridging summer or winter course may be necessary to assist students who have already begun their degrees and whose regular semester schedule cannot adapt to additional courses.

Since the MTeach is a new two-year program, it will need a different solution. The MTeach has more incoming students with basic computer skills from their undergraduate degrees and work experience but it also has many mature age returning students with high levels of computer anxiety and low levels of prior skills and exposure.

**Conclusion**

The genesis and form of the report offers insight to how the relationship between those who train and those who employ teachers has evolved in New South Wales. It also demonstrates what technology skills employing authorities now deem to be necessary and desirable for beginning teachers. What has not changed during this time is the need to learn by example in order to connect theory and practice. If students do not see an integrated, consistent approach to the application of education technology in their teacher education they may not apply it in their own teaching. If technology is seen as peripheral or a skill to tick off in a box in the overall teacher certification degree, they will almost certainly pass that attitude on to their students.

THE ROLES OF COMPUTERS IN EDUCATION: WHAT ARE THE PERCEPTIONS OF MALAYSIAN VOCATIONAL AND TECHNOLOGY TEACHERS

Ab. Rahim Bakar
University Putra Malaysia

Shamsiah Mohamed
University Putra Malaysia

In the early 1980s there were about 300,000 computers in the elementary and secondary schools in the United States. A year later the number had tripled and has been rising ever since (Office of Technology Assessment, 1988). As reported by the Office of Educational Research and Improvement (1986), almost 99% of all public schools in the United States have purchased microcomputers. Recently, a study by the Office of Technology Assessment (1995) estimated the students and computer ratio in the U. S. schools was about 9 students for every one computer.

The scenario in Malaysian schools was quite different from the schools in the U. S. In Malaysia, computers were first introduced into the secondary schools in 1983. Initially, 20 schools were selected for the pilot project. However, 15 years later studies have shown that there are schools with no computers (Ab. Rahim, 1995). Lately, the Ministry of Education has increased efforts to equip every school in Malaysia with computers. Nowadays, some of the schools in Malaysia are linked to the Internet services. Besides the Ministry of Education, the Ministry of Youth and Sports is also doing its part in educating, especially out-of-school youths to acquire knowledge about and skills in using computers.

Computer technology literacy is an important necessary skill to have. According to Bork (1985), computer technology will be the dominant mean of delivering knowledge over the next 25 years. As computers continue to proliferate in our society and influence our lives, naturally everybody will be expected to be computer literate. Nowadays, computers are widely used in almost all professions all over the world. Thus, parents would like to see their children have basic knowledge and skills in computing in order to have competitive edge when entering the computerized world of work. The responsibility to equip children with computer knowledge and skills will be shouldered by schools and many schools are feeling the pressure. Starr (1996) asserted parents wanted schools to use computers to prepare their children for good jobs and a career.

One of the factors that determine the success of computer integration in education is the teacher’s perception about the usefulness of technology. The purpose of this paper is to share the findings of a study about the importance of computers in education as perceived by Malaysian vocational and technology teachers.

Objectives of the Study
The objectives of the study were to:
- identify the perceptions of Malaysian vocational and technology teachers with regard to the roles of computer technology in education;
- identify the status of computer technology integration by the Malaysian vocational and technology teachers in vocational and technology classrooms;
- identify teachers’ willingness to integrate computer technology in their teaching; and
- assess the relationship between teachers’ perceptions of the role of computer in education with selected variables such as gender, prior training in computer technology, general knowledge about computer, and school location.

Methods
The study employed a correlational research design. The sample consisted of 270 randomly selected vocational and technology teachers from three states in Malaysia (Selangor, Negeri Sembilan, & Melaka). All the three states are located in the vicinity of Multimedia Super Corridor (MSC).

The instrument to procure the needed information consisted of sections on (1) the background of the respondents, (2) the general knowledge about computer, (3) the roles of computer in education, and (4) skills in using computer technology. Three teacher educators in the Department of Education, University Putra Malaysia examined the instrument for face and content validity. The
research instrument was pilot-tested for the reliability estimates. The reliability estimate of the general knowledge section as ascertained by KR-20 was .80. The reliability estimate of the section on the roles of computer in education as ascertained by the Cronbach alpha (a) estimate was .88, and the reliability estimate of the section related to skills in using computers was .85.

Research questionnaires were mailed to 270 selected teachers. Of the 270 questionnaires mailed, 140 were answered and returned. It has resulted in 51.8% response rate. Of the 140 returned questionnaires, 111 of them were found to be useable.

Results

Respondents' Backgrounds

The respondents consisted of 37.8% female teachers and 61.3% male teachers. One of the respondents did not indicate gender. The mean age of the respondents was 34.9 years old (SD.=5.85). They have been in the teaching profession between 1 and 22 years with a mean of 5.88 years. The respondents taught subjects such as economics (20%), accounting (28.3%), home economics (6.4%), commerce (19.1%), and agricultural science (15.5%). The respondents indicated that they were teaching in rural areas (36.9%), small town (37.8%), and big town (23.4%).

Teachers' General Knowledge and Skills

Teachers' general knowledge about computers was assessed using 11 questions (Table 1). For every correct response a score of one was given and for every incorrect response a score of zero was given. The scores on the general knowledge about computers ranged between 0 and 11 with a mean of 6.73 and a standard deviation of 2.97. Teachers' knowledge about computers was organized into three categories: low knowledge (score less than 4), moderate knowledge (score between 4 and 10), and high knowledge (score above 10). The study showed that 38.2% of the respondents have a low knowledge about computer, 43.8% of the respondents have a moderate knowledge about computer, and 18% of the respondents have a high knowledge about computer (mean=6.73, sd.=2.97).

Besides asking their knowledge about computers, the respondents were asked how skillful were they in using computer software such as programming language, word-processing and desktop publishing, electronic spreadsheet, and database management (Table 2). The study showed that the respondents could not do programming, 50.8% were not capable of using word processing and desktop publishing software, 67.9% were not capable of using database software, and 57.1% were not capable of using electronic spreadsheet software.

Extent of Computer Integration

Most of the respondents did not integrate computer technology in their teaching (72.7%). However, the respondents thought computers should be used in teaching vocational and technology subjects (65.1%). Although vocational and technology teachers did not integrate computer technology in their teaching, they planned to do so in the near future (76%). To accomplish it, they planned to attend training to acquire knowledge and skills in computing.

</tr>
</tbody>
</table>

Cumulative scores ranged between 1 and 11 (mean=6.73, sd.=2.97)

Teachers' Beliefs

Eleven statements were constructed to assess teachers' perception about the role of computers in education (Table 3). The reliability estimate of the eleven statements was a .88. The cumulative scores of the teachers' perceptions about the roles of computers in education ranged from 11 to 55 with a mean of 42.6 and a standard deviation of 5.83. In general, vocational and technology teachers have positive perceptions about the role of computers in education. Their perception was categorized as negative, positive, and very positive. The findings indicate that 8.1% of the respondents had a negative perception (scores <36.78), 80.2% had a positive perception (scores ranging between 36.78 and 48.42), and 11.7% had a very positive perception about the role of computers in education (scores >48.42).

Correlational Analysis of Factors

One of the objectives of the study was to assess if there were any relationship between perception of the role of computers in education with selected variables such as: (a) gender, (b) prior training in computer technology, (c) general knowledge about computer, and (d) school location. There was no correlation between the perception of the roles of computers in education with gender ($r_{pb}=.11$, $p=.27$); prior training in computer ($r_{pb}=.13$, $p=.20$); location
of school (r = .08, p = .39); or general knowledge about computers (r = .09, p = .41). Regardless of the differences in their backgrounds, vocational and technology teachers in Malaysia in general, have positive views about the roles of computer technology in education.

Discussion
Computers will play a significant role in the delivery of education. As Bork (1985) indicated, in the next 25 years computer technology will be the dominant mean of delivering knowledge. Thus, teachers have to become computer literate if they are to function as educators of the 21st century. In the future the role of teachers will change. They will have to impart knowledge as well guide students to retrieve knowledge from various sources. They will need to equip students with computer technology skills to enter the world of work that will be more challenging and more competitive. As shown in the study the majority of the teachers do not have a good command of knowledge about computers and related skills. But, they were positive about the roles of computers in education. They were willing to use computer technology in their teaching even though they have not been doing so. Their positive views about the roles of computers and their willingness to integrate technology in teaching were further strengthened by their willingness to attend training to acquire knowledge and skills in computing.

With the positive perception of the roles of computer technology in education, integration of computer technology into the classroom will be much easier. However, we have to be very cautious here. We can have teachers with an adequate amount of computer knowledge and skills, but if they are not supplied with hardware and software, the integration will not take place at all. So, facilities and human resources will have to complement one another. Therefore, to assure that the integration of computer
technology into the classroom will occur, the government, through the Ministry of Education, has suggested that all teacher trainees in teacher training colleges and universities be given adequate training in computer technology. The teachers have to acquire the computer knowledge and skills while the government will equip schools with the necessary computer hardware and software.

Conclusions

The following conclusions based on the findings were:

• The vocational and technology teachers in Malaysia who participated in the study teach economics, home economics, accounting, commerce, and agricultural science.
• About 43% of the respondents had a moderate knowledge of about computers. Almost one-half of the respondents were not able to do programming. Almost one-half of them were not capable of using word-processing. Two-third of them were not capable of using database management program, and about one-half of them were not capable of using electronic spreadsheet program.
• Majority of the respondents did not integrate computer technology in their teaching but they were willing to do so in the future. Majority of them will try their best to acquire knowledge about and skills in using computers.
• Most of the respondents had a positive perception about the roles of computers in education.
• Teachers’ perceptions about the roles of computers in education did not correlate with any of the demographic variables investigated.
• Based on the findings, it is believed that the integration of computer in classrooms will be successful provided teachers have the knowledge and skill in using computers and the availability of computer hardware and software.

Recommendations

1. All teacher education programs in Malaysia should include in the teacher training curriculum, at least one compulsory course on using computers in the classroom.
2. Inservice courses should be conducted on a regular basis to equip teachers with the latest knowledge about and skills in using the latest computer software.
3. The school administration should encourage all teachers to acquire knowledge about and skills in using computers so that it is possible for the teachers to integrate computer technology in their teaching.
4. All schools should have computers if we want to make the integration of computer technology in the classroom a reality. The number of computers should be adequate to provide every student with an opportunity to use the technology.

5. Computer technology should be used in the classroom to prepare the Malaysian workforce for the information age technology.

Owing to the advancements in computer technology and the general availability of the computer network, the manner in which we obtain information, process information and use information will change significantly from the pre-computer, pre-network age. Consequently, the twenty-first century has been dubbed the information age.

To better prepare the next generation for the future, many universities and colleges offer computer literacy courses to non-computer related majors. However such courses were often conducted as an application literacy course. In such a class, students often come away only with the knowledge of a few application software packages. On the other hand, if the lectures were too theoretical, students would deem it as being dull. Our view toward such a course is consistent with other educators in that computer literacy is as important as application literacy. And both types of literacy need to be taught. Many reports and published papers support this view (Curl & Hussin, 1993; Goldweber, Barr, & Leska, 1994; Price, Archer, & Moressi, 1994). The “Revitalizing the Computer Science Course for Non-majors” panel (Burd, Brookshear, Decker, Gustavson, Lintner, & Scragg, 1995) of the 26th ACM-SIGCSE conference in Nashville also touched upon this issue. However, effectiveness of such courses was often reported only as an observation rather than as formal studies. In this article, we present our assessment of the computer literacy course that we have conducted over the years.

In the remainder of this paper, we briefly described our implementation of the Computer Education course, which is required for almost all majors at our University. Full details of the course design philosophy and the actual implementation can be found in Lee and Wu (1997). A formal assessment scale (Selwyn, 1997) was used to evaluate student’s attitude toward using computers after only one semester of our Computer Education course. Moreover, we also report on the students’ written feedback over the conduct of this course. In both cases, the results were most encouraging in that the students enjoyed the class and their attitudes toward computers are on the positive side.

Computer Education at NTNU

National Taiwan Normal University (NTNU) is one of the best-known and highly praised universities in Taiwan. NTNU competes with the other leading universities for the top 5% students of the annual nationwide joint college entrance examinations. Like others, NTNU prides herself in cultivating a sound body and mind as well as the academic development of all students. What sets NTNU apart is her status as the major university in training secondary school teachers. At NTNU, students receive the same rigorous training in terms of course works in their respective majors as with students in other universities. In addition, 26 credit hours of pedagogical theory courses are required for teacher certification. Computer Education is one of those pedagogic courses. Seventeen of 22 degree programs have listed Computer Education as a required course and the remaining departments list it as an elective course. Therefore, it is most likely that a NTNU student will have Computer Education on their transcript before graduation. The course is most often offered as a sophomore level course.

In summarizing terms, students of this course are non-computer science majors with little or no previous computer experience. They are most likely to hold a life-long career as secondary school teachers and thus they are most interested in becoming computer literate in terms of basic operations of the computer, usage of commonly available software, and working knowledge of computer networks. This course is designed with those objectives in mind.

The course contents are divided into four groups of topics:
- **Basic Computer Concepts**: hardware, operating systems, file management, Chinese input methods
- **Computer Networks**: introduction to Internet, Email, Talk, Gopher, BBS, News, WWW, FTP
One third of the semester is spent on the basic computer concepts and its operations. Basic computer concepts serve as a foundation for becoming computer literate. Both the hardware and the software aspects were discussed. Furthermore, time was also allotted for topics on computer viruses and on the copyright laws for computer software.

Computer networks and popular application packages build on the fundamentals to bring the students up-to-date on the current computer technologies and to use these technologies effectively. As part of Taiwan’s National Information Infrastructure Plan, the Ministry of Education has set aside funds to allow all the secondary schools to have direct access to the Internet within the next few years. Furthermore, new computers equipped with Microsoft Windows and its line of products will continuously be added to all the secondary schools. Thus it is important for the teachers to learn how to navigate the Internet, to use the resources available on the net, and to be comfortable using popular software packages. The goal on application packages was not to make master users out of the students but to serve as a foundation for becoming computer literate. Basic computer concepts and its operations. Basic computer concepts serve as a foundation for becoming computer literate. Both the hardware and the software aspects were discussed. Furthermore, time was also allotted for topics on computer viruses and on the copyright laws for computer software.

Pedagogical Issues

Computer Education is a two-credit course that meets for two consecutive hours every week. Since no extra laboratory time was scheduled, we conducted our classes in microcomputer laboratory for ease of class demonstrations. Each week, approximately 60 minutes to 90 minutes of time were spending on lectures and demonstrations of the topic of the week. The remaining time was for students to practice or complete in-class assignment.

The microcomputer laboratory is equipped with 45 Intel Pentium based networked PCs all and is also connected to an instructional broadcast system. This ensures that all students have the same software setup. The broadcast system allows for teacher-to-all, student-to-all, and student-to-teacher modes of broadcasting. With the teacher-to-all mode, all the monitors in the laboratory are synchronized with the instructor’s PC monitor. As such, all students will see the operating commands being entered, either via the keyboard or the pointing device, and the consequences of those commands.

During the semester, homework is assigned in each of the 18 weeks. Each homework assignment is associated with the topic covered that week and computer usage is always involved. To ensure that the assignments are fun and interesting, and to discourage academic dishonesty, each assignment is designed so that students are required to express their own creativity or to interact with the instructor and/or their classmates via the computer network.

Assessments of Attitude towards Computers

One of the goals of this course is to cultivate students’ interests in computers. To understand if that goal has been reached, we conducted a survey to measure students’ attitudes towards computers at the end of the semester. Our scale is based on Selwyn (1997), that was reported to have good reliability and validity, and to have satisfactory internal consistency. The scale contains 21 questions in 4 dimensions: affective - feelings towards computers; perceived usefulness - the degree to which one believes using computers will enhance their job performance; perceived control - perceived easy or difficulty of using computers; and behavioral - behavioral intentions and actions with respect to computers. The questionnaire is accompanied by a five-point Likert response scale (worded “Strongly Agree”, “Agree”, “Neutral”, “Disagree”, and “Strongly Disagree”). Scores ranges from 4 (Strongly Agree) down to 0 (Strongly Disagree). Thus students’ overall score could range from 0 to 84. As with Selwyn, we alternated questions from each dimension to prevent “clustering” effect. Furthermore, 10 of the questions were negatively worded to prohibit students’ giving all positive or negative responses. The questionnaire is given in Table 1.

The questionnaire was administered to three classes of 116 sophomores enrolled in authors Computer Education course. A Cronbach’s coefficient was calculated to collect the reliability data of our Chinese version scale. The result as depicted in Table 3, shows that the coefficient were suitably high for the overall scale as well as for each sub-scale (dimension) suggesting satisfactory internal consistency of the scale.

From the perspective of the students’ raw scores (summing up the score on all questions), the scores ranged from 22 to 78. Using the normative guide obtained by Selwyn (1997) as given in Table 2, 68.1% of our students would deem to have a positive attitude toward using computer, while only 2.6% of the students have a negative attitude after taken this course. Scores along the four dimensions are depicted in Table 3.

**AFF** - affective, **USE** - perceived usefulness, **CON** - perceived control, **BEH** - behavioral

From the Table, we may conclude that students generally have a positive attitude along the perceived usefulness and behavioral dimensions. The average score of 3 (Agree) means that students now perceive computers as being useful and is willing to use computer to enhance their work. Along the affective dimension, the average score of 2.55 falls between "Agree" and "Neutral" in the Likert scale, meaning that students has a somewhat positive feeling toward computers, but not strongly. Further analysis reveals that questions AFF1 and AFF3 have averaged only 2.1 and 2.0 respectively. As far as perceived control goes, the average of 2.08 (Neutral) is to be expected. We submit that one semester of computer education course is not enough for students to feel in total control of the computer, which also explains the not so high score on questions AFF1 and AFF3.

Feedback from Students

To better qualitatively evaluate the success of this course, we asked the students to fill out a feedback form on what and how much they had learned. In addition, comments about the course, about the lectures and about the teaching methodology were welcomed. To encourage true feelings about the course, the feedback forms were not returned to us till the grades were out. The most often cited comments naturally falls into two groups as detailed below.

Best Parts of the Course

Course Contents Are Practical and Useful. Most of the students mentioned that the course contents are just what they needed for the remaining years in school and beyond. Many have begun using what was taught in class
in their school works. Among the topics covered, the weeks spent on computer networks were most welcomed.

Having Hands-on Practice Time during Lecture. Because no lab hours were scheduled for this course, conducting the lectures in a microcomputer lab and interweaving lectures with hands-on practices in the same class period were cited by students as a major reason for the success of this course. With the in-class practice time, major concepts and operational skills can be better mastered, which in turns could save much time when completing the weekly homework assignment. Several students suggested that the in-class practice time should be increased.

Demonstration of CD-Titles. The demonstration of educational CAL CD-Titles was well received by the students. The students liked the chance to experience computer multimedia and were fascinated by how much fun it can be with computer assisted learning.

Interactions with the Instructor Are Good. Many of the homework assignments require interactions between the students and the instructor through the computer network. For example, the homework on e-mail asks the students to complete a rather simple task. However, the process naturally requires the students to communicate with the instructor through e-mails. This strengthens the teacher-students relationship, which enables more interactions inside the classroom.

Complaints, Suggestions, and Future Improvements

Problems with the Computer Equipment. During the course of the semester, due to unexpected hardware malfunctions or computer viruses, some students had to share a computer with one another. The problem is unavoidable for the computer lab was open to the general public. Possible remedies include teaching the students trouble shooting techniques and installation of anti-virus protection software and hardware.

Too Many Homework Assignments. The most frequent complaint from the students were over the number of homework assignments. However, we firmly believe that doing homework is the best way to become computer literate. Thus, we do not plan to change our stance on this issue in the future.

Obsolete Technologies Are Not Useful. To give students a whole picture of how technologies have evolved, we sometimes introduce how things used to work a few years back. For example, the DOS operating systems and the FTP line commands. Nowadays many operations and applications all have user friendly interfaces. Perhaps in the future we could lessen the time allotted to those topics.

Lack of Textbooks. It is rather difficult to find a single book that covered all of the topics that we covered. In the future, we plan to make available lecture notes on the web for the students to browse at their leisure.

Increase the Allotted Time on Networks. Because the weeks on computer networks were best appreciated by the students coupled with the strong desire to learn more about the computer networks, we intend to increase the proportion of time on Networks. This would coincide with the Ministry of Education’s plan to have all secondary school teachers learn to use computer network and to learn it well.

Summary

In this paper we reported on the successs of a computer literacy course delivered to preservice secondary teachers. The topics covered were chosen to ensure that students will become both computer and application literate by the end of the term and that the applications packages so selected prepare them for their future career as secondary school teachers.

From the assessment of students’ attitudes at the end of the term, we conclude that not only have the students become more computer literate, they have even developed positive attitudes toward learning to use computers. The success of teaching a course such as ours can be attributed to the following reasons:

- The course content relates to the practical applications of computers and to students’ future teaching careers.
- In-class hands-on guided practice sessions make the lectures more interesting and makes it easier to master the topics covered.
- Regular homework assignments reinforce the skills acquired in class.
- Good interactions between students-teachers and students-students makes a less pressured and thus a better learning environment.
- A well-equipped computer lab with good instructional tool such as broadcasting systems enables the teacher to better communicate and show the operational aspects of computer literacy.

The difficulties in Africa of gaining access to education and development are well reported. The existing poor standard of communication in many parts of Africa adds to the difficulties of improving the quality of education and standard of living on the continent. Distance education is seen as a key to the broad improvement of education standards in Africa. The notion of flexible learning is rapidly gaining respect that opens more avenues to intra-continental collaboration between all educational institutions.

With rapidly improving access to telecommunications across the continent, educational institutions and learners may now gain improved access to sources of programmes that will enable them to study without leaving their home cities and countries. Concerns of the present and past of the most talented citizens who study abroad and then never return to benefit their mother countries may be reduced through the effective use of combinations of the computer, Internet, satellite television, and other modern and developing technologies.

A number of factors, are appropriate on the continent, need to be taken into account in the enhancement of education using Internet technologies. Access to telecommunications is both limited and costly and it is primarily these that need to be harnessed to improve the skills of educators and learners. By a coordinated approach one can improve access of learners and institutions to telecommunications, support learning materials and expert discussion and advice. The many efforts in this regard on the continent need to be seen within an overall framework for the purpose of advancement and upliftment. This plan provides that framework and identifies additional areas where specific lead projects need to be accelerated or initiated to provide for the next stage of development the continent needs.

This plan has been drafted taking cognisance of the recent policy research documents on technology enhanced learning published by the South African Department of Education and fully support the implementation on the strategic planning document. The authors wish to see that technological support is provided from specific countries initially and then expanded to support other countries in the SADC region. This plan should be seen as complimentary to other initiatives in Africa, especially that of the African Virtual University and the flexible learning projects on the continent.

The intention is to initiate co-operation amongst countries in the SADC region in their renewal and expansion of education through the use of appropriate, available and cost effective technologies. Beneficiaries of the plan will be learners throughout the region being able to gain access local teachers and lecturers who have been able to improve their skills through professional development programmes on the Internet. Communities will be able to benefit through their improved skills and communication powers in the marketing of their products and services internationally. They will be able to gain from expert advice in other countries and offer advice on experience gained in their own areas.

Overview of the Plan
The plan comprises a number of strategic thrusts each of which needs to be started concurrently (see Figure 1). The project components, detailed in the next section are briefly outlined below:

Community Forum Programme
The southern African community forum programme is a framework through which local community structures may be involved in the process. It is expected that full community level support will be needed to implement all aspects of this plan (See Figure 1: Community Forum Programme).

Project Plan for Information
The project plan for information comprises initially two information clearing houses which will be created in a form of Internet web servers which may be located in South Africa and Zimbabwe. These will be expanded to other countries in Africa (or outside Africa) as the plan unfolds. The location of the Internet web servers contain-
ing information will have to be determined by the level of Internet infrastructure, speed and reliability of access by potential users (learners and learning facilitators). These information clearing houses will contain support material for primary, secondary and tertiary level education as well as an index of hyperlinks to sources of appropriate information. A section of the server will be dedicated to continuous education aimed primarily at the upgrading of educator’s skills.

Materials must be made available in a format that enables course materials to be transferred via the Internet while attached to e-mail messages or being viewed on the World Wide Web. Specific programmes available for non-profit and educational use will be utilised for this purpose.

This section of the plan also links to the establishment and development of various centres of excellence in member countries. Centres will vary in nature and learning content depending on national priorities as determined by the respective national departments of education. Examples may be the Malawi Institute of Management (MIM), Eastern and Southern African Management Institute (ESAMI), Institute of Public Administration in Gaborone.

Plan for Internet Connectivity

Access to the information stored in the information clearing houses will only be of benefit to those institutions and individuals able to access the Internet (Plan for Institutional Connectivity). Two sub-strategic thrusts seen to be necessary in this area are: 1) to be the raising and marshalling of funds to support and 2) the necessary infrastructure in all countries in southern Africa. Connectivity will remain constrained by the availability of telecommunication as provided by the national telecoms. The supply of electricity which also remains a constraint can be overcome to a limited extent with the use of alternative sources of electricity such as generators (fuel and solar) and batteries. Internet connectivity is likely to remain largely in the hands of the commercial sector and government agencies.

While the infrastructure for institutions may be linked to the overall Internet connectivity within each country, learners need to be taken care of very specifically (Plan for Learner Connectivity). On-line libraries and learning centres are necessary to support those students who do not have access to computers and the Internet. Internet connectivity through Internet Service Providers (ISPs) may be encouraged through collaborative ventures with the private sector.

Plan for Training of Educators

All of the preceding aspects of the plan are dependent on the ability of educators in the region to access and use the available information. For this reason an educator training programme in the use of computers and the Internet is required even before they are able to access the information clearing houses (Plan for the Training of Educators). Facilitators will need to be trained who can then operate at country, provincial and community levels to provide the basic training required to enable educators to use their institution’s Internet connections to gain further continuing education programmes via the information clearing houses.

It will be seen that each of the five strategic thrusts of the plan need to be undertaken concurrently so as to minimise the implementation period. Each participating country will need to have a full-time project team appointed by its department of education to coordinate the various activities at provincial and local levels. The implementation of the strategic thrusts is outlined in more detail below.

Figure 1. Technology Enhanced Learning Initiative in Southern Africa (TELISA).

Description of the Strategic Thrusts

Project Plan for Information

The Project Plan for information (see Figure 2) involves the establishment of a series of information clearing houses based on the Internet and centres of excellence to be located in a number of major cities throughout the southern African region.

Centres of Excellence

The Centres of Excellence are a series of high quality educational institutions to be located in cities such as Lilongwe, Windhoek, Gaborone, Harare and Pretoria. These will concentrate on the provision of high quality courses in such areas as science, technology and business related to prepare learners for careers and further studies in these fields. This concept finds one model in the Brooklyn School of Science and Technology in New York whose former students have won some five Nobel prizes since its inception 14 years ago. Such centres of excellence will

International — 511

517 BEST COPY AVAILABLE
usually be existing institutions that are leaders in a particular field.

Figure 2. Project Plan for Information.

**Information Clearing Houses**

The Information Clearing Houses are to be based primarily on the Internet and will comprise a sufficiently powerful Internet server connected to the Internet through high-speed data communications links. The four major functions of the Information Clearing Houses will be that of providing supportive course material for primary, secondary and tertiary level institutions, a comprehensive set of global hyperlinks to assist teachers and lecturers in obtaining materials for their teaching, and continuous education programmes to support primarily professional development of educators and various business and community related programmes.

It is envisaged that the Information Clearing House will be a wealth of information and to provide access to information that will be of great value to teachers and lecturers throughout the region. Programme content may vary from Internet based hypertext materials, to multimedia and broadcast programme materials.

Where materials are in hypertext format, lectures, tutors and learners will be able to access information by e-mail by sending messages to an archive facility on the Internet server. The server will be programmed to respond automatically by returning the required file, usually in html format (hypertext mark-up language) plus all appropriate graphics attached to an e-mail message. Graphics will be formatted to require minimum download times and materials are to be created with only those graphics that add value to the study material. Users with Netscape Mail or similar e-mail program will then see fully formatted text and graphics in their e-mail that may studied in e-mail format or printed if required. The relevant html files and graphics may also be saved separately from the message on local PCs or servers to save further telecommunications expenses.

Broadcast technologies are incorporated into the plan via the Clearing House of Information from the following perspective: Information on programmes being broadcast by television, radio or other form of broadcast techniques. Programmes may then be viewed using the required equipment. Where individuals need to collaborate to access the equipment, this may be done under the Plan for Connectivity. As sufficient bandwidth a storage space becomes available, programmes may be stored on the Information Clearing House and provided to uses on demand (e.g. real audio and real video).

**Plan for Internet Connectivity**

The Plan for Internet Connectivity (see Figure 3) rests on three “legs”. The first of these legs is governmental education departments that need to build the necessary infrastructure for national educational institutions. The second leg comprises those regional organisations such as the Distance Education Association of Southern Africa (DEASA), that strive to improve the standard of education and inter-institutional co-operation in the region. The third leg of this strategic thrust is that of developing the infrastructure which supports the various educational institutions such as the supply of electricity and telecommunications by the relevant national utilities.

Regional organisations such as DEASA can serve as a body to assist specific institutions that lack the necessary infrastructure to gain access to the Internet. Once proposals have been drafted for the raising of funds, potential partners need to be identified and approached for assistance. In this way funds may be raised to sponsor the purchase of necessary computer and modem equipment, secure facilities and staff training on the basics of using computers. Such connectivity is not presently included in this plan. Examples of projects already underway in this...
area include ZA Schools (http://www.school.za) and the Acacia Project (http://www.idrc.ca/acacia/acacia_e.htm) and Uninet (http://www.uni.net.za).

Institutional infrastructure is almost entirely dependent on the provision of reliable electricity and telecommunications to the institutions. The infrastructure plan needs to be coordinated at a national level in each member country with the responsible agencies for electricity and telecommunications. With careful liaison adequate facilities may be supplied to individual institutions which will make provision for them to utilise equipment that may be available to them.

**Plan for the Training of Educators**

Educators who have not been exposed to the Internet or have limited computer knowledge will need to receive hands-on training on both using computers and on how to use the Internet. Although more advanced professional development programmes may be housed within the institutions where the Clearing Houses of Information have been established, the basic training required by educators will need to be provided on a local contact basis.

![Figure 4. Plan for the Training of Educators.](image)

An initial programme needs to be developed for the training of facilitators who should emanate from all countries in the SADC region. An initial training programme for these facilitators (see Figure 4) will be run in one venue and then facilitators will return to their home countries where they need to run training programmes for a larger number of facilitators to operate within their country. Facilitators who return home after receiving the basic training will then be expected to run programmes at a national level for their Department of Education, at provincial level and also at community level. Each time a country facilitator runs the programme sufficient skills should be passed on to enable the participants to be able to run the same workshop for others within their community or institution. At community level, the facilitators may work with universities, polytechnics and colleges, thereby helping the integration of these institutions into their respective communities.

Community-based on-line learning and library centres are essential at a local level to help eradicate illiteracy within the sub-continent. These facilities should be given specific support through the Community Development Forum programmes.

**Community Forum Programme and Plan for Learner Connectivity**

The Community Forum programme is a framework that may be used to encourage community level participation in this and other programmes. The programme needs to be coordinated at country level via an appropriate government department or non-governmental agency (see Figure 5).

![Figure 5. Plan for Learner Connectivity.](image)

Community level coordination is required by a member of each participating community which in turn sets about developing a multipurpose information facility which is linked to a telephone shop, should telecommunications not be freely accessible in that particular community. On-line libraries and learning centres are an essential part of giving access to computers and the Internet to students who would otherwise not have any access. These facilities need to be initiated and supported by the community through the Community Development Forum. These on-line libraries and learning centres, in turn, connect via the Internet to the various Centres of Excellence and the Information Clearing Houses. Where a community deems it necessary, additional facilities may be added to a proposal to include facilities to receive programmes via satellite TV (e.g. African Virtual University and the South African Broadcasting Corporation) and radio.

All available course material on the Internet servers of the Information Clearing Houses will be directly available to Community Learning Centres through the Internet and related facilities. Individual learners and groups of learners...
who have their own personal computers may also gain access to the information stored in the Clearing Houses of Information through their Internet service providers.

**Initial Projects**

As stated at the beginning of this plan, all strategic thrusts should be started simultaneously and if started by December 1997, tangible results may begin to be reported by the middle of 1998.

The plan above does not attempt to offer any “correct” form of technology, but rather a conceptual framework within which many projects may be structured. This is expected to assist institutions and countries in the region in their negotiations and alliance forming to aid community development.

Projects may be included by organisations from across the region and each is to be planned, funded and implemented independently from other projects. The motivation to collaborate through the TELISA Plan to minimise duplication of effort and “planning gaps” will be obvious to the reader.

**Project 1: Information Clearing Houses**

It is envisaged that initial Internet servers to house the required information should be located in Johannesburg and Harare. The intention is that each of these servers should be placed on a high-speed link to an Internet backbone. It is further recommended that the details for this project be borrowed from the TELISA Strategic Plan of the National Department of Education in South Africa. It is envisaged that the SA Department of Education will install the first Information Clearing House.

Each site should be an exact mirror of every other one, thereby providing for duplicate familiar sites that may be accessed in the event of slow or faulty Internet lines. A commercial directory facility may be maintained to assist with the self-funding of the sites. Educators and learners who have the necessary capacity will be encouraged to contribute to the contents of these sites. While initially English will be considered the language of communication for the clearing house, other languages used in southern Africa may be included based on the requirements of participating countries.

**Project 2: Centres of Excellence**

These Centres of Excellence should concentrate on the development of skills for top level manpower requirements in each country. The specific subjects taught in each of these Centres must be determined by national priorities within each country.

It is recommended that the draft plans of Professor Casper Schutte at the University of South Africa be used an example by national authorities in the development of these Centres of Excellence.

**Project 3: Infrastructure Planning**

**Institutional Infrastructure.** Learners and tutors may only have access to any of the information and expertise if they have the necessary computer and connectivity. It is recommended that a joint team from the region be charged with the responsibility to establish which institutions require equipment before they may participate in the project. The same team should then draft a comprehensive proposal for the funding of all computer equipment, programmes and necessary internal infrastructure such as local area networks, disks, cabling, etc.

**National Infrastructure Plans.** Institutions may not be feasibly expected to participate in the plan if they do not have a reliable source of electricity and data communications. A separate team from the region must be assigned the task of negotiating the supply of electricity and telephone lines to all institutions involved in the project with the respective authorities within each country. Where institutions are unable to cover the cost of electricity and telephones specifically for their computer laboratories, this should be included in the fundraising proposals created above.

**Project 4: Facilitator Training Programme**

(Courseware)

Facilitators who are to be trained and who return to their own countries to facilitate the training of others will require a comprehensive manual both for their own understanding and to enable them to train other people. A courseware development team must be assigned the task of collating and developing materials for the manual that will be received by all facilitators in the region. This package should include the entire course on print, on computer disk and should also include the necessary minimum programmes required to connect to the Internet.

**Project 5: Facilitator Training Programme**

An initial training programme of country facilitators must be run in an appropriate venue using the materials developed above. Each trained facilitator will be required to return to his or her own country and offer the same programme to groups of facilitators within that country who will in turn be responsible for training educators in schools and tertiary institutions.

Within each country, training programmes will be required at a national, provincial and community level. Educators within communities who have received this training will then be expected to assist in the cross-training of other educators within their own and other communities.

**Project 6: Development of the Community Forum Programme**

A basic outline or framework for the Community Forum Programme is required which may be used across all countries in the region and which may be modified as required at local level. A small team needs to be appointed...
to review courseware that is currently available and to ensure that this will be acceptable at community level across the region. This programme must be made available in print and in digital format (e.g. MS-Word) and an appropriate version for storing in the Information Clearing House (e.g. html).

**Project 7: Community Development Forums**

Using the material developed above (Project 6), Community Development Forums must be initiated at a local community level within each country initially on a pilot basis and spreading out in a structured manner. Materials must be made available free of charge from the Clearing House of Information via those institutions that have developed the required technological infrastructure. These Community Development Forums will be expected to develop their own multipurpose information facilities and to assist in the provision of infrastructure including electricity and telecommunications by providing an environment that is conducive to the national commissions responsible for these matters.

**Project 8: Establishment of Computer/On-line Learning Centres**

A number of initiatives are required across the entire region to create centres to which learners of all ages may go to gain access to computer equipment and access to the Internet. These centres should be based on each specific community’s requirements but in general should comprise an appropriate local area network (LAN) with one server and a number of PCs linked to it. Via the server, users should be able to access e-mail and where possible, the world wide web. Private e-mail accounts should be maintained on the server for all regular users of the centre. Sophistication of connection between the LAN and the Internet will depend on local circumstances.

**Conclusion**

When considering technology as an added instrument to enhance education and capacity development, a holistic view needs to be taken to ensure that the installed technology can be used for the purpose for which it was acquired. Aspects such as the supply of electricity and telephones, training of staff, security of equipment and commitment and acceptance by the user community are all essential.

This plan was the first stage in conceptualising a cohesive way in which multiple projects could be monitored and capacity building effected in Southern Africa. The initial draft was followed by a workshop held in South Africa on 25 September 1997 at which the principles were endorsed. Further documentation is available on the Internet at: <http://vgc.co.za/telisa> that shows the implementation plan and progress to date.

CONSTRUCTIVISM, LEARNING METHODS AND DELIVERY MEDIA:
A SOUTH AFRICAN TALE

Mari Peté
Technikon Natal, Durban

This paper reports a follow-up research project and an in-depth examination of issues raised in “The KwaZulu Concept Burger” presented by Clark and Peté at SITE97. This original study focused on the learning experiences of three students during the cooperative construction of a hypertext concept map. These students are residents of the province of KwaZulu Natal and study towards a Master’s degree in Education at the University of Pretoria, Gauteng Province, South Africa. This report is of a qualitative, comparative study that reflects upon the spectrum of learning experiences of all eleven students in the class.

The Master’s assignment entailed the construction of concept maps on the topic “The evaluation of educational software and its effect on learning”. As stated previously, the creators of “The KwaZulu Concept Burger” (the Burger) delivered their product in electronic media. It was prepared in HyperText Markup Language (HTML) and presented through a World Wide Web (WWW) browser. The other maps produced by cooperative groups took the form of physical representations (models or posters).

Since its construction, the Burger has continued to evolve. The initial product was adapted and used by its creators in their working environment. Other concept maps remained static and unused.

This paper investigates (i) the role the chosen delivery medium (HTML) played in the learning process. It further aims to (ii) examine learning methods which played a role in the learning process. In order to draw any conclusions concerning the influence of delivery media and methods of learning on the learning processes, (iii) the development of the other concept maps are analysed and compared to that of the Burger.

Literature Review of Factors Influencing Learning

The literature review of factors that influence learning included reports on both behavioural and constructivist teaching and learning methods. Articles were reviewed also that looked at the different media that influence teaching and learning.

Teaching and Learning Methods

Behavioural Learning. Behavioural learning follows a pattern of stimulus-response-feedback and reinforcement: “Feedback produced by the consequences of behavior may reinforce that behavior” (Cook, 1993, p. 64). Behavioural learning can be used effectively to reinforce basic subskills, in order to attain “automaticity”, which Bloom defines as follows: “The mastery of any skill - whether a routine daily task or a highly refined talent - depends on the ability to perform it unconsciously with speed and accuracy while consciously carrying on other brain functions” (1986, p. 70). These higher-level brain functions include “retention, understanding, and active use of knowledge and skills” (Perkins, 1991, p. 18).

In the long term, behavioural learning fails to attain the brain functions mentioned above by Perkins. It furthermore does not effectively facilitate transfer of learning to broader environments, outside of the traditional classroom: “The knowledge so acquired is either not accessible or else not relevant for active use in the real world” (Barras-Baker: 24).

Constructivist Learning. The constructivist learning process addresses the weaknesses of behavioural learning. In a constructivist learning environment, learners actively construct knowledge from personal experiences and interpretations of the world (Merrill, 1991). Learning becomes an active process when learners develop their own mental models. This process involves “the organising of memory into structures” (Merrill (1990b), quoted in Merrill, 1991, p. 45). Merrill states that organisation in learning facilitates later retrieval of information. Organisation entails the structuring of knowledge. Retrieval can also be aided by learners’ use of elaboration, which refers to “the explicit specification of relations among knowledge units” (Merrill, 1991, p.45).

Rich Environments for Active Learning (REALS) are a specific form of constructivist learning, and are based on principles such as collaboration, generativity, reflectivity, active engagement and anchored instruction (Dunlap, 1996).
Teaching and Learning Media

Hypertext. Hypertext is "a generic term covering a number of techniques used to create and view multidimensional documents, which may be entered at many points and which may be browsed in any order" (Illingworth, 1990, p. 212). Hypertext can be used in a variety of ways in an educational learning environment. Materials and resources can be delivered to learners in this medium. In addition, learners can output knowledge through hypertext projects.

In either of the above situations, navigation in a hypertext environment provides the learner with the opportunity to develop multiple perspectives. It facilitates the traversal of complex subject matter in non-linear ways. Multi-dimensional navigation enables learners to make links between concepts. Maximum learner control is made possible in such environments. (Mc Manus, 1996; Spiro, Feltovich, Jacobson & Coulson, 1991)

The Internet and The World Wide Web (WWW). The term "Internet" implies the global inter-connectedness of computer networks of information. Web browsers (such as Netscape and Internet Explorer) enable users to access information available on the Internet through a hypertextual Graphical User Interface (GUI).

The Media Debate. Fourteen years ago, Richard Clark stated that media are "mere vehicles that deliver instruction but do not influence student achievement any more than the truck that delivers our groceries causes changes in our nutrition" (1983, p. 445). Clark's article provides research evidence that methods and media were confounded in the past, and that the importance of methods of teaching are often overlooked. As a result of evidence that "many very different media attributes accomplish the same learning goal", he suggests that "the attributes must be proxies for some other variables that are instrumental in learning gains" (Clark, 1994 p. 22). In addition Clark states that media may "affect the economics but not the learning effectiveness of instruction" (Clark, 1994, p. 26).

In a constructivist learning environment, learners, rather than instruction being "delivered" to them, construct knowledge. In such situations Clark's media would include the means students use to deliver the products of their learning. This paper investigates whether successful transfer of knowledge (or lack thereof) in the case of the Burger and its counterparts, can be attributed to "proxies for some other variables", rather than to the delivery media chosen by the learners.

Execution of Mind Map Projects

Stages of Development of the Burger

The three KwaZulu Natal students sketched the development of the KwaZulu Concept Burger as follows:

During the Master's Module. The original concept map was devised as an examination project for the subject "Evaluation of software and its effect on learning".

Back at Work. After the students submitted the Burger as an examination project, it was continuously updated as it was used in their professional practice. It formed the basis of a variety of workshops presented at tertiary institutions. In addition, educational technologists continued to access the Burger on the Internet, using it to evaluate multimedia products. The Burger was eventually presented at the SITE 97 conference in Orlando, USA.

How the WWW Influenced the Learning Process of the KwaZulu Natal Team. The following information was obtained from on-line questionnaires completed by the students:

Effortless and cost-effective updates were facilitated by the dynamic medium of HTML.

As time passed since the Burger's initial construction, HTML editors became more sophisticated, and their added features (e.g. capability to produce tables) were used to improve the product. The technical improvements enhanced the illustration of important concepts such as the evaluation matrix.

The WWW played a dual role in the Burger creators' learning process: it served as construction tool as well as a content provider in the continuous process of improving the product and writing the conference paper.

The need for retention of information became less important in the learning process, as the Burger's creators and other users could access it at any time on the Internet.

In preparing for presentations, knowledge gained in practice was used to update the Burger. It became more multidimensional, through the fine-tuning of conceptual relationships. This resulted in an on-going learning process in a real life context.

Due to the Burger’s availability on the Internet, members of the audience were able to access it after various presentations, and provided presenters with on-line feedback.

The original intention of the product was the representation of a concept map. However, during the evolutionary process, the concept map acquired the additional function of an educational software evaluation tool used in practice.

The team member responsible for the HTML editing, indicated that skills gained during this construction exercise lead to her subsequent choice of "Web-based learning" as a dissertation topic. Her project formed part of an international training programme and she therefore got the opportunity to visit Germany and to collaborate with an international team of experts.

In the space of a year, the Burger became part of a collective knowledge base, when it was linked to virtual classrooms that emerged on the World Wide Web.

Other Factors In The Learning Process

Constructivist Learning. The process of concept map construction is clearly a constructivist exercise, and ties in with Merrill’s (1991) reference to the development of
mental models through the organisation of memory into structures.

Aspects of REALs that were particularly prominent during the learning process are:

Collaboration. The Jigsaw cooperative learning model was followed - learners were divided into expert groups and home groups. Members of the KwaZulu Natal home group (who constructed the Burger) each belonged to a different expert group. Expert groups researched a number of topics and fed the information back to their home groups. This procedure enabled students to cover and share a vast range of information in a short space of time. Burger creators indicated unanimously that the cooperative learning process played a major role in the transfer of learning: "The initial probing and struggling for clarity and accessible metaphors facilitated a way through the more abstract, theoretical stuff and makes it easy to remember". Learners from other teams also emphasised the importance of discussions, to clarify relationships between concepts.

Generative learning. After the exchange of information took place amongst expert group team members, home groups spent most of their time generating ideas around the reorganisation of static information into flexible knowledge structures / concept maps (Dunlap, 1996).

Anchored instruction. Anchored instruction occurs within realistic contexts that are appealing and meaningful to students (Dunlap, 1996). The KwaZulu Natal team chose the burger metaphor, as its layered structure and hierarchy of ingredients are representative of the way in which the students envisaged the relationships between various units of information (Clarke & Peté, 1997). The team felt that their choice of metaphor contributed significantly to the learning process: "The burger concept really is easy to internalise".

According to Viau (1994) metaphoric thinking has the potential to reduce the complexity of a situation "through the use of an image which clarifies, unifies, and inspires". However, a "superficial fit" will not have the desired effect on learning. These two statements are supported by the outcome of this study. Apart from the KwaZulu Natal team, one other group testified that their chosen metaphor (a mother with children) aided retention and internalisation, while other groups indicated that their metaphors were ineffective in connecting "unfamiliar situations to deep affective roots" (Viau, 1994).

Conclusion

The choice of HTML as delivery medium undoubtedly played a facilitative role in the KwaZulu Natal team's learning process. However, it is clear that other teams also recall the construction of their concept maps as valid, meaningful learning experiences, which facilitated transfer of knowledge to other situations: "The actual making of the poster enabled me to retain and transfer knowledge". The process of concept map construction involved constructivist learning methods such as "organisation" and "the explicit specification of relations among knowledge units" (Merrill, 1991:45). Elements of the "Rich Environment for Active Learning" within which all students learnt, are collaboration, generative learning and anchored instruction.

The main advantages of HTML as delivery medium, are that it is multidimensional, quick to update, and easily accessible. These characteristics have economic benefits that enable cost-effective, on-going learning processes.

Acknowledgements

I would like to thank Patsy Clarke and Ari Naidoo, co-creators of the KwaZulu Concept Burger, as well as professor Johannes Cronje, course coordinator and lecturer, for their inspiration and collaboration throughout the MEd programme.

518 — Technology and Teacher Education Annual — 1998
CHANGING ROLES OF LECTURERS IN A RESOURCE-BASED, OPEN LEARNING ENVIRONMENT.

Mari Peté
Technikon Natal

Parivash Khalili
Technikon Natal

In a post-apartheid South Africa, national educational policies are currently being drafted, in order to address the imbalances of the past. The Green Paper on Higher Education Transformation (1996, p. 25) outlines a comprehensive set of initiatives for the transformation of higher education. Amongst others, emphasis is placed on the use of resource-based, open learning systems:

"...distance education and resource-based learning have a crucial role to play in meeting the challenge of greater access and enhanced quality in a context of resource constraints and a diverse student body...Distance education based on the principles of open learning leads to the development of a system which is organised for use by learners at different times, in different ways and for different purposes..."

However, according to the Green Paper resource-based, open learning is not only appropriate for distance education. It can also be used for the "reorganisation of learning and teaching in contact institutions" (1996 p. 25). Its use in this context will lead to the improvement of quality and effectiveness. Open learning seeks to increase access to opportunities by removing all unnecessary barriers to learning. Brevik (in Rakes, 1996 p. 52) defines resource-based learning as "a learning mode in which a student learns from his or her own interaction with a wide range of learning resources, rather than from classroom exposition". Both the above learning modes accommodate the reality of a diverse South African learning environment to a far greater extent than traditional means of teaching.

The Context of this Paper

The following information should provide some idea of the context of this report:

The role of the first author of this paper is educational researcher and the role of the second author is lecturer of the subject under discussion.

Institution: Technikon Natal (a tertiary contact institution)
Qualification: BTech Degree in Information Technology
Year: Final year (4th)
Subject: Operating Systems IV (OS IV)
Course Length: Six months (full-time)
Lecturing style: Traditional ("Chalk and Talk")
Average number of students: 10

Lecturer's Observations

During frequent meetings and discussions between the researcher and the lecturer, it was ascertained that traditional lectures pose the following problems for this particular course:

Academically Weak Students. Two out of nine students who took the course during the first semester of 1997, did not manage to hand in projects at the end of the semester. The lecturer therefore felt the need to speak to students more often on a consultative basis, in order to advise, guide, and keep a check on whether they are coping. The inflexible structures of the current system (fixed hours for lectures and fixed consultation hours of the lecturer) do not allow for sufficient communication between lecturers and senior students who have equally busy schedules.

Academically Competent Students. Senior students in the fast-growing field of information technology are often experts in a wide variety of specialist areas. Traditional lectures, where communication is one-directional, do not capitalise on the collective base of knowledge and experience that such students have. The lecturer noticed that these students often appeared to be bored during lectures. There is therefore a need for an environment where she could use the expertise of these learners in an interactive, collaborative learning environment.

Students' Observations

Unstructured Group Interview with Students. Six out of the twelve group of nine students who completed OS IV during 1997 attended a group interview. The students highlighted the following difficulties with their current course:
• All students held part-time jobs while studying towards their final year. They would welcome a system that had a more flexible time schedule.
• They also felt a need for access to course materials (readings and examples of software) on the network.
• By the end of the course, none of them had seen the projects completed by co-learners. They expressed the need to have easy access to these resources.
• Furthermore, access to previous years’ projects could serve as a foundation upon which to build their research, in a field that rapidly expands every year.
• There was also the need for discussions during the development of projects.

Individual Structured Interview with Non-completing Student. The two students who did not hand in their projects were invited by the researcher to attend an interview. One student attended, and indicated that she experienced the following difficulties during her course:

She worked full-time at another department on campus while completing a full-time course and she found it difficult to attend the lectures.

She did not have frequent contact with other students to discuss problems while she was completing her project. She did not see their projects either during development or after completion. She therefore had the need for more frequent discussion with her lecturer and fellow students.

Interpretation of Interviews

Information from all three interviews indicate that Operating Systems IV in its existing form lacks flexibility of learning time; access to resources, and collaboration.

Strategies for Improvement

In order to improve on the current system, the lecturer and researcher designed and developed an open learning system in the form of a virtual classroom on the World Wide Web. The classroom prototype was designed during the latter half of 1997, and will be implemented during the first half of 1998.

Conventional lectures are replaced with an on-line environment that students can visit in their own time, in order to collect resources, contribute to resources and deliver assignments. The classroom serves as a “dumping site” for lecture materials and resources. A second essential characteristic of the classroom is that it will become a “construction site” as students contribute to the building of the learning environment.

An important component of the virtual classroom is a listserv (asynchronous electronic mail discussion forum) which allows students to share ideas; brainstorm problem solving techniques and consult the lecturer. Asynchronous communication was chosen in order to allow students to post questions and responses in their own time. Time will be made available for synchronous discussions during face-to-face tutorials when the need arises. This is a feasible solution, as students are mostly employed as technicians by other departments on the same campus. In this instance the purpose of open learning is not to overcome problems related to distance. It is used to improve upon the traditional, one-directional, static lecturing system, which is particularly limiting for the teaching of small groups of expert learners.

The OS IV virtual classroom is an adaptation of the University of Pretoria’s Virtual Classroom for Masters in Education students (Cronjé, 1997). In this classroom the metaphor of a physical classroom was used. During a target population analysis of prospective and past OS IV students it was ascertained that the vast majority of students enjoy science fiction novels and films as well as adventure games. As a result, the metaphor chosen for the OS IV classroom is a futuristic, on-line police station named “The COP Shop” (COP being an acronym for Computer OPerating Systems). Students act as an exclusive team of technologically-minded cops and they are expected to solve distributed operating system problems, in order to rid the Internet community of cybercrime and corruption.

The structure of the classroom on the WWW is explained in the table below.

Lecturer as Facilitator and Guide. The role of the lecturer becomes more democratic as she retreats into the background to guide the learning process amongst learners, rather than to provide solutions. The facilitator of a virtual classroom for students at Master’s level at the University of Pretoria comments as follows on his role as facilitator:

“a) I develop NO content. I simply point them to resources. b) I provide NO instruction. I monitor their classroom listserver discussion and prod and prompt here and there. c) I set goals and deadlines. d) I take flak from frustrated learners. e) I share their joy as they discover they can do it for themselves”. (Clarke, 1997)

Lecturer as Participant. As the lecturer becomes merely another member of the listserv discussion group, she has the opportunity to learn from solutions provided by learners. In order to enable the lecturer to stay in touch with the development of discussions, it is important to encourage students to mainly make use of the listserv, rather than to send personal e-mail messages to one another.

Lecturer as Researcher. Embarking upon experimental, innovative methods of teaching also opens up opportunities for lecturers to do action research. This type of research specifically supports reflections upon small cycles of continuous experimental interventions and adjustments to improve teaching environments. Action research is collaborative and participatory (Cohen & Manion, 1993) and therefore lends itself very well to a team teaching approach.

Implications of Open Learning for Lecturers

In an open learning environment, the role of a lecturer becomes more multifaceted. In addition, there is room for participation by other professionals in the teaching and learning process.

Changing Roles

In a cooperative learning environment, the traditional role of a lecturer changes from transmitter of knowledge, to planner, manager, facilitator, guide and participant (Ryba & Anderson, 1990). Another role that can be added to the above is the role of lecturer as researcher of the learning process.

The Lecturer as Planner and Manager. One important aspect of this role is to organise access to adequate resources.

In addition, shared resources include printers and scanners.
Sharing the Load with Other Professionals

Educationalists other than the lecturer accepted the invitation to participate in the teaching of the new OS IV course. For clarification, the team members are divided into the following four categories: virtual classroom facilitator/manager (previously lecturer); learner; educational researcher; librarian.

The role of librarian becomes particularly important in the context of resource-based learning through the medium of the Internet. The World Wide Web (WWW) as a resource base in education has to be used with awareness of the following:

- It is easy to waste vast amounts of time while wandering aimlessly through this unstructured, multidimensional environment.
- Information tends to be updated, improved, rearranged, and moved frequently (Rakes, 1996).
- In collaboration with lecturers, librarians can participate in the evaluation of WWW resources, as well as in teaching students how to evaluate sources for their appropriateness, before they are used.

Implications for the Curriculum

The National Qualifications Framework

In the process of educational transformation, a National Qualifications Framework (NQF) was recently established in South Africa. One of the principles on which the NQF is based, is portability, which will enable learners to transfer credit across different modes of study and qualifications within the national framework: “The Framework will prevent learners from being locked into one learning compartment or another, as happened in the fragmented system.” (Human Sciences Research Council, 1995 p. 6).

The NQF defines a “unit standard” as the smallest unit that can be meaningfully assessed, previously known as a “subject” within a qualification. The curriculum development process of Operating Systems IV is done according to the necessary requirements, so that it can be registered as a unit standard with the NQF.

Performance Outcomes of OS IV

The value of the development of the OS IV virtual classroom lies in the fact that it contains a model that can be used by other teachers who wish to experiment with resource-based, open learning. In this regard, the unit contains: performance outcomes related to study skills (amongst others, information literacy); performance outcomes related to computer literacy, and performance outcomes related to Internet literacy. These outcomes can all be adapted and used by other lecturers. Lastly, performance outcomes related to the specific subject area (e.g. OS IV) will differ for every subject.

Conclusion

The implications of the new structure of OS IV are:
- a more flexible time schedule, to accommodate senior students;
- increased access to resources;
- opportunities for better communication and collaboration;
- a richer and more challenging role for the lecturer of the course; and
- a more flexible curriculum that fits in with NQF requirements and standards.

The course in its new form should therefore make a constructive contribution to higher education transformation in South Africa.

This paper describes the Texas Southern University/University of Dar es Salaam (Tanzania) Fulbright-Hayes Group Project that culminated in the summer of 1997 with a five-week in-county study tour. A team of 12 educators from Texas Southern University and Houston area schools studied the history and culture of Tanzania with a focus on education and the social service system of the country. The Fulbright group visited schools, social service agencies, teacher training colleges, the Open University of Tanzania and many other places of interest in Tanzania and Zanzibar. Moreover, the team interacted with scores of educators and other Tanzanians.

A major intent of the Tanzania based explorations and study was to create an authentic framework from which educators would design resources for use in US classrooms. Project planners recognized that a field experience in Tanzania would both update and invigorate instruction on Africa. Further, teachers are more likely to use resources frequently and to promote their use among colleagues when they are confident that the information is both accurate and current.

The Fulbright Project focus on authenticity parallels this emphasis in educator preparation programs in Texas. A major indicator of authenticity is the field-based, real-world orientation of the new educator preparation programs. Creating teacher preparation programs that more accurately mirror the tasks of teaching will ensure the development of more effective first-year teachers.

In preparation for the study tour, participants were engaged in several weeks of inservice that focused on basic protocol, beginning language instruction in Swahili, and the history and culture of Tanzania. Project Director, Dr. Gregory Maddox, a professor of History at Texas Southern University, conducted the major pre-country inservice. Dr. Zuberi Mwamba, a Tanzanian and a professor in Public Affairs at Texas Southern University, was a Project consultant, as well as a participant. Another consultant to the Project was Tanzanian historian Dr. A. B. Itandala, a former Fulbright Scholar at Wartburg College in Iowa. Moreover, Internet resources were utilized to gain the most up-to-date information. During the pre-country preparation, Fulbright participants had an opportunity to choose the focus of their research in Tanzania. A broad range of study areas was selected since the makeup of the team included educators from the public schools as well as the university.

**Goals of the Project**

**Broaden the Multicultural Component**

The first goal of the project was to broaden the multicultural area studies portion of the academic foundation courses at Texas Southern University. These courses are comprised of a designated sixty hours of baseline courses in the College of Arts and Sciences. Integrating the content into courses that all students take is a way to expand students' knowledge base about the peoples of Africa and expand their cultural world.

A related intent is to increase student interest in international careers by dispelling some of the misconceptions about the peoples of Africa. By building the information into the content of required university courses, the faculty can pique students' interest in international study. Texas Southern University Fulbright participants represented the faculties of art, education, history, public affairs, political science, sociology and social work. Their preliminary curriculum integration efforts are already enriching the courses they teach.

Still another intent is to improve the quality of cross-cultural communication among students at Texas Southern University. The enrollment includes students from most states and more than 60 countries around the world. Sometimes most US students have not had sufficient international travel opportunities to hone these essential cross-cultural skills. Potentially, the infusion of African content will stimulate new dialogue between US students and those from the international community, resulting in enhanced communication among diverse cultural groups of the US as well.
Strengthen the Cross-Cultural

The second goal of the project was to strengthen the cross-cultural strand in the teacher preparation program. At the undergraduate level a new multicultural course is based on three strands—exceptionality, English language learners, and the relationship of culture and learning. Each of these components will extend prospective teachers’ understanding of learners and what variables enhance and inhibit student success. The exceptionality strand will emphasize learning styles, the principle of giftedness, and the assessment of those gifts through multiple-intelligence inventories. The English language learners strand is comprised of research-based teaching strategies that support the success of students whose first language is other than English. The culture and learning strand will be enhanced by the integration of content that identifies the cultural variables that support learning. The study data on urban schools in Dar es Salaam, a large sprawling metropolitan area, will be useful for comparatively discussing issues associated with urban schools.

One area of concern in urban schools is interaction among ethnic and cultural groups, both among teachers and students. Prospective teachers are expected to support the success of students from all learner groups without regard to ethnicity, gender and income. The teacher preparation program designers at TSU are committed to reducing bias and building intercultural competence among prospective teachers. These are essential for teachers who will be equipped to support success among a broad cross section of urban learners.

Strengthen the Multicultural Education Component

The third goal of the project was to strengthen the multicultural education component of the curriculum in Houston area schools. One elementary teacher, one middle-school teacher and two high school teachers participated in the project. One early effort resulted in the collection of 400 books that were shipped to a partner school in Dar es Salaam. A middle school teacher who was among the Fulbright scholars initiated this project. The involvement of Houston area teachers has created a cadre of resource persons for the surrounding school districts. This hands-on, in-country study opportunity was created to ensure that teaching resources would be current and would have an authentic perspective.

Dissemination of the Information

These resources are being disseminated in several ways. Some resources are being shared as PowerPoint presentations in conference settings, community meetings, school-based inservice programs and university classes. Other resources are being shared through the World Wide Web, as well as email and listservs. Links were established between Houston and Tanzanian educators that will lead to joint publications, conference presentations, and research, in addition to other kinds of partnerships between students from various places.

A 1998 special issue of the *TSU Research Journal* will feature papers developed by participants of the TSU Fulbright Project and selected faculty from the University of Dar es Salaam in Tanzania. Some of the invited papers will emphasize the history and culture of Tanzania, the framework for the world-class lectures at the University of Dar es Salaam, during the opening days of the Fulbright study tour. These lectures gave insightful interpretation to information that we had read about Tanzania.

Efforts are also under way to establish a pen pal project that involves students in school-to-school interaction and club-to-club interaction in K-12 settings as well as the university level. Some elementary school projects are already up and running. On the university level, teacher education students at the Forodhani Secondary School are beginning a communication project with teacher preparation students in special education at Texas Southern University. Currently in Tanzania, individual student access to email is limited. Potentially, this project will broaden to include more teacher preparation students at TSU in other disciplines during subsequent semesters.

Other efforts to disseminate information include the development of educational resources on the web. On the Texas Southern University College of Education web site ([http://www.coe.tsu.edu/faculty/ligons](http://www.coe.tsu.edu/faculty/ligons)), there are travel logs, recent in-country photographs, the trip itinerary, lessons and workshops. These resources provide an accurate and detailed description to students, teachers, university faculty, and government officials associated with the Fulbright Program. The portability and instant access of these resources will ensure their usefulness to educators at all levels. These teacher-made resources on the TSU web site provide links to related web sites. These links will be updated and enlarged as collaborative efforts produce additional lessons, thematic units, contemporary photographs and other resources. The main goal will be to provide authentic, virtual experiences to students of all ages as they are preparing to interact in a global community and interact with people of various ethnic groups. These resources are intended to shape the development of more accurate perceptions about culturally different others and build mutual appreciation will develop in students of all ages.

Dissemination of information will also be accomplished as participants conduct workshops and make presentations in university settings, local schools, and Houston area communities. Recently, the authors shared the above resources with upper elementary students at the Texas Southern University/Houston Independent School District (TSU/HISD) Lab School (See Figure 1.). The receptiveness and curiosity of the students and faculty...
validated the need for such interactions. This information was also shared at the fall 1997 conference "Research and the Production of Knowledge in Africa" which was sponsored jointly by the Center for the Study of Culture at Rice University and the Mickey Leland Center on World Hunger and Peace Studies at Texas Southern University.

Community efforts include sessions for Transformations, a program at Wheeler Ave. Baptist Church. Transformations is a mentorship program for pre-teenage girls that provides a variety of enrichment experiences while dealing with some of the contemporary issues of adolescence. The pairing of each girl with an adult mentor is a special feature of the yearlong program. Fulbright participants created hands-on experiences and provided information to expand students' views of the people of Tanzania and their customs.

Conclusion
The five-week study tour was a rewarding professional development experience for all of the Fulbright participants. It was 'real world' since the experiences occurred in Tanzania. As participants teach the content they can present it in more authentic ways as a result of their study tour. Moreover, their positive experiences will influence use of the resources among colleagues at all levels of education.

An important role in the Open Information Society (as knowledge based society) will belong to general education, professional education, and training. A knowledge-based economy demands greater openness and creativity in schools and universities. Citizens will need to acquire new skills and adaptability through life-long training. An open approach to education that combines local and national cultures and promotes mutual understanding between all people is required.

The development of the Internet and Global Information Infrastructure (GII) development in the world changes the main paradigms in education and research. This development requires new skills if humankind is to survive the Information Revolution and start building the Information Society (also defined as the Post-technological Society). The main driving forces are shifting from a focus on technologies that are rapidly changing, to a focus on knowledge, together with learning acquisition.

Education should respond to the global challenges of forming the Information Society by providing the necessary foundation for people to be successful living in this new knowledge based formation. This includes:

- forming base knowledge and the motivation for a constant improvement of knowledge and skills,
- setting up of life-long learning goals, and
- establishing free access for learning and training materials.

This paper describes two years experience and the results of the development and implementation of a new instructional methodology for teaching Internet/Intranet Networking and Information Technologies, this in conditions of emerging new technologies and rapidly developing Internet infrastructure in the Ukraine. The development and implementation of a new educational approach that combines cooperative and contributive learning models has allowed the organization educational processes in the real conditions of restructuring economy with limited state support for the implementation of new technologies.

Principles of Teaching in Networked Information Environment

The proposed instructional methodology is very similar to the Project Based Learning (PBL) in that it signifies the advent of the new educational paradigm in a knowledge based Information Society. In this new environment, students and teacher become collectors and produces of knowledge/information, contrary to their previous respective roles of being just receivers and the source of information in the old models of education prevalent in industrial and technological societies. The main issues of such new approaches belongs to the search, transfer, and acquisition of information and knowledge in an information and knowledge rich environment formed by GII and Internet. These are not limited by classroom and national boundaries. Students in such environment are capable not only of consuming information and knowledge but also of introducing new information and even skills retrieved from the Net.

The main principles of teaching modern information technologies in technical, technological, and non-technical education can be formulated in the following ways:

Learning from the Internet – Contributing to the Internet. The new paradigm of education in a modern networked information environment should be incorporated into the development of instructional methodology. Cooperative Learning Model + Students’ Initiative. Using Internet/Intranet technologies teachers and learners can mutually benefit from the implementation and mastering of new technologies. A key role in exploring this principle belongs to educational projects and relies on a cooperative model of course management that effectively uses students’ initiative in mastering new technologies.

Contributive Learning Model. With students’ wide use of computers and multimedia technologies and the rapid technology changes, teachers can not always have a strong base in practical technological experience in every piece of hardware and software. In these circumstances they should play the role of mentors and/or managers of the educational process or curricula. Teacher can propose
some idea of contributive learning project where students or student groups work on projects that will really be implemented in the building of the campus computer network, the development of information resources, or meeting some other societal technological need.

Integration of Traditional and Distance Learning.
The new networking environment provided by the Internet/Intranet eliminates differences between traditional and distance learning, while stressing interactive on-line (IRC, conferencing) and off-line (e-mail, mailing lists) communication among teachers and students.

Concept of “Active Position”. Complete implementation and full benefits from using Internet and new information technologies in education can be achieved only by using this principle, one that is very close to the idea of contributitional learning. It is not enough to give students and teachers Internet access. To use Internet, effectively faculties should start development of their own Internet resources and creation of their own Internet presentations.

Piloting New Instructional Methodology
A pilot project on the development of an educational program and instructional methodology for teaching computer networking and Internet information technologies has been started at the Computer Aided Design (CAD) Department at Kiev Polytechnic Institute. Two groups of 50 fifth year engineer students began work on their advanced degrees in September 1995 and 1996. Seventeen students of the first group successfully defended their Master theses in June 1997. All students were involved in the development of the technical and information base for a complete educational course.

The pilot educational program includes these main specialized courses on computer networks and networking information technologies and services:
- Computer Networks Basics, LAN, and WAN Technologies
- Internetworking and Network Management
- Internet/Intranet Information Technologies and Services
- Advanced Networking Information Technologies (Security, Java, VRML, Internet Publishing, etc.)
- Internet Business Applications and Information Technologies Business Process Re-Engineering
- Information Society and Advanced Communication Technologies: Social and Cultural Impact

Due to the rapid development of modern networking technologies more than 40% of the course content had to be changed during the second year as well as significant changes in the themes of educational projects. Information about new technologies and standards were directly transferred to students by lectures, classes, and via the departmental server.

All courses are supplied by instructional and computer presentation materials that are distributed among students in paper and/or electronic form. Some materials are available on an educational WWW server (http://cad.ntu-kpi.kiev.ua/). This allowed for the creation of an initial base of instructional and educational materials as well as to adoption and testing of Russian/Ukrainian terminology in real lecturing and educational project development. Some practical experience is acquired by students during the design of real educational network projects for real academic and educational institutions. This includes development of necessary information services for the operational needs of the organization and/or users’ group. Also practical installation of services and pilot information resource development is performed in a special educational laboratory.

Two main components of complex educational projects are: (1) network infrastructure design and information server structure and (2) content development.

Projects are developed by groups of three or four students and include all necessary components of a real networking project design for campus or a company’s network. This includes organisation for the optimal cooperative work of the project group.

During the design period all projects have their homepages on the educational WWW server at CAD Department in special working directories (see reference page at http://cad.ntu-kpi.kiev.ua/academic/projects/webprj96.html). After completion and final editing by webmasters the Web pages or templates are moved to their final location on departmental WWW Server or to other designated servers. Original works are left in their working directories for future use as templates by other students.

The contributive part of these educational projects resulted in development of the information content of an experimental server “U’Pavilion - WWW Server on Historical and Cultural Heritage of Ukraine” (http://www.park.kiev.ua/).

Summary
Supporting the successful realisation of the new educational program complete with new instructional methodology is the idea of cooperative and contributive learning enforced by both students’ enthusiasm and the wide interest of professional and business circles in Ukraine.

Replication of the described experience is very simple to implement but demands an experienced and devoted teacher corps capable of “playing coach”. Some areas for fruitful international cooperation should be found in the development of distance education on the base of these results and existing technologies. These would provide the basis for better utilisation of developed educational courses and instructional methodologies on a wide variety of subjects for Universities.

INFORMATION TECHNOLOGY IN FRANCE:
NEW TRENDS AND PERSPECTIVES

Georges-Louis Baron
Institut National de
Recherche Pédagogique

Eric Bruillard
Institut Universitaire de Formation
des Maîtres de Créteil

In France, as in many industrialized countries, no one can ignore that a new technological wave is coming and that it moves relatively fast. The market of personal multimedia computers is soaring and more and more software can be bought in department stores. Only a minority of homes have an access to the Internet so far. But the topic is quite popular and newspapers publish a lot of articles about it. Some of them consider it as essentially opposed to the classical culture (because it promotes zapping) and hence express doubts about the possibilities it might have any kind of virtue in an educational context. But, on the whole, authors are generally favorable, and sometimes very optimistic indeed.

Once again, there is a public debate with some ambiguity. For example, an amalgam can be noticed between then Internet as a communication system (allowing e-mail forums, etc.) and multimedia software. This is not surprising since this new rise of information technology offers learners new resources to solve problems in quasi-autonomy, whether they are on-line or off-line.

In schools, the new wave is also flowing: multimedia software become available; the number of connected schools increases, giving rise to interesting innovations: research over the Web shows a blossoming of school-based WEB sites, often supported by local and regional academic authorities.

But Internet and multimedia software come in after other technologies (television in the fifties and the sixties, computers in the seventies and the eighties). For these technologies, many innovative, often brilliant enterprises led by teachers with strong commitments have been reported. But most of them have not converted themselves into large scale everyday classroom practices.

The analysis of the French situation shows a great heterogeneity: between subject matters, between school levels and even between schools. Moreover, models of integration are not the same depending on the kind of usage: presentation of information, production of documents, software instruments for subject matters, educational technology (Baron & Bruillard, 1996, Baron, Bruillard, & Chaptal, 1997).

Concerning educational technology, the situation is similar to the one described by authors like Larry Cuban, with cycles of hopes and disenchantment (Cuban, 1993), suggesting that it’s wise to adopt a position of “cautious optimism”. Regarding software instruments, progressive stepwise integration can be recognized on the long term, notably in scientific and technological subjects (Baron & Bruillard, 1994).

In fact, if many people seem convinced of the necessity of using IT in schools and if integration is a key word for all levels and all fields, there is no real consensus about what this really means and about what is really expected from teachers. In colleges of education (IUFM), things are changing slowly, too. When beginning their professional training, most students are willing to learn about IT as a set of professional tools. But only a few of them really can (Baron & Bruillard, 1995).

Overall, integration is a slow process whose end cannot be forecast. There are critical moments when innovations either move forward in development or are abandoned, depending on the support they receive from different interest groups.

Particularly in France, the national level traditionally plays an important part. All the pedagogical issues are under its control; the curriculum is nationally defined and teachers are civil servants appointed by the State. The country is still rather centralized, even if important changes have occurred in the last dozen years, all focusing on local initiative: since 1989, schools must prepare a pedagogical project and receive funds from the local authorities (notably for buying hardware).

A New Impulsion

Politicians have been aware for several years that Multimedia and network are something important, not only for industry and business. Several official reports have been published since 1994; every one of them has considered issues regarding education and advocated measures to help developing information and communication in

International — 529
In the fall of 1997, the minister in charge of education and research announced a global plan for the next three years. This plan, with an announced budget of several billions US dollars, aims at several objectives.

**Promoting a New Global Educational Approach**

In this new plan, the computer is presented as allowing students to have a more active approach to learning; the diversity of media is expected to stimulate their creativity and to promote personal work. What is looked for is a real integration in educational actions. This is recognized as a difficult task relying both on each teacher’s ability to innovate and on the adaptation of software to new pedagogical aims.

**Creating a New Network**

The creation of a new “decentralized network” (called EducNet) has been announced, based on a partnership between teachers, regional authorities, and the national state. New ideas appear, as the recognition of a coordinator in every school, in charge of helping and promoting the diffusion of new practice. Partnership between schools and enterprises (notably in the telecommunication field) is looked for, in order to limit the fees of access to the Internet (in France, local telephone calls are not free). Last but not least, an emergency plan has been announced for the IUFM, providing for the creation of postdoctoral grants for young Ph. D. students.

**Producing and Spreading Pedagogical Contents**

A new policy of support to the industry for multimedia has been announced. The utmost importance of teacher initiative is recognized and support is to be given to those who would want to create their own enterprise. In the same time, the department of education is considering how IT could be introduced in the curricula.

Concretely, three priorities have been defined for the next three years:

- Each student, from pre-elementary school to university should have the opportunity to perform learning activities with information technology (manipulation and drawing in kindergarten, electronic mail for grade 2, Web access for grade 4, network activities for grade 6).
- Each teacher, each class, each university student should have an Internet address by the year 2000.
- All the information needed by teachers should be accessible by a digitized network.

In the field of technologies in education, government support is always welcome and this new public policy will certainly help innovators going forward to invent new ways for improving learning in a classroom setting. The problem, however, is to know what are the new trends and perspectives.

**New Trends**

In the field of IT, the last national plan was called “informatics for all”. Launched in 1985 by the prime minister, it aimed at promoting IT in every school, by equipping them with “nano-networks”, based on home computers made by the national enterprise THOMPSON. Workshops were to be open to the public, helping disseminating knowledge about computer tools. It also had a telecommunication component, since it foresaw the development of electronic communications, following the national standard of the MINITEL (a kind of Network computer very popular in French homes).

This ambitious plan has given rise to many debates. It has certainly lacked protracted political support and has known severe difficulties after a first initial enthusiasm. Its initial objectives have certainly not all be reached. It is rather common in France to consider it as a failure (but this is often the fate of any previous politically driven operation), but research has shown that it has had a profound influence (Baron & Bruillard, 1996).

Of course, it is impossible to compare it with the newly announced plan. However, it is possible to compare initial intentions and to try reanticipating developments. The current plan, which explains the rationale both in pedagogical and political terms, has several original aspects.

**New Partnerships**

First, regarding hardware, their quick obsolescence is taken into consideration; hence, schools are not to purchase computers, but to hire them. Creating cooperatively new pedagogic services is at the core of the plan. Explicit emphasis is put on partnership (between schools, the different academic authorities, and enterprises), the federation of energies is very explicitly wished.

Secondly, the plan insists on the development of new resources for learning and recognizes a prominent role of teachers, notably in the field of software development. This rather new idea contrasts with the previous general opinion. It also explicitly provides for the appointment of special “resource persons” in the schools, whose task will be to disseminate knowledge about good educational uses of technologies.

**One Key Issue, Teacher Education and Professional Development**

The plan pays great attention to teacher training. This point is not wholly new, since France is certainly one of the countries where the investments in teacher training (mostly inservice) have been very important. But preservice training is now clearly identified as a crucial issue, which is coherent with another reform aiming at relating more closely inservice training to preservice education and giving more responsibilities to IUFM. More generally, the education of the different officers in charge...
of education is considered a priority, which certainly corresponds to real needs.

**Perspectives**

Once again, something new is happening. We are in a foundation-building period, with an initial accumulation of expertise (much is expected of teachers' individual initiatives), but zones of uncertainty. IT is seen as a transversal tool and the general recommendations about what teachers have to do in the subject matter they teach are not really precise. There is no requirement about the nature of classroom activities.

Several problems have to be solved. The success of the plan depends on changes in the way teachers teach: for example, collective work is advocated. But creating a new professional culture is not an easy task. Two issues at last remain problematic: the evolution of classical subject matter in schools and changes in assessment. How, for example, can new technologies be integrated if students do not have the opportunity to use them during examinations? It is plausible that much time will pass before new practices emerge.

However, as we have seen, the emphasis of the new plan is on communication. The Internet, because it allows direct communication between peers, might prove a good support to disseminate and capitalize on innovative practices led in school with IT, what many call success stories: The possibility to transfer experiments to other context nevertheless remains an issue.

Teacher education is obviously very important. But which kind of education? Nowadays, many preservice teachers have a personal familiarity with word processing and, more generally, with software for producing documents, even if their approach is more than often rather naive. With time, their technical competencies can be improved, without dramatic changes in the organization of studies at the IUFM. But technical competencies are not enough and it is quite certain that having a personal acquaintance with software is insufficient to guarantee professional use.

The appointment of young postdoctoral students in IUFM is in this respect an interesting idea, especially if they can help trainees understand the role now played by IT in their subject matters. However, as has been remarked many times, a key issue is that trainees have hands-on experience with IT during their practicum, and, therefore, that their mentors be familiar with it.

One of the reasons why using IT in the classroom is not an easy task, specially for young teachers, is that there are no validated models of teaching with technologies compatible with the current constructivist views of learning. This makes difficult identifying the necessary competencies that should be developed among new teachers. An important issue therefore, tied to educational technology, is to elaborate, implement and validate such models.

This poses of course, once again the problem of producing software. Many earlier works have addressed the issue of authoring languages, allowing ordinary teachers to design courseware. Now, conditions have changed. The design of multimedia software is, on the one hand, a growing industry, where developments are done by teams and where markets have an international dimension (with, however, serious problems of adaptation to different cultures). On the other hand, it would be suitable to have easy-to-operate software, allowing teachers to design disposable micro environments, adapted to their particular needs at a given moment.

Thus, many questions are open. A governmental plan gives an important impulse. Many initiatives will take place; many persons will be involved; projects will be planned; and schools will be provided with hardware and Internet access. But it is just a beginning, a new start. New problems are certainly to be solved. Research (notably comparative research) has ideas to provide and a part to play.

E-mail: bruillar@cit2.fr
The meeting of multimedia and telecommunications promises an explosion of new computer-based applications for education. Only a few years ago it was assumed that packet-switched networks, such as the Internet, could not be used to transmit real-time audio and video because of the delays inherent in shared networks. However, improved compression techniques and the advent of multicast in the 1990s have changed this. (Multicast is an efficient way of routing traffic over networks that makes multi-way conferences possible at reasonable cost and without causing undue network congestion. See Macedonia & Brutzman, 1994) It is now possible to take part in real-time, multiparty videoconferences, from a desktop computer. Educational institutions at all levels are connecting to computer networks and the potential to enrich student learning is huge. Yet, whilst university research staff hold “live” project meetings with partners all over the world, or watch lectures transmitted from conferences they cannot attend, teaching staff are only beginning to explore the possibilities of this new technology.

Barriers to the acceptance and use of computer-based technology in schools and colleges are well documented. There may well be resistance to change amongst both management and teachers but underlying this are a number of other factors. Williams (1994) describes vividly the pressures on teachers and institutions that limit access to training. Bates (1995), however, suggests that the greatest obstacle is the unfamiliarity of the technology, which erodes teachers’ confidence. He too points to inadequate training as the key underlying cause. He states that the problem is not simply ignorance about how to use a piece of technology but, more importantly, the “lack of an appropriate conceptual framework to guide the use.” This problem is particularly acute in the Higher Education sector, where few of those who teach have a foundation in educational theory or instructional design. He warns that, without such a framework, people will fall back on the methods that were used to teach them – a strategy wholly inadequate where social and technological changes are rapid.

To make effective use of information technology, teachers must learn more than just how to make the system function; they need to use it to communicate with their students and to deliver appropriate and effective courses over a period of time. Whatever conflicting theories exist about teacher training, it is generally accepted that those who deliver it will be able to draw upon extensive practical experience within a rigorous theoretical framework. It would therefore seem reasonable that teachers should be introduced to new technology by experts from their own domain, rather than by experts from the technology domain who might be seen to have different objectives and not to understand what teachers and students need. At present, however, not enough teachers have the relevant technical knowledge and even fewer know how to combine it with appropriate practical experience. In the case of very new technologies the shortage is even more acute and the content of a training programme may be hard to determine.

The work presented arises from research into the design of real-time multimedia systems for education. Approaches derived from the participatory design movement (see next section) have enabled teachers to play an important part in developing a language tutoring system. The paper discusses the techniques used and considers the implications of the work for staff development and training. The aim was to make the technology acceptable to teachers and to empower them to shape it to their needs.

The Technology and the Teaching

A joint project was established between University College London(UCL) and the University of Exeter, forming a partnership between computer scientists and teachers to investigate the feasibility and implications of teaching foreign languages over computer networks (See Hughes & Sasse, 1997). The project, Remote Language Teaching over SuperJanet (ReLaTe), is a real-time system for small-group distance language learning, incorporating audio, video and a shared workspace. It uses ordinary
computer workstations and runs over the multicast backbone of the Internet. Separate tools for each medium (audio, video, and shared workspace) are combined into a single window (see Figure 1). This interface was designed for small group tutoring but it could be configured for larger groups.

On the left is the video area, where four images can be displayed with a choice of size. Participants select the image to be displayed in the larger rectangle by clicking on the name bar above it. The shared whiteboard on the right allows displayed text and graphics to be seen and annotated by all, and all may write or draw on it simultaneously. Users can replace this with a shared text editor by pressing a button. The audio controls allow users to adjust incoming and outgoing volume.

The prototype system has been used in 10 and 22-week field trials, with language learners at levels from beginner to advanced. Five courses were run, in three different languages. In all of them, the tutor and students were geographically dispersed, sitting at individual computers at various locations in London and Exeter, connected via the UK academic network. Five tutors and twelve students participated.

Why use a PD Approach?

Participatory design (PD) originated in Scandinavia as part of the workplace democracy movement (Clement & Van den Besselaar, 1993) but the term now covers a continuum of user-centred design approaches. Carmel, Whittaker, and George (1993) give an indication of the range. Participatory design was used here for a number of reasons. First, Grudin (1991) has stated that a participatory approach suites novel, interactive applications. Secondly, participatory methods have traditionally been used for custom-built systems and this is exactly what was required in the instance. There was no existing blueprint and the application being designed was very specific. A PD approach also suited the work situation because teaching and learning can not be described adequately in terms of data flow and task analysis, favourite designers’ tools.

Another factor was the participatory design view that changes in work practice should run alongside the development of computer systems. This fitted the philosophy of the project. PD also tackles cross-domain communication problems, certainly relevant in this project, where computer scientists and language teachers would be working together. The PD view is that development is cooperative, learning a two-way process, rather than one where “expert” technologists transfer information to “inexpert” users. Finally, PD evolved to combat the idea that technology was a threat to the worker, instead regarding its introduction as a way to improve the quality of people’s working lives.

PD Principles and Practices

Participatory design does not follow a rigid formula. Instead, researchers have developed a repertoire of tools and techniques to promote equal participation of users in design. Whatever techniques are used, a few broad principles underpin most work. Apart from those mentioned above, practitioners believe that concrete experience is needed to inform abstractions (so developers must gain workplace experience and users experience with the proposed system) and that requirements will not be understood fully until users have worked with a system for an extended period.

Muller, Wilman, and White (1993) present a taxonomy of PD techniques. Wall and Mosher (1994) and Kensing and Munk-Madsen (1993) also provide reviews of methods. Those most commonly used are unstructured interviews, formal and informal group discussions, future workshops, graphical techniques to aid both visualisation of the future system and representation of the workplace, and prototyping. Prototyping is a particularly important tool and includes everything from storyboards, through HyperCard-based simulations to working systems. Often low-tech artifacts, such as plastic tokens or post-it notes (Muller 1991) are used, in order to diminish the intimidating effects of unfamiliar technology. Observation of the workplace and of prototype systems in use is essential. Extensive records are kept, including audio and videotapes, notebooks and illustrations. These may form the basis of further discussion and in certain cases may be reused in future projects.

Methods Used in the Project

Central to this project was the creation of a fully functional prototype, and its use in field trials. The working demonstrator system described above was constructed and used in trials over a period of nearly two years. Because there are separate tools for audio, video, and shared workspace and these are configurable, it is possible to construct conferencing systems to support a range of different applications. (In this case the tools used were vic [Jacobson, 1994], rat [Hardman et al 1995], wb [Jacobson 1993] and nte [Handley 1996]. The references
are to technical papers.) In effect, the team had access to an immensely flexible rapid prototyping tool. Not only the appearance of the interface can be configured, but also modes of communication (An example, in our configuration, is the choice of full duplex audio rather than the default push-to-talk mode. See Watson and Sasse (1996) UCL) New elements can also be attached as required. The process has been cyclical, with the activities described below feeding into development of the system, which in turn led to further associated activity.

Observation was a key part of the process. Teachers were observed both using the system and in the classroom, by developers and education experts. Results were recorded digitally and on paper and formed the basis for discussion and written reports. At key times, questionnaires and rating scales were administered, and unstructured interviews were conducted with students, tutors and other language teachers outside the project. A variety of group activities were constructed, using focus groups to draw out participants’ opinions and experiences, and workshops to encourage thinking about future developments. The composition of groups was varied (with teachers and students sometimes together and sometimes apart). Digital recordings of lessons were made using a conference recorder developed at UCL. This has proved to be a non-intrusive way of obtaining a full record and has produced a huge amount of data, the use of which is discussed in the next section. Alongside this, written and spoken comments from teachers and students have been analysed with a view to determining which terminology and concepts cause difficulty and to evolving a shared vocabulary for discussing certain aspects of the system, particularly audio and video quality.

Results

As reported by Watson and Sasse (1996) and Hughes and Sasse (1997), the efforts to involve users in design have resulted in a system that is fun and easy to use. The highly interactive tutorials were agreed to be rewarding, intense and involving. Language teacher assessors particularly applauded the fact that reading, writing, listening, and speaking skills were developed together. Although the system was designed for teaching foreign languages, the lessons for teacher development are probably applicable to other subjects.

Uncertainties of Networks

Teachers have gained a greater understanding about the nature of networked systems and, in particular, appreciate the uncertainties involved and have learned to plan for them. Conditions in shared networks can fluctuate rapidly. Congestion may cause sudden changes in video or audio quality that can be alarming but are usually transitory. Once teachers experience this a few times, they learn to plan for a change in activity in the same way that they are flexible in a classroom. Training can prepare them for this.

Another disconcerting factor is that in such systems some things can not be known for certain. Failure to reply to a question, for example, can be the result of local equipment failure, software failure, a problem with a link in the network or simply the fact that someone has taken off a headset or muted a microphone. Teachers gradually learned how to eliminate the most obvious causes but the problems this can cause should still not be underestimated.

New Ways to Communicate

Superficially, a lesson over the ReLrTe system is similar to one in a classroom, but computer-mediated communication, even with the aid of audio and video, differs from face-to-face communication. Teachers found it harder to sense the group atmosphere or to detect when the class needed a change of activity. They did, however, feel they could still sense an individual student’s personality, and they talked of their students in the same ways as do face-to-face teachers. During lessons, more overt signaling was needed. Teachers could not use eye contact to indicate which student was to speak and, similarly, students could not convey by body language that they would rather not be asked a particular question. Remembering that others could see only what was within the camera’s field of vision also had to be learned; words were needed to explain actions that would be obvious in a face-to-face situation. The interplay between communications channels (the whiteboard, audio and video) was also slightly different from that between the face-to-face equivalents.

Managing a New Environment

Teachers developed experience and greater understanding about managing this unfamiliar working environment. They were constrained physically by the equipment and cut off from external stimulus by headsets. This made it harder to retain a sense of time and to pace a lesson. The trials also raised questions about the boundary between technician and teacher. To have full control over resources, the tutor must understand a computer file system and the formats in which material can be stored. Finally, the physical environment must be managed, so that there is sufficient space for equipment and the lighting enables people to see one another but is not uncomfortably hot or bright.

Preparing Teaching Materials

It is easy to assume teachers know already how to choose material and devise activities around it. Here, as elsewhere, some lessons had to be unlearned. For example, incorrect assumptions were sometimes made about translating from classroom to system domain. Although the shared workspace usually performed the function of a photocopied worksheet, there were times when the camera was a better means of showing things to students. Similarly, the camera was not always an adequate substitute for
holding an object up for the class to see. Material may have to be altered in order to display it effectively on a computer screen and if teachers are not to be over-reliant on technical support they must learn to use machines, such as a scanner.

**Adding New Elements**

As in most courses, a varied mode of delivery was needed. Teachers began to explore ways of integrating this real-time communication with e-mail and the World Wide Web. Having to learn more new applications was a burden, however, and this was a good example of the extra cognitive load imposed on both tutors and students by the use of multiple software applications.

**Training Materials**

Because these lessons were observed and discussed so fully there is now a large store of materials, including recordings of lessons, images of whiteboard and text editor screens, audio recordings, observers' notes and reports. These have already proved an effective stimulus to discussion but they could also be used in training. It is hard to give teachers the time to watch their colleagues at work. Recordings offer them the chance to observe lessons in their own time. It is also possible to interact with the recordings, adding commentary or questions, and to transmit them to remote locations. Trainees need not all be on one site.

**Terminology and Concepts**

There was an evident gulf between teachers and developers here. It also proved to be important. Language is so closely linked with thought that one cannot assume teachers do not need to know any technical terms. The teachers found it difficult to discuss aspects of audio and video quality and to understand the factors that affected these. This made it harder for them to explain what changes were needed and had implications for their use of the system, especially understanding its limitations. It also made some functionality inaccessible to them. The interface was specifically designed to hide complexity but some of the hidden, more advanced features are useful. Unfortunately, they are labeled in technical terms. It is in this area that the meeting between designers and users is so crucial; the implications for interface design are as important as those for training.

**Conclusions**

As suggested in the previous paragraph, not all issues should be tackled by training the teachers; system and interface design must minimise usability problems too. Some of the findings from this study have fed into work on redesigning the interfaces to a number of conferencing tools. The main idea behind this re-design is that users bring to their work with a computer system a model based on general knowledge and knowledge of the task they are trying to perform. This model is not always appropriate; misconceptions embedded in it can lead to problems in using the software. Interface designers can facilitate the acquisition of a more appropriate user's model by choosing labels compatible with the user's general knowledge and the tasks to be performed. Clark and Sasse (1997) provide an example of successful application of this theory of conceptual design to an Internet tool.

The main message, however, is that training is needed if teaching and learning with such systems are to be optimised. Such training must extend beyond operating the controls and it is likely that a good programme would cover all the areas outlined above, as well as a number of discipline-specific topics. Some areas can be dealt with quickly but many require discussion and reflection, which takes time.

Not surprisingly, time is also needed to develop expertise in teaching with such systems. However, this should not be seen as discouraging. Reasonable performance can be achieved quickly, provided the system is designed appropriately. As was found with the use of a "minimal manual" by Anderson et al (1993), it is not necessary or advisable to introduce every possible function at the start. A more gradual approach is particularly well suited to in-service training. In higher education, even new recruits must learn while in service, whilst in every sector established staff need training to respond to change. Also encouraging is the fact that small-scale, discipline-specific trials can generate material that is more widely useful in staff development.

Teachers are highly skilled experts. They can be introduced to new technology without being made to feel de-skilled or lacking in competence. The teachers in this project have shown that they can participate in system design and shape the technology to suit their needs. In follow-up work, it is also the teachers and students who will select the materials to train others. However, an unexpected benefit is that members of the development team have gained greater understanding of the teachers' domain. Perhaps this will enable them, too, to train teachers effectively?

Finally, the focus of this paper has been on the tutors' learning. At times, the literature (such as Williams (1994)) suggests there is a conflict between evaluating educational software as a tool for the teacher and evaluating it as a tool for the learner. In the type of real-time system under discussion, however, the participants interact throughout. The approach in this project has been to involve students fully and the expectation is that they too will benefit from further work in this area. Interestingly, they regarded the fact that their teachers were, like them, learning to use the technology as a positive and equalizing factor.
Acknowledgements

ReLaTe has been funded by British Telecom and the UK Joint Information Systems Committee (JISC). The authors also wish to acknowledge the following contributors to the work reported here:

At UCL: Vicky Hardman, Isidor Kouvelas, Anna Watson, Louise Clark, Colin Perkins, Kristian Hasler.

At Exeter: John Buckett, Mark Pack and Gary Stringer.

Special thanks are due to teachers and students from the Foreign Language Centre at the University of Exeter (Director Elizabeth Matthews) and the UCL Language Centre (Director Dolores Ditner) and to the expert assessors, Marie-Danielle Chamary, Marc-Georges Nowicki, and Dr. Carmo Ponte.

Towards a New Pedagogy for Information Technology: A Report on the IT and Motivation Project - 1995/97

Tim Denning
Keele University

The conference delegates settled comfortably in their seats as the speaker rose to begin his presentation. "How many of you can think of a piece of educational research that has changed the way that you teach?" he asked. Not one hand was raised....

IT and Motivation Conference, Coventry, England 1995

This paper documents some of the outcomes of an IT and Motivation study conducted in nine secondary schools (pupils aged 11 - 16) in England and draws on a more extensive report prepared by the author for the National Council for Educational Technology (NCET) in the United Kingdom who funded the project. (Denning, 1997). The project was established following a pilot study undertaken in collaboration with the City of Birmingham Education Committee during 1994/95 and explored staff and pupil perceptions of Information Technology (IT) and the particular characteristics of IT use that motivate learners.

A guiding principle throughout the project was a concern that the experience and understanding of established teachers should underpin and inform the work at every stage and that the outcomes should be of direct practical significance to classroom teachers and others who use IT to support teaching and learning.

This strong relationship with practical teaching and learning activities was made possible by the generous help and support of teachers and local education authority officers in West Sussex, Sheffield and Birmingham and runs as a thread through all the elements of the investigation.

Setting the Scene

It is clear that the nature of motivation is complex and the author would not wish to claim that he has done more than probe some small component of a much wider domain. For the purposes of the project I adopted a definition proposed in 1955.

'Motivation has to do with "how behaviour gets started, is energised, is sustained, is directed, is stopped."' (Marshall Jones, 1955)

This provided a gentle focus that was broad enough to accommodate the wide variety of contexts and activities encountered during the project. These ranged from the enthusiastic pupil, "You press a key and WOW it is up there (on screen) - it is like smoking - you get addicted!" to the adult learner, "The computer 'listened' without judging me in any shape or form.... I was the one in control."

A day conference of all the participating schools and non-school organisations was held in the summer of 1995 to launch the research. This provided an opportunity to set out themes and priorities and to give an initial impetus to the school and non-school institution based work. This was conducted during the academic year 1995 to 1996 and incorporated three concurrent elements or strands comprising questionnaires, school based action research and pupil interviews.

Survey Questionnaires

The first strand, which was also part of the earlier pilot study conducted in Birmingham England, was based on the already established attitudinal survey of pupils developed at the Centre For Successful Schools at Keele University in the UK (Johnson & Gough, 1996). This questionnaire was extended to include 15 extra items designed to gather information about the pattern of IT use experienced by pupils and their views of how this helped or hindered their work.

At the same time a staff survey questionnaire was used to gather information about current levels of IT use in the project schools and staff views on the impact that using IT can have on the process of teaching and learning.

Action Research in Schools and Other Training Organisations

The second strand provided a firm anchor in the real world of school and training. Staff from each of the organisations in the survey were provided with funding and...
professional support so that they could conduct an IT focused action research study of their own choosing.

**Interviewing the Pupils**

The third and final strand was provided by interviews with pupils in schools. These were conducted in many of the schools alongside the action research activities and provided a rich vein of material that has added perspective to the results of the survey work. The interviews were all conducted using a standardised set of questions to prompt discussion and the text of the notes taken during the interviews was agreed with the participants when each session concluded.

**Summary of Results - Survey Questionnaires**

The staff and pupil surveys were conducted in 9 schools in three English local authorities. Responses were analysed for 1313 pupils and 287 staff.

**Pupil Survey**

The results of the pupil survey can be considered under two broad themes: levels of IT access and use experienced in school and at home; and pupil perceptions of IT and its use in their lessons.

**IT Access and Use.** Pupils were asked to indicate how often they used a computer at school themselves or with a partner. This phrase was used in order to discriminate between individual use or use with a partner on the one hand and those occasions when computers might have been employed for demonstration or class level activities on the other.

An encouraging 55% recorded use of at least once a week or more with 7.5% indicating that they used computers every day. By contrast, it is disturbing that 6% claim never to use a computer and about 21% suggest they use computers less than once a month. The National Curriculum for England and Wales makes access to a programme of study in Information Technology Capability mandatory for all pupils from 5 to 16.

**Pupil perceptions of IT and motivation**

This group of questions was developed from a family of questions in the attitudinal survey that provide information about pupil perceptions of their learning experiences and their readiness to learn. For the purposes of the project these were “contextualised” by incorporating the use of computers in the question stem. For example, the question “I usually work as hard as I can in lessons” was modified to become “I usually work as hard as I can in lessons where we use computers”.

The next question sought to establish the curriculum context for the IT activities undertaken by individual pupils. The largest group, 46%, indicated that they used computers in at least a few subjects while 40% of pupils recorded computer use only in IT lessons and nearly 7% in most subjects. Some 7% indicated that they made no use of computers at all confirming the low levels of access reported in the responses to the earlier question.

The final question in this section asked pupils to indicate whether or not they had access to a computer at home. This question had proved problematic in the pilot study and was revised to distinguish between ‘games’ machines and mainstream computers such as PCs and Macintosh systems. The Archimedes computer used in some UK schools was also included.

Some 83% of the pupils reported some form of computer available at home and although 34% described the computer as a ‘games’ machine 42% of the pupils claimed to have access to a PC.
pupils responded positively to this suggestion and whilst a distinct gender difference is apparent here this may be a feature of a general tendency for boys to affirm more strongly than girls in questions of this type.

I get so interested in work that uses computers that I don’t want to stop. In the responses to this question 43% of all pupils claimed that they can get so interested in work with computers that they don’t want to stop. This compares with only a 16% response to the equivalent question in the general survey that was set in the general context of ‘work at school.

Three further questions were used to probe the relationship that pupils see between their use of IT and their level of understanding, interest and learning. More than 70% of pupils responding to these questions agree that using computers makes lessons seem more interesting whilst more than half agree that using computers seems to help them ‘understand things better’ and a similar number that ‘they learn much more quickly’.

It is, however, important to be cautious when interpreting these responses, they represent pupils’ self reported views about the use of computers in their learning and need to be explored further with an objective evaluation of real learning outcomes and improvement.

The Staff Surveys

The first four charts drawn from the staff survey results deal with current and ‘potential’ levels of IT use. The questions ask staff to consider how much use they currently make of IT as personal tools in their lesson preparation and how often they deploy IT to support their teaching. In each case the questions that follows provides an insight into how frequent the ‘actual’ level of use is compared with the levels they would aspire to. It is here that the disparity between current and sought after levels of use in classroom activity becomes most obvious.

The scale of this unfulfilled aspiration suggests that there remains a very significant opportunity to make much wider and more effective use of IT to support teaching activities.

IT in Lesson Preparation
The ambition of many of the teachers in the survey sample to make wider use of IT to support their work in the classroom suggests that there is considerable potential for expanding the current levels of IT activity across the curriculum in England and Wales. Currently some 20% of staff surveyed would claim to use IT in half their lessons or more. This figure rises threefold to 60% when staff are asked to indicate the level of IT use they would ‘like’ to achieve.

The staff questionnaire also asked staff to indicate if they had received any training in the use of IT. These results show that staff who have received some form of IT training are more than twice as likely to use IT in their lessons than those who have none.

**Interviewing the Pupils**

The interviews with pupils established firmly that there is almost universal enthusiasm for the use of IT to support work in schools. The quality of the unprompted comments was almost always high, demonstrating a sophisticated and well-informed view of the technology and its use.

Although some pupils were evidently impressed by the technology itself, the majority of comments were more concerned with the process of communicating and handling information and the high standard of presentation that could be achieved.

The following comments were typical:
- *It looks real ... it’s interactive and you can change the view*
- *You can try new ideas and change things later*
- *It takes longer at first but you can do more with it*
- *It is easier to use work again and change it for different things*

A number of common themes emerged in the pupil comments echoing many of the features of motivated activity described in the literature. These included: a sense of empowerment and autonomy; improved self esteem; moderate levels of challenge coupled with fairly immediate satisfaction at having ‘got it right’; and the freedom to operate in a non-judgmental environment, i.e., ‘the computer doesn’t shout if I get it wrong!’ A number of pupils felt that using IT made information more accessible or more ‘valid’ than traditional sources.

- *You get control over this machine (feeling of power)*
- *You can try new ideas and change things later*
- *It makes you think because you are in control*
- *It takes longer at first but you can do more with it*
- *It doesn’t mind if you make mistakes*
- *... drawing the graph makes it easier to understand (what is going on)*
- *You understand it more because you get a clear set of results*

At one school the interview groups had been selected on the basis of their apparent lack of interest in IT activities. Discussion with these pupils soon revealed that the absence of motivation was frequently related to both the nature of the tasks set and unfavourable comparisons between the poor level of technology available in school and the generally better resources available at home. These negative views were expressed in a number of schools.
We spend too long going over what to do and the tasks are not worthwhile.

It is frustrating (echoed by all) - you know how to do it at home but the school programme is different.

The school computers do not have enough power.

The work is too complicated for the results we get - could do it better with a pencil.

The system is much too slow - it takes a long time for changes to show.

Tentative Propositions

Maximum motivation score is achieved where IT is used in a range of subject contexts. An 'index' of motivation was constructed by combining the responses to a group of related questions in the Pupil Questionnaire. The 'index' score, maximum value 100, is 72 when IT is used in range of subjects, compared with 58 when IT usage is confined to IT lessons.

Most pupils were enthusiastic and well informed about IT. They commented frequently on the benefits of using IT in a purposeful way, concerned more with utility than the more superficial features of the technology such as speed, modernity or colourful screen presentation.

Autonomy, self esteem, challenge and the timely confirmation of success are all-important features of IT based activities. Pupils are motivated by positive experiences of using the technology for a range of activities and the fact that the computer is non-judgmental.

Some pupils were demotivated by the poor quality of IT resources in school compared with those available at home. 83% of pupils say they have some form of computer at home. More than half of these are reported as 'Windows' capable PCs.

Patterns of IT use across the curriculum are very variable with some 40% of pupils only using computers in IT lessons. Better information about the deployment of IT resources, the use of specialist staff and the level of effective cross-curricular use is needed.

Only 20% of staff surveyed use IT regularly in lessons although 60% of staff in the survey say that they would like to use IT in at least half of their lessons and 80% of staff who use IT regularly find that pupils are well motivated.

The range and suitability of IT tasks can be a source of concern. Pupils sometimes see tasks as repetitive and unchallenging. There is often little time to embark on worthwhile activities. Teachers need clear guidance and support if IT use is to lead to more effective teaching and learning.

Acknowledgements

The author would like to thank the National Council for Educational Technology for their generous support in enabling the project and for permission to use material from the IT and Motivation Report (Denning, 1997) in this paper.

INTERNET READINESS: PRESERVICE TEACHERS’ ATTITUDES TO HIGH TECHNOLOGY IN SCHOOLS

Ann FitzGibbon
Trinity College Dublin

Elizabeth Oldham
Trinity College Dublin

This paper examines the views and attitudes of student teachers (that is, preservice teachers) regarding the use of information technology, and in particular the Internet, as a resource for teaching and learning. It focuses on the declared beliefs of the cohort of students currently taking preservice teacher education courses at Trinity College Dublin, Ireland; and it investigates aspects of their readiness to implement newly announced policies on information and communication technologies (ICTs) in education. The work provides a case study of a system in transition, and offers a set of snapshots — or perhaps video excerpts — of the attitudes these student teachers bring to the course with regard to ICTs and their potential as an educational resource.

Ireland has a fairly long history of use of ICTs in schools, but a comparatively limited record in formulating official policy in the area and in providing resources. Policy and provision are now being addressed; ambitious plans have been announced (Department of Education and Science, 1997):

- to establish appropriate resources, including multimedia facilities and internet connections, in all schools;
- to introduce programmes for enhancing teacher education; and
- to provide backup, in terms of both human and electronic support mechanisms, for use of ICTs in teaching and learning.

Thus, an important movement is in progress: from "free enterprise" to "national prescription." It is a truism to say that the teacher education element will be crucial in the success of the plan. Older teachers at least have pedagogical experience to support them; but people involved in initial teacher education need to look at the readiness of student teachers, especially those that had little experience of ICTs in their schooldays. This paper contributes to such examination.

The background to the study — historical footage, so to speak — is provided in the first section. This briefly outlines the ICT provision in the school system through which the student teachers came; it then describes the knowledge and attitudes of past student teachers at Trinity College in the context of the provision made for their ICT education over the years. The methodology of the present study is described in the second section. As the new project "Schools IT 2000" was launched (after some delay) only at the end of November 1997, the later parts of the study had not been carried out when the present version of the paper was written. However, the third section contains “snapshots” from the first part of the study, dealing with students’ prior experience of ICTs and with their views of ICTs in education before the impact of the initiative was felt. Some tentative conclusions can be drawn; an updated paper will be provided when the work is presented at the SITE conference.

Historical Footage: ICTs in the Irish Education System

It is not the purpose of this paper to give an account of the development of ICTs in Irish education over the past thirty years; such an account can be found elsewhere (National Council for Curriculum and Assessment, 1993). However, given the view of Knowles (1992) that teachers are trained in the classrooms they attended as pupils, a brief summary is relevant. While Ireland did not take part in the IEA COMPEd study, its descriptions of education systems which make only restricted instructional use of computers fit the country well (Pelgrum & Plomp, 1991).

Moves at national level have given [ICT] education a place in the country’s education system. However, developments have been heavily constrained by lack of resources and notably short on policy and planning at the highest levels [emphasis added]. The results can best be described as “patchy”; some schools, teachers and students (at both primary and post-primary level) are involved in work that has drawn international recognition, but others have not yet made a start (National Council for Curriculum and Assessment, 1993, p. 12).

Moves at national level have given [ICT] education a place in the country’s education system. However, developments have been heavily constrained by lack of resources and notably short on policy and planning at the highest levels [emphasis added]. The results can best be described as “patchy”; some schools, teachers and students (at both primary and post-primary level) are involved in work that has drawn international recognition, but others have not yet made a start (National Council for Curriculum and Assessment, 1993, p. 12).

The lowly official position of ICTs up to now has posed problems for preservice teacher education, and especially for the preservice education of secondary teachers (teaching grades 7 to 12). Secondary teachers are...
As recently as 1990-91, one-third of the class reported negative feelings ("I detest computers"), the relevance of ICTs, especially the Internet, as resources for teaching and learning.

### Methodology

The study was designed in two parts, to be carried out respectively immediately before and some time after the announcement of the initiative “Schools IT 2000”: hence, to capture the students’ views respectively before the content of the initiative was known and after its implications had become clear. As indicated above, the launch of the initiative was delayed (by a change in government), and the paper in its present form therefore refers only to the first part of the study.

For that first part, data were collected by means of a questionnaire administered to most classes of preservice student teachers at Trinity College. The groups involved were:

- intending [preservice] secondary teachers;
- intending [preservice] primary teachers in their first, second and third year of study (the students based in the College of Education at which the second author teaches);
- a small group taking a post-graduate course which would qualify them as primary teachers; and
- a group of students who had already completed the Ordinary Bachelor’s degree but were taking a fourth year of study, while teaching, in order to raise the degree to Honor level (and still describable as “preservice” teachers because most were doing the Department of Education diploma that completes their qualification).

A subset of the latter group was used for pilot purposes. The final version of the questionnaire had two main sections. One dealt with the students’ experience of ICTs in the school system (and, for graduate students, in third level education before entering their current course). A further question asked the students to describe their level of ICT literacy in broad terms: highly literate, somewhat literate, barely literate or illiterate. The other main section of the questionnaire asked about their intentions regarding their, and their pupils’, use of ICTs in their first year of teaching, in five years’ time, and in ten years’ time. It also included a semantic differential section designed to investigate the students’ view of the impact of ICTs on aspects of the education system in general, and an open-ended question asking them to describe the Internet and its training, and to use the skills for instance in preparing materials for their teaching practice; that is, again, they have recognised the importance of the tool for teachers’ own work.

Against this background, the main research question addressed in the present study is whether — in the current climate of increasing access to powerful ICT facilities — there has been a corresponding change in acknowledging the relevance of ICTs, especially the Internet, as resources for teaching and learning.
possible role in education. The intention was not only to collect baseline data, but also to identify groups, individuals and issues for further study in the second part of the research.

Students were given time in lectures in which to complete the questionnaires. The data were entered into an Excel spreadsheet; categorical and quantitative data were analysed using Data Desk, while the free-response questions were processed by hand.

Results: Snapshot of Students' Readiness

Responses were received from 195 students: 66 intending secondary teachers; 36, 23 and 19 students respectively from the first, second and third year primary course; 11 from the post-graduate course for intending primary teachers; and 40 from the "Honor" group. This represents a response rate of around 60 per cent, with the shortfall being accounted for chiefly by absence from the relevant lectures on the (very wet!) days in which the questionnaires were administered. Of the 189 students declaring their gender, 163 were female and 26 male. The mean age was 22.5 with a standard deviation of 5.0; eleven of the first year students were only 17 years of age, while the oldest student, an intending secondary teacher, was 50.

Results of interest at this stage have been picked out for comment, rather than presented in statistical form, and are described under three headings: prior experience, intended use and effect on education, and metaphors for the internet and its use.

Prior Experience

If Knowles (1992) is correct in his view — quoted above — that teachers are trained in the classrooms they attended as pupils, then the current cohort of student teachers is ill-prepared for using ICTs as a tool in teaching and learning. Only nine reported such use from their primary schooldays, and while 46 did so from their second level experience, this figure arises largely from use in teaching computer skills. In terms of high-end technology (such as multimedia and the web), the older students could not have experienced it in their schooldays, but the younger ones were not much better off. Altogether, in fact, small numbers of web users (not necessarily users in an educational setting) were scattered over all the classes.

However, the intending secondary teachers do have considerably more experience of computers than did their counterparts five to ten years ago. While only slightly more than half the respondents reported some exposure in their schooldays — almost always at second level, and generally slight and focused on skills — nearly all used computers (typically for word processing) in their third level colleges before entering their teacher education course. Their modal choice for their present level of literacy was "somewhat literate."

The intending primary teachers are less well prepared. While exposure at second level is growing (in general the more junior the students have greater exposure), and while some exposure at primary level was reported, again usage was generally slight. The first and second year students, who had yet to be given their main ICT inputs on the teacher education course, gave their modal choice of literacy level as "barely literate." The Honor cohort's modal description was also "barely literate" despite their experience in their various colleges during their Ordinary degree years. This substantiated the feeling, reported earlier, that the ICT module taught by the second author has not been as effective as would be desired; and the same may be true of equivalent work at the other associated colleges. However, for the third year students — who had not only attended their second-year module on ICTs in its most recent form (and experienced some usage in other College courses), but coincidentally had just been evaluating a piece of mathematics education software as part of their Mathematics Teaching Methods course — the modal description was "somewhat literate": hopefully, a move in the right direction.

Intended Use and Effect on Education

While the questions on the future role and use of ICTs did not demand detailed identification of the activities involved, students at least showed an openness to development rather than a technophobic response. Indeed, in comparison with findings from earlier studies (Oldham & FitzGibbon, 1992; Summers, 1990), technophobes were few. Over half the group strongly agreed, and only one disagreed (with none at all strongly disagreeing) that "computers are very relevant to the future of education." In terms of the extent of their own and their pupils' use of computers in general and the internet in particular, both for personal work and in class, predictable patterns of increase over the next ten years emerged. More than other groups, the Honor primary cohort — already teaching as well as studying — tended to foresee usage "never" or "often" (rather than "occasionally"), notably in the short term; this may reflect respectively poor or good facilities in their schools.

The semantic differential section of the questionnaire asked students to indicate their view on a scale of 1 to 7 between two stated extremes: for example "ICT improves education ... ICT disimproves education" — there was a high level of endorsement for improvement. Students were fairly equally divided as to whether ICTs would increase the teacher's workload, decrease it, or leave it unchanged. Several items addressed the issue of the teaching/learning environment, and again the results displayed an openness to change. There was a clear tendency to envisage classes becoming more student-centred (rather than more teacher-centred); creativity was seen as being encouraged (rather than inhibited); equally, the involvement of new teaching and new learning strategies was strongly endorsed, though one-fifth of the intending secondary teachers saw tradi-
tional teaching strategies as being involved — perhaps reflecting the dominance of traditional teaching under the pressures of the national examinations in the upper grades. There was a less clear tendency in support of general pressures of the national examinations in the upper grades. reflecting the dominance of traditional teaching under the intending secondary and the Honor primary groups — the two groups most regularly in classrooms at the time of data collection — being most cautious; and there were differences both between and within the groups regarding whether student-student rapport would be increased, with the third year intending primary teachers being the most positive. ICTs were viewed as encouraging (rather than inhibiting) curriculum change, but other items dealing with system level issues elicited many neutral or “don’t know” responses; perhaps student teachers cannot yet focus easily on national or global issues.

Metaphors for the Internet and Its Use

To start with the bad news: a small cluster of students scattered across the different classes denied having any information regarding the Internet and its uses. Their responses included: “I don’t know” (most common within this group), “completely ignorant!” and “not familiar with it.” Others were willing to attempt a reply but unadventurous in their descriptions of and metaphors for the Internet. Two favourite metaphors emerged: “encyclopaedia” and (poetically but rather simplistically!) “information at the touch of a button.” “Encyclopaedia” had qualifiers such as: huge, infinite, vast, ever changing, up to date.

The uses can be categorised under three headings: information, communication and education. Information concerns are exemplified in the two metaphors discussed above. The downside was recognised by some students who mention, for example, “utter rubbish available,” but most were uncritical and in apparent awe of the range of information: “wide range of topics” and “access to other cultures and traditions.” The information was seen as “constantly changing” and “updated as it happens.” Communication was viewed as being between people and between schools, as being direct and worldwide, creating a “community of people” and leading to “a multi-cultural correspondence.”

The specifically educational uses are interesting. The opportunity for increasing the personal autonomy of the learner was clearly realised, as was the possible role of technology in “develop[ing] children to be more independent thinkers” who can “discover the world without the limitation of the teacher’s knowledge.” The teacher “falls into the background”; the need for teacher education was identified. The Internet was seen as motivational, being “a creative varied means for learning and teaching” which the children enjoy (“children are hooked”). Two students, in the secondary teachers’ group, were dubious of the value of the Internet in primary education, a view not endorsed by their primary colleagues.

Conclusion

With the announcement of the policy encapsulated in “Schools IT 2000,” there are interesting times ahead for those concerned with ICT education in Ireland. The snapshots described above indicate the need for much work before new entrants to the teaching profession are ready to avail of enhanced facilities and to integrate ICTs into their teaching in a meaningful way. While students displayed considerable goodwill towards ICTs in education and acceptance of coming change, the nature of the data collection exercise was such that they could respond “naively” — without having to tease out what their responses would mean in terms, for example, of their day-to-day classroom work or of reconceptualisation of their approach to teaching. Such issues will be addressed in the second part of the study, to be conducted in early spring 1998 by using focus groups of selected students. It remains to see if the apparent general goodwill and good intentions regarding the use of ICTs, as revealed by the initial snapshots, can be translated into genuine commitment to the appropriate use of ICTs in education in the time to come.

Acknowledgments

Thanks are due to Rebecca Quinn for help with data processing.

AN ICT COMPETENCE-BASED ENVIRONMENT FOR (RE)TRAINING EDUCATORS IN EDUCATIONAL INNOVATION AND TECHNOLOGY

Paul A. Kirschner
Open University of the Netherlands

Gerard van den Boom

Henry Hermans
Open University of the Netherlands

Henk Münstermann
Open University of the Netherlands

Higher education - be it academic, vocational or professional - should ensure that students attain a certain level of competence upon completion of their studies to allow them to function intelligently, independently and flexibly within their chosen profession. Graduates should reach a point where they are capable of choosing an adequate response or action from a variety of possibilities in a variety of situations, and of correctly carrying out these actions in order to achieve their goals. As such, competence is defined here as a unique combination of knowledge (knowing what, how, when and why) and skill (being able to perform certain actions) in a goal directed way in a specific situation or context (Kirschner, Vilsteren, Hummel, & Wigman, 1997).

Educators are just such professionals. It is no longer enough to longer simply ‘teach’. Educators are constantly being confronted with new demands on their functioning. New tasks are constantly being added to their job descriptions. This situation is due to the ever-increasing tempo of changes in the educational system, school organization, society, technology, educational content or all of these combined. It may also be the result of the never-ending stream of pedagogical problems that each individual educator confronts in his or her ‘normal’ classroom situation. In order to survive, the professional educator must be flexible and be able to continually adapt and evolve. In other words, the teacher must become an educational innovator.

Learning to innovate requires a learning situation where the learner can acquire necessary knowledge, skills and attitudes in a real life, recognizable and meaningful context. This combination, together with the ability to make an adequate choice from a number of possibilities/possible actions in different situations, we consider to be a competence. Only in this way can traditional teachers be transformed into reflective practitioners, able to adapt their teaching to any and all changes that confront them. In other words, to be practitioners who are able to systematically reflect upon their situations and flexibly (re)design their education by offering their learners effective learning paths and pedagogic instruments to assure high quality education.

This ability to innovate is not only necessary for those who teach, but also for educational managers (heads of schools, et cetera). They are the ones who, on the one hand, create the necessary conditions for educational innovation and on the other hand establish policy that is an adequate reaction to external influences on the school. In other words, the educational manager must be able to (re)design education and manage innovation at the meso-level.

Premises of the Environment

The information and communication technology (ICT) environment for (re)training educators in educational innovation and technology is based upon:

- teaching what/as one preaches;
- competence acquisition / skill development / knowledge gain;
- a study environment (student centered) instead of teaching environment (teacher centered);
- just in time instead of just in case;
- task based, situated, contextual learning;
- flexible education for different groups;
- producing reflective practitioners of educational design;
- integration of learning, instruction and testing (intake, progress and certification);
• affective aspects of innovation;
• collaborative learning as precursor to collaborative teaching;
• educational innovation and design as integral processes;
• process en product evaluation integrated in the process;
• the premise that innovation never stops; and
• structural use of ICT as a tool in the (re)training program and in education.

Competencies

At this moment the teaching profession, from kindergarten through college and university, is a topic of discussion and change within the Netherlands. The government has installed a number of official working groups to redefine the profession and redesign the educational programs for initial certification and retraining. Based upon a thorough review of official memoranda and reports of the Dutch government and professional organizations we comprised a list of competencies relevant to being/becoming a professional educator. These competencies are:

• The ability to determine (via analysis) those aspects of classroom, school and societal situations and developments which influence the educational process (problem definition) so that possible solutions for the problems as well as adequate implementation strategies for the necessary changes can be evaluated and implemented. In other words the ability to adequately react to the challenges of the profession and of society with respect to the organization of education at the classroom and school level.

• The ability to work with others to design innovative changes in education which are necessary to meet the specific needs or requirements of the class, school, school board or government.

• The ability to work with others to develop innovative changes in education which are necessary to meet the specific needs or requirements of the class, school, school board or government.

• The ability to work with others to implement innovative changes in education which are necessary to meet the specific needs or requirements of the class, school, school board or government.

• The ability to manage the process of innovating education (from initiation through implementation to evaluation) at the classroom and school level.

• The ability to apply those aspects of educational theory, educational psychology, pedagogy, and didactic theory for designing, developing and implementing education.

• The ability to functionally apply (both effectively and efficiently) modern information and communication technologies at the classroom and school level.

• The ability to develop into a life long learner with respect to one’s own profession as teacher or educational manager.

Cognitive skills that are integrated into the (re)training program are: Analysis, Synthesis, Evaluation, and Reflection.

Required attitudes and affective skills that will be integrated into the (re)training program are: adaptivity, lifelong learning, professionalism, confidence in one’s own possibilities, and professional cooperation.

Educational design

Educational design (as profession or study) must try to achieve a balance between praxis (the craftsman) and empirical science through a methodology based upon the regulative (van Strien, 1986) and reflective cycles (Van Aken, 1996). According to Van Aken, the job of the professional is the solution of a unique problem within a specific situation. He or she does this via a cycle encompassing: problem choice, diagnosis, planning/design, operation/implementation, and evaluation.

By working one’s way through the regulative cycle, the professional makes use of reflection-in-action (Reflective cycle: Van Strien, 1986). This cycle makes use of a series of ‘cases’ to develop design knowledge and skills (heuristics). Reflection is directed towards detection of new solution possibilities for problems and as such is primarily busy with a not existing reality. In this cycle, the practitioner selects a specific case, applies the regulative cycle, reflects upon the results of his or her actions and then chooses a new case from the original class of cases.

A loose integration of these two cycles forms the basis of the educational design of the (re)training environment (see Figure 1.).

Figure 1. Approach for the Use of Problems and Cases in the (Re)Training Program.

If Van Strien and Van Aken provide a good educational design, Kolb’s learning cycle (Kolb, 1982, 1984; Kolb, Lublin, Spoth, & Baker, 1986) seems to present a good pedagogical basis for training ‘reflective practitioners’. As such it is the second pillar of the study environment. Kolb’s learning cycle is based upon ‘experiential learning’, learning while doing. This should not to be
confused with “learning by doing. Learning by doing implies that by doing something one will gain the necessary background knowledge and skills by oneself. “Learning while doing” implies that the learner is presented the necessary knowledge and skills at their most relevant moment during the experience. The experiential learning method creates an environment that requires the participant to be involved in some type of personally meaningful activity. Such an environment allows the participant to apply prior knowledge of theory and principles while developing commitment to the exercise and experiencing a real sense of personal accomplishment or failure for the results obtained (Walter & Marks, 1981). This type of learning resembles the previously described approach, but emphasizes personal experience as the basis for conferring meaning to knowledge and skills. In order to bring about behavioral, attitudinal, and knowledge change, Kolb advanced a circular, four-state experiential learning model. Learning can start at any point in the cycle, but must go through all four activities.

![Kolb's Experiential Learning Cycle](Figure 2. Kolb's Experiential Learning Cycle.)

The learning activities take place along two dimensions: concrete experience versus abstract conceptualization and active experimentation versus reflective experimentation (Urban, 1992). Within the study environment the learner makes use of:

- concrete experience: the learner experiences the results of his/her active experimentation and is open for those experiences;
- reflective observation: the learner observes the situations from different perspectives (the results of the experience) and reflects upon them;
- abstract conceptualization: the learner integrates these perspectives in logical theories and explanations; and
- active experimentation: the learner tests the theories in practice.

**Structure/Design**

Educational innovation and technology as content domain is not based upon some abstract, academic or historic conceptualization of the domain, but rather upon a set of professional competencies needed by the reflective practitioner. These competencies are interrelated and form a competency map.

Composing a curriculum means selecting competencies according to certain criteria. In our environment, each competency can be achieved by working through one or more case studies or problem situations. The choice of case or problem depends upon such student variables as function (teacher /principal/et cetera), study aim/objective (teaching better/innovating one’s own teaching/adapting the school organization/aspiring to another job/and so on), type of school (elementary/high school/adult and continuing education) and so on.

A number of parameters are distinguished within each case that are related to other student variables such as prior education or prior knowledge. The case can be automatically adapted to all of these parameters with respect to:

- its formulation,
- the tasks required,
- the study support devices offered, and
- the products and performance for assessment.

The global design of the environment can be seen in Figure 3.

![Global Design of the Environment](Figure 3. Global Design of the Environment.)
Summing up

Summing up, the (re)training program:
- is based upon competencies that are linked to (clusters) of tasks within the study environment;
- makes use of 'just-in-time' knowledge and skills acquisition;
- is adaptive with respect to student learning style;
- is adaptive with respect to the prior knowledge of the student;
- is based upon the regulative and reflective design cycles and Kolb's learning cycle;
- contains the necessary study advice to stimulate, facilitate and promote learning;
- is aimed at the stimulation of reflective activities and the acquisition of attitudes; and
- makes use of well defined and well ordered study tasks.

COURSE-BASED DESKTOP VIDEOCONFERENCING BETWEEN THE UNITED STATES AND NORWAY

Clayton Keller  
University of Minnesota  
Duluth

Ragnar Thygesen  
Norwegian University of Science and Technology

What if your students could receive lectures in your course from internationally recognized experts and ask them questions after class, all without you having to pay for their travel expenses or arrange a satellite downlink to a specially equipped classroom reserved a year in advance? What if your class could have a face-to-face discussion of a case study with peers in another country to see how the values and contexts of another culture lead to similar and different perspectives on issues and solutions? Then they repeat the experience the next week with colleagues in a different country. What if these same students could continue their interactions outside of class, exploring their own personal and professional interests further? What if students in elementary and secondary schools could have similar opportunities to participate in multiple, extended interactions during their lessons over their school careers? How could students' educational experiences be transformed? What would be the impact on learners? How could it expand your teaching?

A variety of current, commonly-used applications of the Internet and the World Wide Web begin to provide low-cost opportunities for university and K-12 students to interact with their peers at distant locations in educational situations. These applications include electronic mail, chat rooms, asynchronous discussion boards, whole courses with audio and video delivered via Web pages. We have found that these instructional options, though, can only cultivate the social, human side of the interpersonal relationships that are the basis of all educational interactions so far because they lack the capacity to provide live, real-time audio and video interactions between the participants.

Desktop videoconferencing over the Internet—through programs like Cornell University's CU-SeeMe, Microsoft's NetMeeting, Connectix's VideoPhone, and Intel's Internet Video Phone with Proshare—provides the capability of inexpensive opportunities for face-to-face human interactions for teaching and learning no matter what the distance. The educational use of these applications, though, has been minimal when compared to their uses in business or to the frequency of use of other Internet and World Wide Web applications in education.

Two projects have been relative pioneers in the educational uses of desktop videoconferencing. The Global SchoolNet Foundation (GSN; see, http://www.gsn.org/) started in 1984, ran the Global Schoolhouse Project sponsored by the National Science Foundation and continues to work to link classrooms and experts around the world in a variety of exciting, videoconferencing-based special projects. Faculty at the University of Virginia's (UVa) Curry School of Education have developed a World Wide Web-based course on interdisciplinary teaching that makes an extensive use of the course's Web site to provide instructional materials and interactions among students enrolled in the course at different universities. In addition the course involves real-time videoconferencing sessions using CU-SeeMe among students at various sites (see, http://curry.edschool.Virginia.EDU/go/casecourse/). One drawback that we see in the efforts of both of these projects, though, is that the use of videoconferencing has generally remained a special or isolated event. This event is often separate from or even an interruption of—albeit a very exciting one that is too good to miss—the everyday life of classrooms or the sequence of courses that comprise a major field of study.

This paper describes our course-based uses of Internet videoconferencing between faculty and students at the Norwegian University of Science and Technology (NTNU) and their peers at the University of Minnesota, Duluth (UMD). We provide information about the project, equipment and software, our efforts, and the lessons we learned.

The Project

Our project started when interests met with an opportunity. We in the Department of Education at UMD directly experienced the potential of desktop videoconferencing by participating as a site the first time Virginia offered its
course in spring, 1996. Because of that, we looked for other ways in which we could use this application. NTNU’s Department of Education wanted to develop its competence in the instructional uses of technology. In spring, 1997, they hosted Keller as a Fulbright professor of special education. Faculty in the two departments decided to collaborate on expanding the ways in which to use desktop videoconferencing in education and extending its use internationally through sessions with each other. We saw this as a way to continue the educational exchange between Norway and the United States and the comparative examinations of education beyond the tenure of the visiting professorship.

**Equipment and Software**

To run the videoconferencing, we have used a Windows platform in Norway and a Macintosh platform in Minnesota. We use QuickCams by Connectix and external microphones. Each computer runs appropriate versions of CU-SeeMe, shareware created by Cornell University to support videoconferencing on the Internet (see http://CU-SeeMe.cornell.edu). We have found this software to be one of the few desktop videoconferencing programs at this time that works across the two platforms. CU-SeeMe’s video transmission capabilities have generally been adequate. We have had more difficulties with the audio portion of the application. At times the sound has either been absent or of such low quality that we have had to rely on telephone calls for this part of our videoconferencing sessions.

We also plan to try out other desktop videoconferencing programs from vendors like Intel, Connectix, and Microsoft that can only run on a Windows platform. Some of these contain additional features like white boards and the capability of sharing documents and applications that would be very useful in course-based videoconferencing sessions.

**Videoconferencing Sessions**

We now describe the different ways we planned to use desktop videoconferencing in our courses over two semesters and what happened with or in those sessions as a way of identifying some of the problems, solutions, and outcomes we have found with our project.

One idea in spring, 1997 was to use videoconferencing to exchange course lectures between faculty at NTNU and an institution in the United States like UMD or the University of Virginia. This could provide NTNU students with direct access to someone with particular expertise—for example, the author of one of their readings—who would not normally be available to them. This author could present his or her ideas. The students could discuss them directly with this person. A reciprocal lecture by an NTNU faculty member would provide students in the United States with another perspective on one of their course topics as well as an opportunity for real-time interaction. During our trial attempts at videoconferencing, we felt that certain characteristics of the transmissions (e.g., slowly altering or even static pictures in the video transmissions; interruptions and extra noises in the audio portion) might impede the delivery of a lecture. Classrooms for such lecture-based courses that were connected to the Internet were not available on the NTNU campus where the Department of Education was located, though extra cables could have been used to connect a classroom to a computer lab where such Internet connections were present. Most importantly, it was difficult with short notice to identify places in course schedules where such guest lectures could occur as well as the personnel in each country who could deliver them.

A second idea during that semester was to have a group of NTNU students participate in the spring, 1997, offering UVA’s World Wide Web-based course mentioned earlier. Here a course structure was already in place that provided opportunities for communication among students at different institutions through CU-SeeMe videoconferences. The UVa instructors allowed a group of NTNU students to try out components of the course as a way of seeing how their instructional methods and materials worked with students from another country. We found three masters-level students with interests in instructional technology who volunteered to participate after the course had already started in the United States. Because the course relies heavily on the use of teaching cases as a vehicle for generating course content, an instructional approach that is relatively uncommon at NTNU, the first meetings of the students focused on case analysis. From the beginning the students did very well with the cases, generating insightful analyses that contained a Norwegian perspective on issues and solutions, though they often found it difficult to understand on their own many details of the American contexts of the cases. One student left the experiment, though, because it took too much time to read all the materials in English. The other two students eventually found it too difficult to catch up to where the American students were in the course activities as their involvement was in addition to their already heavy school and work schedules.

The third idea involved having a group of NTNU students in a masters-level seminar in special education discuss a teaching case with a group of peers at UMD. Because of the seven-hour time difference between the two sites, it was not feasible to find a comparable group of educators in Minnesota. Arrangements to connect with a group of preservice, elementary education students for the conference were not successful either because of class scheduling conflicts at UMD and those students’ other responsibilities. A group of UMD education faculty and one student, however, volunteered for the session. After a few technical problems were solved, the two groups began their discussion of the case of Lenny, a hyperactive,
American Indian kindergarten student, by presenting different issues that each group saw in the case. The session turned into more of a discussion when one of the Norwegian educators disagreed with the American student’s point that Lenny’s cultural background should be de-emphasized. The participants then considered how some of the other country’s proposed solutions might be difficult to implement in their own educational contexts. The groups started asking more general questions about each other’s educational systems when we ended the session after one and one-quarter hours. Students and faculty at both institutions were very excited by and pleased with the videoconference.

Because of this success, arrangements were made for another session. A group of preservice educators from the teachers’ college in Trondheim, who either had already participated in or were about to embark upon a year abroad at an American college, discussed the characteristics of a good teacher with a group of preservice, elementary education majors at UMD. This was the final course project for the UMD students. In preparation for this session, students at both schools were assigned the same reading and were to interview pupils in their field placements for their ideas about what makes a teacher good. This proposed topic for the videoconference was addressed but students from both sides often shifted the discussion to other topics of a more general nature, like how the job market was and whether they had to take exams. It seemed as if the participants had to know this basic, contextual information—which was probably more personally meaningful to them than our assignment was—before they could or wanted to address the discussion topic. The question about exams also illustrates a potential difficulty of international videoconferencing. The UMD students were referring to entrance exams to gain admission to their teacher preparation program; the Norwegian students thought they were asking about final exams for their courses. Each side came away with the idea that their peers have to take the kinds of exams they had in mind. Norwegian students, though, do not have to take similar kinds of entrance examinations and the UMD students do not take the kinds of comprehensive final course examinations (that can cover a whole year’s content) that Norwegian students do.

For Fall Semester, 1997, we decided to return to try to deliver lectures via videoconferencing. One of our adjunct faculty members at UMD, who is the immediate past president of the Orton Dyslexia Society, had also had a Fulbright professorship in the Department of Education at NTNU six years earlier. We planned to have her present two lectures in NTNU’s special education reading course, the course that she had taught when she was in Norway. Thus, she was familiar with the course’s content, arrangements, and teaching methods as well as with the NTNU faculty currently teaching the course. She sent overhead transparencies and student handouts to illustrate her points through the mail ahead of time. Because of difficulties with the audio part of CU-SeeMe, despite many test sessions to adjust the program’s various settings for transmission and reception, we used a telephone hook-up, with a headset for her and a speakerphone in Norway, for the audio part of the session. (The use of a separate system for the audio actually seemed to speed up the video transmission on CU-SeeMe.) The first lecture went very well. The lecturer verbally cued most of her overheads though a couple of times she had to hold them up to the camera to clarify, for example, which of the two possible matrices she wanted shown. She received a few questions and comments from the class in Norway, which provided for some interaction and discussion. The second lecture was not able to take place, however, as the Norwegians were unable, for some undetermined reason, to connect to the Internet that evening and it could not be rescheduled for a different date.

We also tried another discussion of a teaching case study. This time the participants were students in a behavior management course at UMD and, in Norway, Thygessen and a consultant at one of Norway’s national centers on special education for students with emotional and behavioral disorders. Difficulties with the audio again affected the session. A telephone connection was used but, because there was no speaker phone available to the class in Minnesota, individuals had to take turns speaking into the phone, listening to the responses from Norway, and then providing a summary of the message to the rest of the class. Despite these limitations, the participants were able to identify many interesting similarities and differences between the American and Norwegian special education systems and societies.

Several sessions are planned for the rest of the school year. Staff from the above mentioned special education center in Norway will have a general discussion about special education with special education administrators from local school districts around UMD. A UMD professor who teaches the elementary education science methods course wants to have a Norwegian peer talk to his class about the ways science is taught in Norway. And students in masters-level special education seminars at UMD and NTNU will conduct several discussions on special education issues and their own research projects over the course of a term.

Summary
We have provided many details of the sessions as a way of illustrating some of the lessons we have learned. Technically, this approach to videoconferencing can be relatively inexpensive and easy to use; though its use benefits from technical support and back-up transmission systems. Logistically, differences in time, language, types of students, and instructional arrangements present time-
consuming problems, at least when initially developing plans for international sessions. Many of these difficulties have diminished, however, as our experiences with such sessions have increased. Educationally, the end results are worth all of the effort. The act of real-time communication with peers in another country, the exposure to new perspectives, the opportunity to expand institutional capacity and expertise, and the chance to develop relationships with others in the world are not as readily available through any other means.

This paper discusses some of the theoretical and practical issues of extending computer mediated learning environments across cultural borders. While it will be of interest to any instructor whose courses entail a cultural dimension, the following discussion speaks to an audience who is familiar with the technical and educational implications of incorporating the use of computer mediated communication systems in course work. Its overall purpose is to convey to the reader the benefits of incorporating a computer mediated cross-cultural learning environment into a course whose content and objectives are conducive to such an activity. The criteria for successful applications are presented and issues relating to training and design are discussed.

Value of Extending the Classroom

The value of extending the university classroom beyond national boundaries is only one of the many reasons for increased intercultural communication relate to the growing internationalization of business (Adler, 1991; Brislin & Yoshida, 1994). The state of today’s business world requires workers to interact with others from different cultural backgrounds, whether they are well prepared to do so or not (Manning, Curtis & McMillen, 1996). In the hope of building strong international working relationships between people and organizations of different cultures, it is important that students be prepared for the emerging future where cross-cultural communication skills will be of great importance.

A strong international work community is one where cultural identities are preserved while simultaneously transcended. That is to say that a healthy international work community does not eliminate diversity but rather welcomes other perspectives and seeks to understand all sides of every issue (Manning, Curtis, & McMillen, 1996). In order to meet the challenges of working in a global industry, tomorrow’s worker must be able to view the world from a cultural perspective other than his/her own. This will require an understanding of the issues surrounding the diversity and tolerance of different points of views, work habits, communication patterns, social roles, and a myriad of other work-related issues. In short, the future workforce will have to possess a cross-cultural awareness of how individuals and groups of people vary from one another in terms of culturally based expectations, values and needs.

Powell (1997) defines cross-cultural awareness as a person’s ability to:
• be sensitive to the existence and legitimacy of other cultures;
• understand and accept other cultures; and,
• view cultural phenomena from the perspective of the culture in which they occur, from the point of view of his/her own culture, and from that of others.

One way of developing these abilities is to present students with authentic opportunities to work with people of diverse backgrounds. By designing a computer mediated learning environment that stretches over different cultures, students can engage in activities that will promote an awareness of cultural differences.

Rationale for Using CMC

Computer mediated conferencing (CMC) does not, merely provide a different medium for traditional classroom interactions, but creates an environment for students to take part in much richer and relevant educational activities (Newman, 1990). By incorporating a computer mediated cross-cultural learning activity into the course curriculum, students are presented with new and greater challenges that extend beyond their traditional, and often passive, learning of theories and content.

With respect to building cultural awareness and tolerance, computer mediated cross-cultural learning activities have the potential of bringing about behavioural and attitudinal changes in people that otherwise would not occur. For example, business students may develop a deeper sensitivity for culturally based differences in work habits by interacting with students of diverse cultures.
rather than reading about how one should be culturally aware of these differences in textbooks. Likewise, preservice teachers may acquire a better understanding of culturally based differences in learning styles, knowledge representation and cognition if they are given the opportunity to interact with students from diverse cultures.

Perhaps more important, however, is providing students with the opportunity to participate in an authentic cross-cultural exchange releases them from the proverbial academic vacuum in which they typically build knowledge and understanding from readings and in-class discussions. Computer mediated communication technology has already changed the image of the classroom. What used to be thought of as a place confined by four walls is now perceived as part of a distributed learning system that is connected to the world. The "new" classroom is connected to others by computer networks (Dyrli & Kinnaman, 1995; Kook, 1997). These networks stretch across international borders to form cross-cultural learning environments where teachers and students of diverse cultures can learn with and from each other. With its capability of bringing world views to the classroom instantaneously, CMC presents students with unprecedented opportunities to develop cultural awareness and build shared knowledge.

Other advantages of CMC are that, regardless of subject area, it introduces new opportunities for collaborative learning, facilitates individualized feedback as well as contact with peers and faculty, promotes reflective and critical thinking due to its asynchronous nature, and permits students to work at a time and pace that is convenient to them (Harasim, 1989; Boyd, 1990). McMahen and Dawson’s (1995) recent review of the use of CMC in environmental education affirms that providing students with the opportunity to share data and discuss issues with others around the world increases motivation. Dyrli and Kinnaman (1996a) contend that CMC brings immediacy and individualization to the curriculum. In consideration of these benefits that CMC can bring to a learning environment, cross-cultural educational applications of computer mediated conferencing have the potential of being extremely useful and relevant to students’ learning. Therefore, it is more than worthwhile to review current curriculum goals for real and potential computer mediated cross-cultural learning activities.

**Preparing Students for Cross-cultural Learning Environments**

A prime concern is that students be adequately trained to use the CMC system so that any anxieties or apprehensions about using the technology are overcome by the time the cross-cultural computer mediated learning activity begins. This entails building sufficient practice time into the course curriculum. A number of studies conclude that giving students the time and freedom to explore the new technology reduces anxiety and enhances performance (O’Malley, 1995; Kolodner & Guzdial, 1996). Therefore, CMC training should be designed to meet the specific needs and ability of the using group (McMahen & Dawson, 1995) and be fully integrated into the course so that students can hone the technological skills they require to contribute to a cross-cultural learning environment.

In addition to acquiring the technological skills and course content required to participate in an international forum, students should be specifically trained on the issue of cultural diversity. This type of training should introduce an awareness that there is a major influence called culture, that it has major effects on people’s lives, and that different behaviours are considered culturally appropriate/inappropriate in different parts of the world. It should also cover the knowledge necessary to work and learn in other cultures, that is, the knowledge, broadly defined, that is considered important in other cultures.

**Preparing Faculty for Cross-cultural Learning Environments**

In their new roles as facilitators of learning, instructors are charged with the design, implementation and maintenance of purposeful and productive virtual learning environments (Kook, 1997). In the best of situations, instructors can design and facilitate a computer mediated environment conducive to collaborative learning (Ahern, Peck, & Laycock, 1992). However, the CMC literature indicates that learning through computer mediated systems requires skills not commonly found among faculty of higher education institutions (Ahern, Peck, & Laycock, 1992; Bailey & Cotlar, 1994). Creating and participating in an online community of learners are new strategies for some instructors. Therefore, to ensure the success of a computer mediated cross-cultural learning activity, faculty must develop competencies in the following areas:

**General Uses of CMC in Education**

Using the CMC system. Instructors, like their students, need to feel comfortable and confident with the technology prior to implementing an elaborate application. Hiltz (1986) estimates that an instructor requires between 30-50 hours of online practice time to sufficiently learn computerized conferencing. Hiltz recommends that instructors master their CMC skills experientially, that is, by incorporating the use of CMC learning activities in a course, beginning with small, easy-to-manage projects first.

**Accepting New Responsibilities.** In a computer mediated learning environment, the structure of the teaching changes. Rather than being the source of information, the instructor assumes the role of facilitator, releasing control of learning to the students (Snedletsky, 1997; Knupfer, 1993). In a computer mediated learning environment, there is great potential for students and teachers to learn together and to learn by discovery. Faculty training must therefore include helping instructors to feel secure
about their new role and to become comfortable with the idea that it is the learning community, not the authority, which is well represented in CMC (Shedletsky, 1997) and that this mindset naturally extends to computer mediated cross-cultural learning environments.

**Facilitating the Learning Activity.** It is the instructor’s responsibility to guide the online activity so that its learning objectives are attained. Facilitating online is synonymous to moderating, which entails the instructor’s ability to organize and manage the virtual space, ask and answer questions, provide feedback, direct discussion, and encourage cooperative and collaborative learning (Kook, 1997).

**Related to Cross-cultural Applications of CMC**

**Cross-cultural Awareness.** In order to properly design and implement a cross-cultural activity that will encourage and promote academic achievement, instructors must believe in cultural differences and similarities, believe in the uniqueness of people, and hold the opinion that cultures are neither superior nor inferior to one another (Powell, 1997).

**Identifying Learning Styles.** Researchers suggest that individuals tend to fall into distinct categories with regard to the manner in which they prefer to learn and, to a large degree, that these preferences are culturally determined (Adler, 1991; Brislin & Yoshida, 1994; Sheffield, 1997). Differences in learning styles must, therefore, be taken into consideration when designing the computer mediated learning environment and cognitive activity.

**Finding Common Ground.** It is important to identify common ground without diminishing the importance of cultural differences. Both cultural-general and cultural-specific approaches to designing the virtual space and learning activity should be considered (Brislin & Yoshida, 1994). At the university level, the literature (i.e., assigned readings) may easily serve as the common ground.

**Resolving Communication Issues.** Verbal and nonverbal messages have significant impact on teaching and learning processes (Brislin & Yoshida, 1994). Research carried out by Hiltz (1995) suggests that failure in computer mediated learning environments occurs far more often on the social level, rather than the technical level. Critical to the development of any educational relationship is the degree to which trust and mutual understanding emerge (Boyd, 1990). As a result of the extent to which differences in language and communication styles can result in significant misunderstandings or misjudgments about the motivations of others, instructors must be able to help students transcend communication problems.

**Designing the Virtual Learning Environment**

The very first step in designing a successful computer mediated cross-cultural learning environment is to analyze learner characteristics and then, based on this analysis, select activities that encourage and support the academic achievement of all students participating in the international forum (Sheffield, 1997; Powell, 1997). More precisely, instructors must determine how the needs of students with culturally based differences in learning styles, cognitive orientations and motivational cues can be met. By identifying the commonalities and differences, instructors can design learning activities that recognize and celebrate cultural diversity. A challenging learning activity would deal with issues common to diverse cultures, yet show variations significant enough for analysis and discussion (McMahan & Dawson, 1995).

With regard to the issue of motivation, Romiszowski and de Haas (1989) report on difficulties they encountered in motivating students to participate in a computer mediated activity. The design of the virtual learning environment is a critical factor in motivating students to participate. The computer mediated cross-cultural learning environment should be structured (i.e., in terms of navigability, pace of learning, type of learning activity, types of assignments) such that students want to enter, contribute and belong. According to Hiltz (1995), the most successful computer mediated learning environments are those designed to encourage participation, collaboration, critical thinking and knowledge building. Therefore, it would be worthwhile to include these same social and cognitive activities in computer mediated learning environments that stretch across international borders.

Finally, a number of scholars contend that CMC learning activities meet with more success if they are integrated into the course rather than remaining an appendage (Bailey & Cotlar, 1994; Bork, 1993; Romiszowski & de Haas, 1989). The same principle applies to learning activities designed to promote cross-cultural collaboration. Group work, for example, could be carried out in a cross-cultural computer mediated environment provided that its purpose is useful and relevant to the students' learning of course content. To ensure that the learning activity is consistent with, and applicable to, other elements in the course, design issues relating to the planning and coordinating of both its online and off-line components should be addressed. It is crucial that students have activity-related off-line work to engage in while they wait for responses or when technical difficulties interrupt communication.

**Implementing Computer Mediated Cross-cultural Learning Activities**

The point of incorporating CMC activities into the curriculum is to present students with unique learning experiences to which they wouldn’t normally be exposed (Dyrti & Kinnaman, 1996b). Stretching a computer mediated learning environment over international borders, for example, provides students with the opportunity to learn with and from students of different cultures. Recent
work by Dyrli and Kinnaman (1996b) confirm that learning activities that require collaboration among students in different countries are among the richest offerings an instructor can present to his/her students. Such activities are often organized around analyses and discussions of “real-world” problems or issues (McMahen & Dawson, 1995) that are relevant and important to culturally diverse groups of students. Trying to resolve the issues, or at least coming to an agreement about possible solutions to the problems, not only increases students’ knowledge of the content area but heightens their cultural awareness.

The first step in implementing any kind of computer mediated cross-cultural learning environment is to connect with instructors teaching a similar course in another country (i.e., similar content and objectives). A comparative education course, for example, would be well suited to a cross-cultural exchange of ideas because its course objectives are to contrast educational systems and practices in Western nations with developing nations. Other content area suited to cross-cultural discussion include, but are not limited to, international business, education studies, educational technology, teacher training, sociology, environmental studies, science and engineering. Once contact has been made, the collaborating instructors can begin to plan and design their learning environments and activities.

While computer mediated cross-cultural learning environments may vary according to content area and learning objectives, Dyrli and Kinnaman (1996b) point out that some fundamental elements of incorporating this type of application into the curriculum transcend all subject matter. A list of criteria for implementing successful computer mediated cross-cultural learning activities is presented below.

- The activity must be relevant to the course and integrated into the curriculum goals.
- The activity’s learning objectives must be clearly stated so that instructors and teachers from all cultural backgrounds understand its purpose.
- The activity should be important and relevant to culturally diverse groups of students in order to sustain learner interest, motivation and participation.
- The activity must include some aspect of work or learning that could not be accomplished without cross-cultural computer mediation. Student interest in, and commitment to, the virtual learning environment may diminish if they perceive that the learning activities could be done just as easily, if not better, outside of the international forum. It is crucial that the cross-cultural activity contain a unique element or dimension that otherwise would not be present.

- The activity should have a clear and definite timeframe. Students aware of the time-frame within which they are working may be more inclined to adopt proactive writing habits so that the virtual learning environment isn’t deteriorated by prolonged inactivity.
- The activity should begin as simply and uncluttered as possible. Overly complex activities may lead to information overload resulting in frustration, loss of interest and inactivity.
- The activity should be preceded with greetings and introductions. Students should be given the opportunity to “meet” online before engaging in the structured learning activity.
- The activity should encourage information sharing and knowledge building. One of the greatest potentials of a computer mediated cross-cultural exchange is to overcome the barriers that restrict the flow of ideas and the sharing of knowledge.
- The activity should not compromise the learning quality. Although it may provide new and innovative learning opportunities, the academic standards and levels of achievement must not be compromised.

Grading should take both online and off-line CMC efforts into account. Not to recognize and evaluate both types of work would be to ignore the vital impact that the CMC learning activity has within the classroom.

Types of computer mediated cross-cultural learning activities include, but are not limited to, debates; collaborative writing projects; concept mapping; posting summaries of readings; group discussions; question & answer forums; building shared databases and inter-bibliographies. With respect to learning tasks, online activities range from low-level cognitive tasks, such as brainstorming and idea generation (Hollingshead & McGrath, 1994), planning, collecting, organizing, and pooling information for a common purpose (Dyrli & Kinnaman, 1996b), to high-level cognitive tasks which include problem solving and conflict resolution (Hollingshead & McGrath, 1994). Regardless of the cognitive level of the learning tasks, they should always be relevant to curriculum goals and appropriate for the specific cultural groups of students to whom they are being assigned.

**Conclusion**

In this era of effective and reliable electronic means of communication, planned or intentional learning activities should no longer be confined to the classroom. Students’ learning environments are expanding beyond physical and cultural borders and faculty must acquire the competencies required to help students take advantage of the new and challenging learning opportunities with which they are being presented. As is suggested in this paper, computer mediated exchanges between students of different cultures...
is an innovative and purposeful way to make use of the technological and social resources readily available in the university milieu.

Acknowledgments

Using Multimedia/Hypermedia Projects to Integrate Global Themes in a Teacher Education Technology Course

Deborah J. Pulliam
Missouri Southern State College

Recognizing the need for a college education with a strong global perspective, Missouri Southern State College recently enhanced its educational mission to expand an existing international emphasis. The institution supports activities it deems necessary and appropriate to establish international or global education as a distinctive theme of its mission. One such activity is curriculum revision to include a global perspective in every possible course. For example, the fall 1997 semester has been designated as the "China Semester". The spring 1997 semester saw numerous speakers, activities and events offered to faculty and students in preparation for the "China Semester". Faculty were encouraged, but not required to integrate this theme into activities for the semester.

Teacher Education Technology Course

All elementary and secondary teacher education majors are required to take a technology course offered within the Teacher Education Department. This course includes such topics as: the changing role of the teacher; activity-based approaches to learning; cognitive learning and technology tools; instructional software; constructivism and project-based learning; using tool applications; multimedia/hypermedia applications; creating multimedia projects; working with images and sound; and principles of hypermedia design. One of the projects required of students completing this course is the creation of a collaborative hypermedia/multimedia project. This project must be thematic in nature and give evidence of mastery of certain technical skills including image scanning, video capture and editing, audio capture and CD-ROM mastering. Completed projects are then converted to Web pages and published on the college's internal home page.

Integration of Global Theme

Integrating the China theme with the required multimedia projects, Education 301 students (teacher candidates) enrolled in the fall 1997 semester created products to be used in multidisciplinary thematic units with students at the K-12 level. Teacher candidates were assigned to groups of like-teaching levels to complete the projects. For example, early childhood teacher candidates worked together to design and create multimedia projects to be integrated into a China or global thematic unit. Likewise, secondary education majors from a variety of disciplines collaborated in creating a similar project. To meet the course requirements for the project, it had to be interactive and student-controlled by design.

Design Process

Students brainstormed in their assigned groups to choose a theme related to China to develop for the multimedia project. After this initial decision was made, many groups used webbing or similar techniques to select clusters of ideas to use as topics within the theme. Content to support each cluster, as well as resources for this information was then selected. For outside resources, permission for use requests were written. Students were also locating sources for proper citing of these references. At this point, most groups decided to assign topics to each group member for research extending beyond class time. In-class time was primarily utilized developing a storyboard for the project, creating a color scheme, and then subsequently creating slides complete with hyperlinks to serve as the backbone for the project. Once this was accomplished, students began entering text on slides, leaving placeholders for future insertion of images, video and audio clips. Classroom demonstrations and practice sessions were given for students to master recording and storing audio clips from microphone and CD. The more complex process of video capture techniques occupied much more time. Students worked with the instructor in small groups to accomplish this task. Throughout these stages of development, on-going editing occurred and revisions were being made. Students discovered that initial topics were too broad or too narrow in scope to develop properly in a multimedia format. When the initial topic...
had been too narrowly defined, students were required to
develop additional supporting nodes to develop in their
Storyboard. In the case of topics being too broad, the
groups would simply leave some nodes for future develop-
ment or projects and focus on limited clusters or nodes for
the immediate project development.

**Hardware and Software for Project**

Class size for this course is limited to sixteen students
due to the number of computers in the Education technol-
yogy labs. At the time this project was first implemented,
there were two labs available to students in the Education
building and numerous labs across campus. The labs were
equipped with twenty-three Windows-95 based, networked
computers with Internet access. Eight of these were
multimedia equipped; all had hard drives. In addition,
there was one mobile multimedia system equipped with a
video capture card, ZIP drive, and CD-R drive. Two of the
systems in labs had flatbed, color scanners, and three
had ZIP drives.

Initial plans were to utilize Astound multimedia
authoring software. Due to the time pressures inherent in
such a technology course, Microsoft PowerPoint 97 was
selected for use since students utilized it earlier in the
semester to create an electronic slide show. This version of
PowerPoint had incorporated hyperlink features not found
in previous versions, which allowed a non-linear product to
be created. One of the drawbacks of using this software
included the absence of a tool to create scrollable text
boxes, such as those found in Astound. In future semesters,
Astound software will probably be used for just that reason.
This will require streamlining the course in other areas to
free-up additional time resources to learn another software
program. At the time, the reduced learning curve of using
PowerPoint offered too great an advantage to ignore.

Projects were stored on the hard drives of the net-
worked workstations, with backup copies stored on the
server hard drive. Zip drives were used for transporting
video clips from the machine with the video capture card
to individual workstations and also, for carrying the
finished project to the computer housing the CD-R drive
for final storage on a CD. Students designed their own CD
labels for each finished product.

**Project Assessment**

Two instruments were used for assessment of the final
project. An assessment rubric was created for evaluating
the quality of the student project. Because this was a group
project, there had to be some means of determining the
extent of involvement, participation and contribution of
individual group members. For that aspect of evaluation,
each group member completed a peer evaluation form to
assess the individual group member’s performance as part
of the team. This factor was then applied to the overall
evaluation derived from the rubric to attain a final indi-
vidual grade for each student. In addition, many of the
skills utilized in creating this project were assessed
individually in a hands-on skill test administered during
the final exam session.

**Problems Encountered and Future
Considerations**

Limited access to specialized equipment such as
scanners, video capture cards, sound cards and micro-
phones restricted the level of development reflected in the
student projects. Eight multimedia systems equipped with
internal Zip drives, an additional CD-R drive and video
capture card were planned for expansion at the time of this
writing. The course will be modified to allow students to
acquire enabling multimedia related skills earlier in the
semester.

E-mail: pulliam-d@mail.mssc.edu
In our attempts to include technology in mathematics teacher education there are several concerns which must be addressed: What needs to take place and why?; How can set up an infrastructure supporting the change?; and, What would programs implementing such changes look like? In addition to describing some fascinating programs and approaches, the papers in this year's mathematics section can be loosely categorized as falling into these three areas. Although we recognize that there are many other themes present in the papers presented before you, we hope that you will find this loose organization and these themes helpful in your reading and analysis.

**What needs to take place and why?**

In addressing this first question, it is helpful to begin by examining current thinking in the mathematics reform movement for guidance. Naturally there are many aspects of the mathematics reform effort, and not all of them lend themselves to immediate support by technology. This is to be expected, and we should not fall into the trap of forcing an answer on an unasked question. I am sure we have all heard that when you only have a hammer, the entire world looks like a nail.

Mathematics education, however, has many areas which are supported by technology and the reforms suggested are no exception. Two current foci of the reform effort come forward which could both be highly supported by technology: the increasing importance of “Function” as a unifying concept, and the ongoing inclusion of Algebra and algebraic thinking throughout the entire K-12 curriculum.

Function is rapidly becoming one of the organizing concepts within mathematics education. The day is long past when mere mathematical computation is adequate. We do not need students who can follow functions, we need students who can create new functions which adequately represent the mathematical situation of hand. In addition to it's mathematical power, the notion of function is uniquely suited for teaching and learning with technology. With algebra assuming a greater importance over time, and technology taking over more and more mundane number crunching details of mathematics, it is perhaps this area - the creation and editing of functions to fit problem situations, where students have their greatest opportunity to experience what it is to think mathematically.

In Pullano's paper and associated website we see a marvelous response to this identified need. As research has documented numerous learning difficulties associated with acquiring functional concepts, this paper presents and discusses some of these - including several studies where technology was used to enhance the mathematics classrooms. The WebSite, designed by the author, is valuable if or no other purpose than serving as a reference for the field. You will want to bookmark this location at your earliest opportunity.

In dealing with the importance of function within the mathematics community Telese describes a staff development program for middle and high school teachers. This program was designed to improve teachers understanding of mathematics and foster specific techniques for improving mathematics performance. Within his project we see the development of powerful representations for functions using symbolic and graphical representation. The use of information technology within this approach is quite natural, with graphing technology used to enhance students understandings of the function concept. As we later shift to thinking about methods and policies it will do us well to remember his approach. The technology is transparent and does not drive the program, rather, it serves as a natural tool and enhancement for the teachers and students to use - or not use - as appropriate.

The theme of utilizing technology to promote functional development and algebraic awareness is further developed in the paper by Abramovich and Brantlinger. As they point out, the nature of the tools which one has to think with influences those questions which one may think about.
Taking this as a starting point they suggest ideas using spreadsheet based toolkit and provide concrete examples in exploring infinite processes through simple alter great word problems. By taking example problems firmly rooted within the NCTM standards they argue, quite successfully, that the spreadsheet can help teachers enable students to make connections between their ideas in their representations. In particular, the multiple representations presented in the spreadsheet enable changes in student viewpoint and thinking about the problem. In this work the spreadsheet becomes a true cognitive tool enhancing the students abilities to think, represent the problem in new and novel ways, and create new representations for further use.

Technology as a means of thinking about algebraic concepts also form the framework of Zehavi's paper. As this paper correctly notes, despite the growing power of symbolic and numeric calculations enabled by the computer, many secondary teachers remain unaware of the degree to which such systems can be effective in teaching algebra. Software has long since evolved to the point where what is technically feasible is ahead of what is currently being done in the mathematics classroom. This paper reports efforts of a professional development course designed to help teachers use powerful new programs in algebra. The teachers quickly assumed ownership of the program and began using it is a natural extension of their own thinking style. In the examples, there are some classical problems used to show how teachers were thinking about their technology, the mathematics, and degree to which tools work together well.

Lee and St. John's paper provides some quantitative backing to Zehavi's position regarding the relatively low level of use of technology in secondary mathematics. Their study presents results from a survey of 800 secondary mathematics chairs who were questioned regarding their use of computing technology in mathematics instruction - particularly in the areas of probability and statistics. In addition to pointing to the perennial need for additional hardware and software, this study clearly shows that we need to make great strides in improving our integration between technology and the teaching courses themselves. They also note that if one expands the definition of instructional technology to include graphing calculators the usage picture becomes much brighter. This is an exciting as well as daunting prospect, for as the current proliferation of palmtop computers shows, we are in a situation where the gap between the computer and calculator is narrowing on a daily basis. We will soon no longer be able to rest upon the excuses we do not have the equipment, but instead must deal with doing a better job in preparing our future teacher educators.

Lest one get the idea that technology is only suited for the secondary level, we see described in Spikell, Behrouz, Bannan-Ritland, and Egerton's paper a truly marvelous website geared for the 4th through the 8th grades which presents a set of virtual manipulatives for student use. The authentic tasks which are presented here take advantage of traditional math manipulatives and are presented in realistic situations. Students are able to draw upon these resources in combinations and fashions which would not be possible within their classroom using traditional manipulatives.

How can set up an infrastructure supporting the change?

Whenever change is made there needs to be changes in the support systems if that change is to be maintained. Sometimes this involves policy considerations, changes in resources, and careful analysis of the desired directions and outcomes of a program. The papers within this subsection address these and more.

We choose to begin this section with Garofalo, Shockey, and Drier's guidelines for developing mathematical activities incorporating technology. This paper provides some common sense, timely, and easy to follow guidelines which are a must read for the technology using mathematics educator. These guidelines have both policy and instructional implications. They should certainly be taken into account when planning beginning efforts in introducing technology into the mathematics classroom and in evaluating existing programs.

Continuing with this evaluative emphasis, Coe's paper gives us a set of workable screens through which to examine mathematics education websites. Her key questions of accessibility, accuracy, authority, content, etc., should be addressed in any well-designed WebSite. This paper provides valuable insight in terms of some worthwhile and global investigations and evaluations of existing WebSite's and presents a very manageable approach. As this paper appears to have been designed as a companion to her presentation it would be well worthwhile to attend this session if at all possible.

Of course, bringing new methods requires new approaches - and these should be carefully studied from both policy and logistical perspectives. In Miles-Grant's paper we see a careful and thoughtful analysis of a three-year intervention including summer workshops, follow-up classroom visits and consultations, focus group meetings, consultation, and email together with professionals from a variety of levels. In addition to its rich descriptions, another finding which this paper serves to illustrate is the power of the data to function approach. If we're to be effective in mathematics is developing function as a primary concept, as we suggest in the earlier subsection, a source of data from which functions are to be created is of crucial importance. As this paper serves to illustrate when teachers are presented with real data, the solutions are not only more personally meaningful but the functions which are derived from his data are more mathematically relevant as well as
powerful. A careful review of this paper would be beneficial for any planning similar multi-year projects.

In thinking about setting up support systems it is highly important not to leave out the needs of the individual. In Charles’ paper we see a qualitative case study examining how one teacher used the interactive development program, “Understanding Teaching”, to learn and apply the professional standards for teaching mathematics. Results from this study indicate that she improved her ability to correctly identifying strands from the NCTM Standards and was successful in incorporating new questioning strategies into her practice. This case study shows how one can become a better mathematics teacher in light of the NCTM standards. Charles notes that “Understanding Teaching” has been the subject of several previous studies indicating its effectiveness. We recommend a careful reading of this paper for those unfamiliar with the program.

In the last paper within this subsection, Davis provides us with a model for addressing teacher change which is worthy of reflection and possible use in planning research, policy, and implementation. Although one may disagree with certain features of this model it does lend itself towards the creation of testable experimental hypotheses, which can serve as the foundation for further research. For example, just because we describe in policy papers the need to better integrate technology into mathematics classrooms, that alone is guarantee that this will occur. This certainly plays often mathematics education. Despite problem sea of large numbers of policy documents requesting technology to be used as a tool in the mathematics classroom, we still see a predominant use of drill and practice technology. The research presented in this paper is a case study focusing upon the experience of one teacher using technology in mathematics instruction.

What would programs implementing such changes look like?

In actual implementation we find that there are many different features of the suggested and supported change which can be implemented. As each institution will bring their own spin to this, it is interesting to see the unique features of each of the programs described within this subsection. As might be expected, many of these approaches are still “under construction”, different, and exciting.

We will begin with Bruillard and Baron’s case study describing a novel treatment of video clips wherein the teacher candidate created the material for study. Starting with over 2 1/2 hours of classroom instruction which had been digitized into QuickTime format over 100 short fragments between 10 and 25 seconds each were identified, typed, and indexed. These video fragments were then used by preservice teachers as a part of their teacher training. This exercise helped the teacher candidates in identifying the logic behind teacher actions and to further develop their skills using image processing software.

In what the authors identify as a “lets have our cake and eat it too” mode we will next look at Connell, Kemper, White, and Williams discussions of their attempts to integrate technology, methods content, and field basing. This paper describes a transdisciplinary course within which the mathematics, social studies, science, and language arts areas were taught in a field based collaborative fashion. From this work several suggestions may be made for others. Start with people you like, and try to find some unifying philosophical themes around which you have agreement. Once this is done, technology can provide a set of transdisciplinary “soft” tools supporting the transdisciplinary methods being developed.

The final paper in this subsection provides a powerful policy analysis of the curriculum in England and Wales as well as a thorough description of one institutions responses to the changes in policy. Miller and Denning begin by providing a historical background concerning the state of mathematics and technology within England in Wales which is a must read for those unfamiliar with this system. The described Keele University’s model for the use of instructional technology in math education grew out of a four-year series of efforts. It includes several novel features such as integration of notebook computers, a broad variety of Web based resources, and calculators.

Concluding Thoughts

And what if you are satisfied with the status quo? Then write about it and share it with SITE next year! We look forward to seeing you at the conference and in further discussing these, and other themes, with you.
One of the most important, if not the most important, unifying ideas throughout all areas of mathematics is that of functions (Dreyfus & Eisenberg, 1983; Eisenberg, 1991). From the day elementary students begin constructing algorithms for addition and subtraction, through graduate level mathematics courses, function ideas saturate the curriculum. Functions have “become one of the fundamental ideas of modern mathematics, permeating virtually all the areas of the subject. Yet...it proves to be one of the most difficult concepts to master” (Eisenberg, 1991, p. 140).

The importance of function within mathematics curricula has been echoed in recent reform documents. For grades 9-12, the Curriculum and Evaluation Standards for School Mathematics (National Council of Teachers of Mathematics [NCTM], 1989) Standard 6: Functions states:

In grades 9-12, the mathematics curriculum should include the continued study of functions so that all students can:
- model real-world phenomena with a variety of functions;
- represent and analyze relationships using tables, verbal rule, equations and graphs;
- translate among tabular, symbolic, and graphical representations of functions;
- recognize that a variety of problem situations can be modeled by the same type of function;
- analyze the effects of parameter changes on the graphs of functions; and so that, in addition, college-intending students can-
- understand operations on, and the general properties and behaviors of, classes of functions (p.154).

In addition, Standard 8: Patterns and Functions for Grades 5-8 contains the following:

In grades 5-8, the mathematics curriculum should include exploration of patterns and functions so that students can
- describe, extend, analyze, and create a wide variety of patterns;
- describe and represent relationships with tables, graphs, and rules;
- analyze functional relationships to explain how a change in one quantity results in a change in another;
- use patterns and functions to represent and solve problems (p.98).

Finally, the Standards call for a movement away from rote “memorization of isolated facts and procedures and by proficiency with pencil and paper skills” to the emphasis of “conceptual understandings, multiple representations and connections, mathematical modeling and mathematical problem solving.” To make this possible, one underlying assumption made by NCTM for grades 9-12 is that all students will have access to graphing calculators (p. 124).

On the whole, the Standards advocate the use of multiple representations when exploring functions, connections to meaningful problem situations, understanding relationships among classes and families of functions, the incorporation of graphing technology into the mathematics classroom, as well as emphasizing the role of variable within functions. These goals evolved directly from the existing body of research on the teaching and learning of functions.

The remainder of this paper is divided into three sections. In the first section, several of these difficulties as reported in the literature will be explained. The second section will focus on literature reporting on the use of graphing utilities when teaching function concepts. The third section contains a description of a website developed by this author consisting of a reference list of function literature, synopses of this literature, and classroom activities based on the research findings.

Functions and Associated Learning Difficulties

There exists a vast body of research which examines difficulties students have when learning and working with functional concepts. Such difficulties include an inability to correctly interpret graphical representations of data (Monk, 1992), compartmentalization (Vinner & Dreyfus, 1989) a reluctance to use visualization and visual techniques to solve problems (Eisenberg & Dreyfus, 1991), the inability to make connections among the multiple representations of functions (Movshovitz-Hadar, 1993), conflicts between the formal concept definition of function and students’ concept image of function (Vinner, 1992) and scaling, notational, and representational difficulties (Goldenberg, 1988).
Difficulties students have interpreting graphs displaying either qualitative or quantitative data are numerous. One manifestation of such difficulties has come to be known as iconic translation. Iconic translation can be thought of as the literal interpretation of information represented graphically. For example, a student might interpret the distance vs. time graph for a cyclist shown below as the cyclist riding uphill.

![Distance vs. Time Graph for a Cyclist](image)

Compartmentalization is the inability to apply knowledge acquired in a prior context to a new context. Often, a student is unaware that s/he possesses knowledge which would be relevant to the current context. This may lead to inefficient problem solving behavior or worse, total failure. Vinner & Dreyfus (1989), examined compartmentalization by compiling all cases in which students gave the Dirichlet-Bourbaki definition for function but failed to use that definition when answering the researchers questions. The researchers found students enrolled in higher level mathematics courses exhibited fewer instances of compartmentalization quite possibly because they were more aware of their thought processes.

Eisenberg & Dreyfus (1991) discussed several reasons why students avoid the use of visualization when completing mathematical tasks. These included commonly held beliefs that mathematics is inherently nonvisual (proofs without words are generally not accepted as true proofs), a sociologically based rational called didactical transposition (school mathematics is severely linearized, compartmentalized, and algorithmized and hence is more efficiently presented to students in a nonvisual manner), and that cognitively, visual arguments can be more difficult to understand requiring skills which are underdeveloped in most students.

There exists a general consensus among mathematics educators and researchers that many students fail to build conceptual bridges among multiple representations of functions. The failure of students to understand that the roots of a quadratic function found algebraically are represented graphically by the x-intercepts of a parabola is one such example. It is important that students understand how different presentations of a function stress and reveal different aspects of the function while fostering connections among representations.

Frequently, students are unable to connect their personal concept images of function to the textbook definition of function. When facing problem situations, students often make use of their concept image of function while ignoring the concept definition. Concept images are constructed as a result of everyday experiences and include examples, non-examples, theorems, and all the facts they know about the particular concept, in this case functions. Many times, concept images and concept definitions differ greatly. This disparity may result in a student’s concept image distorting his/her concept definition (Vinner, 1992).

The reasons for the difficulties listed above are myriad. Perhaps the most compelling of these is the traditional point of entry used to introduce functions. Traditional instruction of functions begins with the presentation of a textbook definition of function such as “a function is a relation that assigns to each element of a set X exactly one element of set Y” (Lial, Miller, & Schneider, 1990). Such a definition is structural in nature referring to sets and elements of these sets as objects.

A second method for explaining the concept of function is the use of a diagrams similar to the one below.

![Function defined as a Mapping](image)
the exploration of real world functions, and it shifts the focus away from understanding and interpretation to graph construction - a task easily handled by graphing calculators. This method may also encourage the development of misconceptions such as students coming to view graphs of functions as a set of discrete points and not as continuous entities (Kerslake, 1981).

Research Findings

Processes and patterns make up the operational aspects of functional conceptions and must be investigated before the learner can move to the more abstract notions of functions as objects. Technologies of today, such as graphing calculators and micro-computers, make investigations of this sort readily accessible to students and teachers alike.

Ayers, Davis, Dubinsky, & Lewin (1988) incorporated instructional interventions consisting of both directed and nondirected instructional experiences using a modified Unix operating system. Posttest results suggested that students exposed to these types of interventions were better able to construct the concepts of function and composition through reflective abstraction. Student responses to specific posttest questions led the researchers to conclude that experimental groups were “better at interiorizing the processes of functions and forming mental representations,” “more likely to encapsulate a function as a cognitive object,” and more able to generalize “the concept of function beyond algebraic formulas” (p. 257).

Ruthven (1990) reported on the performance of upper secondary school students tested on symbolization items and interpretation items. Test results of students using graphing calculators regularly were compared to results of students who did not have regular access to such technology. This comparison suggested that regular use of graphing calculators fostered more frequent uses of graphical approaches to problem solving.

Mokros & Tinker (1987) observed groups of students using Microcomputer-Based Labs (MBL) with motion detectors. A posttest was also administered. The observations focused on how students developed graphing skills through the use of such equipment. Posttest scores indicated significant changes in students’ ability to correctly interpret and use graphs. For example, instances of iconic translation occurred substantially less frequently. MBL use of multiple modalities, their ability to produce real time graphs, and the ability to incorporate meaningful scientific experiments into the mathematics curriculum made them powerful teaching tools. Furthermore, MBL eliminate the need for labor intensive graph production freeing time for more “what if” and “why” explorations.

Yerushalmy (1991) examined how a multi-representation computer environment effected students’ conception of when being introduced to algebraic functions for the first time. The software Function ANALYZER was the main tool used in this study. The students in this study spent less time on traditional graphing drill and practice experiences and more time observing the multiple representations of functions. Results showed however, that these students did not lack the skills need to solve traditional graphing problems. In fact, students were frequently more capable of matching a linear graph with its equation regardless of the imposition of scales on the graphs designed to mislead. These results support “the use of new learning environments as teaching aids for the changing of priorities in the learning and teaching of algebra, as well as the revision of the traditional curriculum so that more emphasis would be placed on the inquiry into functions within linked multiple representations environments” (p. 55).

The Website

The above pages include many references to literature in the area of the teaching and learning of functions. In an effort to provide educators with an easily accessible and somewhat comprehensive listing of this literature, this author has created The Teaching and Learning of Functions: A Collection of Research Findings and Classroom Activities website. The website can be found at http://curry.edschool.virginia.edu/~fbp2r/function.

This website is comprised of two main sections. The first section contains a listing of almost eighty references of function literature in APA form. Visitors may choose to view the references in one of three ways - alphabetized as an entire list, alphabetized by author’s last name, or alphabetized by one of five categories. The categories include Literature Presenting Analyses of Understanding of Functional Concepts, Studies on the Understanding of Functional Concepts, Literature Supporting the Use of Technology, Studies Incorporating the Use of Technology, and Reviews of Function Literature. Each reference listed is linked to a synopsis of that reference.

The second section contains several function related activities which teachers may use in their classrooms. Some of these activities have been adapted from the literature on functions while others are original works developed by this author. All of the activities are designed to address the learning difficulties discussed in this paper. Some of the activities suggest alternative methods to the introduction of functional concepts. Others explore functional concepts within meaningful contexts including business applications and projectile motion. All of the activities incorporate the use of graphing calculators although other graphing utilities may be used. It is hoped that students, as well as teachers, will enjoy these activities and develop a more complete concept of function given the opportunity to work through them.

566 — Technology and Teacher Education Annual — 1998
Summary

Leinhardt, Zaslavsky, & Stein (1990) point out that functions and graphs represent "one of the earliest points in mathematics at which a student uses one symbolic system to expand and understand another (e.g., algebraic functions and their graphs, data patterns and their graphs, etc.)" (p.2). The authors also believe that graphing is a critical moment in early mathematics, i.e. it is a site "within a discipline when the opportunity for powerful learning - different in kind from other episodes - may take place" (p. 2). A clear understanding of functional concepts provides a gateway for students to study higher level mathematics. It is imperative that mathematics educators realize this importance by incorporating sound instructional practices which make use of available technologies into their teaching methods.

Learning of Function Concepts through Graphing Technology and Problem-based Learning

James A. Telese
University of Texas, Brownsville

Algebraic knowledge is considered a requirement for a new literacy. The point is made by Schoenfeld (1995) who stated: With too few exceptions, students who do not study algebra are therefore relegated to menial jobs and are unable often to undertake training programs for jobs in which they might be interested. They are sorted out of the opportunities to be productive citizens in our society (p. 11-12). Moreover, algebra is a mathematics class that has been described as the "new civil right" (Moses, 1995). The view of algebraic knowledge as a "civil right" implies that this knowledge should be made accessible to all students. Algebra I is the first non arithmetic class encountered by both high school and some middle school students. If students are not successful at this stage, then students may not be able to take advantage of this "new civil right." Now that algebraic knowledge is considered a contributing factor toward success in life by the mathematics education community, it becomes necessary to provide learning opportunities that have the best chance to engage students' interests while improving their understanding of algebraic concepts.

The purposes of this paper is to report on a staff development program for middle and high school teachers, and to introduce a process model used for mathematical modeling. The goals of the program is two-fold: i) to improve the teachers' understanding of mathematics, and ii) foster the development of techniques for improving the mathematics performance of culturally diverse students.

Theoretical Background

According to Schwartz (1992), the content of secondary school mathematics should be "made coherent and pedagogically workable" (p. 303). The coherence of algebra curriculum can be achieved through a central concept, such as functions which has been considered a unifying topic in both algebra and other secondary school mathematics courses. Mathematics educators (e.g., Bednarz, Kieran, & Lee, 1996; Romberg, Fennema, & Carpenter, 1993) have issued a call to center algebraic teaching around both problem solving and the function concept. Algebra can be made "pedagogically workable" through appropriate use of problem solving activities designed to enhance students' understanding of concepts related to functions, such as variables, linear and quadratic equations. The algebra curriculum centered around functions and problem solving offers students an opportunity to take advantage of their "new civil right."

The notion of function should be expanded from its view of an abstract object to an understanding that functions describe real-world phenomena. Families of functions, such as linear, exponential, and rational, are reasonable models to study because their properties relate to real world situations. The various types of functions may be studied through the analysis of the meaning for various rates of change, zeroes, maximum and minimum values within contextual settings (Heid, 1996). With an understanding of the various families of function, coupled with real world phenomena, connections are established, and students begin to see mathematical models as pictorial representations that have meaning.

Mathematical modeling is a description of the relationship between dependent quantities. The process employs two powerful representations of functions, symbolic and graphical (Schwartz, 1992). The use of graphing technology provides both symbolic and graphical representations of functions. The use of graphing technology enhances students' understanding of the function concept. For example, Heid (1996), used a function grapher and found that when students experience a curriculum centered around applications, their ability to problem solve increases or out performs those of students in conventional algebra classes. Hence, the combination of mathematical modeling and graphing technology offers an outstanding opportunity for teachers to present the function concept in a meaningful manner.

Teachers are often under pressure to teach toward particular goals and outcomes, especially a curriculum driven by high stakes testing, which produces an intended curriculum (Telese, in press). The process of modeling is not necessarily seen as a teaching strategy suitable for obtaining high scores on standardized test. A “survival
trait" for teachers who do not view the advantages of algebraic problem solving is to continue teaching with the textbook and worksheets in preparation for the testing.

An answer to this dilemma is to provide professional development opportunities to facilitate changes in the teacher's curriculum. The intended curriculum is one aspect that influences mathematics teachers' actions. Three other factors are: i) teacher cognition's (Putnam, Heaton, Prawat, & Remillard, 1992), ii) previous experiences of the teacher which includes pedagogical and subject training(Pearce & Loyd, 1987), and iv) characteristics of the teacher's environment (Haimes, 1996). A study conducted by Telesse (1996) found that the majority of a high school's Algebra I teachers rarely related the function concept to real life applications and there was a heavy reliance on textbooks and worksheets. This may indicate that the teachers lack a thorough knowledge of functions to fully integrate them into applicable situations or do not have the ability to "see" mathematics in real world events. Haimes (1996) observed that an experienced teacher with a Bachelor's of Science degree in mathematics used a procedural orientation to the teaching of linear functions, although the teacher had a strong background in mathematics she failed to, for example, to place emphasis on the link between functions and equations. Although content knowledge is an important feature of a teacher's background, beliefs about algebra and its teaching provide a powerful influence on a teacher's actions. Through the use of real world problem solving situations, the role of the teacher will change to that of a facilitator, and the teachers will be assisted in the metamorphic process from classroom dispenser of information to a facilitator of information.

Hence, teaching algebra in a unifying manner requires a change in pedagogy. A shift should occur in pedagogical strategies from traditional methods of algebra teaching where, for example, students complete volumes of worksheets to a strategy where students are actively involved in constructing and applying mathematics, with problem solving as a means as well as a goal of instruction. The shift should make available tools, such as graphing calculators and computers, for both learning and doing mathematics in a variety of instructional settings (Heid, 1996). For the shift to be effective, algebra teachers must change their view of the subject and present the content in a meaningful manner.

**Project Description**

Project GATEway, Graphing, Algebra, Technology, and Excellence, is designed to indoctrinate middle and high school teachers into situated problem-based learning techniques for algebra classes. The use of technological tools in the algebra classroom is infused with the integrated mathematics and science content. The function concept is presented as a unifying theme in high school mathematics courses. Real world problems, related to the local area, are identified as a focal point for the application of function knowledge in a context. Two major goals of the program are: i) to strengthen teachers' knowledge of mathematics, and ii) to foster the development of strategies for improving the mathematics performance of culturally diverse students.

Teachers experience first hand the process of situational, problem-based learning, which has an underlying foundation taken from both constructivist and problem-based learning theories (e.g., Brooks, & Dunn, 1993; Fosnot, 1996; Savery & Duffy, 1995). A problem stems from the observation of daily phenomenon. Successful problem solving involves the use of a repertoire of tools and knowledge, i.e., procedural and conceptual understanding (Heibert, 1988; Schoenfeld, 1992). When a situation has personal relevance, there is a greater opportunity for learning to occur. With enhanced observational and analytical abilities, a change in one's perceptual field may occur, leading to other insightful observations, the recognition of a problem and its solutions. Through this experience, teachers returned to the classroom armed with content knowledge related to functions and its application to real life phenomenon.

**Pedagogical Model**

This process represents an individual experience as one begins to see mathematics in our surrounding world. Depending on the individual, there may be more than one starting point. A good starting point is through observation led by a scientific hypothesis, or insightful ideas. The central feature of the model is reflection, which is integral to the other six components. Reflection or metacognitive awareness is the key that begins to unlock and improve perceptual ability, recognize a problem, and to understand the type of knowledge, and tools needed to arrive at a solution. The boundaries between the phases are not static but rather have a dynamic nature. In that, each phase incorporates features of its adjacent phase.

The observation and evaluation of daily phenomenon leads to the change in one's perceptual field. In other words, a change occurs that modifies how a person views
their world. Mathematics can be seen in many situations, but remains unnoticed unless one comes to recognize the mathematics in real-world events and systems. Situations are then developed using everyday language. The translation of the situation into mathematical language includes the use of mathematical symbols and expressions. During this phase, situational dissonance can occur when an individual’s background knowledge does not fully meet with an aspect of the presented information in the problem. A feeling of discomfort develops that interferes with the individual’s perception of the situation and perhaps preventing the individual from fully engaging in the situation.

Once the situation is developed, described in everyday language, and translated into mathematical language, the next phase involves the modeling process. To model the situation, the use of various mathematical tools, such as graphs or tables, equations, graphing calculators, and mathematical knowledge—both procedural and conceptual knowledge—are necessary ingredients. Parenthetically, an interaction occurs between the modeling phase and the translation phase because the everyday language translation process into mathematical language also requires both procedural and conceptual knowledge.

The next phase is to develop the mathematical model. As a mathematical tool, algorithmic processes, and other tools, are used at this stage for the creation of the model, leading to mathematical solutions. Note, that algorithms are also used in the prior stage of choosing a model. Since mathematical modeling is a type of problem solving, the use of algorithms, and aspects of mathematical knowledge are necessary to develop a model and seek solutions.

Now that the model has been created, conclusions are made based on the model. This is the stage where the mathematical solutions are interpreted and compared to real-world events. The conclusions are tested and evaluated against the real world in order to determine to what degree the model reflects the actual event, or its usefulness. The model may have to be revisited if it shows that it does an inadequate job of predicting. On many occasions, it may be shown that real world phenomena are too complicated and decisions must be made as to what aspects can be ignored to make the problem simpler. Real world solutions then develop as a result of applying the model.

**Example Situation—Resaca Rangers**

The workshop begins with setting the stage for establishing a community of researchers. Participants enter the room while theme music is played. A skit is performed to engage the participants with the situation. They are presented with a series of reports from a hypothetical research organization and are challenged to seek solutions to the presented environmental problems, in this case, the health of resacas. The purpose of the skit to help facilitate the perceptual change necessary to begin to see mathematics in daily phenomena.

The teachers are placed into three cooperative groups based on their area of expertise. Each group addresses a different problem, but each group must supply the other groups with necessary information. Upon receiving the situation, the teachers experience a brainstorming session to seek out methods for obtaining solutions and develop hypothesis. The teachers are introduced to algebraic content related to functions and modeling. Various families of functions are presented in a contextualized fashion, such as linear, power, and exponential, in order to discuss discriminatory methods for choosing the most appropriate model to base predictions. Technological tools are used at this point to enter data and produce graphical representations for the data.

The problem situation dealt with the clean-up of the area’s resacas. A resaca is a small body of water, an oxbow, similar to a pond formed by a river. One resaca is nearby one of the teacher’s middle school called, Land O’ Lakes. Data collected from the resaca included air temperature in degrees Celsius, dissolved oxygen in milligrams per liter, water temperature, and pH. Dissolved oxygen plays an important role in the health of a resaca. The teachers decided to investigate and to model the relationship between water temperature and dissolved oxygen.

The data was entered into a TI-82 graphing calculator, but any other software with similar capabilities may be used. Figures 2 and 3 present a scatter plot of the data for two models, linear and exponential. A discussion ensued related to which family of functions would be the best predictive model. The topics include the correlation coefficient, shape of the curve, and practical significance of the model. There are other variables that may enter into the situation, but in order to make the problem simpler, only the water temperature and the amount of dissolved oxygen were considered. A discussion followed the graphing concerning which model is best for use in making predictions. Topics for the discussion included line of best fit, regression, behavior of the model within given parameters, equations of the line, and correlation coefficient. It was decided after the discussion that the exponential model was the best model since the amount of dissolved oxygen could only reach a particular value and then level off.

**Conclusion**

Project GATE(way) emphasized an approach to teaching mathematical concepts through complex and ill-structured problems. Opportunities were provided for the participants to experience authentic activities, similar to those that mathematicians/scientists would engage while seeking solutions to problems. Situational problem-based learning is one avenue that may lead to teachers and students to change their perceptual field, to recognize mathematics in real-life situations. The metacognitive skill
of reflection is essential to view mathematics in daily phenomena and using that knowledge to represent the phenomena while seeking solutions to associated problems. One high school teacher commented that his students cannot see mathematics around them. In order to change their perceptual field, he has to ask questions or relate anecdotes that reveal how mathematics is situated around them. A certified middle school mathematics teacher commented, “I thought you had to be a rocket scientist in order to apply math.” Both teachers and students should come to the realization that their mathematical knowledge is sufficient and can be used to support research efforts.

The final outcome for the program is confident teachers who have trust in the value of teaching in a meaningful manner although it is not exactly the intended curriculum. To succeed in the use of problem-based scenarios, teachers need to feel comfortable with their ability to incorporate meaningful problem solving activities and technology. The middle school teacher, who thought that only a rocket scientist could model real world events mathematically, at the beginning of the program was reluctant to adapt the presented strategies, but now has the confidence to research data sources and identify problems for use in his class. The changes are difficult to make in the beginning, but with more experience, teachers will gain confidence in themselves to design and implement powerful situations centered around students’ interests. The ultimate goal is to foster within students mathematical power, reasoning, and critical thinking skills so that they can take full advantage of their “new civil right.”

572 — Technology and Teacher Education Annual — 1998
One of the central tenets of the current reform movement in mathematics teacher education is that the appropriate use of the tools of technology is integral to teaching and learning mathematics at all grade levels. A major force in this reform, the National Council of Teachers of Mathematics (NCTM), places a high priority on the development and implementation of instructional materials that capitalize on the unique power of these technological tools (National Council of Teachers of Mathematics, 1991). As far as secondary school mathematics is concerned, the NCTM’s Curriculum and Evaluation Standards for School Mathematics (National Council of Teachers of Mathematics, 1989) highlights the importance of introducing students to new concepts, such as infinite processes, through extending their knowledge of the properties of functions and algebraic equations. The Standards, however, do not provide specific suggestions about how to accomplish the desired outcomes using the unique power of computing technology. This suggests that secondary mathematics teacher education courses should foster the ability of prospective teachers to design technology-integrated lessons that focus on the development of new modes of thinking through exploring familiar concepts.

In spite of the NCTM’s emphasis on technology, a recent report by a task force of the National Council for Accreditation of Teacher Education warns that new teacher education graduates are not prepared to use technology to the fullest extent possible in the classroom (National Council for Accreditation of Teacher Education, 1997). The lack of preparation of mathematics teachers may be due, in part, to a gap between technology offered in mathematics teacher education courses and what new teacher graduates find available in schools. Novice mathematics teachers may be well prepared to teach mathematics using computer graphics, dynamic geometry programs, and other special purpose software to which they were exposed in teacher education courses. However, lacking a tool kit of diverse software in the classroom, novice mathematics teachers may be unclear about how to best integrate technology with only general purpose software available. This paper attempts to address these challenges for computer-mediated mathematics pedagogy and ongoing inservice and preservice programs.

**Spreadsheet as a tool kit**

In the context of this paper, the metaphor of a tool kit means an array of representational formats which mediate students’ mathematical thinking in a technology-rich environment. The major claim of a tool kit approach to teaching and learning mathematics in a computer environment is that the variety of qualitatively different representational formats (notation systems) provided by the environment affects students’ acquisition of new concepts in different ways. Such an environment is typically comprised of different computer programs which provide numeric, graphic and geometric notations for the development of mathematical concepts. In particular, the software triple - Excel, Graph Wiz, and Geometer’s Sketchpad - was found to be an effective technology tool kit in mathematics teacher education courses (Abramovich & Brown, 1996).

The fact is that the typical secondary mathematics classroom is often not well equipped with a diverse set of mathematical software. Yet, mathematics teachers are required to integrate numeric, graphic, and geometric notations in the teaching of mathematics using the appropriate tools of technology. We argue that one way to overcome this difficulty is to shift the emphasis from specific computer programs to a broader and more sophisticated use of general purpose software, such as spreadsheets, which have become increasingly available at both the secondary and the university levels.

As far as a spreadsheet is concerned, such a shift in emphasis makes it necessary to re-think the concept of a tool kit from multiple programs to a spreadsheet program alone, which can be singled out because it is itself a tool kit due to its complex and heterogeneous semiotic structure. In this paper, the authors present teaching ideas that concern the use of a spreadsheet-based tool kit in exploring infinite processes. These ideas were included in a mathematics
teacher education course. The course introduced prospective and practicing teachers to spreadsheets and demonstrated how to develop advanced concepts in secondary mathematics using a tool kit approach.

**Linking concepts of algebra and calculus through computer graphics**

The Curriculum and Evaluation Standards for School Mathematics (National Council of Teachers of Mathematics, 1989) suggest that the study of infinite processes in high school should be based on an empirical approach influenced both by graphical and numerical perspectives. The Standards advocate an informal introduction of advanced concepts. In particular, Standard 13 emphasizes that students should be introduced to infinite processes through extending their knowledge of the properties of functions and algebraic equations. Solving an algebraic equation, such as a linear equation in one variable, is an example of a finite process with which high school students are familiar. Indeed, a solution to a linear algebraic equation can be obtained by performing a number of equivalent transformations. However, a graphic approach makes it possible to look at the process of solving a linear algebraic equation from a new perspective. Computer graphics can play an important role in developing this new perspective for students.

How can a teacher help students make connections between new ideas about infinite processes and their previous experience with algebraic equations? Using computer graphics, a solution to a linear equation in one variable can be introduced as an iterative process. In turn, the geometrization of the iterative process can facilitate the acquisition of the concept of infinity. In the following sections, an algebraic word problem is explored from this new perspective using a tool kit of available representational formats of a spreadsheet environment. The assumption is made that the interaction of these tools facilitates the development of advanced mathematical thinking with regard to the behavior of infinite sequences.

**Two Vehicles Problem**

A discussion of the following algebraic problem opens the gate for the development of the important concepts of convergence and divergence of infinite sequences.

The driver of an automobile would like to catch up with a motorcycle that is traveling at one half the speed of the automobile on a long highway. To reach the motorcycle's initial location it would take the automobile 4.5 hours. How long does it take for the automobile to catch up with the motorcycle? The solution to this uniform velocity problem can be found algebraically. If we let \( x \) be the time sought, then there are two related, but distinct, ways to reduce the problem to a linear algebraic equation in the variable \( x \). Although both ways lead to the same solution, it is of great importance to distinguish between the two different ways. First, if one concentrates on the original distance between the vehicles, then the distance can be represented either by \( Vx-0.5Vx \) or by \( 4.5V \), where \( V \) denotes the velocity of the motorcycle (Figure 1). This leads to the equation

\[
(1) \quad Vx-0.5Vx=4.5V.
\]

Dividing equation (1) through by \( V \), yields \( 0.5x=4.5 \), implying \( x=9 \). In other words, it takes the automobile 9 hours to catch up with the motorcycle.

Second, one may concentrate on the total distance traveled. Once again, Figure 1 helps to clarify this new line of reasoning. The first solution, involving the difference of distances traveled, can be replaced by a solution involving the sum of the corresponding distances. This yields the equation

\[
(2) \quad Vx=4.5V+0.5Vx, \text{ whence } x=0.5x+4.5 \text{ which gives the same solution, } x=9.
\]

While a discussion of equation (1) will be provided later, we would presently like to make the point that equation (2) is not just another mathematical model of the problem in question. Rather, the form of equation (2) is suitable for a graphical solution where one makes use of the graphs of its right and left hand sides (Figure 2). This graphical solution makes it possible to establish a link from students' previous experience with functions and graphs to new concepts dealing with infinite processes. In much the same way as any computer graphics software can be used for graphing linear equations, the spreadsheet program can be utilized to show how the solution may occur from iterating the following recursive formula
(3) \( x_{n+1} = 0.5x_n + 4.5 \)

starting from an arbitrary seed value \( x_1 \).

As Figure 2 shows, the graphs of the left and right hand sides of equation (2) are, respectively, a straight line with slope \( k=1 \) (the line bisecting the first and third quadrants) and the straight line with slope \( k=0.5 \) and y-intercept 4.5. The solution \( x=9 \) is the x-coordinate of the intersection point of the lines \( y = 0.5x + 4.5 \) and \( y = x \). The number 9, like any other number, is an abstraction and its image, a point, is a geometric representation of the number rather than the number itself. The point that one sees as a common point for the two straight lines is an approximate geometric representation for the solution of equation (2).

Construction of the bisector-bounded staircase

The above considerations lead to the following geometric process of approaching the exact solution, \( x=9 \), no matter how close to the solution one selects a starting point. This process can be described as follows. Take any starting point and mark it \( x_1 \) on the x-axis. Draw a vertical line segment from \((x_1,0)\) to the point \((x_1,0.5x_1+4.5)=(x_1,x_2)\) which belongs to the straight line \( y=0.5x+4.5 \). Draw a horizontal segment from the point \((x_1,x_2)\) to the point \((x_2,x_2)\), which is on the bisector \( y=x \). Continue by drawing a vertical segment from \((x_2,x_2)\) to \((x_2,0.5x_2+4.5)=(x_2,x_3)\), which is again on the line \( y=0.5x+4.5 \). Draw a segment from \((x_2,x_3)\) to \((x_3,x_3)\), and so on. The resulting geometric construction (sometimes called the bisector-bounded staircase) has the appearance of a staircase trapped between the bisector \( y=x \) and the line \( y=0.5x+4.5 \). The point \((9,9)\) appears to be the point of attraction for the bisector-bounded staircase. In other words, by iterating sequence (3) one can approach the solution to the two vehicles problem.

The above considerations lead to the following geometrization of the solution of equation (2).

Visualizing the \( \varepsilon-N \) definition of limit

The use of a spreadsheet supports an intuitive approach to the concept of a limit through exploring the behavior of iterative sequences. In particular, using the numeric and graphic notations of the spreadsheet program was used to generate all staircases/cobwebs pictured in this article. This program is able to instantly generate a geometrization of any iterative sequence of the form \( x_{n+1} = f(x_n) \).

Note that it is possible to make this program dynamic so that one can instantly construct geometrizations of different recursions by changing their parameters (entries of a numeric spreadsheet template). In fact, a more general spreadsheet program was used to generate all staircases/cobwebs pictured in this article. This program is able to instantly generate a geometrization of any iterative sequence of the form \( x_{n+1} = f(x_n) \).

Figure 3. (a) the numeric template; (b) the bisector-bounded staircase.

It is not immediately apparent how a spreadsheet can be used to graph the process described above. Different spreadsheet programs may be developed toward this end. These become more complex as we attempt to create a dynamic environment which makes it possible to visualize the development of different recursive formulas through their geometrization. In particular, the geometric representation of recursion (3) is shown in Figure 3b. A simple spreadsheet program described below can be used to this end. The numeric template shown in Figure 3a should be constructed first. In column A from cell A1 to cell A21 we enter numbers 0, 0.5, 1, \( \ldots \), 10. Cells C1 and D1 are entered, respectively, with the formulas \( =A1 \) and \( =0.5*A1+4.5 \) which are then replicated down to row 21. This data is used to bound the staircase. To construct data for the staircase itself, the range A23:B44 is used. Cell A23 is entered with the starting point \( x_1=2 \), cell B23 is entered with \( (x_2,x_2) \), which is on the bisector \( y=x \) and the line \( y=0.5x+4.5 \). The entire quadruple A24:B25 is then replicated down to row 44. To construct the graph shown in Figure 3, one should highlight the range A15:D44, and choose the XY-Scatter Format #2 in the Chart wizard menu.

The use of a spreadsheet supports an intuitive approach to the concept of a limit through exploring the behavior of iterative sequences. In particular, using the numeric and graphic notations of the spreadsheet-based tool kit, one can explore the limiting behavior of the sequence generated by formula (3). Figure 4 displays how this sequence is ultimately captured in the interval \( (9-\varepsilon, 9+\varepsilon) \) no matter how small \( \varepsilon \) is taken to be. By decreasing the value of \( \varepsilon \), students can see that it is always possible to come across such a number \( N \) so that for all \( n>N \)
the inequality $|x_n-9|<\varepsilon$ is true. Thus we have both a numeric and graphic representation of the $\varepsilon$-$N$ definition of the limit of a sequence. More on the use of a spreadsheet in modeling the $\varepsilon$-$N$ definition is described elsewhere (Abramovich & Levin, 1994).

**Exploring divergence through the spreadsheet-based tool kit**

Proceeding as we did above, the behavior of numeric sequences known as divergence can be visualized. To this end, note that a solution of the Two Vehicles Problem can be approached through equation (1) which can be written in the form

$$x = 2x - 9.$$

In much the same way as in the case of equation (2), students can construct the bisector-bounded staircase for equation (4) using the recursive formula

$$x_{n+1} = 2x_n - 9.$$  

![Figure 5. Runaway staircase.](image)

Figure 5. Runaway staircase.

In the same way as in the case of equation (2), one can visualize the process of divergence using three different representations - the geometric representation (a bisector-bounded staircase), the numeric representation (a numeric template) and the analytic representation (a graph on the $(x,y)$-plane).

At this point, the important question that can be raised is: What is the difference between Figure 3b and Figure 5? In other words, what is special about a straight line that allows the staircase to be attracted by the point of concurrency $(9, 9)$? The visual analysis of the diagrams makes it clear that the slope of a straight line should not exceed 1 in absolute value in order for a point of concurrency to be a point of attraction (Figure 3b). Bruce, Giblin, and Rippon (1990) provide a detailed discussion of the behavior of iterative sequences.

**From bisector-bounded staircases to cobweb diagrams**

Mathematics education research suggests that teaching the concept of a limit of a sequence through examples of monotonous sequences may cause misconceptions which, in turn, may lead to erroneous operations with limits. Using a spreadsheet as a visual aid for calculus, sequences exhibiting more complex behavior can be introduced. For example, one can rewrite equation (2) in the equivalent form

$$x = -0.5x + 13.5$$

(which also has the root $x = 9$), and then construct the bisector-bounded staircase for the related iterative sequence $x_{n+1} = -0.5x_n + 13.5$. In the same way, one can rewrite equation (2) in the equivalent form

$$x = -2x + 27$$

(which also has the root $x = 9$), and then construct the bisector-bounded staircase for the related iterative sequence $x_{n+1} = -2x_n + 27$. These staircases, known as cobweb diagrams, are shown in Figure 7 and Figure 8.

![Figure 7. Oscillating convergence.](image)

Figure 7. Oscillating convergence.
The pictured cobweb diagrams represent processes called oscillating convergence and oscillating divergence, respectively. The diagrams can be complemented by the numeric and graphic representations of these processes.

To conclude this section note that yet another equivalent form of equation (2) leads to the recursion \( x_{n+1} = -x_n + 18 \), which can be used to introduce the concept of periodicity (cycles). Finally, through the spreadsheet-based geometrization of the piece-wise recursion \( x_{n+1} = 1 - |2x_n - 1| \), students can also be exposed to chaotic behavior of infinite sequences. The use of spreadsheets to introduce chaos through exploring the intriguing behavior of quadratic-like sequences is discussed by Abramovich & Levin (1993), Durkin & Nevils (1994), and Iseke-Barnes (1997).

**Conclusion**

Because of the increasing availability of computer spreadsheets, the authors believe that mathematics teacher education courses may consider re-thinking the concept of a tool kit from multiple programs to this single type of program. This paper demonstrated how the complex semiotic structure of the spreadsheet makes it possible to use a single computer program as a tool kit. The advanced topics in secondary mathematics discussed above were chosen to illustrate this point. However, in an attempt to conceptualize the tool kit approach as a framework for technology-mediated mathematics teacher education research and development, the major questions to be answered are: (i) What is special about each element of the array of representational formats available in the spreadsheet environment? (ii) Can these elements be distinguished in terms of their representational power? (iii) To what extent can any two notation systems of the spreadsheet be considered cognitively equivalent to each other in terms of their representational power? The authors will elaborate on these questions in a separate paper.

**Mathematics — 577**
The idea of using computers to perform symbolic rather than numerical calculations led to the development of Computer Algebra Systems (CAS) in the early sixties (Harper, Wooff & Hodgkinson, 1991). In the mid-eighties the availability of CAS for personal computers attracted mathematics educators to the possibility of using them in the classroom. CAS technology with its powerful combination of numeric and symbolic computation, 2D & 3D graphic and programming facilities is a natural and logical continuation of the scientific and graphical calculators that have become popular in school mathematics. Each new technology greatly affects the way mathematics is practiced and CAS technology is a big step forward. Most teachers, however, are not aware of the existence of CAS software. Teacher education is an important factor for the successful integration of CAS (Zehavi, 1996; Lachambre & Abboud-Blanchard, 1996). In considering the future needs of teacher preparation and involvement, we have designed and implemented a 90-hour professional development course with the following goals:

- To enable teachers to take advantage of the new possibilities offered by CAS, to refresh and extend their mathematical knowledge.
- To have teachers experience learning with this new technology as a motivation to acquire further knowledge, to experiment with CAS and use it in their teaching.
- To familiarize teachers with CAS and make it an integral part of their mathematical environment.

After an initial introduction to the computer algebra system, Derive (Soft Warehouse), teachers begin working on problems at their own level. In doing so they become aware of how CAS can assist their own mathematical thinking, especially regarding the multiple representations available by the software. Mathematicians, educators, and policy makers have asked how computer algebra will affect mathematics education. Studying its use by teachers can provide further knowledge and enable better implementation of it in the classroom.

Two examples will be presented from tests given in the course. The first one is a problem that was given after one-third of the course. The problem became a turning point for the teachers; they realized the use of CAS as a cognitive technology (Hillel, 1991). The second problem was given toward the end of the course and helped transform teachers to the stage where they began to rethink pedagogical and curricular aspects of mathematics.

**Example I**

The first three parts in the course include examples from number theory, a wide range of symbolic manipulations, and illustrations of the advantages of graphical representations. In the test that was given to the teachers at this stage we used a problem taken from Alan Schoenfeld’s mathematical problem-solving class, cited by Arcavi (1994).

“Explore the relationships between the values of ‘a’ and the number of solutions of the pair of equations:

\[ x^2 - y^2 = 0 \]
\[ (x - a)^2 + y^2 = 1 \]

Since the problem is stated in algebraic terms the teachers used Derive to perform the laborious algebraic manipulation. The solution, \( x = 0.5(a \pm \sqrt{2 - a^2}) \), led to the interpretation that “any solution of \( x \) represents two points in the plane”, ignoring when \( x = 0 \), which occurs for \( a = 1 \). Some teachers also tried to change the representation to graphics. Derive enables implicit plotting of equations. Figure 1 shows the graph of the first equation, which is represented as two lines, \( y = \pm x \), and several circles whose centers lie on the \( x \)-axis for specific values of \( 'a' \). We can see that when \( a = 1 \) there are three rather than four intersection points. After observing this some teachers performed a multi-representation analysis of the problem and gave the correct answer of 0, 2, 3, or 4 solutions: for \( |a| > \sqrt{2} \) there is no solution; for \( a = \pm \sqrt{2} \) there are two solutions; for \( a = \pm 1 \) there are 3 solutions; and for \( |a| < \sqrt{2} \), \( a \neq \pm 1 \) there are four solutions.

</table>

The reaction of those teachers who got a wrong answer, even when using a symbolic manipulator, was very marked. The following anecdote describes a change of attitudes. After the test, one of the participants, a quite experienced high-school teacher, compared notes with another teacher. She would not agree about the possibility of three solutions. He suggested plotting. She said, “I am pragmatic, the graph does not add information, it just illustrates what we know. I like solving the algebra with Derive and that should be enough.” He explained how implicit plotting, when \( a = 1 \), helped him complete the solution and understand the algebraic explanation. When she found her mistake she became enthusiastic and changed her approach, “I must educate myself to use the graph more seriously, especially when implicit plotting is available.” Here the new facility, namely, implicit plotting integrated with the symbolic mechanism of the software enhanced cognitive mathematical integration.

Example II

The second problem, although appears simple is even less standard than the first one (Bruckheimer & Inbar, 1995).

“Search for three numbers for which the sum is -9 and their product is -20.

What is the range of the solutions?”

The solution of the problem is rich in mathematical relationships and thus requires the solver to coordinate actions among different mathematical representations. The teachers became very involved in creating their own representations (some of them even surprising the course team), and they suggested follow-up ideas for teaching.

The teachers were asked to submit their answers including screen dumps and annotated Derive files created while solving the problems. The files enabled us to see the order of actions performed for solving each problem. The screen dumps revealed the mathematical and pedagogical ideas that the teachers wanted to emphasize. For example, one teacher chose to present Figures 2 and 3. Figure 2 contains the symbolic manipulations performed by the software. Line #4 shows the bivariate equation that describes the problem. Solving this equation for \( y \) gives two functions (in lines #5, #6), and we can see then how the range of the solution was calculated. Figure 3 compares two graphical representations of the problem. The graph on the left side was obtained simply by the automatic implicit plotting of the software. Note that if plotting is performed in the standard graphical window only some parts of the graph are seen. Clearly, the expression that describes the problem, \( x \cdot y(x + y + 9) = 20 \), is symmetric for \( x \) and \( y \) - and thus we must zoom out until we obtain a symmetric graph and then set the adequate scale. The right-side graphical window contains an unusual representation created using the VECTOR function, a helpful feature of Derive for quickly investigating and the presenting results. A vector is a row of elements separated by commas and enclosed in square brackets which is generated algebraically. In the current example “vector(x,y(x + y + 9) = 20, y, -20, 20, 1)” comprises 41 equations that need to be solved for \( x \). By one key stroke the results can also be plotted illustrating the geometrical properties of the mathematics. Figure 2-3 show three representations of the solutions for \( x \) in the range \( x > 0, x < -11.623, -5 < x < -1.372 \).

#1: \( x + y + z = 9 \)

#2: \( x + y + z = -20 \)

#3: " " "

#4: \( x \cdot y(x + y + 9) = 20 \)

\[
3
\frac{2}{J(x + 18 \cdot x + 81 \cdot x + 801) + Jx \cdot (x + y)}
\]

#5: \( y \cdot j = \frac{2}{2 \cdot Jx} \)

\[
3
\frac{2}{J(x + 18 \cdot x + 81 \cdot x + 801) - Jx \cdot (x + 4)}
\]

#6: \( y \cdot j = \frac{2}{2 \cdot Jx} \)

#7: \( \text{SIN}(x + 10, x - 10, x) \)

#8: \( \{x = 5, x = 1.37652, x = 11.6231\} \)

Figure 2: Symbolic solution
In checking the teachers’ answers we had the following categories:

(a) **Correctness of the answer**
Most of the teachers identified the correct domain. About 25% gave a partial answer.

(b) **Type of initial strategy**
At this stage of the course the teachers were very enthusiastic about the availability of implicit plotting, and therefore more than half of them started to solve the problem graphically. Some elaborated this representation, as explained previously, whereas others switched to the symbolic manipulation. Many teachers experimented first with specific numerical values before analyzing the general case.

(c) **Additional creative representations**
The representation in the right-hand side window of Figure 3 surprised the course team. We suggested adding the symmetric vector which goes for x and yields y solutions. There were other interesting ideas. Three teachers combined algebraic work and graphs in the following way.

#1: \[ x + y + z = -9 \]
#2: \[ x \cdot y \cdot z = -20 \]
#3: \[ z = 15 \]
#4: \[ z = 10 \]
#5: \[ z = -10 \]

They drew conclusions from solving algebraically and graphically the first two equations for different values of z.

Another remarkable representation used the 3-D graphic window to plot the bivariate expression \( \text{MAX}(-9 - x - y, -20(x,y)) \).

(d) **Related teaching ideas**
The teachers were asked to solve the problems at their own level and were also asked to suggest related activities at the student level. Here are several follow-up ideas.

- Using equations like \( 15y(y + 9) = 20 \) to practice manipulations with irrational numbers.
- Comparing properties of other interesting expressions and their graphs; e.g., domain, symmetry, endpoints, extrema.
- Illustrating inverse functions.

**Conclusion**
During the course we identified four stages of teachers’ technological professional development:

1. Initially teachers are skeptical about the possible contribution of technology to teaching and learning. However, they are curious enough to familiarize themselves with the new technology.
2. Teachers adapt readily to the symbolic mechanism of the software and make it their professional tool for doing mathematics. The graphical representations are used only for illustration.
3. Teachers view the new technology as encouraging versatile thinking in mathematics.
4. Teachers believe that CAS technology requires continually rethinking the pedagogical and curricular aspects of mathematics.

The first example presented helped to transform teachers from the second to the third stage and the second example motivated teachers to reach the fourth stage. The coursework made teachers aware of the variety of possible preferences for processing information when carrying out a learning activity, in addition to providing teachers with many teaching ideas. They all expressed their desire to participate in a follow-up course for designing curricular materials.

Figure 3: Two graphical representations
The World Wide Web (WWW) is becoming one of the fastest growing resources available to educators today. Its vast resources are being utilized more and more for research, data collection, communication and instructional delivery in nearly every field and content area. In fact, this medium has the potential to revolutionize the way instruction is delivered. However, educators are only beginning to test the instructional value of this ‘network of networks’. Currently the majority of instructional content on the WWW demonstrates a very low level of interactivity and engagement with the instructional content primarily delivering information in a static manner through displaying textual and graphical information on Web pages. From an instructional viewpoint, this limited interaction can be viewed as didactic in delivering or providing information to students rather than giving them the opportunity to interact with the material and become cognitively engaged. Due to recent software developments, instructional modules on the WWW can engage the user in dynamic activities and cause deeper cognitive processing of the content. In contrast to the more common approach of static display of information on the Web, a few innovative examples of Web-based educational material with engaging interaction strategies are beginning to emerge. Dr. Super’s Virtual Manipulatives project offers this interactive potential.

Theoretical Basis for Dr. Super’s Virtual Manipulatives Project

Mathematical manipulatives have been used extensively in the concrete form and have been shown to enhance mathematics achievement (Suydam, 1984). Manipulation of the parts of an object may allow for students to actively form their own generative associations in relating the parts together. Manipulations of objects may enhance students’ abstract representations allowing students to potentially achieve a higher level of learning (Haag, 1995)

Opportunities for higher level learning goals also exist for computer-based manipulative objects, referred to as Virtual Manipulatives (Spike II & Aghevli, 1997). Virtual manipulatives are a relatively new instructional approach. Allowing for student-directed engagement with objects on the screen, the computer’s direct manipulation interface enables learners to move and interact with visuals through mouse input (Hutchins, Hollan & Norman, 1986). Manipulating computer generated objects, students have the opportunity to explore spatial relationships through generating new associations and concepts about the objects. This type of activity places students in control of their own learning and creates the potential to apply newly discovered
computer are important tools to assist students with the manipulatives may also have this potential. The National (Suydam, 1984). Therefore, it is expected that virtual manipulatives contribute to problem solving skills not been empirically tested, there is evidence that concrete relations between knowledge and experience (Wittrock, 1974a; Wittrock, 1974b), learning becomes the generation of meaningful relations between knowledge and experience (Wittrock, 1992).

Although the effectiveness of virtual manipulatives has not been empirically tested, there is evidence that concrete manipulatives contribute to problem solving skills (Suydam, 1984). Therefore, it is expected that virtual manipulatives may also have this potential. The National Council of Teachers of Mathematics maintains that computers are important tools to assist students with the exploration and discovery of concepts allowing a smooth transition from concrete experiences to abstract mathematical ideas (Perl, 1990). Accordingly, Alesandrini (1984) believes it is the act of manipulation that seems to be important.

Virtual manipulatives may provide a strong link in the learner's mind from physical, concrete objects to the semi-concrete representation of concepts on computer, therefore, enhancing abstract thought (Berlin & White, 1986). Through the use of virtual manipulatives, the learner is actively participating and cognitively engaged in the instruction by physically maneuvering visual elements. This may provoke the conscious construction of associations between various visual elements as well as the association between those visuals and the learner's prior knowledge (Haag, 1995). Furthermore, learning is enhanced when students can hypothesize the placement of graphical elements, configure the objects on-screen and evaluate the impact of their actions. Mathematical concepts are synthesized in this iterative process as students use their invented configuration to solve complex problems.

Incorporating a constructivist approach and principles from Roger Schank's Goal-Based Scenarios, virtual manipulatives are best introduced by a story or situation. By following a created cover story which involves a mission, students plan their operations and test out their approaches. This context furnishes a rich learning environment to support students' acquisition of spatial relations and problem solving skills.

One of the components which makes the use of Dr. Super's Virtual Manipulatives Project so unique is the ability to make the task at hand authentic. "Authentic tasks," state Brown et al. (Brown, J.S., Collins, A.S. & Duguid, P., 1989), "are coherent meaningful and purposeful activities that represent the ordinary practices of a culture. These tasks involve activities that practitioners and experts engage in during real problem-solving rather than the simulated processes typically demanded in formal schooling (Wilson, 1993). According to Scardamalia, M., Bereiter, C., McLean, R. Swallow, J., & Woodruff, E. (1989), real world tasks...tend to be wide open in the kinds of knowledge that may be drawn on in handling the task.

Rather than have students learn arithmetic facts or geometric concepts and relationships in isolation, meaning is derived from the situation in which it is presented. Because the emphasis is on providing enabling experiences in authentic versus decontextualized contexts, it promotes understanding that cultivates learning processes rather than learning outcomes (Choi and Hannafin, 1995).

This authenticity has great motivating potential. Students construct unique understanding of geometric principles through interaction with the real world context and are guided toward the application of these concepts to a realistic situation. Quite often in traditional classrooms students are given problems or tasks that have little relevance or meaning (Newmann, 1991). Conversely, authentic tasks are ordinary activities in relevant situations that purposefully engage the learner and possess extraordinary motivational potential (Choi and Hannafin, 1995).

The Dr. Super's Virtual Manipulatives Project is also designed to attempt to facilitate transfer of skills from one context to another. By providing contextual anchors students learn to use their knowledge flexibly as a tool to deal with everyday, as well as novel, situations (Choi and Hannafin, 1995). In support of this, Collins (1988) maintains that lesson content, when acquired in meaningful contexts, becomes more transferable because the context provides support for its use. This approach to learning capitalizes on students' ability to create interpretations for themselves (Cunningham, 1991) and actively manipulate the material until it makes sense (Perkins, 1991). Learners, in turn, reference their personal experiences and apply strategies which evolve through interaction with the program and other students. In this way, knowledge is not simply being transmitted, but instead opportunities for meaningful learning are created.

Another way in which meaningful learning occurs is through group interaction. The Dr. Super's Virtual Manipulatives Project activities can be used in a cooperative environment whereby students are given the responsibility to contribute to each other's learning. According to Scardamalia et al. (1989), in order for cooperative learning to occur, students must recognize what they are trying to learn, value it and wish to share its value. With the project's activities students are encouraged to collaborate and share their efforts and ideas to solve the problems and tasks at hand.

This cooperative approach allows students to construct multiple perspectives on an issue as well as appreciate and
understand alternate views. Students are encouraged to evaluate and defend these different perspectives, identifying shortcomings as well as strengths. By collaborating their efforts and defending their answers, ultimately students will adopt the perspective that is most useful, meaningful or relevant to them in that particular context (Bednar, A.K., Cunningham, D., Duffy, T.M., & Perry, J.D., 1991).

Finally, the evaluation portion of the Dr. Super’s Virtual Manipulatives Project materials involves asking learners to address a problem posed in the context of the situation and defend their decisions. Reflecting the constructivist view, content and process are blended to encourage meaningful learning. Bednar et al. (1991) expand on this with the belief that the two most important elements of evaluation include 1) the ability to function within a given discipline and 2) the ability to defend judgments. In contrast to the mastery model, the program does not lead students to one answer or set of answers that is correct. Because students will approach this program from a variety of backgrounds and collaborative efforts, interpretations of learning experiences as well as students’ applications of their learning will lead to a variety of responses. Evaluation, therefore, centers around students’ ability to explain and defend their perspectives.

**Classroom Implications**

Concrete manipulatives have been shown to be effective in students’ assimilation of complex ideas and skills in mathematics. Traditionally, other static representations depicting graphical objects have also been used in mathematical instruction and do not allow for dynamic interaction with the content. Virtual manipulatives as developed by the Dr. Super’s Virtual Manipulatives Project, however, permits increased student interaction and provides a representation that goes beyond merely pictorial. Students flip, slide, turn and scale virtual versions of manipulatives which consist of geometric shapes to study and master mathematics concepts and skills in a context rich setting. By using the virtual manipulatives as an extension of the concrete manipulatives, students are able to continue this discovery process and make the leap from concrete to more abstract thinking.

In the classroom environment virtual manipulatives have strong curricular implications either through teacher-directed, student-directed or independent learning. The context rich and authentic activities provide opportunities for either individual or collaborative problem solving efforts. Students are encouraged to reflect on the strategies used to solve math puzzles or problems while recognizing the interrelationship of components.

Because the Dr. Super’s Virtual Manipulative materials are designed for cooperative learning, there is potential for a group of students to be actively engaged in a “virtual learning environment” while the teacher conducts small-group instruction for the remaining students. Therefore, a classroom with six computers could essentially occupy twelve students. Most “virtual lessons” are broken into approximately 30 minute segments and allow for instruction independent of teacher support. Furthermore, objectives are easily identifiable so teachers can choose activities to enhance classroom instruction.

Virtual manipulatives can help foster an understanding of a variety of mathematical concepts which include but are not limited to, perimeter, area, conservation of matter, fractions, whole number arithmetic and writing abstract algebraic expressions. Furthermore, the virtual manipulatives can incorporate a language arts component giving it useful cross-curricular implications. Through reflection and journal responses students can verbally express their own problem solving approaches. Students can also use the virtual manipulatives to construct their own activities or puzzle problems and then create their own cover story in order to give meaning to their own experiences with this content.

A final advantage to the virtual manipulatives is that they provide an alternate form of instruction for students coming into learning situations with varied backgrounds and learning styles. This may be especially valuable for students whose personal learning styles are not suited to the pace and public quality of classroom learning (Scardamalia et al., 1989). Furthermore, this vehicle of instruction provides for self-paced learning that allows time for reflection to think about what they are doing and why. Students are encouraged to interact with the program and ask questions it might bring to mind in a safe, non-threatening, private environment.

**Historical Roots of Virtual Manipulatives**

The Dr. Super’s Virtual Manipulatives Project is a curriculum research and development effort of the Metamedia Mathematics Program at George Mason University. Students enrolled in the doctoral and master’s degree programs work directly and collaborate with faculty in the Graduate School of Education, the School of Technology and Engineering, as well as with teachers and students in various northern Virginia schools to develop virtual manipulatives activities for grades K-12.

**The Super Mosaic Apprentice Activity, An Example of Dr. Super’s Virtual Manipulatives Project**

Although there are a variety of applications using the virtual manipulatives being developed at George Mason University, one, the Super Mosaic Apprentice Activity, provides a particularly context-rich application. It is based on a new set of physical manipulatives consisting of small, medium, and large multi-colored triangular shapes. The Super Mosaic Apprentice Activity provides a learning situation whereby students are encouraged solve a variety of problems as they relate to the creation of mosaic designs.
using geometric concepts and principles. A company which manufactures mosaic tiles and its goals (mosaic tile creation) are initially introduced to the students, and their job as "employees will be to learn to design mosaics after learning the "tricks of the trade" (a.k.a. geometric skills).

They are required to work within certain parameters (i.e. limitations set by geometric definitions) established by the head of the company. Students will directly interact with the computer to manipulate the mosaic pieces to meet each successive goal of the assigned project. Each of the computer-based activities is designed to last approximately 30 minutes. Skills and concepts are introduced in the context of the task at hand, as the activity is designed to build interest with realistic directions and purpose for given context of the task at hand, as the activity is designed to 30 minutes. Skills and concepts are introduced in the context of the task at hand, as the activity is designed to build interest with realistic directions and purpose for given context of the task at hand, as the activity is designed to transitions from concrete manipulation of computer objects to abstract thinking in elementary school mathematics. School Science and Mathematics, 86(6), 468-479.

584 — Technology and Teacher Education Annual — 1998

590
The Center for Technology and Teacher Education at the Curry School of Education is currently funded to develop materials to help pre-service and in-service secondary mathematics and social studies teachers incorporate technology into their teaching. The Center’s mathematics group is focusing their efforts on developing activities that will prepare teachers to use technology to enhance and extend students’ learning of mathematics. We acknowledge that technology can be used effectively by teachers to present information, search for information, keep records and communicate, and that such uses of technology by teachers can result in improved student learning. However, we believe that the most direct and effective way to bring about enhanced student learning of mathematics through technology is to prepare teachers to incorporate into their teaching classroom and project activities that will engage students in technology-augmented mathematical thinking. Hence, our materials for teachers will be developed around significant mathematical activities for students. We are currently devising a set of guidelines to help shape our development of these activities and materials. At this point we are following the guidelines below:

Introduce technology in meaningful mathematical contexts. Features of technology, whether mathematics-specific or more generic, should be introduced and illustrated in the context of meaningful content-based activities. Teaching students a set of technology or software-based skills and then trying to find mathematics topics for which they might be useful is comparable to teaching students a set of procedural mathematical skills and then giving them a collection of “word problems” to solve using the procedures. Such an approach can obscure the purpose of learning and using technology, make mathematics appear as an afterthought, and lead to contrived activities and curricular fragmentation. The use of technology in mathematics teaching is not for the purpose of teaching about technology, but for the purpose of enhancing mathematics teaching and learning with technology. This guideline is in accord with the first recommendation of the President’s Committee of Advisors on Science and Technology, Panel on Educational Technology (1997): “Focus on learning with technology, not about technology” (p. 7).

Use technology to address worthwhile mathematics and support appropriate pedagogy. Content-based activities using technology should address worthwhile mathematics concepts, procedures and strategies, and should reflect the nature and spirit of mathematics. Activities should support sound mathematical curricular goals and should not be developed merely because technology makes them possible. Moreover, the use of technology in mathematics teaching should support and facilitate conceptual development, exploration, reasoning and problem solving, as described by the National Council of Teachers of Mathematics (NCTM, 1989; 1991). Technology-enhanced activities should involve students in higher-order mathematical thinking and should not engage students in carrying out procedures and finding answers without appropriate mathematical and technological understanding. This guideline is in accord with the second recommendation of the President’s Committee of Advisors on Science and Technology, Panel on Educational Technology (1997): “Emphasize content and pedagogy, and not just hardware” (p. 7).

Take advantage of technology to enhance teaching. Activities should take advantage of the capabilities of technology, and hence should extend beyond or significantly enhance or facilitate what could be done without technology. Using technology to teach the same mathematical topics, in fundamentally the same ways, that could be taught without technology does not enhance students’ learning of mathematics and belies the usefulness of technology. Furthermore, using technology to perform tasks that are just as easily or even better carried out without technology may actually be a hindrance to learning. Such uses of technology may convince teachers and administrators that preparing teachers to use technology is not worth the considerable effort and expense necessary to do so.

Connect mathematical topics. Technology-enhanced activities should help students connect mathematics to real-
Incorporate multiple representations and multiple approaches. When apropos, activities should incorporate multiple representations of mathematical topics and/or multiple approaches to representing and solving mathematics problems. Research shows that many students have difficulty connecting the verbal, graphical, numerical and algebraic representations of mathematical functions (Goldenberg, 1988; Leinhardt, Zaslasky and Stein, 1990). Appropriate use of technology can be effective in helping students make such connections. Furthermore, use of technology allows students to set up and solve problems in diverse ways, involving different mathematical concepts, by removing both computational and time constraints.

The above set of guidelines is still evolving along with our work, and we expect that they will be modified as our work continues. We are aware that there are worthwhile mathematics activities that do not conform to all of these guidelines, and hence we do not intend to apply the guidelines, as a set, rigidly to all of our developed materials. We do not want the guidelines to eliminate otherwise useful activities, nor do we want them to lead to contrived activities. Although, a guideline such as “...address worthwhile mathematics and appropriate pedagogy,” should always be followed, whether using technology or not.

Looking at the Quality of Web Sites

Mary Ann Coe  
Midwestern State University

Michael Land  
Midwestern State University

There is little question about the potential of the use of the World Wide Web in classroom learning. The ease of use, the immediacy of information, and the global viewpoints, allow learners to generate meaningful learning for themselves. But the big question is what to do with all of this information. Is the information accurate? Is the information free of cultural, gender, and age bias? Simply because the information on the Web is easily accessible, is it the best resource for the information that is needed? Glitz and glimmer can be great motivators but are they needed in all areas of learning? For all learners? With the extensive use of hypertext on the WWW, issues of cognitive mapping and cognitive flexibility also come into question. This paper will highlight some of these issues and pose questions that need to be answered about remaining issues. It will also include on-line resources that can be used to help in the evaluation of World Wide Web educational sites.

World Wide Web’s Potential in Education

Today’s educational systems are in the midst of change, chaos and confusion. The curriculum that we have determined to be what needs to be “learned” is no longer relevant. Requiring students to learn facts, as is common under the didactic system that is evident in so many school and school districts, is no longer a viable proposition. We need to equip our students with all the necessary skills to be able to locate and evaluate any information they need. They must become information managers, not information regurgitators (Mann, 1994). In order for this to occur, information on the World Wide Web (WWW) must relate to the curriculum and the ability of the students who will use the information to help them organize the information into learning.

Another job for today’s busy educators - evaluate the resources that will facilitate students’ learning, or better yet, teach the students to evaluate the site themselves. Is this job as important as teaching students to read, to add, to take tests? If one reads and studies the literature on using the WWW as a resource for learning, the answer is a resounding YES! (Schrock, 1997; Collins, 1996; Descy, 1996; Engle, 1996; Ormondroyd, et al., 1996; Tate & Alexander, 1996).

Okay. So now what? What do we as educators need to know in order to evaluate sites and to support our students’ learning of this process of evaluation?

Evaluation of Information

Much of the literature concerning the evaluation of WWW sites has been written by educational librarians. Who better to do so. These remarkable generalists have been working with the evaluation process for many years. This is what they have been educated to do. Librarians and other information professionals have developed a set of criteria that they use to evaluate information in books, journals, magazines, pamphlets, etc. (Smith, 1991). In short, they study the format, scope, relation to other works, authority, treatment and cost (Hinchliffe, 1997).

These aspects of information found on the WWW are also of importance. But, there are even more details that need to be studied and evaluated before information from the WWW can be determined to be useful and appropriate.

The remainder of this paper will deal with a synthesis of ideas, concepts, and details that various educators (librarians, media specialists, classroom teachers, university professionals) have designated as important in the evaluation process of WWW educational sites.

We distinguish between educational sites and other sites as those that contain information that relates to curriculum issues, problem solving, and research opportunities, and cooperative or collaborative projects that are part of the Web.

Criteria for Evaluation Educational Web Sites

Twenty-five educational resources were used to gather information for the synthesis that follows. These resources were found in research journals, journal articles, and on-line sites. There are currently on-line and off-line resources that include a “top-ten list” of web sites. This is one place that educators “could” begin when initiating use of the WWW. However, all of these resources may not have education/curriculum in mind when they are conducting their evaluation. For example, some evaluate the design but do not look at the content. These resources include Lycos Top 5%, Webcrawler Best of the Net, and HotBot, just to name a few.
According to the resources that we read and studied, the following are the criteria for evaluation of educational websites. To determine if a site meets these criteria, ask the following questions:

**Accessibility**
- Who are the intended users and is the level of information provided appropriate?
- Do parts of it take too long to load?
- Is the site open to everyone or do parts require a fee?
- Is the site available on a consistent basis?
- Can the resource be accessed easily, or are there special software, password, or network requirements?

**Accuracy**
- Is the information in the resource accurate?
- How does this information compare with that in other sources in the field?

**Authority**
- Does the resource have some reputable organization or expert behind it?
- Can you tell who the author(s) is (are)?
- Does the author have a standing in the field?
- Are sources of information stated?

**Content**
- How comprehensive is this site?
- What is the relationship to curriculum?
- What is the purpose of the resource? Is this clearly stated?
- Is the content organized by the needs of the user, or does it reflect an internal hierarchy?
- Is the origin of the information stated?
- What is the scope of the site - what is included as well as what is excluded?
- Does content format vary - text, video, audio, etc.?

**Cooperative/Collaborative Projects**
- Is collaboration between schools, universities, government agencies, and businesses a vital part of the site?
- Can students from around the world exchange data on topics?

**Correct Grammar**
- Does the text follow basic rules of grammar, spelling and literacy composition?
- Is the site organized logically?

**Currency**
- How frequently is the resource updated, or is it a static resource?
- Do the stated dates correspond to the information in the resource?
- Is the publication date clearly labeled?
- Is the information primary or secondary in nature?

**Ease of Use**
- Is navigation through the page easy and logical?
- Who are the intended users of this resource?
- Does this resource work with multiple browsers (Netscape, Microsoft Explorer, etc.)?
- Does the three-click rule apply to this site? If it takes more than three clicks to get to something useful or interesting, then it’s buried too deep.

**E-mail**
- Is contact information for the author included in the document?
- Is a mail-to link offered for submission of questions or comments?

**Graphic Design**
- Does the document follow good design principles and do the graphics serve a function or are they decorative?
- Is the writing style appropriate for the intended audience?
- Are the web pages concise, or do you have to scroll indefinitely?
- Do all of the parts of the site function correctly?
- Does the site look and feel friendly?
- Are the pages readable? Does the color of the background or font preclude ease in reading the information?

**Interactivity**
- Does the site facilitate person-to-person interactivity?
- Can students share and display their work?
- Does the content facilitate independent investigations as well as cooperative problem solving?
- Can users communicate with “the experts” in the field?

**Linkage to Other Appropriate Sites**
- Are links relevant and appropriate?
- Do links to remote sites work?

**Multimedia Capabilities**
- Does the site use unique features of multimedia to accommodate multiple modalities and learning styles?
- Is the quality of sound, as well as the time for downloading of sound files, appropriate and worthwhile for the learning environment?

**Objectivity**
- Is any sort of bias evident?
- Are there political or ideological biases?
- Does the material inform? explain? persuade?
- Is there advertising on the page, is it clearly differentiated from informational content?

**Search engine**
- Is a search engine provided?
Uniqueness of Information

- To what degree of redundancy does the content have with other traditional resources?
- Is this the best resource for achieving the purpose intended?
- Is information in this resource available in other forms (other sites, print, photos, etc.)
- Is the depth of information appropriate for the intended users?

The World Wide Web and the Learning Environment

The Internet can offer educators immediate access to curriculum resources, lesson plans, on-line experts, discussion groups, and teacher forums. It can provide students with resources they might not otherwise have, invite higher order thinking skills, provide real-world learning experiences, and provide purposeful and motivational learning activities (Gray, 1996).

The WWW offers a variety of learning experiences for students. In this way students construct their own meaning while creating, writing, and publishing their ideas. It also provides a vehicle to distribute their work and to work collaboratively with others, including other students at remote sites and subject field experts (Carvin, 1996).

The Web also gives the learner the opportunity to experience a non-linear way of thinking and learning through hypertext/hypermedia. The work being done at Vanderbilt University in the area of cognitive flexibility strengthens our knowledge in this area and gives us guidance in the use of this new and unique learning tool that is only a click or two away.

Conclusion

Through the asking of the questions listed above when first visiting a site, an educator or learner can critically evaluate some of the information that is contained there. Both students and teachers need to be aware of the authenticity, applicability, authorship, bias, and usability of the site. The ability to critically evaluate information is an important skill in this Information Age. It is a skill that can be strengthened through continued use within all curriculum areas.

Remember that the critical evaluation of web sites can be started by looking at the top-ten-lists, sites that have been mentioned in educational journals, and those suggested by fellow educators, all followed by your own evaluation - keeping foremost in mind, the learner and the curriculum.

Lehman, L. (1996). From library to lab: The web's effect on teaching the internet. ERIC Clearinghouse Document ED 403899

Countless teachers are facing the dual demands of incorporating into their practice both information technologies and new curricula adopted by their school systems. While in theory many teachers are open to the promise of these technologies, curricula, and accompanying pedagogies, in practice many of them are overwhelmed by the demands they place on their teaching. It is no wonder that so many fall back on drill-based computer software, which are far less insistent in requiring alterations to the transmission model of teaching. “This is so exciting. I’m loving it. I took the ideas you presented to me and we just took off on it!” (Teacher, Hanau Schools)

In order to illuminate the issues that arise when technology tools are introduced alongside of a newly-adopted curriculum, and to highlight ways of addressing them, this paper will describe the evolution of professional development in three United States Department of Defense Education Activities (DoDEA) elementary and middle schools in Hanau, Germany.

I will begin to outline our efforts to prepare teachers to make discerning decisions about their use of electronic spreadsheet and graphing tools with their system’s newly-adopted mathematics curriculum and beyond with a description of the Hanau Model Schools Partnership and its mathematics strand. I will lay out the philosophical underpinnings of our work with a description of the introductory workshop we have offered. I will then describe adaptations to the curriculum, which we assembled to help teachers integrate technology tools with sound mathematics. I will discuss our co-teaching model, which has made it possible to tailor follow-up support to individual teachers’ and classes’ needs and interests. And finally I will step up from these descriptions, which are particular to the math program, into a broader discussion of ways in which the Hanau Model Schools Partnership has designed its entire professional development plan to support teachers as they seek to introduce new technologies in ways that powerfully support teaching and learning in their schools.

Mathematics in the Hanau Model Schools Partnership

Our work with elementary mathematics has taken place in the context of the Hanau Model Schools Partnership. This National Science Foundation-funded project is a joint effort between TERC and the four schools in a K-12 complex at the United States Army Base in Hanau, Germany. The
The mathematics work described in this article is one part of a comprehensive research program designed to document the process of technology integration and to develop research-grounded recommendations for the field. In addition to the mathematics work described in this article, we conducted a comprehensive qualitatively research study of the process of technology infusion.

A key component of the professional development work for this project has been in support of the integration of electronic graphing and spreadsheet tools in elementary mathematics. We have worked primarily with The Graph Club and The Cruncher, the recommended tools of the system's newly-adopted mathematics curriculum, MathLand. An important goal of our work has been to support use of these tools that reflect the National Council of Teachers of Mathematics Standards (NCTM, 1991) have highlighted as central to students' developing deep understandings of data collection, representation, and analysis.

The three-year Hanau Model School Partnership had its kick-off September 1995. In the first year we broke ground for the partnership, conducting a ground-level assessment, developing a planning committee, and then with them creating the two-year implementation plan for the project. During years two (1996-97) and three (1997-98) we have implemented that plan. That implementation plan spelled out the hardware, software, and connectivity plans for the four-school cluster, as well as detailing plans for an ongoing community-based group to oversee implementation, a comprehensive professional development plan (including on-site support from a curriculum-focused “educational technologist”), and a broad-based research and evaluation plan. The mathematics work described in this article is one of the pillars of the professional development work.

My mathematics work with teachers in Hanau (15 elementary and one middle school) has been a long-term process. It has included: summer workshops for participating teachers in Years Two and Three; follow-up classroom visits and consultations; focus group meetings; consultation to the on-site educational technologist, who meets periodically with the focus group; informal support through e-mail correspondence; collaborative “demonstration” and co-teaching lessons; and adaptations to the adopted curriculum. We have combined these efforts with work with professionals from all levels of the DoDEA system — principals, the school-based educational technologist, and content specialists from district and headquarters levels — to support our efforts to help teachers make discerning decisions about their use of electronic graphing tools in the classroom.

The following is a brief chronology of my work to support the technology in elementary mathematics program in the Hanau Schools:

**Year One.**
- Needs assessment (review of the DODEA mathematics and technology programs, materials, and plans for professional development); consultation with district and headquarters math specialists; materials development (creation of MathLand Technology Framework, writing of grade-specific recommendations for tool use in elementary mathematics)

**Year Two.**
- Introductory summer workshop; ongoing work with teachers (research and informal support, and consultation to educational technologist); piloting of co-teaching model; collection of student work

**Year Three.**
- Continuation of above activities, including full implementation of co-teaching model; broadening teacher participation (consultation, classroom visits, after school introductory and update workshops); plans for “scaling up” of professional development approaches across Hessen district

**Introducing Tools in the Context of Content and Curricula**

Because electronic spreadsheet and graphing tools are fairly complex, most professional development for these tools becomes training on the software itself. Our priority, though, has been to help teachers integrate these tools into their teaching practice. Thus, even when first introducing them to the tools we have worked with mathematical activities that teachers can, with minor adaptations, bring back to their classrooms to teach beyond the tool to the content.

As we reviewed MathLand’s materials in the first year of our project it became clear to us that, without substantial professional development and supporting materials, electronic spreadsheet and graphing tools might be introduced in ways that would inadvertently undercut the processes that the DoDEA curricular guides and standards, which reflect the NCTM Standards, are attempting to build. Electronic graphing tools are too often used only as a way to make quick and professional-looking charts for final presentations. Rather than enriching children’s understanding of the nature of the data with which they are working, this approach reduces graphing to a mere set of efficient procedures (Ainley and Pratt, 1995, Grant, in press). And spreadsheets are too often introduced as a mere set of procedures, without applying their power in a meaningful context.

Therefore, we offered an introductory summer two-day workshop for electronic spreadsheet and graphing tools, which included a combination of tool training (with a focus on learning to use the tools themselves), exploration of the power of the tools for communicating and making sense of
data, an introduction to the application of these tools to content goals and classroom practice, within and beyond mathematics, and consideration of students' understandings through analysis of their work.

Prior to coming to the workshop many teachers had little or no exposure to spreadsheets, or to their electronic graphing capacities. Through work that went beyond "being trained to use the tools," we helped them develop understandings of ways in which spreadsheets and graphs can help describe and make inferences from data, as an integral part of a wider analytical activity. We worked with a combination of activities that were mathematically challenging to teachers, and ones that were drawn from the adopted curriculum and its accompanying software.

Teachers worked with real data (e.g., about weather patterns, modes of transportation, relative sizes of squares) as they learned the mechanics of graphing electronically. They then explored different graphing options. For example, after discussing what they thought was the intended message of a graph about the regional distribution of baseball card collectors, they used The Cruncher and Excel to alter the message of the graph, with changes in graph type, scale, and title. They used spreadsheets to extend Growing Shapes, an activity from the 5th grade curriculum that involves identifying patterns in the relative lengths of sides, perimeter, and area in squares of increasing sizes. And they worked with a spreadsheet to plan a party within a limited budget.

We used grounded examples of class investigations about topics of genuine interest, in order to communicate the power of these tools, and their potential both within and beyond the mathematics curriculum. Rather than emphasizing formulaic approaches, we stressed the capacity of these electronic tools to deal with "messy" numbers and large data sets; to do rapid calculations; and to use scale changes and a variety of graph types to provide different views of the same information.

Teachers discussed where and when within a given activity (and with which activities) electronic graphing tools might further understandings of data. As others' experience suggests (Lewis, 1997), we found that some of teachers' most powerful insights came when the sessions included the analysis of actual students' work, both hand and electronically-generated. Some of the discussions centered on what teachers might not want to lose with the introduction of electronically-generated graphs (namely multiple experiences with hand-generated graphs, both as opportunities for students to construct understandings of essential features of graphs, and as teachers' windows into their students' understandings) (Grant, in press).

Certainly teachers need to learn the mechanics of electronic graphing tools. This requires a substantial commitment of resources and time. But without opportunities to deepen their own understanding of the mathematics of data, as well as to consider use of these tools that will support efforts to make their students more critical generators and consumers of data, key components of the mathematics reform effort will be undercut by the introduction of these tools.

Adaptations to the Adopted Curriculum

The DODEA system is far from alone in working with a curriculum in which the role of technology tools is poorly conceived and articulated. As in many school curricula, technology in MathLand is an afterthought: the main curriculum refers to a different set of technology tools than the accompanying technology guide; there is no summary description of the role of the recommended tools in mathematics, or their relevance in the elementary classroom; the fit between activities and tools in the technology guide is often poor, with only occasional instances in which the activity design exploits the real power of the tools; and the activities contain no objectives for tool use. Nevertheless we felt that the mathematical tools recommended in the technology guide (The Graph Club and The Cruncher) are worth working with and building on.

At the request of teachers, we have developed an adapted suite of materials to guide the use of these tools in the MathLand curriculum and beyond. These include: 1) a general description of the function of each tool, and its potential contributions and limitations for mathematics learning in the elementary grades; 2) recommendations of exemplary activities incorporating the tools at each level, with objectives for tool use; 3) "cheat sheets" for each tool; 4) "road maps" to the key resources in the software itself (e.g., tutorials, projects), and their relationship to the curriculum; 5) further resources (recommended math websites, articles about data investigations in other elementary schools)

These materials have helped teachers identify optimal uses of new tools in the context of their new curriculum. Yet given that both of these involve new relationships to content and pedagogical processes, a number of teachers have also requested additional, customized, in-person assistance in incorporating these tools into their regular classroom practice.

The Development of the Co-Teaching Model

Just as there is no single type of student with a suite of learning needs that is applicable to all students, any given school houses a vast array of teacher styles, experience, preferred approaches to learning, and immediate needs. In Hanau there grew a steady stream of requests from teachers for "help with managing computers in my classroom." Yet when we talked with individual teachers we found that what they meant by "management" varied greatly. Some wanted tips and actual assistance with teaching the tool itself to their students. Others wanted help designing off- and on-
computer tasks in order to make optimal use of the limited number of computers in the classroom. Some classes had done extensive work with data collection projects, but had specific technical questions to address in the context of a specific activity. Some teachers wanted help with a follow-up discussion of students’ representations of their findings, both on and off computer. Still others wanted the opportunity to take stock of what they had done to date, and help with planning next steps next steps. How could all of this take place in a single workshop?

In response to this need we have developed what we are calling a co-teaching model of professional development, a planned program of optional co-teaching opportunities, planning time, and consulting designed to provide support for teachers as they encounter the challenges that come with putting into practice their evolving understandings about the use of technology to support inquiry-based learning.

Following a pilot in several classrooms in May 1997, my November 1997 visit to Hanau consisted of a full week of individualized classroom support. During that week I divided my time between the two elementary schools and the middle school, following up on requests from individual teachers. Through advance e-mail communications these teachers had chosen from among several options for my role (that of consultant/fellow-planner, that of observer/consultant, or that of co-teacher), and we had established a shared plan. Whether I took the lead or served as a background resource for work that was already in progress, I counted on teachers’ playing an active role in preparation, participation, and follow-through after my departure. In addition to extending curricular links, I made a point of introducing teachers to a range of technology configurations (e.g., small groups rotating through stations that involved on- and off-computer work, students working individually or in pairs in the computer lab; using the in-focus projector in discussions).

The fact that these teachers had corresponded with me well in advance made it possible for us to collaboratively shape our time together. E-mail communications, both prior to and as a follow-up to the visit, transformed what might have been an isolated visit into a customized, shared activity that was well integrated into the ongoing work of the class.

If the elementary math work is any indication, this co-teaching offering is filling a keenly felt need. Every minute of my week was filled with work with various combinations of teachers and students, within and outside the classroom. I consulted or co-taught with 14 teachers (in one or two sessions), offered an in-service workshop to the entire faculty of one school, and met with the technical support teams, the principals, and the district math liaison, to update their work.

It is significant that the teachers who initiated these collaborations ranged from the technology trailblazers to the wary. This is a striking development in the educational arena, in which often it is only the innovators or early adopters who engage with technology (OTA, 1995). We are seeing teachers across the system make substantial commitments of time and energy in their efforts to integrate technology tools in their teaching.

What began as complementary support to an elementary math focus group has grown into a model for supporting the integration of technology tools in science, social studies, and language arts as well. Co-teaching weeks with five experts, coordinated to bring a cohesive approach to their offerings, have been scheduled across this third year of the project.

Conclusions

A fourth grade teacher who, last spring, had been new to the school, new to technology, and quiet in her public presence, this Fall presented her students’ work to her colleagues at an inservice workshop. They had worked by hand and with the computer to represent and make sense of their findings from their survey on people’s beliefs about whether animals, humans, or plants can live longest without food or water. Students had been deeply engaged in their investigations, and this teacher’s colleagues expressed admiration for the quality of their work.

What, beyond this teacher’s own talent for teaching and her appetite for learning, makes possible such growth? Our work on professional development with the Hanau Model Schools Partnership has pointed to the convergence of a number of key points.

In our work with teachers to answer the two critical questions, Why are you using these technologies in your classroom? and What support do you need to make the best use of these technologies to meet your instructional goals? we have emphasized how important it is for teachers to take responsibility for their own learning. Yet this responsibility cannot be exercised in a vacuum. The following are additional elements we have found crucial to professional development in the Hanau Model Schools Partnership:

1) The provision of classroom support “where you need it and when you need it,” from the Educational Technologist, has provided a key link between curriculum and technology. He complements the work of the technical support staff by serving as a responsive presence who keeps in touch with teachers, supports them with the tools, and points them to possible links and extensions.

2) The selection of a common tool kit, made up of a limited yet comprehensive suite of tools that the technology and curriculum support team can “have at their fingertips” as they move in and out of work with teachers across content areas and grade levels, makes possible the kind of on-site support that is so crucial.

3) The provision of common planning time has been an important component of introductory and follow-up workshops. We brought a phased approach to planning for use of the tools in teaching with individual Technol-
ogy Action Plans (TAPS). These invited teachers to step back from their practice, consider their goals, and think about how new tools and ideas might support them. The TAPS process, which begins with making a commitment to learn something new, is stretched out over time to include tool and resource exploration, planning, test trials, and reflection. It culminates in teachers designing an extended plan for infusion of tools into specific content areas, in multiple units across the year. These TAPS have become reference points for teachers across the four schools, to which they refer often.

4) The provision of after school technology update workshops have helped carry the learning from introductory workshops into the school year. In addition to reviewing the tools and introducing new features, these give teachers a chance to address questions and needs that emerged after they had a chance to work with them in the classroom.

5) The Hanau principals have taken the role of learner alongside of their teachers, recognizing that in order to lead and support teachers they themselves need to understand what their faculty are grappling with. Through their participation they have come to understand that learning about technology takes time, energy, and risk-taking, and that they need to give their teachers room for all three.

6) Hanau teachers have become key supports to one another, whether in clusters, teams or informal groups. The fact that they are using common tools from the tool kit makes it possible for them to invite each other to try something new, pass on tips, offer a sympathetic ear when something goes wrong, and generate excitement about collaborative projects.

7) In initiating this work with technology tools, we wanted to be sure that our efforts complemented, rather than competed with, the work that was already underway in the DODEA system. Regular meetings with district and headquarters content specialists have helped to ensure that the curricular and technology goals are mutually beneficial, and have built capacity within the system to sustain long-range viability of the work.

The processes described above provide an essential backdrop for constructive professional development for technology in education. These, combined with the efforts described earlier in the paper to make meaningful links between tools and content areas, are key to a thriving professional development program for technology that is closely linked with curricular goals.

We have found that the fact that, having technology tools and technical support in place and an active e-mail culture across the schools, it has been possible to capitalize on face to face professional development opportunities for teachers. Because it is not so resource-intensive to only be within reach of wealthy school districts, this approach is usable and scalable. By leveraging resources that are already in place, it is possible for school districts to provide the kinds of support that teachers need, within the constraints of budgets and personnel.

The literature on technology in education acknowledges that ample resources need to be devoted to professional development for technology use. But that professional development musts go far beyond “training” with the goal of tool mastery. If we aim to use technology to support school reform, we need to make a concerted effort to deepen teachers’ understanding of the potential and the limitations of tools in the context of specific content areas, to revise adopted curricula to reflect those understandings, to provide customized support, and to include involved parties from all levels of the system in these processes.

USING AN INTERACTIVE MULTIMEDIA PROFESSIONAL DEVELOPMENT TOOL TO DEVELOP AN EDUCATOR’S UNDERSTANDING OF MATHEMATICS TEACHING

Michael T. Charles
Eastern Michigan University

This qualitative case study investigates how one teacher used an interactive multimedia professional development program (Understanding Teaching — UT) to help learn and apply the Professional Standards for Teaching Mathematics published by the National Council of Teachers of Mathematics (NCTM). This teacher spent 14 hours using UT over the course of one school year. Pre/post-assessment data indicated that she improved in her ability to correctly identify the NCTM Professional Standards for Teaching Mathematics and in her attentiveness to mathematical discourse in the videos. Observation and interview data indicated that she incorporated new questioning strategies into her teaching practice and began trying more challenging mathematics with her students.

Professional development for practicing teachers is a topic demanding increasing attention in forums on critical issues facing education (Tally, 1995). The publication of the Curriculum and Evaluation Standards for School Mathematics (1989), and the Professional Standards for Teaching Mathematics (1991) by the National Council of Teachers of Mathematics (NCTM) created the basis for an unparalleled program of professional development in mathematics education (Aichele, 1994).

David Cohen (1991) told the story of Mrs. O, a teacher who believed that the NCTM Standards had made a change in her classroom. She had moved from teaching calculational mathematics (Thompson et al., 1994) in a traditional way to using “math manipulatives” and new activities to develop her students’ mathematical understanding. But the revolution wasn’t really finished. Little attention was given to the importance of students explaining mathematical ideas, i.e. engaging in mathematical discourse. Mrs. O. was not really teaching the conceptual math called for in the NCTM Standards.

This paper tells the story of Mrs. N., a teacher who, like Mrs. O., was engaged in teaching “manipulative mathematics” with her students. But Mrs. N. was able to use a tool that modeled Standards-based mathematics. The goal of this research study was to investigate how an interactive multimedia system might be used as a professional development tool to help a practicing teacher move her vision of teaching and learning toward the conceptual mathematics described in the NCTM’s Professional Teaching Standards.

A Summary of Interactive Multimedia Use in Mathematics Education

Previous studies have shown the effectiveness of using interactive multimedia technology in the field of mathematics education. Goldman & Barron (1993) found that when video illustrations are used in a math methods class with pre-service teachers to demonstrate teaching techniques, these techniques are incorporated into their field experiences. Van Galen (1993) found that video vignettes of classroom situations can facilitate reflection among in-service teachers in mathematics when used as part of a course in The Netherlands led by a teacher educator. Bitter & Hatfield (1993) found that preservice students in a mathematics methods course who used an interactive multimedia system showed more appreciation for using manipulatives, demonstrated better observational power, and reported gaining a better sense of the elementary classroom. Clark (1995) evaluated an updated version of that same program and found that preservice teachers were better able to recognize, identify, and explain more of the NCTM’s Professional Teaching Standards than preservice teachers who used the NCTM’s text publication. Her report recommended using the same Understanding Teaching program as a professional development seminar with in-service teachers in the field. Bitter and Pryor’s (1995) pilot evaluation of another updated version of this program with a group of in-service teachers indicated that it was perceived by potential users as an appropriate means of teaching the Standards. More recently, Lambdin, Duffy, & Moore (1997) found that preservice teachers in a mathematics
methods course who used an interactive multimedia product (The Strategic Teaching Framework—STF) modeled their own teaching on the examples provided in STF as well as using the videos as a basis for their own reflections. Research suggests that interactive multimedia may provide an effective means for doing professional development with teachers.

**Understanding Teaching, an interactive multimedia professional development tool**

Understanding Teaching: Implementing the NCTM Professional Standards for Teaching Mathematics (UT) is an interactive multimedia program on CD-ROM designed as a professional development tool to help teachers learn and implement the NCTM Professional Standards for Teaching Mathematics. Developed by Technology Based Learning and Research (TBLR) at Arizona State University, this set of four CD-ROM disks provides the user with guided observation experiences in classrooms to demonstrate the NCTM Professional Standards for Teaching Mathematics. The videotaped lessons teach concepts of geometry and numeration.

UT is composed of four learning modules: Professional Development, Teachable Moments, Application, and Assessment. In the Professional Development module, users view 46 full-motion video vignettes of approximately two to five minutes in length demonstrating each aspect of the six NCTM Professional Standards for Teaching Mathematics. In the Teachable Moments module, users practice identifying the Standards as they naturally occur in a classroom. In the Applications module, users apply their knowledge by creating a lesson plan. With the Assessment module, users view a video vignette, select all of the NCTM Standards that are shown in that vignette, write their rationales for each selection, and compare their final selections to experts.

**Mrs. N. and her professional setting**

Mrs. N. is a 15 year veteran of teaching who works with two classes of kindergartners every day. She is considerate of her students and brings considerable energy to the classroom. Hers is the kind of classroom one would wish for one's own kindergarten-aged child: orderly, friendly, active; a community of learners.

She had access to an Intel-based multimedia computer in her classroom as a part of the district’s efforts to upgrade their technology. Her principal arranged for their participation in this research project along with other teachers in her school. He gave them professional development credit for the time they spent using UT, and hoped that they would then use UT to teach others on the staff.

**Method**

A qualitative case study approach was chosen for this investigation. Researchers in mathematics teaching and learning find case studies useful in understanding the complexities of practice (Lampert, 1986). Stake (1995) and others (Shulman, 1987) have noted that case studies provide particularly rich illustrations. Case study research has been critiqued for its limited scale (Bogden & Biklen, 1982), but others (Erickson, 1986; Stake, 1995; Peshkin, 1993) suggest that the depth of case study inquiry provides unique insights that are useful in other contexts.

There were three data sources for this study:

1. An instrument for assessing the participant’s understanding of the NCTM Professional Standards for Teaching Mathematics before and after using UT.
2. Observations of Mrs. N. as she taught mathematics lessons and after she used UT. Lessons were observed and scripted both near the beginning of their use of UT and after their use of UT. Formal observations of their use of UT were audiotaped and transcribed.
3. Participant interviews, both individual and focus group. These interviews were audiotaped and transcribed.

The primary method of analysis used in the study was direct interpretation (Stake, 1995). Interpretive memos were written after observations, after interviews, after transcribing the interviews, and after reading documents. In this way a growing list of assertions about the case was kept. These assertions were made and then checked against other data. Evidence was sought to confirm or disconfirm assertions and further elaborate on each assertion as new data was collected. Participants were asked to confirm assertions in member checks.

**Asking the Why Questions: The Case of Mrs. N.**

Mrs. N.’s classroom has changed this year. She knows the Standards better as a result of using UT, and she is beginning to implement Standards-based mathematics in two ways: she is using some new questioning strategies that are enriching the mathematical discourse in her classroom, and she has introduced more challenging content into her mathematical curriculum.

**Using Understanding Teaching**

Mrs. N. reported using UT for 14 hours total over a period from October to April, with most sessions using UT lasting for 1 hour. Nine hours of that time was split equally between learning the Professional Standards for Teaching Mathematics in the Professional Development module and seeing those Standards applied in everyday lessons in the Teachable Moments module. She spent one hour taking the pretest, and two hours each in the Assessment and Application modules. The investigator observed Mrs. N. using UT for 2.5 hours.

In observing Mrs. N. using the UT program, one of the things that consistently preoccupied her was determining the mathematical task for the students in each segment.
shown. Determining the task proved to be very difficult, not only for her but also for other teachers in the group.

Just what the students were being asked to do in each lesson interested Mrs. N. a great deal more than it did the program designers. Mrs. N. expected to learn some specific new activities to try with her students, whereas the designers thought that she would be learning a set of generic teaching techniques. When Mrs. N. visits another classroom vicariously through the video camera, she does not look first for exemplars of correct technique, but for a set of activities that she can do successfully with her students. This observation fits with Thompson et al. 's (1994) recommendation of providing a “repository of rich problems” (p. 90) for teachers to begin using with their students as a critical element in helping teachers begin to move toward conceptual mathematics.

**Improved Understanding of the Professional Standards for Teaching Mathematics**

In the pre-/post-assessment analysis there was further evidence that Mrs. N.'s understanding had changed through her experience with UT. After using UT, she selected 30% more of the correct Standards as defined by the experts cited in the Assessment module. More importantly, Mrs. N.’s rationales more closely resembled that of the experts. For example, before using UT she said that the teacher’s role in discourse was limited to requiring the students to discuss with a partner. After UT she mentions new roles that align with notions of discourse: questions stimulate thinking, the teacher responds to what the students say, and most importantly, that the students clarified their ideas orally. This corresponds with what the experts saw in this segment. One of their stated rationales for Standard 2.1 in the same video is that “The task engages some students and had them compare answers and discuss responses.” Their answers share Mrs. N.’s emphasis on the importance of the oral clarification of the student’s mathematical ideas.

**Changes in Teaching Practice**

Using UT changed Mrs. N.’s teaching practice in two ways. She began using new questioning strategies, and she began doing more challenging mathematics with her students.

New questioning strategies. In a November interview, Mrs. N. explained how her graphing lessons were changing: When you first saw me graph apples I did every-thing. Today I had them put the cookies— they were graphing who likes cookies [for snack], who likes doughnuts—they would put the markers on the graph. Then I would ask the class, “Should it be there? Did they put it in the right place?” And then I would say to them, “How do you know?” And they would start discussing. “I think it’s this,” and “I think it’s that,” and “I don’t think it’s fair.” Then they had to show us. Well look! They started talking and interacting. And I’m kind of out of the picture. Isn’t that what I want? I want to be out of the picture. . . . You enjoy them discussing it!

Mrs. N. is not a teacher who is new to the idea of active discussion in her classroom. But what is new is the idea of active discussion in mathematics. Mrs. N. has used the Mathematics Their Way (MTW) program for a number of years in her classroom. The assumption of that program are not fully aligned with the NCTM Standards and notions of conceptual mathematics (Cohen, 1991). The “manipulative mathematics” of MTW is still focused on learning the procedures of mathematics, but by using new materials and new methods to accomplish this. The critical new element in MTW is new mathematical activities, not new mathematical discourse. This same belief was reflected in Mrs. N.’s practice, but it is changing after using UT.

In April at the conclusion of the study a final focus group interview was conducted. This gathering provided closure to the project as well as addressing concerns about the brevity of the UT videos that the teachers in the project had expressed. The participants were shown a 45 minute videotape of a teacher doing one lesson that particularly focused on demonstrating mathematical discourse. This video was made as part of the Math Discourse Project (MDP), an effort funded by the National Science Foundation aimed at better showing mathematical discourse in actual classroom lessons. After watching this video of a lesson, Mrs. N. had this to say:

You know what she does a lot of, and its like a light going on for me. She doesn’t give them paper and give them an assignment and tell them to do this. Instead she gives them a task that has a problem, and she allows the students to solve it . . . She allows them to defend their reasoning, and to show her how they arrived at their conclusion.

For Mrs. N. this video clip was much better than UT because it focused on improving mathematical discourse in the classroom. As she watched the students in the video defend their reasoning, she realized the value of having students make their thinking public. At the end of the study Mrs. N. states very clearly that she has learned new questioning strategies from UT. The key to these new questioning strategies is that they allow her to “see my student’s thinking.” She saw more of those new strategies in UT and the MDP video, and she began to encourage her students to defend and explain their responses in the classroom.

More challenging mathematics. There is a second and related way that Mrs. N. says that her teaching changed: she has begun teaching more challenging mathematics to her kindergartners. In November Mrs. N. and a colleague were using UT with the investigator serving as an observer. They...
were watching a lesson from the Teachable Moments module. Mrs. N. was concerned whether or not second graders should even be doing long division since that content is usually reserved (in her mind) for third grade. Next she wondered if they really understood the division. The breakthrough in her own understanding came when she saw how easily division can be demonstrated using the manipulative materials. In the video, the students initially struggle with the task, but are successful with the teacher's help on the second try.

What so impressed Mrs. N. in the video is how higher level mathematical operations like division could be brought down to a primary level through the use of manipulatives. She had used manipulatives in her own classroom with her assigned content, but had not thought about how manipulatives might provide a window to more challenging content. Mrs. N. was taken with the idea of exploring more challenging mathematics with her students despite her concerns that she might be intruding into what next year's teachers cover in mathematics.

So Mrs. N. began teaching addition with regrouping to her kindergarten students in the context of a flash card racing game that they play. She and her kindergarten students were adding numbers like 38 and 14. They did this together on the board, and for some of her students it is an exercise in counting (not regrouping), but in the context of the flash card game it is something that her whole class can participate in doing.

Providing challenging mathematics activities that was "above grade level" was new to Mrs. N. She is now thinking about mathematics differently. Mrs. N. now has higher expectations for her students in mathematics, and higher expectations for herself as a facilitator of mathematical discourse. These higher expectations came through her interactions with the investigator and through her use of UT.

Discussion: UT as a Facilitator of Changed Practice

Mrs. N. knows the Standards better after using UT. The analysis of her pre- and post-assessment responses also reveals an eye that is sharper at looking for mathematical discourse. She is employing new questioning strategies and has developed higher expectations for her students' mathematical endeavors through both her conversations with the investigator and by finding examples of discourse and mathematical activities in UT.

Does the case of Mrs. N. show that interactive multimedia can provide the kind of professional development resource that can change teacher thinking and tilt their practice toward that of conceptual mathematics? The results suggest that Understanding Teaching provided the resources that helped Mrs. N. learn how to change her practice. The change in this case happened through interaction with the researcher as well as interaction with a larger group of teachers, much as van Galen et al. (1993) reported earlier.

One could argue that Mrs. N. is certainly better off than most teachers for having seen examples of the Professional Standards for Teaching Mathematics. She is better off than Cohen's (1991) Mrs. O., who mistakenly believed she was teaching in accord with the Standards. Mrs. N. is at least beginning to engage in the newer forms of mathematical discourse that are critical to the NCTM Standards, and part of what helped her do this is her chance to vicariously visit the practice of other teachers through UT.

There has been an increase in emphasis for using various technologies in classroom. Whether the reason is giving students access to interactive learning environments, or promoting a more technological literate society, K-12 classroom implementation of technology is becoming very popular. Some of the technologies being used in classrooms are computers, calculators, videodisk players, as well as other multimedia devices.

In an analysis of policy documents, Ragsdale (1991) reports a large and growing preference for computers to be used as tools in the classroom. Policy documents in mathematics education, such as the Curriculum and Evaluation Standards [NCTM Standards] call for the integration of technology into mathematics instruction. According to the NCTM Standards “thoughtful and creative uses of technology can greatly improve both the quality of the curriculum and the quality of children’s learning” (NCTM, 1989, p.18). Fagan (1996) mentions the appropriate use of technology as one of the shifts occurring in mathematics teaching and learning as reported by teachers.

Central to the integration of technology into mathematics curriculum is the question of how teachers effectively integrate it in their mathematics classrooms. Ragsdale (1991) argues that computer use as an instructional tool requires teachers to be knowledgeable users of the tool in the classroom. Certainly, for many teachers becoming knowledgeable users of technological tools for classroom use can be a new, challenging, and complex endeavor - one that involves change.

This paper focuses on gaining an understanding of the extent to which one teacher’s movement in the direction of change has interacted with his commitment to using technology in his mathematics instruction. The study will document specific characteristics of this teacher and relate his experiences with a model of teacher change that I propose. The study addresses two research questions:
1. Where is this teacher located in the proposed model of teacher change?
2. To what extent does this teacher’s experience follow the proposed model of teacher

In Search of An Appropriate Model of Teacher Change

What seems to be missing in this call for implementing technology into classroom instruction is a good description of the process. In particular, it would be useful to understand how teachers change as they integrate technology into mathematics instruction.

In trying to develop an appropriate model describing the change process of teachers as they integrate technology into mathematics instruction, I have considered several models related to teacher change (i.e., Guskey, 1996; Sandholtz et al., 1992; Shaw & Jakubowski, 1991), then combined parts of these models into a whole.

Movement in the direction of Change

Shaw and Jakubowski (1991) indicate the need for a mathematics teacher to have a perturbation in order to change. Perturbations cause a teacher to reflect on and question his/her classroom practices. Shaw and Jakubowski explain that without a perturbation, a mathematics teacher is satisfied with their practice. A perturbation may occur as a result of observations of one’s own classroom practice, curiosity about more effective classroom practice, teacher inservice programs, and so forth. Shaw and Jakubowski discuss how perturbations result in the disruption of a mental state of equilibrium. One of three things happens:
1. a teacher blocks out the perturbation, therefore, preventing the opportunity to change;
2. a teacher develops a rationale for not dealing with the perturbation; or
3. a teacher plans to make a change.

Commitment to Change

Teachers who plan to make a change are faced with decisions about how to act upon their intent to change. They have gone beyond the perturbation state and have committed to making change. This commitment is the second requirement in Shaw and Jakubowski’s (1991) process of teacher change. Commitment to change can manifest itself in many different ways. For example, the teacher may collaborate with other teachers in sharing innovative ideas.

602 — Technology and Teacher Education Annual — 1998
This sharing of ideas may lead to the teacher discovering alternative approaches to using technology in the mathematics classroom.

However, there exists the possibility that teachers who are committed to change do not have the support or opportunities that would allow them to discover alternatives to their existing practice. For example, a teacher with ideas about alternative approaches incorporating technology may not have access to a computer or computer lab to try ideas out. In this case, it is unlikely that significant change will occur, despite the commitment to change.

Change in Practice

When teachers attempt to implement an innovation, they have to learn techniques for enhancing their instruction during the innovation. They have to find ways to use the innovation to their advantage. They have to become more focused on the effects of their teaching on students’ learning of mathematics, as opposed to reflection on their own survival while teaching mathematics using technology. In short, they have to change their practice.

Once teachers decide to change their practice, they observe the effects the change has on their teaching and their students. They refine their beliefs and attitudes about the innovation. They are reflective. They are able to make decisions about whether or not to modify their practice so that significant change is made. They may abandon the new practice in favor of previous methods of teaching, if things are not working as intended. This continuous reflection may cause them to have other perturbations (Shaw & Jakubowski, 1991), hence, the process of change continues.

An Improved Model of Teacher Change

Based on existing models, and a synthesis of the literature, I propose the following model for describing the process of change teachers experience when integrating technology in mathematics curricula. The model consists of six major locations. These locations are the following:

1. perturbation,
2. commitment,
3. absence of commitment,
4. attempts at changing practice
5. significant change in practice, and
6. no significant change

The model also contains intermediate locations that teachers reach before moving to one of the major locations listed above. These intermediate locations are the following:

1. teacher plans to make change
2. teacher lacks resources for discovering alternatives to current practice,
3. teacher creates his/her own alternatives to current practice,
4. teacher retains some aspects of alternative practice, and
5. teacher abandons attempted practice.

It is possible for teachers to move back and forth between the locations in the model. It is also possible that teachers would be in more than one location simultaneously.

Recall that perturbations initiate movement in the direction of change (Shaw & Jakubowski, 1991). As a result of the perturbation, two things may happen:

1. teachers may plan to make a change in their own classrooms, or
2. they may ignore the perturbation (absence of commitment).

Teachers who plan to change might develop a rationale for postponing change. Therefore, there is an absence of commitment to change here also. An absence of commitment leads to two possibilities:

1. If teachers are perturbed to thinking about practice again, they may start the change process over, therefore they are back at perturbation.
2. If they ignore perturbations and are satisfied with their practice of teaching mathematics, then there will be no significant change in practice and the current practice of the teacher remains unchanged.

What are the characteristics of the teachers who plan to make change and actually commit to making the change? Teachers who make the commitment to change begin to make decisions about how to go about it. They may look to colleagues as resources for ideas to use in their classroom. They may look for opportunities to alter their existing practice through staff and professional development.

Now teachers at this stage may be ready to make an attempt at changing their practices. But what happens to the teachers lacking sufficient resources for discovering alternatives to practice? In this instance, three things may happen:

1. teachers may create their own alternatives to practice,
2. continue to plan to make change by looking for additional (opportunities to discover new ideas), or
3. develop a rationale for prolonging the situation, in which case they have lost their commitment to change, either permanently, or until they are perturbed to consider modifying their practice again.

Let us return to the teachers who make the commitment to change. Once these teachers have committed to making a change and created a vision of change in their classrooms, then they can attempt to change their practices, hence moving to the next component of the model. As they attempt changing their classroom practices, teachers compare their vision of the change with actual classroom outcomes. If they are satisfied that the change has been beneficial for them and their students, then they retain the attempted practice. Some aspects of their practice may be beneficial and some may not. In this scenario, teachers tend...
to retain those aspects of the practice which are beneficial to themselves and the students, and those that are not, they abandon them. This phenomenon represents an intermediate stage in the proposed model. In an extreme case, if teachers are unsatisfied with most, if not all aspects of the attempted practice, then they abandon it. When abandonment occurs, teachers may be perturbed to examine new practices (perturbation) or they may revert to their original practice (no significant change).

It is possible that with the retention of the attempted practice, teachers may be perturbed even more to find ways of improving practice so that it will continue to benefit them and their students. Recall that one criterion for having a perturbation is observing one own actions and/or practice. Therefore, such a reflection on practice may lead to more attempts at changing practice. It is likely that significant change in practice occurs only after there has been several cycles of movement back and forth between the attempt and the perturbation components of the model. However, the validation of that component of the model goes beyond the scope of this study.

Background
The participants of this study are middle school teachers from two Midwest school districts. These teachers chose to participate in a workshop designed for teachers interested in pursuing personal knowledge of technology and mathematics, and in translating that knowledge into the classroom teaching of mathematics. Participants of the workshop were given the opportunity to become more familiar with technological tools and computer software. This paper will focus on the change experienced by one teacher, Tim, who uses technology in his mathematics instruction.

Case Study
A case study research design was used to determine further the extent to which the proposed model accurately reflects the process Tim goes through when he attempts to integrate technology into his instruction. This teacher was observed teaching a lesson involving technology during the Fall of 1997.

Data Collection and Analysis
Several instruments and documents were used to collect data in this case study. They included a personal history questionnaire, a pre-observation interview, classroom observations, and a post-observation interview. The personal history questionnaire of Tim was analyzed by identifying possible questions to ask during the pre-observation interview. During the classroom observations, I wrote comments in my notes that indicated the extent to which his plan, goals, and expectations, as stated during the pre-observation interview were met. I also took note of how technology seemed to be influencing Tim’s teaching of mathematics. During the post-observation interview, I collaborated with Tim on themes that emerged during the course of the observations related to students’ learning of mathematics and influence of technology on teaching mathematics. Tim and I revisited classroom events, incidents, behaviors, etc. We compared these events with Tim’s intentions and expectations for the lessons as stated during the pre-observation interview. I have selected themes from the personal history questionnaire, the pre-observation interview, and the post-observation interview to discuss below.

Tim’s Experience with Using Technology
Tim teaches fifth and sixth grade mathematics at an elementary school in the Midwest. He has been teaching for 20 years. He has taught mathematics for 19 of those 20 years. He has used many technologies in his classroom to teach mathematics. Such technologies include computer software programs, tool software (e.g., spreadsheet, database, and word-processing programs), calculators, the Internet, videodisks and videodisk players, and video cassette recorders. He has received formal training with technology through inservice programs within his school and school district, at professional meetings, and at a university project. He has received informal training with technology by self-instruction and demonstration by colleagues.

Tim indicated that he participates in a study group of sixth grade teachers interested in using technology in mathematics instruction. This group was put together by Tim’s school district. Tim feels that he is a mentor to this group since he has been exposed to much of the technology that is fairly new to the rest of the group. Tim is also on the technology committee of his school. The committee applied for a grant to receive funding for technology. They were awarded the grant and will be receiving laptop computers, computer hardware, and computer software for use in classroom.

Tim’s Pre-Observation Interview
Tim indicated that he uses various computer instructional software programs with his students. One of his purposes for using instructional software is to develop his students’ logical thought processes. He plans to “have students use spreadsheets so they can become comfortable with entering data. The spreadsheet activity will prepare them for a special lesson that he will teach on automobile traffic flow that relies on the use of spreadsheets. He will teach this lesson later on in the school year. He has found that in the past, it was difficult to teach students how to use spreadsheets while teaching this lesson.

Tim will be teaching a multi-day activity. The activity consists of an adventure that tells a story about a man interested in purchasing a boat. The man is faced with some important decisions to make about the feasibility of making the purchase based on several factors including the cost of the boat, size of the boat’s gas tank, and other key factors.
The adventure is presented to students on a videodisk Tim will have the students watch the video adventure. At the end of the adventure, challenge questions are asked and students will be required to discuss and attempt to answer those questions based on information given in the story.

Tim will make sure that students understand the challenge questions by discussing them with the class. Once he feels they understand the challenge questions, then he will divide the students into groups of 3 or 4 and ask the students to brainstorm information they should be looking for to answer the challenge questions. Then the class will watch the video adventure to allow the groups to gain as much information as possible. After watching the video for a second time, the students will return to their groups to organize and analyze the data that they obtained from the video. When the student groups realize they need more information, they will be allowed to access the videodisk to retrieve that information. Groups will eventually present their solutions to Tim, and he will further challenge them and direct them towards improving their answers.

Tim describes his roles in these situations as “receiver, challenger, redirector, and acceptor.” Tim says that the goal of this adventure is not necessarily to have all the groups arrive at one correct solution. He says there are many different ways that students can arrive at a solution. Tim simply expects the groups to carefully document information given in their solution and to justify their answers.

Tim indicates that the major mathematics concepts targeted for this lesson are rates and proportions. He will teach a mini-lesson on rates to develop students’ understanding so they can use the information in solving the challenge questions from the videodisk adventure. He says that his students have not typically done a lot with rates as part of the traditional school curriculum. He feels that this is a good way to introduce rates in a meaningful situation.

**Tim’s Post-Observation Interview**

Tim felt the majority of the students picked up on the objectives of the lesson including working with rates, developing questions to ask to about the adventure, discarding unneeded information, and interacting with other students in the group. He admits some students “cruised” while other students worked much harder to give input to their groups. He coped with this by asking the students who “cruised” for information about the group’s solution, rather than asking group members who significantly contributed towards coming up with a group solution. He felt that this made all students accountable for group participation.

Tim felt that for the most part, he fulfilled the roles of receiver, challenger, redirector, and acceptor as mentioned in the pre-observation interview. However, he felt some groups needed more redirection and less challenge. He says that in some cases, his students focused on aspects of the story that were neither critical nor relevant to the solution. He said that he had to redirect students so they would not spend any unnecessary time focusing on irrelevant material without telling the students a solution.

He felt that the students’ solutions were less refined than previous classes for which he has taught the activity. Although he felt that a few of the groups had good solutions that were well documented and justified, he had to give certain groups, who had less refined solutions, direct hints to move them towards better solutions.

He felt that students during this lesson were presented with a situation that required open-ended thinking and problem solving. He indicated that students’ ability to access information directly using a bar code reader with the videodisk technology enhanced the lesson. Student groups were given free reign to use the bar code reader to access any scenes from the adventure which provided any information they felt was relevant to solving the challenge questions. In the future Tim wants to connect the videodisk player to the computer and use computer software to allow the students to access certain scenes in the videodisk.

Tim feels that student interest and motivation would not have been the same had the technology been present. Furthermore, he believes that the quality of the solutions would not have been the same. He stated, “The technology enhanced the lesson and the lesson benefited from the technology.” Tim says that he will definitely teach this lesson again. He feels that it is excellent mathematics, motivating, and fun.

**Relating Tim’s Experiences to a Model of Teacher Change**

Tim is very reflective about his classroom practices. This is what led him to think about how he can improve on this activity and others that he uses with students. For example, his difficulty with teaching spreadsheets during the traffic lesson has caused a perturbation for him. He has decided to change by introducing a spreadsheet activity before the students are taught the lesson on traffic flow. Another example of Tim’s reflection and subsequent action is given when he observes that some of the student groups consider information that is irrelevant to the challenge questions. He felt that he had to serve as a redirector to help the students focus on relevant information.

Tim has shown his commitment to using technology in his mathematics instruction in several ways. Commitment is evident by the fact that he has looked for ways to learn how to use certain technologies. For example, he has sought training for learning how to use technology, taught himself how to use some technology, and attended professional meetings to learn more about technology use.

He has also shown his commitment to using technology by collaborating with other teachers and colleagues. For example, he serves on his school’s technology committee. He also participates in a study group of teachers interested that in the classroom use of technology in mathematics instruction.

Mathematics — 605
Tim’s commitment to use technology in his mathematics instruction manifests itself in his willingness to attempt, refine, and retry mathematics lessons involving technology. He has looked for and continues to look for opportunities to implement technology into his mathematics instruction. One example of this is Tim’s desire to use computer software to access scenes in the videodisk adventure the next time he teaches the activity. This is consistent with the notion that change is a complex, on-going process.

Hopefully Tim’s experience can shed some light on how a teacher can go about changing his/her instruction. Tim’s experience is only one that explores the issue. This ongoing study will explore other teachers’ experiences with integrating technology into mathematics instruction. I believe that the study will further our understanding of how teachers change their practices when trying to be innovative. I also believe that by attempting to validate a model of teacher change as it relates to integrating technology into mathematics instruction, one would be able to use the proposed model to look at other innovations that are being attempted in the classroom.

In France, as in other countries, there is a long tradition of using video in teacher education centers. (Nowadays, IUFM, University Institutes for teacher training). It is in effect possible for the trainees to observe the organization of a classroom, the practices of expert teachers, students' activities and so on, short videos. This is in part, because they show the dynamics of pedagogical processes, the reactions of students and are adapted to the purpose of enlightening about pedagogical practices.

For example, showing different classroom sequences based on distinct learning models helps developing an understanding about ways of teaching and learning (Ara, et al. 1996). Such pedagogical films offer an interesting support for discussion during training sessions. Other films can be used in order to train teachers to find the objectives of a sequence and to write the corresponding preparation.

Many trainers even think useful to go further and offer trainees the opportunity to create their own pedagogical films. But, going into classrooms to film sequences is a very time consuming task, that cannot be reasonably performed during preservice education. Furthermore, setting up rushes requires heavy hardware, whose access is not easy to insure, and demands specific training.

What can "new" technologies offer?

One common drawback or traditional video is it's lack of interactivity. Multimedia computers are, nowadays widely spread in the teacher education centers, and video can be soon with personal machines and associated with other resources (text, hypertext, educational software and so on). Several institutes have included interactive video (see Lamdin & al., 1997, for a review), which can be used in a more flexible way.

New software offer the opportunity to digitize video and to act up virtual films. This last task can be performed with personal computers. It is thus possible to work with several groups at the same time. But, even with the increasing possibilities of multimedia computers, filming in classrooms remains a very time-consuming activity. So it seemed to us convenient to focus on setting up existing videotapes. We provided teachers with digitized sequences and decided to train preservice teachers to the virtual setting up of them.

The Project

This project takes place at the IUFM of Cretcil (France) but takes into account ideas and resources developed in the framework of a research project about the transfer of mathematical textbooks in electronic manuals (Bruillard & Baron, 1996; Baron & Bruillard, 1996). In the following sections, we briefly describe this research project and the successive design phases of virtual pedagogical films.

Context: The electronic manual project

A research about the mutations between paper manuals and electronic books led us to design all electronic handbook of mathematics for grade 6 students, starting from an existing manual (Chapiron & al., 1996).

We had in mind not only to offer new resources to learners, but also to teachers (notably novice teachers). The teachers manual and a special booklet explained the authors' pedagogical ideas. But the painted material does not offer a clear image of what is really possible. More to the pot at, the socio-constructivist conceptions of the authors of the manual are not widely spread among French mathematical teachers. This kind of approach is therefore not straightforward for teachers who do not practice it. They may encounter many unexpected problems in installing pedagogical situations described in the textbook, because they do not know how to organize the classroom according to a constructivist view of learning and to predict classical student behavior and proposals. Thus, we decided that our prototype would also offer teachers multimedia resources helping them designing classes and coaching students.

First phase: segmenting

We filmed two different classes of students performing the same tasks in an author's classroom. These tasks were described in the mathematical textbook and chosen by tile
authors. During filming, which was continuous two main ideas were followed:

- Getting images of the teacher’s instructions at each moment in order to be able to show the sequence of events;
- Collecting as many sequences as possible of six graders working, discussing or explaining to a small group or to the whole classroom.

The total duration of the rushes was about two hours and a half. After a careful study of these rushes, it appeared that several different film editings could be created, according to different points of view. So, we decided to extract and digitize a set of short fragments, that could be rearranged in ninny ways. We digitized around a hundred of such fragments (between 10 and 25 seconds each) in Quicktime format. Technical and logistical considerations (keeping only high quality and relevant shots) were involved in tile choice of these sequences.

In order to identify all these elements, we chose to associate to each one a filename describing roughly its content. Working with different platforms (Macs and PC’s), we limited the filename length to eight characters:

- First character: unique identifier of the task
- Second character: classroom number
- Third and fourth character: type of activity (e.g.: recall, orders issued by the teacher, individual work, collective work, explanation, discussion between students1 sharing of results, cognitive conflict.)
- Fifth character: number of persons involved
- Sixth character: kind of shot
- Seventh and eight character: main person involved in the sequence (teacher, student number)

These short video fragments represent specific sequences of interaction, but the continuity is lost. We observed that viewing one of them without knowing the context is not relevant, and that we lacked good tools to navigate through a film database. Continuity had to be recreated by editing. It appeared to us that setting up such a material could be very profitable for training in two aspects; they could reflect about the logic of teachers’ practice and, second, they could become familiar with the problems posed by using image processing software, which is now part of the common culture in IT.

Design Phases

Trainees were first shown the complete video. In-depth discussion was led with them about the dynamics of what was really happening; the activities of two groups of twenty students with the same mathematics teacher were compared. It seemed interesting to ask the trainees to set up video fragments using Adobe Premiere in order to illustrate key issues: the method followed by the teacher, the discussions between peers, the exchanges between groups and, notably the periods of socio-cognitive conflicts.

After a very short presentation of the software Adobe Premiere, they were asked to choose a point of view for their video editing, to find relevant video fragments and to link them to create a film.

First results

Four different groups of three preservice teachers worked on this project and two of them (the most advanced in information technology) were able to finish a first version in about six hours, working in a very autonomous way. These two films are very different. The first one (about two minutes) focus on the teachers’ role and the second one (about five minutes) on the students activities. These two videos were shown to an expert group including the four authors of the mathematical textbooks. Their reactions were neither lukewarm for the first film, sniffed with video effects, and very positive for the second one, in which they reorganized their own ideas.

We made no real formal assessment, neither have we yet shown the two films to other student teachers. But we observed that the preservice teachers were really engaged in this activity, and discussing with them convinced us that have increased their understanding both in organization of mathematical situations and in sixth graders behavior. This can be illustrated by a short example of one situation of the film.

An example

Given a rectangle ABCD, the problem is to find another rectangle whose area is smaller and than perimeter is larger than those of rectangle ABCD.

The underlying idea of the situation is to convince students that area and perimeter do not vary in the same way. This is not easy to admit for many students, who believe that these two sizes necessarily grow at the same time. Paying attention to the drawings made by the pupils or to their gestures can give important hints about their way of reasoning.

Perspectives

Overall, less than 10 hours were necessary for two groups of preservice teachers to finish a first version of high quality. The students really produced a film; this activity has modified their representation of teaching and has increased their familiarity with IT. Other groups are also finishing their own films, using the same set of video fragments with others points of view. The feasibility of our approach has thus been proven, at least for students having received a sound previous training in informatics. However, problems arose, that need considerations and might lead to further research.

First, it would he necessary to improve students education in video writing, in order to obtain, better productions. This is being considered at the IUFM level. We will present these films to other preservice teachers, not
involved in this project, with a double aim: test the peda-
gogical relevance of these films and lead with them a
general reflection on audio visual media and on film
designing.

Secondly, we intend to design a system aiming at
facilitating the exploration of a database of video documents
which should be necessary if we were to use this kind of
approach on a large scale.

In this kind of project pedagogical and technical
considerations are intertwined. Pedagogical ideas are
constrained by the discovery of implementation needs and
state of the art tools. We expect, after the end of this first
experimentation, to have a better insight in the problems
fled to setting up virtual films in order to train teachers.
What is at stake is developing, in a constructivist perspec-
tive activities of production in teacher education.

Acknowledgments

The authors wish to thank Gisele Chapiron for her very
kindly reception in the classrooms and Christian Gautherau
who filmed and participated at all phases of the project. We
also thank the preservice teachers for their contribution to
this study.

The electronic manual project is funded by the CNRS
(Groupe d'interet scientifique, Sciences de la Cogni-
tion) and by the INRP (National Institute of Pedagogical
Research).

Technology as a Unifying Theme in a Transdisciplinary Teacher Education Program

Michael L. Connell  
University of Houston

Jacqueline Kemper  
University of Houston

Cameron White  
University of Houston

Nancy L. Williams  
University of Houston

Teacher education is currently undergoing some marked shifts in “personality”. Two of the more noticeable to the casual observer (and not so casual researcher) are the increased emphasis upon “field-basing the courses” and in providing “rich and personally meaningful contexts for learning.” And although each of these directions are worthy of following, the question of whether both can be traveled simultaneously remains open. In fact, such very basic questions as what constitutes effective methods instruction in the light of these, and other, new emphasis are up for grabs.

Regardless of which of the many “buzz-words” are used to describe the evolving teacher education programs which arise to address these concerns (and indeed, the acronyms constructed to describe these programs - we operated under the umbrella of the University of Houston’s nationally recognized PUMA program, Pedagogy for Urban Multicultural Action for those who just had to know!) there are some common elements which must be addressed.

Common to many of these approaches, however, are two elements - a) site basing the methods course itself. This is done most often to take advantage of the authentic context of the school itself and the expanded opportunities this allows; and b) encouraging a more collaborative approach toward the instruction of methods courses to allow for multiple contents to be simultaneously presented.

Discussion of Trans-PUMA

To this point, a reform effort in teacher education will typically take one of these two broad approaches - site basing and increasing the collaborative foci. It must be noted that this approach has certainly lead to the development of many worthy programs and arguably has improved the instruction and caliber of the teachers which participate in such programs. And yet, there has always remained the feeling that more could be done.

In the spirit of “We want our cake and we will eat it too” the four of us decided to pilot a program which would do both - be totally field based and rely upon an intensive shared collaborative effort in content methods instruction. Finding the term collaborative an inappropriate fit given the intensive nature of the collaborative effort, we have adopted the term transdisciplinary following a review of the literature. The transdisciplinary metaphor with its emphasis upon authentic problem contexts, multiple embedded problems naturally arising from these contexts, and multiple domain specific approaches which may be used in addressing these problems does a much better job in capturing the look and feel of the methods courses which we co-teach.

Early steps along this line were taken in the 1996-1997 school year when the four of us had the opportunity of co-teaching our methods courses in a field based setting. This co-teaching was extensive and involved the four of us working and teaching together for a full day a week. These sessions were intensive and challenged each of us to the limits as we determined what constituted a “good fit” for our own respective area of emphasis (which for the record are: a) Connell - Mathematics; b) Kemper - Science; c) White - Social Studies; and d) Williams - Literacy, Language Arts, and Reading). Finding this fit within the transdisciplinary methods course we advocated required continuous energy and focus. It must be noted that this was a true pilot in that there were many rough edges which needed to be worked out. As we will describe in the following section, however, we managed to work through many of the toughest ones. Based upon this year-long experience, we are now in our second year utilizing this approach.

Keeping the “dance” in the “trans-”

Although affect is not always thought of in terms of a professor variable in evaluating such programs, it must be mentioned here. It is a truly a tribute to the friendships and professional respect which we had for each other (and which was strengthened greatly as a result of this experi-
ence), that in each case where problems might have caused the whole enterprise to collapse we were able to come to a workable accommodation. Furthermore, this did not require any of us to lower either our standards or to abandon our beliefs. But rather, reflected the content expectations we are responsible for, the needs of the student candidates, and our own abilities as methods professors.

In the process of working together, there was much redefinition of our core courses for the teacher education program. This was due in no small measure to the opportunity which we have had to work together for extended periods. This alone is a positive outcome of the program, as it has enabled each of us to learn from the others, and to see much better “hooks” into the respective content areas which we may utilize in our own instruction.

As might be expected, it has also lead to some very significant observations concerning ways in which our respective contents truly overlap in a natural fashion. From this ongoing interaction there have been major changes in the structure and method of teaching the methods - in this case the core courses of mathematics, science, social studies, and language arts. We feel that although there is still much progress to be made, we are approaching one protocol which is both doable for us and transferable to other settings.

As you might expect, there were many opportunities for the project’s self-destruction. Such challenges are inherent in nearly any radically different approach, and we had gone into the pilot expecting them. We found, however, that despite the seeming differences (which are often due to matters of form and not substance) there were more powerful commonalities which united us and helped ensure the project’s continuance.

Taking the liberty of speaking for just a moment with a singular “mathematics education voice”, Connell and Bouniaev (1997) suggest that in current educational research there has been quite a bit of the paradigm wars lately. It almost seems that in the “your paradigm” vs. “my paradigm” schism that the learner and the teacher - two key groups in educational settings to say the least - are often left by the wayside in the interests of theoretical “purity”.

This is a quite unfortunate state of affairs because occasionally, upon a critical examination of exactly what is to be done in actually implementing specific instructional implications, the actual recommendations for actions are quite similar. Although by their very nature education research, and researchers, must ground their work firmly within a specific theoretical orientation, typical classroom teachers are less concerned with theoretical purity then they are efficacy of results. If we are to make our research more useful we must on occasion set aside what divides us theoretically and look toward what unites us in the actions which we would propose.

In our transdisciplinary efforts we had the added benefit, however, of sharing a strong commitment to the constructivist stance and the associated implications this holds toward our content areas. Speaking for myself at this point (Connell), I would suggest that this combination of mutual respect and shared philosophy did a great deal toward smoothing out the rough edges.

The shared constructivist stance, however, makes for a few interesting problematics for us. The first, and most immediately relevant to this paper is that it makes a description (at least in a typical prescriptive and pre-scripted fashion) of the day to day structure of our combined course (formerly the four separate methods courses) difficult. You see, a primary difficulty in describing constructivist classrooms is that the teachers within these classrooms tend to be natural “constructivists” themselves. As a result, their constructivist approaches and methods are often created dynamically from day to day practice.

These methods and approaches often tend to be idiosyncratic, highly influenced by personal experience, fluid and often share only the constructivist label when compared with other “constructivist” classrooms. Now, imagine taking four such constructivists and putting them in the same classroom for, in many cases, two full days per week. It is little wonder that the term transdisciplinary mentally morphed to “Trance-disciplinary” by the end of the year.

Technology

Yet, in addition to the near Zen-like uniting and dividing which the constructivist stance offered us, there was an additional unifying force. This lay in the incredibly powerful unifying force which technology can be in such a transdisciplinary effort.

Some of this is reflected in last year’s editorial comments within this very text (Connell, Williams, & Gannon, 1997). As was noted at the time, within mathematics education the process strands of the NCTM 1989 Standards for Curriculum and Evaluation describe mathematics as consisting of problem solving, communication, reasoning, and building connections. Furthermore, the case was presented at this time that the papers describing technology within mathematics education could likewise be organized around similar themes.

Well, although this is the mathematics section of the annual, it must be confessed that these process strands are certainly present in each of the other disciplines we respectively represented in our approaches. Furthermore, technology has proven itself to be the nearly universal tool of choice to use in developing these foundational skills.

And if last years experience in reading the SITE Annual is any guide, this volume (which you are now reading) will contain numerous approaches and suggestions appropriate for field basing and for a transdisciplinary and constructivist
approach. Take these suggestions and use them as a starting point. After all, we did!

**Reality Checks and Recommendations**

Lest one get the impression that we have achieved some type of Nirvana here in Houston, there are some difficulties which still must be fully addressed if we are to achieve the full benefits which we feel this approach affords us. And, just as technology serves as a powerful unifying agent, it can also be a source of many difficulties.

The site-basing of the methods course causes the necessity to revisit some old issues. The first, was the platform issue. Most schools have settled for one flavor or another of computers by now - due to simple logistics in most cases. Based upon our experience we find that university professors show much more variety. Despite being affiliated with the same university, our computer platform of preferences were different. To be blunt, although we would all do windows there was not consensus as to whether they were of the “95” or the “Mae” variety. For others attempting to follow our example, this is a problem which will be more on the university side than the school site.

A rather interesting situation can also develop concerning maintenance of the computers themselves. Since the computers are neither housed at the university, nor belonging to the schools, just exactly who and how maintains them can be a bit problematic. This came to haunt us as our site-based computer went down in the first week of this year and is yet to be replaced. Were it not for the presence of our supporting notebook computers the technological aspects of this project would have had to have been scrapped.

An additional requirement which we quickly became aware of was the need for notebook computers to support our work. Although not essential, to be used in a transdisciplinary fashion it is certainly helpful to have your computer mobile. Our class has met in multiple locations including: museums, zoos, classrooms, meeting halls, traditional university classrooms, and parking lots. The ability to have a constant set of technological tools and resources, despite the location, has proved to be tremendous benefit.

Another recommendation which we might offer is the need for a reliable internet service provider. We were highly fortunate in that our on-site classroom had an analog phone line. But, quite often the site based classrooms do not come equipped with a T-1 line, nor in many cases even an analog phone line for a modem connect. It seems that the schools locally will occasionally offer a phone in each classroom, but in most cases it is digital. A simple precaution, here. I have heard of quite a few folk whose modems have bit the dust because they were told, “Sure we have phone lines in each classroom”. Which was true, but they happened to be the wrong type.

We have found software programs which allow you to “download” websites together with their associated graphics and links are an invaluable resource in meeting the needs identified in the preceding two paragraphs. Having the NCTM site “in the can”, as it were, made the linked thinking surrounding the standards and their implementation immediately applicable in the field.

**Concluding Thoughts.**

The only problem with wanting your cake and eating it too is that you surely end up with a lot of cake. There were times when each of us felt overwhelmed by the work to be done, the time commitment, and the challenges. Would we do it again? Certainly. We are continuing and have plans to keep doing so. Have we came up with a set of easy recommendations for simple adoption? No, because the task is fluid and must reflect the local variable of the site and personalities involved.

We are, however, much closer to providing a “look and feel” description for others. First, start with people you like. This may seem trite, but it is very true. Second, try to find some unifying philosophical themes around which you have agreement. It is tough enough to make the content areas fit, without having to align your underlying motivations and guiding precepts. Third, technology is essential. We finally have a set of transdisciplinary “soft” tools supporting the transdisciplinary methods we have been developing.

612 — Technology and Teacher Education Annual — 1998
Since 1989 there has been a statutory curriculum in schools in both England and Wales. The curriculum for mathematics has been revised twice, with each new version requiring teachers to use information technology (IT) with students in mathematics. In the first two versions (Department of Education and Science [DES], 1989b, 1991), the statutory requirements for secondary pupils (age 12-16) included the use of Computers to: generate and transform 2-D shapes, devise instructions to produce desired shapes and paths; and explore number patterns with a computer (DES, 1991). The other limited references to IT always provided an alternative. For example, generate trigonometric functions using a calculator or computer (DES, 1989b, 1991). The most recent version (Department for Education and Employment, [DEE] 1995b) has a general requirement that “Pupils should be given opportunities where appropriate to develop and apply their information capability in their study of mathematics”. Specifically at the secondary level. Pupils should be given opportunities to: use calculators and computer software for number related work; use computers to generate and transform graphic images and to solve problems; and use computers as a source of large samples, a tool for exploring graphical representations, and as a means to simulate events.

The Use of IT in School Mathematics

In the ImpacT study (Watson, 1993, cited in Johnson, Cox & Watson, 1994) positive learning effects attributed to the use of IT in mathematics were found, however a minimum threshold of IT access, experience and use was required for these effects to be measurable. The study also reported on heightened pupils’ interest and enjoyment and increased subject status. More recently Denning (1997) reports on the motivational effects of IT use in school, provided the activities are purposeful, meaningful and challenging.

Where computers are used in mathematics in England and Wales, there is evidence to suggest that it is more likely to be used by pupils aged 12 - 14 than by pupils aged 15 - 16 (Harris & Preston, 1993; Miller, Eagle, Gough & Johnson, 1996). Typical “High” use is likely to consist of several hours of Logo, spreadsheets and graph plotting software as well as use of a number of special use short programs (Miller, 1997).

In practice there is a wide variation in the use of IT in mathematics lessons. Jared (1995), for example, notes the wide recognition of the relative neglect or the use of IT in mathematics, a view confirmed by Andrews (1997). In the survey by Denning (1997) the vast majority of teachers indicated they seldom or never, used computers with pupils. This finding is similar to the case in France where Artigue (1998) reports “even in the many schools now provided with quality equipment, the use of computers for mathematics teaching; remains marginal”.

Factors Affecting IT Use in Schools

In our view the major factors include: the statutory requirements set out in the national curriculum, the beliefs and attitudes or teachers: their IT related pedagogical knowledge and skills; and access to and quality of equipment.

Statutory Requirements. As Andrews (1997) points out the wording of the statutory curriculum “has been sufficiently general for teachers to exploit whatever software has been available. This undoubtedly helped some teachers increase their use of IT in lessons. However, the limited requirements of the first two versions also helped teachers avoid using IT. Often the requirements were fulfilled in general IT lessons taken by IT specialists.

Beliefs and attitudes. Veen (1993) comments on how teachers’ strongly held beliefs about content and pedagogy are slow to change. In a latter study, Andrews (1997) notes that many teachers are unconvincing of the need to use IT in mathematics, and that the mathematics schemes they use to little to dissuade teachers from this belief. Fullan (1992) also suggests that teachers’ beliefs and attitudes regarding the use of IT are difficult to change.
The IT Related Pedagogical Knowledge and Skills. It is widely recognized that teacher skills to exploit IT need to be developed (for example, Oliver, 1994). The DEE survey of schools (1997d), reported in DfEE (1997c), reveals a decline in both primary and secondary teachers fully confident to teach using information and communications technology (ICT).

New teachers' IT skills are increasing, but Downes (1993), who looked at a number of studies undertaken in the UK and the US, comments “beginning teachers use computers in their classrooms much less than would expected given the increasing competence and confidence rate of recent graduates”.

Access to and Quality of Equipment. DfEE (1997c) reports on the findings of DfEE (1997c & 1997d) stating that the two reports “revealed significant problems in terms of the age of ICT equipment. the availability of software directly related to the curriculum, and the confidence of teaching staff in the use of ICT to teach.

Preservice Teacher Education and IT: Statutory' Requirements

In 1989 a statutory requirement was placed on all courses of preservice teacher education in England and Wales (DES, 1989a). For IT:

On completion of their courses, all students should be able to select and make appropriate use of a range of equipment and resources to promote learning in particular, all courses should contain compulsory and clearly identifiable elements which enable students to make effective use or IT in the classroom and provide a sound basis for their subsequent development in this field. They should be trained to be able to: i) make confident use of a range of software packages and IT devices appropriate to their subject specialization and age range; ii) review critically the relevance of software packages and IT devices to their specialization and age range and judge the potential value of these in classroom use; iii) make constructive use of IT in their teaching and in particular prepare and put into effect schemes of work incorporating appropriate uses of IT; and iv) evaluate the ways in which the use of IT changes the nature of teaching and learning.

A new document (Department for Education [DFE], 1992) changed the emphasis, so that all requirements were stated in terms of ‘competence expected of newly qualified teachers’. The IT section stated: 'Newly qualified teachers should be able to demonstrate ability to select and use appropriate resources including Information Technology.

The election of a new UK Government in 1997 resulted in a new document (DfEE, 1997e) with the following requirement:

For all courses, those awarded Qualified Teacher Status must when assessed demonstrate that they have a working knowledge of information technology (IT) to a degree equivalent to Level 8 in the National Curriculum for pupils and understand the contribution that IT makes to their specialist subject(s).

This comes into operation in September 1998. The standard equivalent to Level 8 (found in DfEE, 1995a) is:

Pupils select the appropriate IT facilities for specific tasks, taking into account ease of use and suitability for purpose. They design and implement systems for others to use. They design successful means of capturing and, if necessary preparing information for computer processing. When assembling devices that respond to data from sensors, they describe how feedback might improve the performance of the system. They discuss in an informed way, the social, economic, ethical and moral issues raised by IT.

The control element does not apply to mathematics.

In the two consultation papers, Excellence in Schools (1997a) and the National Grid for Learning (1997c), the UK Government indicates clearly the priority it attaches to the use of IT by teachers. The former looks to the improvement of education in general and the latter to the creation of a national network for ICT.

Preservice Teacher Education and IT: A Research Proposal

A number of studies report the wide variation in prior computer experiences of entrants to preservice courses (for example, Mellar and Jackson, 1994), with increasingly fewer students starting with not previous IT experience (Lienard, 1995). In addition, there is an increase with time in computer usage and experience of use as pupils in schools, for the under 25 age group, as well as an increase in the importance attached to most IT training priorities (Mellar & Jackson, 1994).

Following work on children’s learning using portable computers, Gardner, Morrison, Jarman, Reilly, & McNally (1992) suggest that teachers should be encouraged to equip themselves with portables in order to develop their IT skills and their subsequent IT-related classroom practice. Downes (1993) suggest that encouraging teachers to own a personal computer may prove a long term benefit to the profession.

A number of studies look at the effect of the subject department on the use of IT by trainees. Downes (1993) finds that the key factor for influencing classroom use of computers is the supervising teacher’s use. Easdown (1994) and Barton (1996) identify the importance of attitude and practice of the subject department in the teaching practice.
school in determining IT use during teaching practice. Byard (1995) finds a high correlation, at the 1% level for mathematics between students’ use of IT and that of their supervising teachers (mentors) and, at the 5% level for mathematics, a correlation between IT confidence and the use on teaching practices. Though more generally Barton (1996) comments “It would seem that previous IT experience and even good support for personal IT skills are not sufficient to overcome the effect of a department which makes little of no use of IT their teaching. This is in keeping with the general findings of Byard (1995).

The partnership nature of preservice training in England and Wales, where trainees must spend 24 weeks of a 36 week course in schools, places a considerable responsibility for training on supervising teachers (mentors). In IT terms, Collison and Murray (1995) found little evidence that teachers are able to act as effective mentors.

The Keele Mathematics IT Course: A way forward?

Course Principles

The Keele University Department of Education has adopted a pattern for ICT education for those undertaking preservice training which is set firmly in the subject contexts. This decision has been informed by a number of concerns: providing a purposeful and realistic context for ICT learning, using subject pedagogy as the framework of ICT skills development, building on existing knowledge, recognizing the importance of accommodating subject diversity, and using subject tutors as role models.

The importance of locating the development and acquisition of IT skills, knowledge and understanding in a setting which the learner identifies as purposeful and realistic is well documented and often offered to those in preservice training as a cornerstone of good practice. A range of studies (for example, Oliver, 1994) have explored this issue and all draw attention to the need to translate this principle into the everyday practice of teacher trainers.

The Importance of pedagogy

The importance of pedagogy as a key component of the rationale for requiring ICT capability in those undergoing preservice training has been given further substance by the recent work of the Teacher Training Agency (TTA) in the UK. This seeks to set out a national curriculum in ICT for students engaged in preservice training courses, and in the early drafts currently available gives prominence to pedagogical knowledge as the basis for the effective development of ICT to support teaching and learning.

The impact of student perceptions of “subject culture” is discussed by McMahon and Gardner (1995), who draw attention to the powerful influence exerted by the attitudes and practices of lecturer’s and other professionals. Students are quick to adopt the current climate of opinion about the role of new technologies that they see exemplified by their own subject teachers. This view is reinforced by Waggoner (1994) in a paper which sets out a comprehensive model for the interplay between “faculty assumptions about students, faculty beliefs/perceptions about technology, environmental context, and preparation and experiences as a teacher.”

This concern is also raised by Easdown (1994) in a steady which explores the relationship between the staff in school who provide support teachers in training - mentors - and the beginning teachers in their care. Both of these studies reinforced the importance of the attitudes of trainers towards the new technologies as key influences on those being trained.

Background activity

Over the last four years, the tutors have tried to address the combined problems of IT competence and pedagogical knowledge of teachers in partnership schools by providing a rolling program of three-day inservice courses, where teachers are asked complete certain tasks between course days. This approach, advocated by Robinson: “In the context of information technology, in-service education of teachers must go alongside the preservice education students entrusted to teachers.” The training has been offered to all teachers in partnership schools. It has met with some success: teachers have started to use IT with pupils, but usually only to a limited extent.

In addition, the department purchased four notebook computers, which were used in 1993-1996 by students in IT specific training workshops, in general pedagogic sessions, at home and in classrooms. This did improve the overall used by students of IT in schools, but there was still a small number of students who did not use any IT in the school. Four new notebook are available beginning in 1997.

Course design

There are seven features of the course: Enculturalization, Acclimatization, Integration, Differentiation, Teamwork, Confidence, and Assessment.

Enculturalization

IT is embedded into the culture of course; an audit of IT experiences undertaken before the course starts; course members are made aware of the importance of IT and, where knowledge is limited, advised to begin acquiring skills; special compulsory subject specific IT courses run throughout the period of training, there are several classroom experiences; access to facilities is provided both in the training institution and teaching placements schools; and finally, the institution has part-financed special arrangements so that all course members have access to email and the Internet while on their school placements.

Acclimatization

There is an initial early experience of IT use with primary age pupils, followed by a requirement to use and evaluate an IT activity in school using a notebook computer
with a small group of pupils. Finally, group and class activities follow.

Integration

The IT course is delivered by mathematics tutors in both the pedagogical course and in subject specific IT workshops.

Differentiated Provision

It is recognized there will be considerable differences in pre-course IT experiences. Activities take this into account following the initial audit.

Teamwork

Groups are encouraged to learn together, this is further reinforced by the requirement to produce collective products for used by pupils and future course members.

Confidence Building

Peer group support is encouraged and expected; positive experiences are shared so that all are involved as teachers and learners.

Assessment

The IT element is formally assessed. Some parts are indirectly assessed, since all course members have to communicate with tutors by email and all assignments at the word processed and spell-checked. The assessment of other knowledge and skills involves specific tasks, for example, to design in produce a poster with the aim of generating interest in mathematics, so that it includes at least one picture and a text extract downloaded from the Internet. This then has to be used with pupils.

The success, or otherwise, of this course, will be reported in a further paper.

ON THE USE OF TECHNOLOGY FOR MATHEMATICS AT SECONDARY SCHOOLS

Carl Lee
Central Michigan University

Dennis St. John
Central Michigan University

The purpose of this study is to examine the use of computing technology in secondary school mathematics, particularly in the probability and statistics curriculum. In recent years, secondary mathematics reform has called for inclusion of probability and statistics into high school curriculum. The recommendation made by the National Council of Teachers of Mathematics (NCTM, 1989) for secondary schools stated that “Collecting, representing, and processing data are activities of major importance to contemporary society”, “Statistical data summaries and inferences appear more frequently in the work and everyday lives of people than any other form of mathematical analysis”. Experience with probability and statistics activities can enhance student understanding of likelihood of uncertain events and to reason and communicate about statistical claims made by others. In order to examine the progress of the current reform effort of statistics and probability curriculum at secondary schools, Lee and St. John (1997) investigated mathematics department chairpersons’ beliefs about probability and statistics, and the difficulties encountered in the implementation of the curriculum. That study found that two of the major reasons of offering little or no statistics and probability curriculum were directly related to computing technology. This study investigates the availability of computing technology for mathematics, probability and statistics, and how computers and calculators were used for mathematics instruction.

Probability and statistics, traditionally learned with a lecture and note taking approach, is often considered a boring and difficult subject. Recent research efforts suggest that many students learn best by constructing the knowledge themselves (e.g., Garfield, 1995) There have been many efforts by mathematics and statistics educators to rethink this curriculum and to develop innovative strategies and instructional material to teach statistics and probability concepts (e.g., the Quantitative Literacy Project endorsed and designed by the American Statistical Association and the National Council of Teachers of Mathematics since 1984; see also Hogg, 1992; Cobb and Moore, 1997). These innovative strategies and material are designed to take the advantage of computing technology, in particular, personal computers and graphing calculators. It is, now, accepted that statistics and probability should be delivered using activities in a cooperative learning environment (e.g., Moore, 1997; Lee, 1997).

At the collegiate level, there have been studies to investigate the effectiveness of computing technology for teaching and learning probability and statistics (e.g., Snell and Peterson, 1992; Tijms, 1992; Tanis, 1992; Fetta, 1992). Snell and Peterson (1992) identified three broad areas in which computing technology is helpful: reducing the need for lengthy manual computation, exploring graphical data analysis, and illustrating concepts using computer simulation experiments. Little attention has been paid to these issues at the K-12 level. Watkins, Burrill, Landwehr and Scheaffer (1992) discussed in length the concerns of secondary students and teachers. The use of computing technology in instruction was addressed. An understanding of the availability of computing technology and how these tools are used in mathematics, probability and statistics instruction will provide researchers and educators important information for designing innovative strategies and instructional material for both inservice and preservice secondary mathematics teachers.

Methodology
A questionnaire was developed and sent to the mathematics department chairpersons of the secondary schools in the entire state of Michigan. A total of 334 out of 809 chairpersons returned the survey. Background information included school size (classified as small (1-499), middle (500-1000) and large (1000 or more) schools), school setting (rural and urban), school type (private, public), etc. The items related to computing technology included (a) reasons of offering little or no statistics and probability, (b) six items on the availability and the status of computer technology, (c) eleven items on how computer was used in eleven commonly covered topics in an introductory
statistics and probability curriculum, and (d) eight items on
the use of calculators in mathematics, statistics and prob-
ability curriculum. The data were processed and analyzed
using SPSS/PC statistical software.

Results
Among the 334 responded chairpersons, 54 of them
indicated they offered little or no statistics and probability in
their high school mathematics curriculum. Their reasons for
offering little or no statistics and probability were the
following: Do not have enough time (78% chose it), Do not
have enough training in computer and software (67%), High
school curriculum does not require it (65%), Student
background is not adequate (31%), Adequate technology is
not available (29%), Do not have enough expertise (27%),
and Do not need for high school students (15%). It indicates
that computing technology and training are two major
obstacles for inclusion of statistics and probability curricu-
lum.

The Availability and Usage of
Computers
About 56% of chairpersons responding reported having
more than 30 computers, there were about every 2 in 10
schools reporting less than 20 computers available for
students. Sixty seven percent of the responding chairpersons
said there were computers available on the daily basis, but
only 18% used them once or more per week in mathematics
classes, while 24% used them in probability and statistics
courses. Use of computer for homework was even more
rare (15%). The results are summarized in Table 1.

Comparison of Demographics for the
Availability and Usage of Computers
Demographic: Schools Offered Probability and
Statistics Vs. Schools Offered Little or no Probability and
Statistics. Table 1 summarizes the number of schools and
the corresponding percentages within each demographic
category, and the p-values of the Chi-square tests. It clearly
indicated that the availability and usage of computers were
significantly different between schools offered probability
and statistics curriculum and schools offered little or no
such curriculum. A significantly higher percentage of
schools offered probability and statistics curriculum tended
to have more computers available for students, for teaching
aides, and assigning homework using computers.

Demographic: School Size. The comparison of the
availability and usage of computers among three school
sizes (1-499, 500-999, 1000 or more) is summarized in
Table 2. Chi-square test was conducted to make the
comparison. As expected, the larger the schools the more
the computers were (p-value = .000). However, we did not
find significant difference among school sizes for the
availability of computers for daily basis, neither for using as
teaching aides. In fact, higher percent of chairpersons from
small schools responded they had computers as teaching

aides than larger schools (72% Vs. 65%). When asked
about the assignments using computers and teaching
probability and statistics using computers, larger schools
had significantly higher percentages.

</table>
statistics. We found that less than 10% of mathematics departments used computers to teach most of statistics and probability topics except data summary (21%), graphical methods (27%), curve fitting (21%) and normal distribution (17%). The availability and the usage of computer for mathematics, statistics and probability courses in this survey indicated that the computer technology was not yet common in the secondary mathematics departments in Michigan. One major reason was the lack of training in computers for the in-service teachers. The implementation of innovative curriculum using technology has a long way to go in secondary schools.

Discussion

Although the idea that students learn the best by actively participating in a cooperative learning environment to construct knowledge themselves may have been well accepted by educators and teachers, the findings of this study indicated that there is still a huge gap between the ideal situation and reality. This is particularly clear for probability and statistics. Neither personal computers nor graphing calculators were used extensively for probability and statistics (only 24% indicated using computers and 24% using graphing calculators for probability and statistics instruction). In contrast, Weiss (1995) gave a report on K-12 mathematics teachers’ response to the reform agenda. In this report, over 95% of surveyed secondary mathematics teachers indicated that emphasizing on solving real problems, applications of mathematics in daily life and mathematics reasoning were important part of mathematics instruction, and 81% indicated the use of computers was important. When asked if they were qualified to teach various of mathematics subjects, only about 3 out of 10 high school mathematics teachers felt well qualified to teach probability and statistics. It is clear that high school teachers realized the importance of integrating real applications into mathematics curriculum and understand the importance of computing technology for making this curriculum possible. The curriculum of integrating real problems into probability and statistics with the help of computing technology should become the norm for both secondary and collegiate levels. This study and the results by Weiss (1995) suggest that there is a great need for improvement on computing technology, training and content knowledge for the probability and statistics curriculum at the secondary level.

Those interested in mathematics education in high schools should help secondary in service and pre-service teachers learn and implement innovative curriculum in probability and statistics. More efforts should be made by mathematics and statistics educators to provide guidance for topic selection and for development of adequate classroom activities as well as training so that teachers can utilize up-to-date technology.

It is always exciting and invigorating to read articles about the latest research and methodologies in the use and development of multimedia and hypermedia in educational settings. This section describes a wide variety of projects which are rapidly expanding the ways we understand, manage and disseminate the information that contributes to both our teaching and learning. There are six main areas this year, and each presents descriptions of unique applications of new technologies.

MultiMedia and Learning

Two papers explore how multimedia and new technologies have changed the ways we teach and learn. Cohen explores several issues of multimedia development as they relate to teacher education. Her paper examines the potentially negative attributes of new technological media as well as the attributes of multimedia that affect cognition such as visual literacy, multi-sensory learning, non-linear learning, self-paced instruction and individualized instruction. Cohen emphasizes the need for those who train teachers to examine many of the hidden attributes of technology that affect the process of learning.

Putnik discusses issues about the relationship of education and multimedia technology, and examines the relationship between the human learning process and educational multimedia. He emphasizes the need to motivate and challenge the learner with authentic and relevant learning activities.

Developing Multimedia Materials

Two papers describe the development of multimedia software by graduate students in teacher education programs. The authors emphasize the critical skills that are developed by designing and developing educational multimedia materials. Using a case study methodology, Lee analyzes the factors in hypermedia learning. This study describes how a hypermedia was designed by incorporating important learning factors. First, students were given increasingly challenging exercises to enhance computer skills. In addition, students were allowed both the time to learn and progression from basic to more difficult skills. Finally, Lee states that repeated success throughout the entire learning process was a critical factor. This case study also presents student responses to a questionnaire that inquired reactions toward those factors.

Shopland and Kannegieser suggest that undergraduate and graduate teacher education students who have engaged in the process of designing and developing instructional materials are better equipped to evaluate commercially prepared instructional materials and match these materials with individual learning styles and needs. They believe the development of multimedia instructional materials is an essential precursor to effective and meaningful evaluation of the wide range of multimedia software available to teachers. In addition, Shopland and Kannegieser state that the design of multimedia instructional materials requires the designer to consider the range of learning styles of the intended user. They suggest that such consideration, coupled with meaningful instructor and peer feedback during the design and development stages facilitate the designer’s skill in selecting appropriate instructional multimedia materials to meet the specific needs of learners. The basic premise of this paper is that the design of multimedia materials is a critical educational technology experience for undergraduate and graduate teacher education.

Assessment

Two papers offer methods for assessing multimedia and hypermedia projects. Dickens presents a preliminary rationale and describes a critical method for assessing student multimedia and hypermedia projects. The method is adapted from an existential-phenomenological model for aesthetic criticism developed by Eugene Kaelin and is suggested for its ability to take into account the content and structure of complex objects. In his paper this framework is presented and parallels drawn between the critical role in aesthetics and the facilitators role in assessing complex objects to communicate understanding of substantive content in teaching and learning.
Lennex describes the development of a digital portfolio on CD-ROM in which students represent their student teaching experience with digital media. Preservice teachers are required to produce an interview portfolio by the end of student teaching, and the digital portfolio serves a dual purpose: it demonstrates the New Teacher Standards developed as part of the Kentucky Education Reform Act (KERA), and also the technological proficiency desired by administrators and school systems. The objectives of this study include determining the present perception and current technologies regarding digital media, especially among MSU preservice secondary teachers; developing a model for a digital portfolio; and producing digital portfolios among MSU preservice teachers as an alternative to traditional portfolios. This article describes the various processes used to create and complete a digital portfolio during a twelve week student teaching experience.

Special Areas Of Multimedia Development

In the area of medical education, Weidner and Gifford describe a study which examines a multimedia program used in different contexts. This paper presents data from a preliminary study that addresses several important issues such as rote memorization of facts and vocabulary in traditional science education classes such as anatomy. The study compared the way pairs of students used the representationally rich multimedia program BrainStorm: An Interactive Neuroanatomy under two conditions. In the first problem-based condition, pairs were given a patient case featuring symptoms resulting from injury to neurological structures, and were asked to solve the case by identifying the structures involved. This type of problem-based learning offers alternative learning strategies to counter the acquisition of inert knowledge, knowledge that is not easily applied to new situations. In the second question-response (QR) condition, student pairs were given more traditional questions to answer about these neuroanatomy structures. The results of this study offer interesting insights into the usefulness of different learning strategies.

In the area of special education, DeMartino and Prinz examine several important issues that apply to the use of technology in special education. Their paper describes the learning needs of special education students and includes an overview of technological needs and instructional modifications as well. The authors note that the main obstacle for using technology in special education is the apprehension of teachers to learn the technology.

Video Technology

Four papers describe the use of video technology in a variety of educational settings. Abate describes the preliminary development of a technology in the classroom video project. The product is targeted for use with an audience of pre-service and in-service teachers and includes examples of teachers using a variety of technologies with their students in a manner that reflects how comparable technologies are currently implemented in the workplace. The video examples include elementary, middle and secondary classrooms from urban and suburban schools across the nation. The goals of the video project include showing what occurs when teachers place students in realistic situations that require them to collect, analyze, apply and communicate information. The second goal is to encourage teachers to examine how classroom experiences may relate to employment and career opportunities.

Kurth and Thompson describe the process of creating, developing, and evaluating a video which uses an “anchored instruction” approach to modeling the integration of technology and teaching. The results described include descriptions of the processes in which video model examples were created and edited, and the intended use of the videos in staff development training for higher education faculty. The authors cite the need of teacher educators to see specific, concrete examples demonstrating effective technology integration.

Banks describes the development of an interactive training tool, Virtual Classroom Visits, that captures the expertise of third through seventh grade teachers who taught units in science, social studies, and language arts using multimedia composition software with their students. The program on CD-ROM contains detailed information and behind the scenes work these teachers performed in order to facilitate successful student projects. The program includes video footage of classrooms in action, and the types of information that teachers would gather on their own if they had the luxury to participate in a week-long site visit to a school where accomplished teachers were using multimedia in the classroom. Preliminary results of this study show that the teachers did learn a great deal from the interactive application.

Stephens and Byrum describe the properties and uses of Digital Versatile Disks (DVD) as a new medium for more powerful applications of video in the preparation of teachers. This paper discusses the structure of DVD, variations, cost, and the process for mastering. The potential value of this new tool in video-case methodology is addressed.

Collaborative Development Teams

Finally, McNeil shares some preliminary insights in the development of educational multimedia software by collaborative development teams. Critical factors in team communication, collaboration and cooperation are examined and explored in a case study format of two graduate classes.

These thirteen articles address the various aspects in which new media, in the forms of multimedia and hypermedia, have influenced teacher education. Current technological and training issues are identified as well as various educational benefits of this new media. These articles
provide excellent examples and a firm foundation for improving teacher education programs.

MULTIMEDIA AND COGNITION: TRAINING TEACHERS ABOUT USING TECHNOLOGY

Vicki L. Cohen
Fairleigh Dickinson University

Multimedia has changed the way that information is being transmitted and received in our society. Examples of this range from CD-ROM's that use larger-than-life graphics, realistic video and compelling music, to the Internet where one can play an interactive game, listen to a favorite band from Denver, or watch a NASA video clip of Mars. Multimedia is part of a new way that information is being repackaged and delivered and thereby processed by the end-user. Multimedia is usually defined as a program that uses a combination of media to present information for entertainment or education; however, this definition does not really go far enough. It overlooks the assumption that interactivity is a significant component of multimedia and that the user must interact in accessing the information. The term “multimedia” connotes a user who is actively engaged accessing, interacting and processing information.

Multimedia and Interactivity

This definition of multimedia has significant implications for current perceptions of learning. Learning at home has become a more active, self-guided process especially as more problem-based explorations of the Internet or interactive gaming across phone-lines occurs. Learning has become a constructive process (Salomon, 1997), whereby students are independently constructing networks of interconnected meanings on their own without the formal guidance of a teacher. Our students are starting to access information in a highly interactive, multimedia format. Their perceptions of the world are being shaped by not only what type of information they can quickly access but also by the way the information is accessed. Oftentimes, the information itself is not the important message but how it is accessed and through what delivery system.

This paper explores these issues as they relate to teacher education. Multimedia Production is a required course in the 18-credit Instructional Technology Certificate Program at Fairleigh Dickinson University (FDU), the largest private university in New Jersey. Most students who take this course are enrolled in the School of Education’s Master of Arts in Teaching (MAT) program and are studying to be a teacher or are currently teaching. This course becomes a significant experience for those who take it because it offers an in-depth examination of how multimedia can be used in the classroom. Not only do students explore how to produce a multimedia program, but they explore current issues and research about using multimedia in the classroom, as well. As technology becomes such a pervasive aspect in our lives, all teachers must understand the implications of technology and how it is affecting the learning process, regardless of whether they use technology in their own classroom or not. The question becomes whether this course should become a required course for all students who will become certified as teachers.

Multimedia as a Symbolic Form of Representation

Multimedia is a new symbolic form of representation, much as language or mathematics is a form of representation. As a representational form, multimedia influences the meanings one arrives at, the cognitive skills that are called for, and the perceptions one derives of the world (Salomon, 1997). Students using multimedia as a presentation device represent their thoughts in different ways than those who use paper and pencil. Similarly, those who access information via multimedia formats, must call upon different mental processes than those who use a book or video. Researchers have shown that different symbolic forms of representation are processed by different sets of mental skills and capacities (Eisner, 1997; Greeno & Hall, 1997; Salomon, 1997). This has powerful implications for teachers who must understand the positive and negative implications of this phenomenon that is currently occurring. If different mental capacities are being called upon, teachers must be aware of how to positively develop them so that they are “mindful” and purposeful. Students need to become technologically literate, not in the sense of learning new software programs, but in the sense of knowing how to use these new tools to promote higher order thinking skills and how these tools can help in the process of creative problem solving. Teachers
multimedia is considered a part of the new communication paradigm. The Multimedia Production course taught by the teachers in the classroom today, children are increasingly being introduced to the use of electronic media as a tool for communication and learning. The Multimedia Production course addresses the potential negative attributes of using multimedia technology in the classroom. It teaches students to think critically and to evaluate the effectiveness of multimedia tools.

The Multimedia Production course also examines the attributes of multimedia. Multimedia is a combination of different types of media, such as audio, video, and text, that are presented simultaneously. This approach allows for a more natural and engaging learning experience. Multimedia is also interactive, allowing students to manipulate and control the content in different ways. This interactivity can help improve retention and comprehension.

Another area that is explored in the Multimedia Production course is the impact of multimedia on thinking patterns. The course examines how multimedia can affect cognition and promote thinking in a holistic, impulsive way. The course also explores how multimedia can affect reading and writing skills.

The course also examines how multimedia can be used to promote literacy. Multimedia can be a powerful tool for teaching reading and writing skills. It can also be used to promote critical thinking and problem-solving skills.

Finally, the course examines how multimedia can be used to promote creativity and innovation. Multimedia can be used to create new and innovative forms of expression, such as digital art and video. The course also explores how multimedia can be used to promote collaboration and interdependence.

Overall, the Multimedia Production course is designed to provide students with a comprehensive understanding of multimedia and its impact on thinking patterns. It is designed to help students develop critical thinking skills and to promote creativity and innovation. The course is also designed to help students understand how multimedia can be used to promote literacy and to encourage students to think critically and creatively.
products, such as HyperStudio or HyperCard stacks, to use in the classroom, and by having teachers and students access information which is presented in a multimedia format. Visual literacy is promoted in both cases because it becomes the symbolic means of representation that is being used. When multimedia is used extensively in a classroom, the way a teacher presents the content changes from didactic presentation of facts and concepts to a more process-oriented approach which emphasizes how content can be effectively presented and graphically represented (Cohen, 1997). Cohen (1997) studied a technology-rich social studies class that was using HyperCard stacks to present projects. She found that classroom discourse changed dramatically in this classroom. Conversation often addressed visual representation of concepts: how should pictures be placed on a screen to enhance learning, how should a template for a project be formatted to expedite learning, how and where can images be scanned in effectively. These issues all contributed to students becoming more visually attuned and literate so that when they accessed information they were aware of high quality images that promoted learning, and they were aware of low quality images that confused and confounded them. These are important issues for teachers to be aware of.

Another attribute of multimedia that affects cognition is its ability to promote multi-sensory learning. Multimedia integrates all different types of media into one program. Because of this, multimedia allows a student to use a multitude of senses in accessing and interpreting information; it allows students to use their unique combinations of intelligences to study a topic. Students usually prefer one style of learning and feel highly motivated when using that style in pursuing their studies. Some learners prefer information to be written; others prefer it to be spoken; some need concrete examples; others need visual representation. Multimedia programs allow a student to utilize their preferred style of learning while also developing those areas they are not as strong in. Thus, if a student is a visual learner, he or she will be motivated to visually access information from a multimedia program while also having the capability of reading the information, or even hearing the information read to him or her. Thus, a multi-sensory approach is inherently taken with multimedia learning.

Furthermore, cognitive science and research on the brain tells us that students learn best when information is taken off the page and brought to life in the minds of students. The objective is to immerse students in compelling experiences which are evocative, challenging, meaningful and coherent environments for the brain to effectively process information (Caine & Caine, 1991). Students must have opportunities to make connections, and extract meaningful patterns and global relationships in what Caine and Caine (1991) have called “dynamic gestalts.” Caine and Caine claim that multi-sensory representations such as multimedia programs is one such gestalt which facilitates learning.

Non-linear learning is another attribute of multimedia that affects cognition. Multimedia is unique in that there is not one linear path through the program but a multitude of branches in which a learner can explore each topic as interest dictates. Although some researchers criticize the non-linear format as being detrimental to the development of logical reasoning, the ability to explore a subject matter based on personal interest and choice can be highly motivating for students and offers them a “dynamic gestalt.” It allows them to see the big picture when desired and to narrow in on details at other times. As Reinking (1997) says of hypertext, multiple digressions might be considered a defining attribute of hypermedia programs. On the way to looking up one topic, a student digresses to other related or oftentimes marginally related topics. As he points out, digression can be positive and enjoyable because there is no compulsion to follow the one main idea. Reinking (1997) also points out how elementary students reading science texts, explored the meanings of more difficult words, and recalled more of their content when they read passages displayed by a computer that provided immediate context-specific assistance through branching and non-linear format. Although students can get “lost” in digressions or teachers might not be sure all material is “covered”, non-linear format can be highly motivational, effective, and facilitate learning in a highly engaging environment.

The last two attributes of multimedia, self-paced and individualized instruction, are significant factors that affect cognition. Students learn best when they can go at their own pace, they can explore the subject matter in their own style, and they can make their way through the material in their own path. Individualized instruction allows a student to repeat the content or the process when desired or needed, gives immediate feedback, and branches to material that help support the student’s process of learning. Individualized and self-paced instruction also allow a student to go back and reread, if necessary, supporting the metacognitive skill of rehearsal. It can provide the necessary scaffolding to support a student or remove it quickly as the student progresses to the next level. The ability of a student to receive individualized instruction comfortably at his or her own desk is a strong and compelling attribute of multimedia instruction.

In summary, when we examine many of the features and attributes of multimedia instruction, they are many of the same features that researchers and educators are promoting as part of the reform movement toward more meaningful, relevant classrooms. The important point is that many of the attributes of multimedia discussed here do affect cognition and teachers should be aware of what this effect is as part of their training. Attributes such as visual literacy, multi-sensory learning, non-linear learning, self-paced instruction...
and individualized instruction all affect the way a student learns and processes information.

**Conclusion**

As our society shifts from using print as a primary symbol of representation to using electronic media to present information, there are major implications for the classroom. Whether this shift provides impetus for those who wish to further stress the importance of print and language as a symbol of representation in our culture, or it provides a rationale for those who wish to include visual literacy as part of the curriculum, we as educators cannot choose to ignore either the positive or negative implications of this change. Multimedia has become very much a part of our life and will continue to exert a large influence over the way information is presented and processed. Those who train teachers must start examining many of the “hidden” attributes of technology that affect the process of learning. Technology has become such a pervasive force in our society, teacher trainers must start addressing these key issues in their classes.

628 — Technology and Teacher Education Annual — 1998
ON THE EFFECTS OF THE EXPANSION OF MULTIMEDIA ON TEACHING

Zoran Putnik
University of Novi Sad

We can claim that computers are the most important invention of the twentieth century. They have dramatically and irreversibly changed the ways we live and work. One of the implications of this is that all educated people should be computer literate. Developments in the area of multimedia technology and the introduction of it into education processes have changed the character and methods of education. Computer associations are united in their wish to help the field by providing guidelines for school curricula, courses and knowledge. This paper discusses issues about the relationship of education and multimedia technology.

Multimedia systems handle different media types - text, graphics, animation, images, video and audio. They depend critically on available hardware technologies - high performance CPU and I/O bus architectures, high quality audio-visual input/output devices, large capacity data-storage devices and high-speed networks. In addition, these systems require a much higher level of system software support in comparison to past computational and communication environments.

Depending on type of education in which multimedia systems are employed, emphasis is put on different elements of multimedia. Scientific and engineering applications usually serve as a tool for simulation, understanding and visualisation of scientific and physical phenomena. Applications used in arts and lower level education categories include multimedia authoring and presentation, hypermedia browsers and digital libraries (Putnik, 1994).

Introductory computer education courses have several characteristics. Traditional "computer literacy" courses were developed years ago at universities and colleges and emphasised learning the "alphabet" of computing, gaining experience with basic kinds of software packages such as word-processors, spreadsheets, and database systems and studying some historical and social aspects of computing. These courses familiarized thousands of students with computers and enabled many of them to actually start using them.

Recently a new philosophy has emerged. With computers beginning to play a more important role in people's lives, a deeper understanding of them has become a necessity. A new concept has emerged for teaching scientific principles and requiring problem solving, rather than memorization (Biermann, 1994).

Educational Aspects of Multimedia
Multimedia technology employs methods and techniques for organizing, retrieving and presenting information in a wide variety of formats. This can improve the effectiveness of the educational process. It is important that educational software use active learning techniques and the learner be expected to "do things". This also leads to implementation of techniques in artificial intelligence in the design and implementation of educational multimedia systems.

If we want to use multimedia in education, we must take into consideration characteristics of human learning process:
- It is goal-directed. People are willing to learn if they have an interesting goal.
- It is failure driven. Mistakes are the causes for learning.
- It is case-based. Facing a problem, people think of similar situations they encountered, helping them to solve the problem.
- It occurs naturally by doing.

Using this approach, we want to build a multimedia educational system that will:
- create engaging environments for learning,
- create situations which allow student to make mistakes,
- give student the access to expert opinions relevant to the problem,
- use the advantages of the multimedia environment making education more realistic.

What kind of lecturing should be used in a specific school depends on materials available and the teachers' education. Still, when using multimedia technology in education, some characteristics of learning process can be given:
- Pure theoretical lectures are not suitable and should always be combined with some kind of practical training;
• A system for CAL (Computer Assisted Learning) should enable professors to present topics, explain difficulties, emphasise details and illustrate contents of a lesson.

• Intelligent tutoring systems (ITSs) integrate course material, student models and diagnostic capabilities within a unified framework. Such system incorporates two stages: an authoring system that enables an instructor to develop/tailor the course contents and a course presentation system that communicates this information to the user. An example of this kind of system was developed at the Institute of Mathematics in Novi Sad (Budimac, Putnik, Ivanovic, Paunic, & Jerinic, 1992) and used at the school for talented pupil in Loznica. Later, a programming language LESS (Ivanovic, 1992) for creation of lessons in ITS has been defined, and its creation is in process.

Apart from negative aspects of such a system, the need to learn a manipulation interface, the positive achievements gained by such systems are much greater and knowledge is more easily accessible than through the use of the traditional methods of learning.

To date, education multimedia systems such as multimedia encyclopedias, are useful in the presentation of information, and usually employ “page-turning” architecture. These pleasurable and luxuriously designed systems may divert attention from the more fundamental issue in everyday education - reforming the outdated and ineffective methods of teaching. This brings us to the same place we were before computers entered the field. Pure information representation technique in education fails for the same reason as the table-lecture system failed at some level to bring more advancement in education. It brings to a pupil inert knowledge, not connected to the real-life situations, too often not useful and applicable and usually forgotten. Improving this paradigm by the introduction of multimedia technology will not change the basic problems of this teaching method. Asking the pupil to turn the next page of information is a bad idea, regardless of whether the “page” is text, graphics, or video (Schank 1996).

**Conclusion**

The availability of sound and moving video on desktop computers started a revolution in the way information is viewed. Students are more willing to learn since they perceive multimedia information as data that can be stored and manipulated, rather than as material delivered from cinema or television over which they have no control. Each media display, graphic, text, simulation, or animation, is connected to and identified by the system as a different representation of the same information (Woolf, 1995).

Evaluation of such systems shows that students progress to the same mastery level in one-third of the time required by conventional education. Furthermore, students using these systems show a 40% improvement over their performance from classroom instruction (Lajoie & Lesgold, 1992).

We must make clear distinction, however, that lectures are not fancy slide-shows, musicals or animated experiences but learning experiences. Audio-visual material can provide valuable aids for teaching systems, however the system is only useful if the learner remains active and motivated and if he wants to learn and is involved. The learner needs to be challenged to reason about the material presented. Flashy graphics and simulations are not enough; the experience has to be authentic and relevant to the learner’s life.

Multimedia learning environments must be educationally effective and provide students better quality of experience than traditional teaching methods. When they work well, they can let teachers spend less time lecturing and more time working with individual students. Such systems with a motivated and well educated teacher can make computer education as effective as one-on-one tutoring and still as affordable and widespread as television.

ANALYZING INFLUENCING FACTORS IN HYPERMEDIA LEARNING: A CASE STUDY

Doris Lee
Penn State University

Hypermedia is software technology. The basic elements of hypermedia include nodes, links, buttons, browsers, trails, navigational tools, and programming language. It can contain discrete information nodes to present texts, graphics, audio, video, animation, film clips, or other types of information. These nodes can be further linked, associated, or networked with other sets of information, nodes, technologies, or media. By using hypermedia, learners can view from node to node, jump around nodes, or further determine the interrelationships among all of the connected nodes. Some of the often-used commercial hypermedia packages are HyperCard and HyperStudio for Macintosh computers, ToolBook and LinkWay for Windows, and Authorware for both Macintosh and Windows.

Regarding hypermedia learning, most of the research effort was on revealing the effects of using hypermedia to enhance learning, rather than on the factors that enhance the process of hypermedia learning. Past research on the acquisition of basic computer skills including computer operating, word processing and data managing, suggests the use of increasingly challenging exercises to enhance computer skills learning (Compeau & Higgins, 1995). Research also suggests that learners should be given time to learn, and they should be allowed to learn from basic to more advanced computer skills (Lee, 1997). Learners should be allowed to experience repeated success throughout the whole learning process (Compeau & Higgins, 1995).

The purpose of this study is two-fold. First, it covers how a hypermedia course offered to part-time graduate students was designed by incorporating the above suggestions as important learning factors. Second, it presents the student responses to a questionnaire that inquired students' reactions toward those factors.

The Hypermedia Course and the Incorporated Factors

This graduate level hypermedia course was designed to train students to produce a hypermedia program by using the selected hypermedia software, ToolBook, from procedures of planning, storyboarding and authoring.

There were seven class sessions in this course. During each class session, the instructor included lectures, discussions and group activities on the theoretical perspectives of computer-based instruction (CBI) or computer-based training (CBT). The instructor also included hands-on demonstrations of functions, tools and usage of ToolBook. A final project was required for the course.

The major factors incorporated were: first, the hands-on exercises followed a hierarchical sequence of presenting new or advanced phases of learning which built upon the progress achieved from earlier exercises. The idea was that students would encounter continuous success and achieve a higher level of comfort and performance. Secondly, although all students learned ToolBook, under request, they were provided with flexibility of using ToolBook or the program of their choice to complete the final project. Such flexibility allowed the students to have more control over their learning. Finally, during the seven-week course students were given three classes to work on their final projects to ensure that they had enough final project development time.

The Students

Each student during the first class completed a pre-assessment questionnaire. Information was gathered on age, educational and occupational background, years of teaching and/or training, and computer knowledge and experience. The 11 adult, part-time students consisted of four males and seven females. Education and corporate training were the two dominant occupational backgrounds.

All of the students had access to computers. Word processing and basic data management procedures were the primary uses. Only two students had experience in the areas of computer and hypermedia programming. These two students were the students who chose to use web-based authoring hypertext to develop their final projects. The remaining nine students used ToolBook to develop their final projects.
"Gone are the days of linear program sequencing. A "hypermedia" authoring tool more closely simulates the speed of human learning and thinking. Students are able to move from concept to concept, enhance performance, and retrieve information on their own terms and at their own pace."

"As experts, I feel that I learned more because ToolBook provided me with more "pieces" to work with. I feel that I learned more because ToolBook focused on the completion of projects. Each project was able to complete your final project. ToolBook offered the flexibility of using ToolBook or through the exercises."

"Though the exercises were very difficult, I felt that I learned more because ToolBook was not at completion of every lesson. I felt that I was an excellent way to learn.."

"A great deal. I thought that I would learn one concept (the tool) and try to figure out the other. Until the exercises and learning the tool, I was able to learn about the tool. Without the exercises, I think that I would have learned less."

"They were broken down into digestible chunks. It was not at all difficult. I think that I learned more because ToolBook was not at the completion of every lesson. I felt that I was an excellent way to learn.."
“By using ToolBook it forced me to learn another program and platform. Although it would have been easier for me to do it on HyperStudio (Macintosh) I would have missed a valuable opportunity. Especially since the world is going to PC.”

“That depends; considering I had no previous multimedia experience I may have learned more in the terms of new concepts and material.”

**Question 2-2-1:**
For students that selected another type of hypermedia for their final project: Do you feel that you learned more, because you were given the flexibility to use a different program?

Students responded to the question by indicating:
“Absolutely. The intent of the program should be to develop an understanding of the underlying principles of CBT development, not limited to a single authoring program.

More? I felt a greater responsibility to achieve, to learn. I felt as if I had a say in my own learning, ownership.”

**Question 2-2-2:**
For students that selected another type of hypermedia for their final project: Did the lack of instructor guidance for using the program of your choice hampered your learning experience?

Students responded to the question by indicating:
“No, It enhanced it. I find Authorware too cumbersome and was allowed the flexibility to make my own decisions.

“No, I found guidance from trial and error. Finally, the instructor can provide evaluative guidance once project is complete.”

**Question 3:**
For all students, how did the flexibility of choosing ToolBook or another hypermedia program, for the final project effect your learning experience?

Student responses were:
“It enhanced it. My program was much better and more functional as a result.

ToolBook is somewhat inflexible. Having to use tool gave me sensitivity for what would make a better tool.”

“It served as a positive aspect of the course. It gave all students the opportunity to learn CBI through a means that was most applicable to them.”

“The experience became more relevant to our actual experiences. We were able to select a hypermedia program that already be available to us. Allowing us to use a tool that would benefit us more outside of this classroom.

“I learned far more by using an application new to me.”

“I thought that it was neat that students were allowed to choose a program. However, the students who chose something besides ToolBook may have chosen a program he/she was already familiar with, therefore he/she may have missed out on learning ToolBook to its capacity.”

“It was good for me to use a different tool because I had to look for the similarities in the tools.”

“I was only interested in learning ToolBook and apply my skills in the final project. To be honest I didn’t realize until last week that we had the option. If the goal was to show our knowledge of instructional design, than any authoring program could accomplish the task. It would have been easier for me to incorporate more graphics and multimedia if I used a program I was more familiar with.”

“It gave me the opportunity (structured) to develop with a tool that has “personal” meaning to me and my future career endeavors.”

“For me not at all; intended to use ToolBook from the start.”

**Question 4:**
During the seven-week course students were given three classes to work on their final projects. Do you feel that the class time provided was helpful or excessive? Please explain.

Student responses included:
“I think that the pace and amount of time was just right. If I suggest any change at all, it is to shift the focus from ToolBook to a web-authoring program so that it is closer to what people will be using.”

“I required much more time. The class time was great, but for me it was not excessive. I liked having class time because of access to instructor input.”

“Very helpful designing and producing a quality CBI takes time and thorough review. Since we are full-time workers and the project was complex, it gave us
the necessary time to do our final project. Three classes is an efficient amount of time.”

“Class time was helpful. We were given the opportunity for individual guidance which would be difficult during a structure class time. The class time allocated to our projects allowed for a better balance between school and other responsibilities.”

“I was fortunately able to use ToolBook at home; at work, but considering the amount of time I spent on my project, I believe one more class time would have been sufficient along with some week-end time put in. I feel that I needed the three class periods for project time. I also spent an extra eight hours beyond that time working to complete this project. However, I don’t feel that you should increase project time, because that would take away the actual instruction time of ToolBook.”

“Very helpful. Without time to practice the theory we learned, it would have been less impactful.”

“I was very grateful for the three classes. I was very anxious in the beginning weeks to get started on the project and by the time the three work classes arrived, I had enough info and skill to begin. I was also glad that Doris was available during these classes. I would have liked to start storyboard sooner or flow-charting. Because I would have felt more organized sooner. But all in all I felt content, time and instruction all met and/or exceeding my expectations!”

“I feel this was essential as I only has access to ToolBook at this campus. As you know most of us put in quite a bit of additional time, besides the three classes, to complete our programs.”

“Very helpful.”

“Class time was very helpful. In fact, I wish we had another half class period.”

Discussion and Conclusion

From the student responses, it is clear that the hierarchical design of the course structure and hands-on exercises allowed the students to work at their own pace with guidance, then build on previous accomplishments. Students’ learning confidence increased as they moved through the exercises. The hierarchical design made learning the selected hypermedia simple and allowed them to focus more on content development. Students felt more confident with the completion of each exercise, and the more confident they felt, the easier it was to pick up a new concept or task.

As for the provision about the flexibility of using ToolBook or another authoring program of their choice, students responded positively. The majority of the students felt that the flexibility of choosing ToolBook or another hypermedia software served as a positive aspect of the course.

Students who used ToolBook for their final project were satisfied with the amount of learning they received using ToolBook. Students who used other types of hypermedia felt they learned as much as other students did. These students believed the intent of the course should be to develop a thorough understanding of CBT development, and should not limited to a single hypermedia or authoring program. They did not feel the lack of instructor guidance for using the program of their choice hampered their learning experience. They suggested the coverage of the web-based hypertext development software should be included in the course content.

Most of the students responded that the project development time allotted was helpful and appropriate. They revealed that designing and producing quality CBT takes time and thorough review. Since most are full-time working professionals, and based on the complexity of the project, there was necessary time to develop their final project.

To conclude, the students in this case study felt very positive about all the factors incorporated in the course. For future research, it may be necessary to examine the necessity and appropriateness of covering both hypermedia and web-based authoring software for computer-based instruction or training.

Traditionally, teacher education programs have focused on introducing undergraduate and graduate teacher education students to a wide range of instructional materials, teaching methodologies and instructional strategies for effectively classroom use. Inadequate attention has been given by teacher education programs to the development of meaningful instructional materials. In the development of instructional materials, teacher education students must think carefully about the specific instructional purpose, use and possible adaptations of the material. In addition, in designing effective instructional materials, designers must consider matching the material with a range of learning styles.

The authors suggest that undergraduate and graduate teacher education students who have engaged in the process of designing and developing instructional materials are better equipped to evaluate commercially prepared instructional materials and match these materials with individual learning styles and needs. The development of multimedia instructional materials, therefore, is an essential precursor to the effective and meaningful evaluation of the wide range of multimedia software available to teachers. Furthermore, the design of multimedia instructional materials requires the designer to consider the range of learning styles of the intended user(s). Such consideration, coupled with meaningful instructor and peer feedback during the design and development stages facilitate the designer’s skill in selecting appropriate instructional multimedia materials to meet the specific needs of learners. In essence, the design of multimedia materials is a critical educational technology experience for undergraduate and graduate teacher education students.

**Multimedia Tool Software**

The use of multimedia tool software provides teacher education students with multifaceted integrated learning experience. The authors’ use of multimedia tool software in undergraduate and graduate educational technology courses indicate that these experiences engage students cognitively, creatively, affectively and socially. During the design stage, students using multimedia tool software engage the higher order cognitive skills, as they create concept maps, storyboards reflecting concept branches, design text, select meaningful images, create or select appropriate sound and music, “draw” and “paint” appropriate graphics, plan animation sequences, and develop related learner activities. Throughout the design process students are constantly engaging their cognitive skills of analysis, evaluation, and synthesis.

In the development stage students have access to multimedia design tools which produce and/or “capture” and present graphics, sound, video, and text. Students use pre-designed graphics and sound libraries, or they use the drawing and sound tools in each program to create original designs and record real time sound and voice. Library video clips may be used, or students may use Quick Cam video cameras or video cam cameras to capture video clips. In addition, non-copyright protected graphics may be imported from other software programs and/or from Internet sites by utilizing the “snap-shot” and copy commands. In this multifaceted design process, students are also expressing their multiple intelligences (Gardner, 1990) and their work evidences specific visual, auditory, conceptual, and interactive emphases.

The authors have worked with undergraduate and graduate students in the design and development of multimedia instructional materials over a period of four semesters and have observed this learning experience to be a powerful, creative, affective and social experience for students. They have also observed that students are willing to invest 20 - 30 hours into the preparation of multimedia instructional materials and are enthusiastic about the opportunity to share their “products” with other students. Students have reported the experience to be a powerful integrating cognitive and affective experience for them. Furthermore, students have reported self-perceptions of being more analytical in regard
to the elements of “good” instructional software as a result of their multimedia design and development experiences.

The authors have used two multimedia tool programs, “Hyperstudio” and “MicroWorlds,” with teacher education students. These programs share a few common features such as drawing and word processing tools.

**Hyperstudio: Software for a Mediacentric World!**

Hyperstudio is an excellent multimedia tool program for teacher education students. Program tools enable the user to design an electronic “stack” which may include video clips, graphics, text and sound. The stack may serve as a presentation or interactive engagement with a concept, idea, mood, setting, etc. Graphics libraries contain over 200 MB of clip-art and clip-sounds. However, users may also import into their stacks non-copyright protected graphics from other programs, CDs or the Internet. Users may also record voice, music and other sounds into their stack. A wide range of drawing tools and word processing tools are provided in the program. The storyboard feature enables students to resequence individual “cards” within each stack.

** Microworlds: A Logo-based Hypermedia Environment**

Microworlds is also an excellent multimedia tool program for use with teacher education students. Sophisticated multimedia projects may be developed using only menus. Microworlds also contains a strong Logo component which enables students to animate graphics. While it is possible to use Microworlds without a knowledge of Logo, the authors have observed that teacher education students with prior knowledge of Logo use the program more effectively than students with no prior knowledge.

**Guidelines for Using Multimedia Tool Software with Teacher Education**

The following guidelines for using multimedia tool software have emerged from the authors work with undergraduate and graduate teacher education students:

- basic computer skills are prerequisite to working with multimedia tool programs,
- use systems with a minimum of 16 MB RAM and Zip drives,
- instructor should demonstration procedures specific to software,
- student may develop individual or cooperative multimedia projects, and
- all students present their multimedia projects in-class.

Multimedia tool programs require large amounts of RAM (minimum 16 MB), and student projects often require more disk space than a floppy disk provides necessitating the use of storage media such as a zip cartridge.

In classes where the instructors demonstrated specific program procedures using a computer projector, prior to student use of the procedure, students were more satisfied with their multimedia instructional design experiences. Whole-class demonstration provided an opportunity for specific questions and discussion related to procedures. Most students preferred to observe a demonstration of specific procedures before they tried the procedure on an individual basis.

Students have reported that the opportunity to work cooperatively on the design and development of multimedia instructional materials has been a positive and meaningful professional experience for them. Students share ideas and “intelligences” and experience a team sense of accomplishment with the completion of the project.

Most often, however, students have chosen to work individually on their multimedia projects.

All students should have an opportunity to share their multimedia projects with the whole class. This experience enables all students to share design and development problems and discoveries. Without exception, the process has been a positive affirming one for each student.

**Concluding Remarks**

Successful student experiences with the design and development of multimedia instructional materials depends on the instructor’s ability to ensure that students develop the necessary prerequisite skills, and have access to adequate hardware. Without both, the student’s multimedia design experiences can be a source of significant frustration and stress. When instructors are able to implement the guidelines suggested by the authors, the design of multimedia instructional materials provides teacher education students with a rich repertoire of technical computer design skills. At the same time, students experience their multimedia design and development experiences as salient integrating professional experiences.

One of the most interesting and innovative approaches to integrate information technology into classroom practice is the use of student created multimedia and hypermedia projects. In this paper, hypermedia is distinguished from multimedia by the use of dynamic “links” which permit items of information to be connected by their relations or associations rather than in a linear page to page manner. The critical method should work equally well for both, but only the hypermedia project will be used in the discussion that follows.

Complex Objects and the Need for a Critical Methodology

The capacity to represent knowledge in a variety of media and to connect items of information dynamically characterizes the hypermedia format. We designate this type of creation a complex object. The way that the complex object represents knowledge and communicates its ideas is distinctive and requires a method for adequately assessing its meaning that is appropriate to its form. In an effort to develop such a critical methodology we have turned to an already established method for critical evaluation from the arts. The model of communication and the framework for the method are based on work initiated by Eugene Kaelin (1962, 1968) for aesthetic criticism grounded in phenomenology and existential philosophy. In this paper, we will present this framework and draw the parallels between the critical role in aesthetics and the facilitators role in assessing complex objects to communicate understanding of substantive content in the teaching and learning context.

Kaelin develops a model of aesthetic communication that we believe to be appropriate for the manner in which other complex objects, i.e., student multimedia and hypermedia creations, embody meaning. Kaelin (1962) deals with two fallacies that represent extremes in the way that a work of art is understood. The first is the “affective fallacy” in which consideration is given only to the psychological effect on the audience. This attitude is evident in expressions like, “I don’t know much about art, but I know what I like.” At the other end of the spectrum is the “intentional fallacy.” In this view, only the creator’s experience is considered, i.e., what was meant or intended whether realized in the work or not. Kaelin proposes a principle of relevance that brings the creator and the appreciator together on the same side of the object.

Only that intention of the artist is relevant which is actually expressed in the work before the artist and appreciator alike, and if this is the case the intention and the work are the same; only those feelings are relevant to the work which are controlled by the phenomenally objective structures of the work itself, entering into an intersubjective experience of both artistic communicants... In aesthetic experience the work serves to mediate the experience of creator and appreciator. (p. 333)

The implication for the case of student creations is not that they are exclusively expressive objects in the same sense that a painting, poem, or sculpture may be said to be, but that their total significance is embodied in what they present and the modes of representation chosen. We suggest that the critical assessment of student creations by both the creator(s) and the critic requires a similar methodology to be adequate. We further submit that few teachers or students are prepared to conduct such assessments without training in an appropriate methodology.

Role of the Critic and Role of the Facilitator

In the aesthetic context the artist/creator by the manipulation of the materials brings into being an expressive object. The audience/appreciator then engages in an analogous dialogue by opening themselves to the work itself which mediates the experience of it. Not all potential appreciators however bring to the engagement the necessary experience and understanding to participate in the artistic communication. The critic’s role, according to Kaelin, is to “lead an audience to the fulfillment of the artistic communication.” (1962, p. 352) What the critic does is “not to state what the work of art means; but rather to show how it is constructed, and of what it is constructed, so that a third person may grasp its significance in an act of integral perception.” (p. 353)
The teacher in the facilitator's role is also attempting to assist the creator and appreciator alike to better understand the significance of the communication embodied in complex objects. We can liken the significance to the expressive understanding embodied in the student work. The facilitator most often is not stating the meaning, but assisting the creators in clarifying their own created knowledge as presented in what they actually do in the creation of the complex object. While there are also matters of the simpler and more direct communication of discursive items within the context of the complex object, the very nature of multimedia and hypermedia objects seems to call for consideration to be given to the manipulations of the various media and the relations established within the complex object in a similar fashion to that of the aesthetic object.

**Postulates for the Interpretation of Significance**

Kaelin develops four postulates for interpreting aesthetic significance based on his existential aesthetic theory (1968).

**Postulate 1.** All aesthetic significance is context bound.

**Postulate 2.** An aesthetic context is composed of counters and their relations.

**Postulate 3.** No aesthetic counter has absolute significance, i.e., each has only that significance which is made apparent by a relationship to some other counter within the context.

**Postulate 4.** The significance of the context is the felt expressiveness of all the counters as they fund or come to closure in a single experience.

With minor modification, these same four postulates may be applied to the interpretation of significance in the context of complex objects. First, we understand the significance to be context bound. This is a direct extension of the communication model in that only what is actually done in the work itself can be said to have significance.

Next, the context is composed of counters and their relations. Counters are the parts that make up the whole. Counters in the aesthetic sense may be further classified into surface counters, non-representational forms, and depth counters when the arrangements (relations) among surface counters further represent objects, ideas, and images.

The third postulate essentially states that the significance will be found not in individual counters, but rather in the way that these individual components relate to other components. This is especially important when considering the context of a hypermedia creation where the links between items of information implicitly or explicitly establish relations between parts.

Postulate Four serves as the basis for our judgment of the significance of the complex object. In the assessment of the student project, all counters and their relations are to be considered and a standard of closure applied. By closure we mean the way in which each and every counter and their relations contributes to or distracts from the clarity and completeness of the complex object's significance.

**The Methodological Framework**

The method for critiquing complex objects based on the four postulates is divided into two main sections, the description and the judgment. While it is possible to intersperse description and judgment in a critique, we have found it most useful in the instructional setting to treat these as separate but related parts. In order to describe the counters and relations that comprise the complex object, we first perform the phenomenological reduction or *epoché.* Based on Husserl's phenomenology, the epoché requires that we "inhibit or suspend (put out of action, 'turn off') all belief in existence that accompanies our everyday life and even our scientific thinking." (Spiegelberg, 1976) In our context, we are simply asked to hold in abeyance the value of our own beliefs and understandings in order to be open to the experience of what the students have actually done. This essential step is intended to adequately describe the counters and their relations and make our judgments as to their significance based only on what is actually done.

By "bracketing" our experience of the object itself, holding off preconceptions, personal knowledge and beliefs in the adequacy of that knowledge we are setting the stage for the phenomenological description of the various counters and relations that make up the complex object in its totality. The importance of the reduction to the process of criticism is that we want our judgments to be about the significance of the object itself, not how it may compare to our own understanding of the content under consideration. The goal of the critical method is to assess the students' understanding as embodied in the context. In other words, we are trying to infer how the students' understanding is communicated by the work itself.

It is for this reason that the method begins with the description of surface and depth counters and their relations as they are presented. Accepting that the complex object is the only context in which significance will be found, it is only what was actually done that can have weight in our judgment.

The distinction between surface and depth counters in our descriptions and the relative importance of each may not be as clear as are the distinctions that Kaelin makes when considering their role in the way that a work of art expresses itself. The sensuous surface of a painting, for example, has surface counters that are readily distinguishable from experiential depth. The direct manipulation of the media by the artist produces such surface counters as line, shape, color, size and position. If and only if these manipulations also represent objects are there depth counters to be considered. Such distinctions may be important in critiquing a work of art that may or may not be, in any sense, representational. Surface counters and their relations may represent...
objects, objects and their relations can suggest ideas, and ideas can have iconographic significance as images. For example, the arrangements of the artists material (paint on canvas) may be used to represent the figure of a woman and an infant. This relationship can be interpreted to also signify the idea of mother and child. The image of mother and child might signify the image of Madonna, nurture, etc.

At this point we have not attempted to create a comprehensive list of possible surface counters for the criticism of complex objects. Color, shape, position on the screen, size of individual components, etc. can be described and may have significance. Generally speaking, however, the type of object that makes up our context is assumed to be a purposeful representation of depth counters by their very nature. What is of greater concern for our purposes is that we describe what was actually done by the creator(s) in constructing the object, interpreting its significance based on what is described, and finally rendering a judgment of the adequacy of the total context in expressing a clear and relatively complete expression of understanding.

By rendering in language what we perceive in the students’ creations, we can use the descriptive component of the critique to initiate dialogue with the creators and assist them in clarifying and constructing representations of their own understanding of the knowledge being considered. By basing judgments only on what we have described we are able to provide valuable feedback to the students regarding the adequacy of their output and help them better understand how the complex object communicates.

Portfolios are a common factor of life for preservice teachers in Kentucky. In this case, they are representations of success in the New Teacher Standards developed as part of the Kentucky Education Reform Act (KERA). These standards represent various aspects of the profession such as content knowledge, classroom instruction, professional development, collaboration, and evaluation of students. Preservice teachers compile evidence throughout their student teaching experience to demonstrate these goals. Appropriate use, instruction of, and the application by students in technology is present in all eight New Teacher Standard areas.

The “notebook” medium of portfolios is changing in many ways. For the last two years, some public schools in Kentucky have been exploring the use of digital media for creating middle and high school student portfolios. As a result, multimedia products such as ClarisWorks, HyperStudio, and PowerPoint have become staples in these classrooms. The argument among these groups, as with others across the country, has been that digital media facilitates the collection, archiving, and transition of portfolios through twelfth grade (Milone, 1995; Lynch, 1996).

At Morehead State University (MSU), I decided to do something “different” with my student teachers. The idea was to create a digital portfolio on CD-ROM in which students would dynamically represent their student teaching experience. Since preservice teachers are required to produce an interview portfolio by the end of student teaching, this would serve a dual purpose: a digital portfolio would demonstrate not only the New Teacher Standards, but also the technological proficiency desired by administrators and school systems. The objectives of this study were to (1) determine the present perception and current technologies regarding digital media, especially among MSU preservice secondary teachers; (2) given these perceptions and technology, develop a model of the successful digital portfolio; and (3) implement the production of digital portfolios among MSU preservice teachers as an alternative to traditional portfolios. This article describes the various processes used to create and complete a digital portfolio during a twelve week student teaching experience.

Background

As a teacher educator with access to preservice secondary students, the next logical steps were to determine my pilot group’s parameters. I began the pilot study of digital portfolios in the 1996-1997 school year. Student teaching consisted of one 15-week semester split between a campus methodology course, EDSE 415 and field experience, EDSE 416. Students would be on campus for four weeks prior to school placement and several follow-up classes throughout the semester for EDSE 415. As a prerequisite to student teaching, MSU students are required to pass two of the following computer skills courses in the Teacher Education Program: “Teaching Skills and Media,” “An Introduction to Computers,” a computer workshop, or a CLEP exam.

Because rudimentary computer skills had been successfully covered in the prerequisite courses, I decided to proceed during the four weeks of campus training with basics in electronic mail, PowerPoint 95, video and audio capture, and scanning of photographs. The time spent on these applications was limited since the nature of the course was focused on instructional methodology in student teaching. Students from Fall semester were required in this course to demonstrate competency in technology basics by completing the following:

1. Locate ERIC documents through an Internet connection and e-mail the results to me.
2. Locate Listservs and Bulletin Boards of interest and e-mail me the purpose of the groups and the procedures to join.
3. Scan one graphic and one text piece, write a summary of procedure, and submit a disk containing the scans to me.
4. Develop a five-slide presentation on PowerPoint and demonstrate the results to the class.
5. Attend a video and audio capture workshop.
6. Send electronic journals each week during the student teaching.
Also, the student teaching semester allowed up to two personal days for absences. I distributed a letter to all cooperating teachers asking that they allow at least two more days for students to work on their portfolios on campus if necessary. A multimedia facility was available for students to schedule.

I changed the assignments in second semester to reflect needs demonstrated in Fall semester. I added the following:

1. HyperStudio instruction and development of a five-slide demonstration.
2. ClarisWorks, Toolbook, and Macromedia demonstrations.
3. Specified weekend training sessions throughout the student teaching semester for audio and video capture, PowerPoint application, HyperStudio application, and specific multimedia work.
4. Development of a World Wide Web page to address student teaching needs on a regular basis.

Conditions at the student teaching sites varied tremendously throughout this pilot. Six students were placed in large, metropolitan/urban school systems, six in large, suburban schools within fifteen miles of a metropolitan center, three in a suburban/rural system within thirty miles of a metropolitan center, and one in a rural school system about forty miles from a metropolitan center. Most of the school systems have internet access for teachers, but at least eight of the students did not have e-mail at their schools. I requested from the school technology coordinator an electronic mail account for each student teacher. This had to be cleared with the Kentucky Department of Education as it was adding an individual to their electronic mail system. The process took up to ten weeks to complete in some cases. Of these, seven students used dial-up accounts at their homes for e-mail and one simply mailed journals to me. The last case eventually did receive e-mail, but could not send it to me successfully without forwarding it through an intermediary at another school. At least two of the schools were very advanced and possessed scanners, audio and video equipment, as well as highly trained personnel capable of facilitating technology knowledge.

Results

On the first day of each semester, students in my section of EDSE 415 were asked to respond to several questions regarding technology. There were eleven student teachers in the fall semester and five in the spring for a total of sixteen in the pilot study. Their attitudes and practices with technology were questioned heavily. All but one of the respondents believed that they were competent in word processing and using a computer. The students had used PC’s most often, but had some experience with a Macintosh. The groups were initially split over the issue of using technology in the classroom. Many believed that technology meant “computers” and stated that they should not replace a living teacher. Others simply stated that technology should be increased so that skills were taught in public schools. The attitudes toward technology were expressed far too vaguely to be described accurately from Fall semester. Spring semester students noted some enthusiasm, but little actual experience with technology.

On the last class meeting of each semester, a similar survey was given to the preservice teachers. At this point, fifteen of the sixteen preservice students had successfully completed student teaching. None had yet completed their portfolio when the survey was given. Students were again asked their attitudes and practices with technology. Of those responding, all claimed to have competency in word processing, PowerPoint, and scanning photographs and text. However, several others noted proficiency in using ClarisWorks, video and audio capture, HyperStudio, and electronic mail.

The attitudes toward technology had clarified somewhat during the semester. Fall semester students were quite vocal about their attitudes after having completed student teaching and the portfolio requirements. All students were heartily in favor in technology incorporation in the classroom. Many stated that they felt this project would increase their worth in the job market as well as provide more creativity to their teaching. Two respondents added that the stress and pressure of student teaching were compounded by trying to complete a digital portfolio during the semester. All but two of the students used the Internet for up to twenty hours of classroom related instruction and job searches. All noted that group instruction on specific workshop dates throughout the semester would have been beneficial.

Spring semester students were given group instruction during Saturday workshops on campus in the multimedia labs. Initially, they were somewhat enthusiastic, but hesitant, because of their admitted lack of technological skill. Their attitudes toward technology became ambiguous as the semester continued. As the workshops progressed, students completed all of the assignments required, but did not go beyond this point. At least two of the students were able to complete all requirements on their own and did not attend the workshop sessions. The remaining students were eager to learn, but did not exceed expectations.

Of the sixteen students involved during 1996-1997, nine successfully completed a digital portfolio. Successful portfolios contained a resume, educational philosophy, lesson plans, student work, and letters of reference and/or transcripts. Another five completed portions of the portfolio which would come to represent their contributions to the project. Two did not complete any work on the digital portfolio.
Conclusions

This pilot project has yielded a good amount of knowledge regarding the attitudes and practices of technology among a small group of preservice teachers. They are generally enthusiastic about using technology, however some think this means computers only. These teachers have used the Internet somewhat and are willing to use it more frequently for classroom applications given the knowledge to do so. Many will use this knowledge to create future classroom activities which will encourage student learning and advancement in specific fields of study.

It would seem, though, that MSU’s preservice teacher education program is not adequately preparing teachers for continued use of educational technology. Basics in word processing simply will not be sufficient for teaching the students in today’s schools. Before having this pilot project, students were comfortable only in word processing. After the project, many admitted that they see a need for revision in the program to reflect current technology. Instruction and application into critical thinking with technology is clearly indicated. Otherwise, we may be facing a future of automation teachers who do not know how to go beyond the textbook.

I believe that the production of digital portfolios is viable, however some variables must be considered before undertaking such a project. The state of Kentucky had promised to upgrade all its schools to Internet capability and classroom readiness before the end of school year 1997. As of this writing, the date has been pushed back to school year 1998. Having seen many of these schools, I suspect that the date will be pushed even further. Also, as with many school systems, monies are not available for professional development and training with technology. These funds must go toward state test score improvement and building maintenance. The technology may be in the schools, but few teachers are actually using it at this point. This, together with college coursework and personal biases unrelated to education, will affect the attitudes of preservice teachers. Anecdotally, those schools with access to technology and the trained personnel to assist teachers, tended to be dens of inquiry and creativity. Six of the nine successful portfolios were produced by preservice students in the highly technologically advanced schools. This semester I have begun a new pilot analyzing the attitudes and practices of preservice personnel and their cooperating teachers.

Teacher Support of Multimedia Use in Problem-Solving vs Question-Response Contexts

Jeanne Weidner
University of California, Berkeley

Bernard Gifford
University of California, Berkeley

Traditional science education, including that in anatomy, has been criticized for promoting a static and disassociated approach to the domain, exemplified by the memorization of specialized vocabulary. This approach to learning may result in knowledge that is not easily applied to new situations, what Bransford and Vye (1989) refer to as inert knowledge.

Problem-Based Learning

One instructional strategy offered as an alternative to counter the acquisition of inert knowledge is Problem-Based Learning (PBL). This method is typically instantiated as a group learning technique involving 5-6 students with a faculty tutor. The role of the tutor is not to provide domain expertise, but to evaluate both group and individual progress in acquiring conceptual understanding and problem solving skills. The domain content is embedded in a series of cases, presented as problems for the group to discuss.

Advantages of Problem-Based Teaching and Learning

The instructional advantages of problem-based teaching and learning (PBTL) over conventional whole-class synchronous instruction have been documented by a number of researchers, representing a broad range of theoretical perspectives in cognition and learning (Barrows, 1983; Albanese & Mitchell, 1993; Nii & Chin, 1996). The learners in these studies have ranged from first-year college students, enrolled in basic science courses, to first-year medical residents, making their first independent hospital rounds. The success of PBTL has been attributed to a number of factors. Norman and Schmidt (1992) argue that PBTL is more effective because it encourages learners to take greater control over their own learning, a stance closely linked to improved metacognitive and self-regulatory skills. Newble and Clarke (1986) contend that PBTL is more effective because it appears to foster a deeper approach to learning; that is, students are more likely to employ elaboration techniques to incorporate new knowledge into existing cognitive structures. Other authors also have claimed that the method appears to result in better retention of material than when presented by traditional means (Norman & Schmidt, 1992; Eisenstaedt, Barry, & Glanz, 1990). Finally, in most of these studies, it is generally preferred by students, who view it as superior to traditional teaching methods because it fosters a more nurturing and enjoyable learning experience (Albanese & Mitchell, 1993; Sobral, 1995).

Disadvantages of Problem-Based Teaching and Learning

However, PBTL is not without its disadvantages as well. For one, the cost of PBTL over the lecture method appears to be greater. Albanese and Mitchell (1993) cite the findings of Donner and Bickley who estimate that PBL requires an average of 17.4 faculty hours/year vs. 4.8 faculty hours for lecture instruction. Some students also have encountered difficulty in building an effective knowledge base. This finding has been evident in the generally lower scores of PBL students on the National Board of Medical Examiners - Part I, which tests for basic biomedical science knowledge (Albanese & Mitchell, 1993). Additionally, some students are simply uncomfortable with the method and prefer more traditional techniques. These students may simply need more direct instruction and guidance, especially early in their medical school careers.

Related to this speculation is the discussion by Norman and Schmidt (1992) on the relationship of structured feedback to successful problem-solving and transfer:

The study of concepts while attempting to solve a problem appears to be an optimal strategy for spontaneous transfer of the concept to new problems... However, it is not sufficient to engage in the act of solving the problem; students must receive corrective feedback during the course of attempting to solve the problem. (p.561)

Norman and Schmidt cite conflicting studies of performance in solving clinical problems by PBL students from two universities: one study found PBL students to perform less well than conventionally trained students, and the other...
study had the opposite results. Norman and Schmidt conjecture that the difference may be due to the former curriculum being “less structured, which may result in less corrective feedback and the persistence of conceptual errors” (p. 562).

**Role of Technology**

Computer technology may prove to be an important component in the support of PBTL, and may help to alleviate some of the shortcomings associated with it, including its cost and potential lack of structured feedback. However, the ultimate impact of this instructional tool, as with all tools, will be directly linked to how it is used in the classroom. Although multimedia programs may provide well-developed and immense information resources just a mouse-click away, the user may become lost in this maze of information, and become frustrated or confused. This possibility may become especially significant when using multimedia to support PBTL, since the lack of direct feedback is frustrating to some students.

Much work is ongoing to investigate how computer technology can provide the feedback necessary to promote effective learning. Merrill, Reiser, Ranney, and Trafton, (1992) compared the guidance offered by human tutors with that offered by intelligent tutoring systems. They found that computer tutors share many of the same characteristics as human tutors, and have been shown to provide comparable instruction, both of which are superior to students learning on their own. However, much of the difference between the two approaches pertains to the increased flexibility and subtlety evidenced by human tutors, which may result in allowing students greater freedom to discover knowledge and control their learning. This difference may change in the future. Computer technology appears to have the long-term potential to provide immediate and personally customized feedback to a student as s/he progresses through an instructional program. Vahey and Gifford (1995) cite examples where feedback can not only be customized for the learner, but can also be optimized for the particular situation. However, at present, the idea of technology personalizing feedback is much easier to appreciate as a concept than to implement in practice. Ross and Morrison (1993) point out that truly personalized feedback will not become possible until computers can analyze a student’s free and spontaneous answer to a question and respond accordingly. This inability to analyze free text remains a major limitation of computer technology, and underscores the importance of the instructor’s role in providing useful feedback to the learner in a timely manner.

**Computer Support of Problem-Based Learning**

To date, relatively few studies have been published with regard to how multimedia can support problem-based teaching and learning. Hooper, O’Connor, Cheesmar, and Price (1995) report on their use of multimedia-based clinical cases to aid in the learning of medicine in a problem-based manner. Advantages which they found included self-paced learning, feedback, and a deeper understanding of the basic physiological processes underlying the problems. Lee, Ruttecki, Whittier, Clarett, and Jarjoura (1997) compared the efficacy of computer assisted instruction (CAI) to a more traditional format in medical students’ acquisition of clinical problem solving skills. Although they found it as effective as a teacher-supervised workshop in transmitting conceptual knowledge, CAI appeared not to be as effective in developing problem-solving skills. In addition, students in the workshop ranked their instructional method higher than those in the CAI group. This study further emphasizes the important role of the teacher in effective instructional settings, and continues to feature the computer’s role as a supplement to, rather than a replacement for the teacher in the classroom.

The authors were unable to find any studies on how multimedia use in a problem-based format may differ from its use in more traditional school tasks. In addition, to our knowledge there authors found no studies that have been published which compared the type of teacher intervention and assistance appropriate for the most effective use of multimedia under a PBL format.

**The Study**

**Methods**

This paper presents data from a preliminary study that addresses some of these issues. The study compared the way pairs of students used the representationally rich multimedia program BrainStorm: An Interactive Neuroanatomy Atlas (Coppa & Tancred, 1995) under two conditions. In the first problem-based (PB) condition, subject pairs were given a patient case featuring symptoms resulting from injury to neurological structures, and were asked to solve the case by identifying the structures involved. In the second question-response (QR) condition, student pairs were given more traditional questions to answer about these neuroanatomy structures.

**Subjects**

The subjects who participated in the project are graduate students enrolled at the University of California at Berkeley. Each group had a comparable educational background including the completion of an introductory neuroanatomy course, and each was previously unfamiliar with the software.

**Analysis**

We assessed subjects’ acquisition of facts and concepts by administering an objective post-test. We also videotaped the subjects while using the program. We paid particular attention to the gestures and references they made to the representations in the program, the discourse they conducted, and the modules they frequented in the software.
Results

The overall average score on the post-test was similar for each condition (PB=66.38%, QR = 68.97%). Both groups performed equally well on items pertaining to terms and similarly on items dealing with symptoms. However, the PB dyad was more likely to answer correctly items relating structure to function (83.3% vs. 58.3%). Conversely, subjects in the QR condition were more likely to answer correctly questions asking for specific details (75% vs. 46.9%). Figure 1 shows these distinctions graphically.

Videotape Analysis

Some of the behaviors that emerged in the analysis of the videotape included: structure/function correlation, summarization, observation of details, visual spatial mapping, error checking, floundering, use of orienting gestures, and feeling overwhelmed with the task. The relative occurrence of some of these behaviors suggested interesting distinctions in learning strategies between the two conditions.

Redefining the Task

One finding that occurred with both dyads was the negotiation to simplify the task by addressing the easiest question first. Ultimately, both groups decided to deal with the questions/problems in a different order than the way they were presented. This type of strategy represents a useful metacognitive skill, which should be fostered by instructors.

Use of Gestures

Both pairs utilized gestures to orient themselves with regard to several of the anatomical terms such as coronal, horizontal, and sagittal. By using their heads as referents, and demonstrating with their hands the type of dissection indicated by the terms, they reinforced both their own and their partner’s understanding of these concepts. These observations support Crowder’s (1996) interpretation of sixth graders using gestures to understand scientific models. Crowder found that when subjects attempted the explanation of a model, they gestured in ways that helped them to coordinate and revise its respective elements. In contrast, when subjects described a previously thought-out model, they were more likely to use gestures that redundantly emphasized speech.

Floundering vs. Frustration

One major difference that emerged from the PB transcript was a long incidence (9 minutes) of what the authors have termed “floundering.” This resulted from the subjects misapplying their previous knowledge through an attempt to map symptoms onto an area of the visual cortex rather than onto a part of the visual pathway. As a result, they explored the program in a “non-productive” manner and attempted to elicit evidence that would support their initial hypothesis. One subject eventually discovered the error, and redirected the search effort onto more productive pursuits. This type of unproductive search was absent from the QR transcript, which seemed to illustrate a more purposeful, directed and efficient search strategy throughout. There is some evidence that this difference may be due to the nature of the assignments. Problem-solving in general often leads to unproductive cognitive search strategies (Newell & Simon,1972), whereas locating factual material is a more straightforward process as long as one is familiar with the resources available.

In contrast, although no specific instances of “floundering” were noted in the QR transcripts, nine separate occurrences of what we termed “feeling overwhelmed” were noted. These were exemplified by utterances such as “there’s so much to know,” “lots of stuff,” and “good grief.” One way to account for this finding was the way in which the subjects in this condition interpreted their assignment. Although the assignment was intended to uncover a total of 25 concepts/details, the QR dyad actually recorded 38 details on their papers and mentioned several more in their discussion. In contrast, no instances of these types of statements were noted in the PB transcripts and no additional details were reported on their paper. As a result, it is possible to speculate the occurrence of these “frustration” statements may be directly related to the task assigned. By focusing on details, subjects may have the feeling of becoming deluged, especially if these details are viewed as a series of unrelated items. Both of these episodes of floundering and frustration have important implications for teachers.

Attention to Details

The QR pair was more likely to notice details in the program, including the discovery of errors in the diagrams and text. Even though both groups accessed a particular diagram containing errors an equal number of times (3), and spent an equivalent amount of time viewing it (2.5 minutes), only the QR dyad noticed several labeling errors. This was exemplified by the following excerpt in the transcript:

N Yeah 1, 2, 3, 4. This should be 44.
Cursor over Broca’s area

New Media — 645
Although it is hazardous to make generalizations about these findings from a single case, one can speculate that they are due directly to the nature of the tasks. Because the question-response pair was directed to answer questions about specific details, the focus which resulted from this assignment may have allowed them to notice more details in the program.

**Integration of Concepts**

Students in the problem-based condition seemed to exhibit more integration of the concepts embedded in their task. This was demonstrated by the presence of more instances of summarization and review in their transcript. Four specific instances of elaborate summarization were found in the PB transcript compared to only one simple reference to a previous question in the QR transcript. The PB pair also engaged in more visual spatial mapping of their problem onto representations provided by the program. This was not unexpected since these students were given a specific visual image as part of their assignment, but it was also reflected in the way they utilized the program. These students spent 6.5 minutes interacting with the cross-section module compared to less than a minute spent by the QR pair. Conversely, the QR dyad was more likely to access textual information cards than the PB pair (15 instances vs. 7). In addition, the following discourse unit which occurred early in the PB transcript as part of their overall strategy to solve the problem, appears to indicate an integrated approach, in that they expected to accomplish several tasks simultaneously.

**Time on Task**

Although both pairs spent approximately the same amount of total time in completing their assignments (45 vs. 47 minutes), and nearly the same amount of time directly interacting with the program (33 vs. 35 minutes), the QR pair engaged in 34% more conversation exchanges (461 vs. 345) and uttered 24% more words and sentences. The greater number of utterances by the QR pair may simply reflect individual differences, i.e., a relatively greater loquaciousness compared to the other dyad. However, it may reflect a more substantial difference in the cognitive processes occurring within the pairs. If the silent pauses represent instances of reflective questioning and thinking, this may have important consequences regarding the relative benefit of these two instructional approaches. One of the most important concepts in recent cognitive theory has been the importance of metacognitive behaviors in effective learning (Brown, 1987). Problem-based learning has been shown to contribute to the development of life-long learning skills (Norman & Schmidt, 1992), so there exists the possibility that PB subjects in this study were exercising metacognitive skills during the pauses in their discourse. Although the interpretation of silence in a transcript is fraught with difficulties, it does suggest an area for further research.
Do you want to do that [determine the terms] first or do you want to figure out where it [the lesion] is, first?

Umm

Or like, what it is?

That would be more fun, to figure out what it is. I guess we can do that, and we can do this at the same time

Okay, want to do it all at the same time?

We'll keep track of...if we find out what's going on, where it is and what's happening then, the terms will probably come out as we go.

Figure 3. Excerpt From PB Dyad Transcript

Discussion

The small sample size makes the task of drawing conclusions from this study tenuous at best and impossible at worst. However, with this caveat in mind, we would like to consider the potential implications these findings may have with regard to the role of the teacher in a classroom utilizing computers for dissimilar instructional tasks.

With regard to both pairs redefining their task in order to simplify it, the question arises as to whether or not the teacher should anticipate this and simplify the task by rearranging the sequence of questions. Some would argue that this would serve to organize the task in a more manageable fashion and reduce the possibility of anxiety on the part of students. Others however, would claim that giving students an opportunity to reorganize the activity for themselves, provides greater engagement in the task, and encourages reflective thinking and planning strategies.

Another related question is whether or not a teacher should intervene when students are “floundering” as they were in the PB condition. What are the dangers in allowing students to pursue non-productive strategies? What are the dangers in not allowing this type of activity? How important is it for students to recognize and correct their own errors compared to the alternative of developing misconceptions? By neglecting to intervene in this situation, one of the students had the time to recognize her error. But is it reasonable to ask teachers not to intervene in similar situations? This may be an area where using a rich source of data, such as multimedia programs, benefits students who are reasoning about a problem. Presumably, by attempting to find evidence to support their hypotheses students will be led to recognize their errors. This appeared to be the case in this study. As a general recommendation, we suggest that teachers use restraint before immediately coming to the rescue of a student searching for answers until it appears that the student is unable to resolve the issue by him/herself.

Similarly, what type of support should be provided when students appear to become overwhelmed by the volume of information as shown by the subjects in the QR condition? In this case, we believe a more immediate form of intervention is appropriate. If a student is misinterpreting an assignment, we believe it is the obligation of the instructor to rectify the situation in order to minimize student anxiety. An even more appropriate remedy would be to pretest written instructions to ensure that they are likely to be interpreted correctly.

Both of these examples raise questions about the support a teacher should provide when students are consulting a computer resource while accomplishing a task. What type of scaffolding should an instructor provide? What form should it take? Should it be available in the software itself or embedded in the task instructions? Should it be offered as direct instruction? Some studies have shown the type of feedback provided within multimedia is not as critical as simply having it available. Generic hints afford opportunities for students to reflect upon and support their thinking, and do not have to be related to the specific topic in the program. By providing this type of support, instructors equip them with a valuable skill that will enable them to continue to be effective life-long learners.

A final issue that emerges as a result of this study is which of the tasks provided for more meaningful learning? It can be argued that if we want students to be able to integrate their knowledge, it tentatively appears that solving a problem fosters this skill more than responding to questions. However, there are instances where it is important to notice
details as well, and the question response condition appears to promote this activity. Perhaps the best course to take is that recommended by Weinert & Helmke (1995) who state "An old piece of educational wisdom is that no single method is the best for all students and for all learning goals." (p. 136)

A Look at the Role Technology Plays in Special Education

Darrell J. DeMartino
University of Houston

Aimee M. Prinz
University of Houston

Hjetland (1995) reports, “Technology can make our lives easier. Everyday tasks are simplified.” (p. 2) In reference to the use of technology for management tasks, calculating grades, and making lesson plans. However, the use of technology in the classroom for special education teachers has moved beyond simple management functions and is being integrated into a child’s education. As technology advances education, it is important that teachers, educators, and special education staff merge technologies’ progress into their instruction. A particular focus should be placed on students with learning disabilities.

Background
In 1975, the United States Congress passed Public Law 94-142, which is better known as the Individuals with Disabilities Act (IDEA). This act has changed the way teachers educate children in this country. IDEA mandates that every child between the ages of 3 and 21, regardless of the type or severity of their disability, shall receive a free, appropriate public education (Heward, 1996, p. 25). One of the major tenets of P.L. 94-142 states that students will be educated in the least restrictive environment. This environment is usually in a resource room or special education classroom. However, many state education agencies are pushing school districts to place these special education students into the regular classroom whenever possible. This means regular education teachers have to be prepared to meet the individual needs of students with disabilities. One recent movement has been to use technological advances to meet the needs of these children.

Learning With a Disability
Students with learning disabilities tend not to learn in the traditional ways. In many classrooms, teachers stand at the head of the class and lecture on a given topic. Students are expected to take notes, sustain attention, participate as appropriate, and retain information being presented. However, many special education students are not able to process information presented in this instructional framework. Research has shown that students with learning disabilities need material to be presented in multiple formats and numerous times for them to understand and retain information. As well, reinforcement has been proven to be an essential facet that is often necessary for remembering learned material. With these considerations, instructional modifications can be made which enhance the education of children with learning disabilities. These instructional modifications can be accomplished by using today’s technology.

Technological Need for Special Education Students
One major educational focus has been on integrating computers into the classroom. This focus has been heightened by the need for technology in the instruction of special education students. Through computers, teachers can offer any student the opportunity to learn and view pedagogical material in unique ways. However, many of these technological advances are not being appropriately applied to fit the needs of special education students. The utilization of computing technology can create multiple educational opportunities that are particularly useful to special education students and is essential to their education within the regular classroom setting.

Instructional Modifications
Now that many special education students are being reassigned to regular classrooms, special education inclusion is occurring. Currently, many districts and states have moved toward higher levels of inclusion, and it has become important that teachers are able to adapt to these changes. Students however do need certain modifications to be successful in this regular classroom setting and technological advances may be part of the answer. There are simple ways computers can be used to modify a special education students class materials; including worksheet alteration or reduction, creating individualized vocabulary lists, and scanning worksheets for the purpose of modifying text. A teacher can use most word processors’ spell check and grammar check functions to create readings that are...
appropriate for a special education student’s instructional level. These simple technological functions can be combined with other computer uses to enhance the education and instruction of most students with learning disabilities.

Technology is able to assist teachers in providing a framework for teaching and learning, but has to be exercised properly. Individualized education plans (IEP) can include specific instructional modifications where technology can be integrated as an essential characteristic for special education students. As well, teachers can use today’s computers for other functions that are beneficial to the education of learning disabled and special education students. A few of the areas where technology can be utilized are:

- Reinforcement
- Providing multiple perspectives, and
- For accessibility options

Reinforcement

Students with disabilities need much reinforcement and computers can be a tool used to attain this goal. One example of reinforcement is through drill-and-practice. Many software programs used in an instructional setting have drill-and-practice activities associated with lessons which act as a reinforcer of learned experiences. The question and answer sessions often compile a score which can be further used for determining where focused instruction is necessary. Another function of drill-and-practice software is the randomization of questions which reduces the chance of boredom due to repetitiveness. For students who have their own home computer, time can be spent working on enhancing skills they have been practicing at home.

Computers can also be used as a behavior modifier and reinforcer. Many students enjoy using the computer and this enjoyment can be transformed by using the computer as a tool to reinforce good behavior and good performance. As a student accomplishes certain goals s/he may be allocated additional time on the computer. This form of award reinforces good behavior, while options to take away computer time punishing bad behavior. Special education students often respond to this punishment/award system and can be used to a teacher’s advantage. For students who have access to computer technology at home, this system of punishment/award is not as effective.

Interactive games can also be used to reinforce concepts previously taught. Through games and simulations students learn. In addition, games have made learning fun and enjoyable, which increases the likelihood of continued learning. This, in turn, reinforces the need for education. However, consideration of a student’s skill level must be examined when using this medium. A student who becomes frustrated with the difficulty of a game often responds negatively to this experience.

Multiple Perspectives

Students with learning disabilities respond better to multiple perspectives rather than one perspective regarding instructional methods. With computer technology, teachers can enhance their lessons by providing various perspectives on information. Multiple formats can be integrated to provide students with a variety of modalities for learning and retaining concepts. One way teachers can use this technology is by instructing with multimedia, or making multi-sensory presentations. By using multimedia or hypermedia in a lesson, teachers can represent information visually, audiologically, and textually. Besides the multiple sensory function of multimedia, the Center for Special Education Technology reported “multimedia tools permit the teacher and learner to interact in new ways.” (Center for Special Education Technology, 1991, p. 1) They go on to report:

The teacher’s goal of helping the student become an independent thinker and learner can be achieved as the student becomes involved with the content presented through multimedia. No longer is the recall of facts sufficient; the focus is on thinking, applying information to new situations, and solving problems. (Center for Special Education Technology, 1991, p. 1)

By using widely available programs such as PowerPoint, Hyperstudio, or Tool Book, educators can appeal to multiple senses, which enhances learning in special education students. Examples of other available multimedia software that has been used with success in special education are (Center for Special Education Technology, 1991, p. 1-2):

- Jasper series software- uses students’ science and math skills as they view Jasper adventures.
- Multimedia Composer- integrated media use to create a composition using texts, video, sounds, and maps.
- GTA, A Geographic Perspective of American History-students create their own show.

These software packages all deal with problem solving and focus on thinking. This new focus is a way of exercising the brain and keep students centered on a learning task without the boredom of straight lecture or question-and-answer periods. As well, the variety offered by these adventures reduce the problem of attention-deficit. These programs also continue to make learning fun.

Accessibility Options

Two major types of modifications are used to accommodate special education students. Modifications and facility/equipment adaptations (Storm, 1993). Curricular and instruction modifications were discussed above, now for some focus on facility/equipment adaptations.
As technology evolves so does the ability to change equipment to suit the needs of any user whether they be a large person, short person, or disabled student. There are two areas where facility/equipment modifications can be studied, one is adaptive technology, and the other is using existing technology and changing the uses to meet the needs of a student. Focus here is on the latter.

One area of concern to many teachers is how to deal with the following problem. The use of computers with special education students is sometimes difficult as their impairment (e.g., hearing, visual) becomes an obstacle. One answer is by using computer operating systems such as Windows 95 and Windows NT. Windows 95 and NT has attempted to solve some of these problems with their built in accessibility options. These options have been designed specifically to facilitate the use of computers by individuals with special needs. These accessibility options can be used to the advantage of classroom teachers in educating their students with special needs. Utilization of these functions can make the difference between success and failure while in front of the computer. A brief review of some functions are in order.

Microsoft in their development of Windows 95 and NT 4.0 was committed to making its products and services easier for everyone to use (Microsoft, 1996). These two operating systems include several accessibility functions that provide users who are movement disabled, hearing disabled, or visually impaired the opportunity to utilize computers with less difficulty. Some of their features enable users to change the display type, mouse, keyboard features, and sound to help users use Windows most effectively (Microsoft, 1996).

A student with visual impairment would be one example of integrating these accessibility options. This student may have trouble seeing the text on the screen, so larger font sizes would be in order. The student could change the display type to enable a higher contrast and/or large default font size. The higher contrast mode makes “objects and texts stand out more visibly.” (Parsons & Oja, 1997, p. 134)

Another accessibility options would be using MouseKeys. One can use “MouseKeys to control the pointer with the numeric keypad as well as with the mouse.” (Parsons & Oja, 1997, p. 129) A third accessibility function incorporated into NT 4.0 and Windows 95 is StickyKeys. StickyKeys is a feature that makes it “easier for users who have trouble holding down one key while pressing another key” (Parsons & Oja, 1997, p. 132), a common function for many applications. These are just a few of the operating systems functions meant to assist special needs patrons.

Besides Microsoft accessibility options, other systems and software are being designed to assist students in their instruction. A recent technological invention, the Kuzweil 3000 PC-based reading system has just been shown to be successful in Columbia, MD. Two hundred students identified with learning disabilities at Howard Community College used this “easy-to-use system that features text-to-speech software that reads on-screen text in clear synthetic speech and displays text and images just as they appear on a page” (Syllabus, 1998, p. 44) to enhance their education.

Until further advances, including more accessibility options in operating systems and additional software is developed, it is up to teachers to be creative in adapting existing technology to suit special education students. Sharing these ideas and success stories are important to enhancing special education.

Changes Necessary in Teacher Education

The main obstacle of using technology for instructional modifications and as a part of education is the apprehension of teachers to learn the technology. They need to realize that computer-assisted modifications often make the difference between a student being successful in the regular classroom and failing. One way of solving this problem is by providing in-service workshops and training session. These sessions should be implemented by school districts and teacher education programs to instruct teachers in ways to use technology.

In addition, pre-service teachers need to be educated about inclusion and understand the implications for their classrooms. Currently in the state of Texas, there is no requirement for teachers to study special education. One recommendation the authors have is for college/university teacher education programs and education state boards to make observation/special education classroom teaching time mandatory for certification. This would expose future teachers to aspects of special education that they may be dealing with once in the classroom.

Likewise, learning about technology is not enough. Through pre-service and in-service teacher education sessions, educators need to be trained on incorporating technology into their classrooms. They need to know that computers are not just a technological baby-sitter, but can be a powerful adjunct to any students’ education.

A fourth issue is dealing with how to put special education and technology training together. As more students are being reassigned to regular classrooms, there will be a greater need for this combined technology/special education instruction. Regular education teachers will need to learn more about and understand the various needs of special education students and technology’s impact on these students. Through adequate training, new teachers will be able to integrate technology to all students. The next goal beyond incorporation is motivating these teachers to utilize the computer more often and in unique ways.
Conclusion

Advances in modern technology can give people with disabilities greater control over their lives and increase participation in education. It has been proven that students with special needs can be positively affected by the application of technology. Technology is a valuable tool for persons with special needs by using repetition, motivation, variety of instruction, and small incremental steps toward learning. Computers, accompanying software, and related equipment can help a concrete thinker follow and learn abstract concepts at an individualized rate. They stimulate and immediately reinforce reluctant learners. These goals can be accomplished when trained, dedicated teachers learn and implement the technology necessary for students to become computer literate, and well educated members of society.

STUDENTS AS TECHNOLOGY APPRENTICES - A VIDEO PROJECT

Ronald J. Abate
Cleveland State University

A technology in the classroom video project targeted for use with an audience of pre-service and in-service teachers is currently under development. The videos in production include examples of teachers using a variety of technologies with their students in a manner that reflects how comparable technologies are currently implemented in the workplace. The video examples include elementary, middle and secondary classrooms from urban and suburban schools across the nation. The goals of the video project are twofold. The first goal is to show what occurs when teachers place students in realistic situations that require students to collect, analyze, apply and communicate information. The second goal is to encourage teachers to examine how classroom experiences may relate to employment and career opportunities.

Technological change is altering how students function at home, at work and in school. The rate of this technological change is frenetic. Common wisdom suggests that by the time a technological innovation is available to most schools it is already obsolete. Attempting to remain current with technological change is a daunting task in any field but it is especially problematic in education where funding levels cannot compete with those available in industry.

There is a fascination with using the latest technology but it is the premise of this paper that a focus on technological innovation in education is misplaced. When considering technology in the classroom the focus should be on relevance. This focus with relevance is based on a basic understanding of teaching. Teaching is fraught with meaning; it is not haphazard or accidental. Consider various teaching strategies, direct instruction, apprenticeship, constructivist approaches, etc.; regardless of the philosophy considered methods employed, or type of assessment used, the act of teaching involves sharing meaning with an audience. Is technology a relevant tool for sharing meaning?

Relevance is a function of the capacity of technology to assist the learner in the acquisition of meaning. As both traditional and new fields of study become dependent on technology so too does preparation for employment in those fields. Examine any occupation and it becomes readily apparent that technology is altering how individuals work. The parcel delivery person downloads data in real time from a hand held device to a computer that uplinks the information to a remote location. The graphic artist uses computer software to produce mock-ups for a magazine layout. A project manager uses spreadsheets to determine the logistics of setting up a construction site. The social worker uses databases connected by telecommunications to verify child support payments.

In each example technology provides the individuals with tools to perform a job more effectively. The goals of production or service industries have not changed but the activities of the workers have. Again, is technology a relevant tool for sharing meaning? It is, when teachers address the issue of technological relevance by engaging students in learning activities that encourage students to use technological tools to solve “real world” problems. The videos under development supply “real world” examples of classroom technology use. Based on experience with other video based teacher education materials, it is hoped that through observation of and reflection on the videos teachers will be guided to consider other forms of relevant technology use in their own teaching (Benghiat & Abate, 1994).

Teacher Involvement

The teachers selected for the School Work videos represent a cross section of grade levels and subject areas. They work in urban schools and suburban schools. To enhance their teaching and their students' learning, some teachers use high technology while others use whatever equipment is available. Often this technology is what many would consider outdated. All provide their students with opportunities to apply the skills and concepts they have learned. In each video, the teachers have identified an activity commonly confronted within a particular occupation, the skills and knowledge required to address the activity and a technological tools commonly used in that occupation. Their lessons require that the students apply what they know to address the issues. The student solutions are shared with a larger audience.

The primary considerations for inclusion in the video project are:

• Do the lessons suggested by the teacher engage students in solving a "real world" type of problem?
• Do the students use technology?
• Do the students share their solutions with a larger audience?

For example, Mike Purnell and Suzanne Malak of Garfield Heights, Ohio presented their eighth grade students with the problem of designing packaging for a fictitious modeling material. In order to protect the integrity of the modeling material, the packaging had to be insulated to withstand temperature fluctuations. The package had to be low cost and easy to assemble, and it had to be attractive in appearance so a consumer would be interested in purchasing it. The students needed to have sufficient knowledge of area, volume, convection, conduction, and radiation as well as basic arithmetic to solve this problem. The students were placed in the roles of engineers and were provided calculators, spreadsheets, and MBL heat probes for conducting insulation tests. Though not as sophisticated, the technology was compatible with the technology real packaging engineers might employ. The students shared the results of their problem solving, the finished packages, with a focus group of fifth graders, the target consumer audience for the modeling product.

Recruitment of teachers was informal. Teachers in the Northeast Ohio area were recruited based on the author’s familiarity with their teaching methods. SITE members who were informed about the project recruited teachers in other parts of the country. In addition, some teachers were recruited “word of mouth” via postings with educational organizations on the Internet.

School-to-Work, Seat Work and School Work

The video project uses the name School Work: Technology in the Classroom to describe the underlying goals of the teachers selected for videotaping. The label School Work juxtaposes the common impression of school work as seat work with the current call for career based “learning by doing” within the School-to-Work movement. Seat work typically includes those activities that students complete with either guided or independent practice. The purpose of seat work is to master skills or concepts after the students have received some instruction. School-to-Work combines the job instruction with school based learning in a structured learning sequence (Churchill, Morales, & O’Flanagan, 1994). The purpose of School-to-Work programs is for students to gain experiences related to specific employment opportunities. The middle ground between these poles is found in what may be referred to as project based school work. The label of School Work emphasizes the relationship between School - the knowledge and skills acquired by students in school and Work - the application of those skills to address real world problems. The Technology in the Classroom label is self-explanatory however several examples included in the videos extend the notion of the classroom beyond the four walls of the average room.

Categories of Technology Use

An important motive of the School Work video project is to provide teachers with general ideas for developing classroom uses of technology. The hope is that the classroom examples recorded on videotape will suggest broader uses of technology across the curriculum. The first consideration to encourage this broader perspective was to establish simple and clear categories of technology use that might be employed to recruit potential teacher candidates. Focus was placed on identifying learning situations that reflect skills typically found in non-academic related occupations. It was assumed that situations would include a technology component but the focus was not on the technology. To simplify the task of narrowing down the candidates for videotaping, it was decided that categories of use be established. The categories needed to be clear and understandable to a teacher regardless of background experiences with technology, and they should not be limited to a particular area of the curriculum or particular technological tool. Finally, the categories must reflect the general skills commonly considered valuable in a wide range of occupations.

It was recognized from the outset that in order to offer a wide range of possibilities the categories would not be mutually exclusive. Three major categories were identified: Communication, Data Collection & Analysis, and Design. Despite vagaries that will inevitably occur when different individuals encounter the categories, they were reasonably clear and understandable when presented to teachers regardless of their experiences with technology. For example, the term communication evokes different skills to every teacher. The language arts teacher concludes written communication, while the music teacher expects audio communication. The learning experiences available that include communication are varied and not limited by content. In addition there are numerous types of technological tools useful in learning how to communicate and the skills needed for successful communication are extensive. The three categories Communication, Data Collection & Analysis, and Design were subdivided further into subcategories in order to assist in the recruitment of teachers.

Communication

Throughout history people have communicated with each other about the world around them. People, events, concepts, feelings, theories - the objects of experiences have been described verbally, in written word and in visual form. The value of the ability to share knowledge through communication cannot be reasonably disputed in or out of the classroom. Communication is a valuable skill in all occupations and there are numerous ways to communicate. In order to assure that a variety of lessons be included in the broad category of communications, seven related sub-
categories of communication were specified. They include: 1) Written Communication, 2) Visual Communication - Single Frame, 3) Presentations or Visual Communication - Multiple Frame, 4) Animation, 5) Video, 6) Visual Communication via Authoring/Programming, and 7) Audio Communication. Table 1 provides examples of the technology tools and sample classroom activities that suggest the creation of a "real world" product associated with the seven communication sub-categories.

### Data Collection & Analysis

The present era is frequently described as a time period plagued by information overload. It is probably more properly described as a time period of data overload. Information is abstracted from raw data. Information has passed through at least one level of interpretation and someone has analyzed the data to create the transformation. As such, one may argue that students need to develop data collection and analysis skills to deal with the mountains of data that will be generated in their lifetimes.

What are data collection and analysis skills? Many data collection and analysis skills are tied to specific domains. However, the ability to search for, organize, compare, explain, generalize, and make predictions about data are general process skills that surface within a wide range of occupations and problem solving. Three sub-categories were created for the data collection and analysis category. The first, Collection, highlights the skills of search and organization. The second, Collection & Analysis, requires greater interpretation of the data and theoretically can include all of six general skills listed. The third, Simulations, focuses primarily on the skills of generalization and prediction.

### Design

Design means different things to different people. Design is something you do to solve a problem but it is somehow more than problem solving; it is a system for problem solving. Design requires identifying a problem, analyzing the problem, examining how others have addressed the problem, sharing the potential solution, applying various skills to prove the solution correct, selecting the appropriate materials, assembling them into a working solution and evaluation throughout the design process (Shadrin, 1992). Two sub-categories were identified within the Design category: Device Construction and Product Design. Both sub-categories provide opportunities to apply many of the skills identified in Communication and Data Collection & Analysis to solve problems.

### Table 3

**Design**

Design
Video Storyboard

Each video consists of three distinct segments. The first segment begins with an individual from one of a variety of occupations describing how technology is changing the way s/he works. One or more technology uses considered in the subsequent lesson are identified during this brief segment. The second segment introduces the viewer to a classroom where a lesson is just beginning. This segment reflects one of the subcategories identified above as well as the criteria of “real world” technology use with a “real” audience. This segment varies in length, as some lessons are quite short whereas others continue over a series of days. However, the edited versions of the second segment are less than twenty minutes regardless of the length of the actual lesson. Each video ends with brief closing comments highlighting what was accomplished by the teacher who taught the lesson.

Conclusions

It is difficult to arrive at any definitive conclusions since the School Work: Technology in the Classroom videos are a work in progress. However, preliminary observations are encouraging. Many hours of teaching have been recorded and prototype videos have been created. The prototype videos were tested with in-service teachers in formal classrooms and informal workshop settings during the past academic year. During the tests, teachers were required to use the technology identified in the video to complete the same or a similar task prior to viewing the prototype tape. This “hands on” experience helped clarify what the students in the video were attempting to accomplish and provided an opportunity for the teachers to consider how these skills might relate to content taught. A common phrase shared with the teachers during this testing was “institutionalize the idea not the activity.” The experience of “doing” first and “observing” second helped the teachers move from the literal lesson idea presented to the larger issue of what is learned by participating in this type of activity and it can be replicated with different content. Additional lessons and numerous hours of videotaping are scheduled for the winter and spring of 1998.

The goals of encouraging relevant use of technology, providing students with opportunities to apply their knowledge and skills toward the solution of “real world” problems, and sharing findings with a real audience have been emphasized throughout the initial development of the video project. As a result of attending to the three goals throughout development, the early prototypes have encourage teachers to consider further relevant uses of technology in the classroom. Much work needs to be completed but with the support and involvement of technology using teachers around the country it is anticipated that use of final videos will provide teachers with instructional materials to assist them in integrating relevant technology into their teaching repertoire.

656 — Technology and Teacher Education Annual — 1998
The process of creating, developing, and evaluating an "anchored instruction" approach to modeling the integration of technology and teaching is discussed in this paper. The results described include descriptions of the processes which video model examples were created and edited, and the intended use of the videos in staff development training for higher education faculty. Although many teacher educators would like to utilize available technologies, often they lack the knowledge for implementation. It is for this reason that teacher educators need specific, concrete examples demonstrating effective technology integration. Our goal in the College of Education at Iowa State University is to provide specific and concrete examples of effective technology integration and to anchor training to the context of a video exemplifying the integration of technology into teaching practices in teacher education.

Background

Although educators and policy makers alike are agreeing that technology needs to be effectively integrated into teacher education, the progress of institutions of teacher education in this area has been disappointing (OTA, 1995). Teacher education institutions are beginning, however, to move toward more integrated and sophisticated uses of technology in preservice teacher education. Though early work in technology in teacher education tended to focus on teaching students how to use the technology or on using technology for completing traditional tasks, teacher education programs are increasingly using technology as a tool to help transform student models of learning and teaching. Teacher education students who have opportunities to work with technology as a tool for their own learning are developing useful strategies for creating their own active learner-centered classrooms.

Proponents of transforming with technology (Bagley & Hunter, 1992; Collins, 1991; David, 1991; Sheingold, 1991) argue that today's technologies have the potential to transform not only the relationships between students and teachers but also how schools now operate. The underlying assumptions of these claims is that computer-related technologies, unlike older media such as TV and film projectors, are also learning devices rather than just teaching devices (Thomas & Boysen, 1984). Thomas and Boysen also suggest that the computer's ability to interact with students and to react to their individual needs has the potential to provide the context for student-centered learning and to assist students in learning to educate themselves.

New Media — 657
Purpose

The purpose of this study is to design, develop, evaluate, and implement a staff development program that incorporates video cases featuring exemplary technology-use by teacher educators.

Procedures

The process of creating, developing, and evaluating this “anchored instruction” approach to modeling the integration of technology and teaching are discussed in this paper. The results described include descriptions of the process in which the model examples were created and edited and the intended use of the videos in staff development training for higher education faculty.

Although many teacher educators would like to utilize the technology that is available, they lack the knowledge for implementation. It is at this point that teacher educators need specific, concrete examples demonstrating technology integration. Our goal at Iowa State University in the College of Education is to provide specific, concrete examples and to anchor the training into the context of a video exemplifying the integration of technology into teaching practices in teacher education.

We have begun videotaping faculty members in the College of Education who exemplify the integration of technology in their teaching methods. Our objective is to create anchored situations in which there is modeling of integration of technology in teacher education. The training process includes teacher educators viewing these anchors together, and, afterwards, an opportunity is provided for reflection and problem solving on how this situation can transfer to individual teaching strategies and classroom environments. Our model is similar to The Cognition and Technology Group at Vanderbilt’s “anchored instruction” (The Cognition and Technology Group at Vanderbilt, 1993).

The process in developing this case study involves four basic initial steps:

a) obtaining various video footage demonstrating appropriate integration of technology;

b) editing videos for short clips demonstrating technology integrated into the curriculum;

c) field testing the video by involving ISU College of Education faculty in critiquing and evaluating the effectiveness of the video; and

d) revising of the project contingent upon the results of the field test.

The description that follows explains two of the four processes that have been accomplished to date.

The selection of the faculty members to be video taped was determined by their reputation for technology integration in their teaching. Participants in the study have included faculty members who teach math, reading, social studies, and science methods, and a graduate professor who teaches in Health and Human Performance. Students in these classrooms were also willing to participate and were aware of the nature of the study.

Work in Progress.

To date, video footage has been collected in three different classes taught by two different faculty members. Each video includes teacher demonstrations, student participation, and debriefings following the class by both the teacher and selected students.

The debriefings consist of questions for the teacher and selected students in order to obtain feedback on their perspective. Questions include:

1. In your opinion, what is a learner-centered environment?
2. In what ways did the technology contribute to a learner-centered environment?
3. In what way was a problem-solving environment created by using the technology?
4. What other methods could have been used to teach this content just as effectively?
5. What other pieces of technology could have been used in place of the tool that was used?
6. Do you feel that the technology enhanced or interfered with the lesson being taught?
7. In what way(s) can the application of the technology used transfer to other environments?

We anticipate that in the staff development environment these debriefings will play an integral role by initiating interactive discussions among the participants to collaboratively envision how the modeled example(s) can be modified to best fit and be implemented in their classroom situation.

One faculty member, Dr. A, demonstrated the use of the Jasper series. This class participated in the filming process for two days due to the length of the lesson. Dr. A initially demonstrated the Jasper series to her students to provide them an overview and eventually presented them with the problem that they were to solve. After the introduction, the students divided into groups and proceeded to problem solve the given situation presented in the Jasper series. A few of the groups were positioned at the computers and were revisiting sites on the Jasper videodisc to assist them in solving their problem. The other groups remained at tables discussing and generating questions that needed to be asked in order to solve the problem at hand. During this process, Dr. A’s role became one of a facilitator, encouraging students to further their problem solving strategies.

A graduate class in the Health and Human Performance area taught by Dr. B was also filmed for the video case study. Dr. B chose a few students to participate in gathering data through the use of sensors and cameras directly connected to the computer that captured body movements on tape. After data was collected on the body movements of a student participant, the professor demonstrated the ease by which calculations could be made by using the available...
technology. Dr. B demonstrated this activity in such a way that the students were generating discussions on how this type of technology could impact their future careers.

After filming was completed, the video editing portion of the project began. This process proved to be a tedious one as the researchers attempted to identify the most meaningful frames of video that would provide the strongest modeling for the targeted audience. Hours were spent examining the videos and marking the clips that were deemed most informative by providing the richest and most meaningful examples. After the clips were marked, they were “captured as a movie” in Adobe Premier. Sequencing the clips and determining the types of transitions and introductions was another time consuming, but imperative, aspect of creating the video.

**Plans**

The intention of the final product is to provide a context in which real-life examples are provided showing how technology can be integrated into the curriculum to enhance and create a more student-centered environment. The modeling demonstrated through the videos will help teacher educators capture the full flavor of the rich environment in which technology is used to impact learning.

As the videotapes are completed, Iowa State College of Education faculty members will review and evaluate them for effective content and generalizability to teacher educator audiences. The goal is to construct the tapes in such a way that they will influence the whole spectrum of educators in higher education.

This is a project that will continually be augmented as new video footage is added to the existing collection of videotapes. The videotapes will be used in staff development situations for the higher education community with the intention of leading the educators to more of a conceptual approach rather than a procedural one. The videos provide information rich environments in which the educators can draw from the experiences shown, reflect on them, discuss them with others in the training, and determine how the technology use can apply to their situations and what steps will need to occur in order to achieve the type of environment that was demonstrated in the videos.

The evaluation of this project will include various formats. Our goal is to obtain measures of behaviors from our participants by trying to answer the question “Do the participants of the staff development program move on to integrate the technology in their classroom as they saw modeled in the training example?” Questionnaires will be given to the participants to gather information about their feelings using technology within the classroom environment both before and after observing the training video. As well, interviews using open-ended questions will be conducted on a regular basis over an extended period of time. Interview data will be gathered on behaviors and attitudes to see if the participants are actually integrating the technology within their classroom environment. Participants’ perceptions of how the use of technology has influenced the learning environment in which they teach is also an integral area from which we will gather data.

**Further Development**

After we collect over 20 hours of footage in technology rich classrooms, we hope to advance this study by creating a multimedia CD-ROM program to increase the accessibility of this information for participants. There will be a main menu where teacher may choose what information they would like to access. We feel that a greater sense of ownership, freedom, and flexibility in the sense that the participants can pick and choose their destination of information and can revisit any sight of interest at any time. Choices of vignettes will be categorized by content, and options will include viewing the debriefings of students and teachers, along with reactions of others who have viewed the video series. We envision a multimedia product that will provide an opportunity for the user to see the video cases and reflect upon those cases within a group of teacher educators or individually.

**Discussion**

The outcome of this project is not intended to be a “quick fix” for staff development programs, but will provide a missing element of the present training situations; i.e. the modeling of appropriate integration of technology to create a learner-centered environment. The educators will require time but, in addition, they need the opportunity to share and reflect on this experience with their colleagues, and an opportunity to practice the modeled activities. Educators will also need support from administrators and trainers, but more importantly, they will need support from each other in this endeavor. Research indicates that the more teachers there are in a location using technology, the better chance that they will continue and grow in the use (Becker, 1994).

Our formal intent is to motivate teacher educators to see a need for change in their classroom, to discuss how this need affects their classroom and teaching methods, and ultimately, to adapt the modeled situation to their specific needs. This collaborative effort of viewing, reflection, problem solving, and construction of meaning will reinforce that the technologies used can improve the learning and transfer of knowledge to the participants classroom environment.

**Acknowledgments**

This type of complex project requires dedicated workers who demonstrate commitment and effort. A special thank you is extended to Jon Cutright, Jody Hall, and Keith Lyles for their hard work.

VIRTUAL CLASSROOM VISITS: TEACHING TEACHERS ABOUT HYPERMEDIA WITH HYPERMEDIA

Gabriela Banks
Stanford University

This research entailed developing an innovative training tool for educators and testing its effectiveness. The tool I have created is an interactive multimedia application on CD-ROM which teaches elementary school teachers how to use multimedia composition with their students by showing them examples of other accomplished teachers doing so in their classrooms. I created this application on my own, which entailed videotaping teachers and students in their classrooms, editing and digitizing the videotapes, designing the software interface, creating the graphics, programming the software, and pressing the CD-ROMs. Ultimately, the goal of my research has been to discover to what extent such a CD-ROM might help teachers learn how to use complex teaching innovations such as multimedia composition with their students.

The “Virtual Classroom Visits” CD-ROM features five accomplished computer-using teachers from the Cupertino Union School District (4 elementary school teachers and one junior high school teacher) who use multimedia composition software with their students for reports in science, social studies and language arts. Often teachers learn about a particular software program but have difficulty actually applying it in the classroom with their students in effective ways. Therefore, the purpose of the CD-ROM is not to teach them how to use the multimedia composition software, but how to integrate it into the curriculum.

The CD-ROM contains detailed information and behind the scenes work these teachers performed in order to orchestrate successful projects with their students, including:

1. Digitized video clips of classrooms in action, showing teachers and students as they used multimedia composition software to complete a group project. This project is shown from beginning to end so that educators can see the entire process – from a teacher’s initial instructions to the students’ final presentations of their work.

2. Detailed pre-work planning checklists for each teacher, outlining the steps they took to organize, plan and execute their units. These steps included preparing a unit plan, planning their calendar for the unit, reserving computers and other materials, typing handouts, planning assessment, creating student groups, and reviewing floor plans. Detailed information on each of these planning items is included on the CD-ROM.

3. Samples of students’ work - This includes the actual hypermedia projects students created for class reports.

The research study for my dissertation involved conducting preliminary interviews with 8 teachers regarding how they would teach a unit using multimedia composition software with their students. I asked questions regarding how they envisioned using the software with their students, what concerns they had for themselves and their students, and then asked them to plan a unit using multimedia composition. I then gave them an opportunity to use the Virtual Classroom Visits CD-ROM. They observed the accomplished teachers on the CD-ROM by reviewing the process each teacher took in completing their units with students. After they used the CD-ROM, I then interviewed them again to determine what they learned from the CD-ROM and how, if at all, it influenced them. During this second interview, I asked them similar questions from the first interview and had them plan their unit again to see if there were any changes from their initial responses.

A preliminary analysis of the results of this study shows that the teachers did learn a great deal from the interactive CD-ROM. In post-interviews which occurred a few days after teachers had used the Virtual Classroom Visits CD-ROM, teachers’ were already beginning to incorporate ideas from the accomplished teachers into their own unit plans. Teachers also reported that the information contained in the CD-ROM was very useful for them and that they would refer to the Virtual Classroom Visits CD-ROM when planning other units that involved using multimedia composition with their students.

New Media — 661
What is DVD? What Are Its Possibilities?

Liz C. Stephens  
Southwest Texas State University

David Byrum  
Southwest Texas State University

Laserdisks and CD-ROMs containing digitized video have been used in recent years for designing video-case methods of instruction in numerous fields. Cognitive flexibility hypertext (Spiro & Jehng, 1990), for instance, uses video-cases for the preparation of professionals in complex domains such as medicine, engineering, and education. Mini-cases, as described by Spiro and Jehng, are brief, edited "pieces" of the video-case (which can be as short as 45 seconds) that are selected to examine closely and analyze interactions. In cognitive flexibility hypertext, mini-cases are engraved on a laserdisc, accessed through computer programs, and are used for a guided, nonlinear, and multi-dimensional analysis of larger cases. Mini-cases delivered on laserdisc can be accessed readily, randomly and repeatedly.

Video-based instructional programs are limited by the amount of video storage allowed and the quality of video playback. Laserdisks provide high resolution images but can store only one hour of frame-by-frame accessible video. CD-ROMs can hold approximately 20 minutes of Quicktime movies, and these video images often have mediocre or poor quality. The advent of the Digital Versatile Disk, or DVD, presents opportunities for new, more powerful applications of video in the preparation of professionals. It is the newest generation of optical disk storage technology and is basically faster CD with more storage capabilities and which can hold video as well as audio and computer data.

Because DVD provides more space for video and high quality video playback, it promises to become a potentially powerful platform for video-case methodology. This paper will briefly describe video-case methodology in teacher preparation and will present a detailed description of DVD technology.

Video-case Methodology

Video-case methodology captures all the dialogue, actions, emotion, gestures, nuances, body language—the rich flavor of a naturalistic environment. Video-cases on CD-ROM and laserdisk have been used in the preparation of educators, as described by Kinzer, Risko, Carson, Meltzer, & Bigenho (1992) and Risko (1991). Close-up focus of classroom events captured on videotape has allowed program developers to narrow the visual environment and capture an interaction or activity involving a particular person or small group.

Video-case methodology can transcend the current practices used in the preparation of teachers by facilitating the exploration of visual representations of curriculum and pedagogy. In traditional teacher education formats, students conduct individual field observations and then attempt to relate their experiences in writing or orally. The complexity of the context observed is filtered and thus may be diminished in the translation.

In contrast, the video-case format provides a shared observation of experienced teachers in action. This shared experience situates exploration and examination as well as provides a forum for discussion that generates contextualized knowledge about classroom dynamics. Broad theme-based "paths" for exploration such as "teacher role" and "student role" can guide the class, small groups, or individuals as they traverse mini-cases within the video-cases of classroom teachers. Each path presents a view of the mini-cases from different but overlapping perspectives. Professionals-in-training and their instructors can also use their visual explorations as the backdrop for discussion and debate on the diverse perspectives found in professional literature. The benefits of using video-case methodology in teacher preparation have been documented in studies that focus on courses for preservice teachers (Risko, 1991; Stephens, 1995; Fabris, 1996).

Digital Versatile Disk

A DVD looks similar to today's CD: it is a silver platter, 4.75 inches in diameter, with a hole in the center. A digital videodisk is made up of a reflective aluminum foil encased in a clear plastic. Data is stored on the foil as a series of tiny pits formed in a tight spiral on the disk. The pits are formed in the foil by stamping it with a glass master.

It is important that a distinction is made between DVD-Video and DVD-ROM. DVD-Video (often called DVD) contains video programs and is played in a DVD player connected to a TV or installed in a computer. DVD-ROM holds computer data and is read by a DVD-ROM drive in a computer. Many people in the industry expect DVD-ROM to be initially more successful than DVD-Video. Conse-
quently, most new computers will come with DVD-ROM drives and will also be able to play DVD Videos with the proper decoding hardware installed.

**Greater storage capacity**

There are basic differences in DVD versus CD-ROM which give DVD its enormous storage capacity. The DVD’s larger capacity is achieved by making the pits smaller, the spiral tighter, and by recording the data in as many as four layers, two on each side of the disk. To read these tightly packed disks, lasers that produce a shorter wavelength beam of light are required, as well as more accurate aiming and focusing mechanisms. The focusing mechanism allows data to be recorded on two layers. The two layers in a double-layer disk are made of differing materials, a semi-transparent gold layer over a reflective silver layer. To access the first layer a low power beam is used to read the data; to read the second layer, the reader simply increases the power and focuses the laser a little deeper into the disk, where the second layer of data is recorded. Not only are two layer disks possible, but so are double-sided disks by bonding two DVDs back to back. The availability of four layers gives DVD its 17-gigabyte capacity. However, since a 135-minute movie fits on a single DVD layer, single-layer DVDs are more common.

Other factors resulting in the increased capacity of DVD are a slightly larger data area, more efficient error correction, and less sector overhead. Total increase for a single layer is about 7 times a standard CD-ROM. The capacity of a dual-layer disk is slightly less than double that of a single-layer disk. The laser has to read “through” the outer layer to the inner layer and to give more room for error the minimum pit length is increased. The bigger pits spaced farther apart are easier to read and less prone to error, but fewer pits result in less capacity.

**Video Compression**

Although the DVD storage technology allows for much more storage on a disk, that alone still would not allow for a reasonable amount of video to be stored. For example, for 120 minutes of video (an average movie), 216,000 megabytes of space is needed. That is roughly the equivalent of 360 CDs. Even with the improved storage, it would take approximately 50 DVDs to store a single movie. Thus, video compression or data compression was created in which signals are compressed during the digitizing process and uncompressed for playback.

There are two kinds of compression, lossless and lossy. A lossless compression means that the unsqueezed signal is a reproduction of the original, with no data lost in the translation. For example, each time you use a Zip or Stuffit file, you are using lossless compression. Using a lossy compression is a way of getting even more compressed files than lossless. Lossy compression strips out data that it has been programmed to regard as either unnecessary or redundant. It assumes that human perception will never miss the missing data. Compression works with software called codecs, an abbreviation for “compress/decompress.”

MPEG, named after a consortium of industry specialists called the Moving Picture Experts Group, have set the industry standards in compression with MPEG-2. As stated earlier, MPEG is dual-ended process where source material is encoded (or re-recorded) with compression and later decoded (or decompressed) for playback. The amount of compression applied is determined by the people who encode the signal. If too much compression is used, picture quality suffers. Use of too little compression, and not enough space is saved. MPEG compression is very impressive, with typical ratios of 25 or 30:1 before image quality becomes unacceptable. When properly used, MPEG can produce outstanding results with image quality better than videodisk.

**DVD Mastering**

Once a videotape is edited, it must be specially formatted before it can be encoded and distributed on a DVD. The mastering process consists of several steps, listed below:

- Scanning the videotape to identify scene changes, key frames would be added where there are scene changes or sudden movements
- Compressing the video in MPEG-2 format
- Compressing the audio tracks into Dolby AC3 Surround Sound format
- Combining the compressed video and audio into a single data stream, a process called multiplexing
- Simulating the playback of the disk in the mastering system, a process called emulation
- Writing out a data tape with the “image” of the DVD
- Creation of a glass master, which replicators then use to “press disks”

Videotapes cost about $2.40 each for replication. CDs cost approximately $1,000 to master and $0.50 to replicate. Laserdisks cost approximately $3,000 to master and about $8 to replicate. DVDs currently cost approximately $3000 to master and about $2.40 to replicate. Since DVD production is based mostly on the same equipment used for CD production, mastering and replication costs should drop to CD levels. Pre-mastering costs are mostly for authoring systems and encoding systems which cost hundreds of thousands of dollars, but these too will get much cheaper in the next few years. There are several which will be on the market in the spring of 1998 for approximately $10,000 for both Windows and Mac platforms.

**Conclusion**

Clearly there are numerous possible benefits offered by the marriage of DVD and video-case methods of instruction. Much more video can be stored on DVD than laserdisk or CD-ROM. Unlike the laserdisk, the DVD does not need to
be flipped—a small but significant inconvenience to the user. And finally, the video and audio quality on DVD is superior to any form of playback form of data storage. Viewing video representations of interactions in a classroom must be as crisp and clear as possible in order to truly benefit from the viewing experience. At the moment, the widespread use of DVD for videocase methodology is limited by cost. However, as is typical of technology, the costs of creating a DVD for educational purposes may soon decrease while the potential value and use of DVD for educational purposes, particularly in well-designed instructional support programs, will surely increase.

Factors that Affect Cooperation, Collaboration and Communication in Educational Multimedia Design Teams

Sara McNeil
University of Houston

Collaboration, cooperation and communication in educational multimedia design teams is the focus of this paper. In the business arena, multimedia design teams have been used extensively over the past decade to develop software for commercial purposes. In educational settings, however, most courseware has been developed by individuals who, for the most part, do not have the wide range of skills needed to produce a quality product. By working in multimedia design teams, educators can combine their skills to produce both a worthwhile and well-designed piece of software expressly for their educational setting. This study reports preliminary findings about critical factors that promote and facilitate collaboration, cooperation and communication between members of design teams. Factors that discourage or contribute negatively to group interaction and production were also considered. Methods employed included pre- and post-team surveys, peer reviews, participant interviews and journals, and observations. Participants were graduate students in two sections of an instructional technology course, CUIN 7327, the Design and Development of Instructional Packages during spring semesters, 1996 and 1997.

This project fits into a larger research focus on educational multimedia courseware development and authoring competencies for educators. Although multimedia design teams in commercial settings have been the focus of many recent articles in business publications, there is little research-based literature about teams composed of educators developing courseware. In order for multimedia design teams to work together effectively, members must possess effective and well-developed skills of collaboration, cooperation and communication. Understanding how these skills may be developed and nurtured plays a critical part in courseware development and may facilitate a more effective model of instruction.

Educational Multimedia

Using the computer to control and deliver a full range of audiovisual media offers educators a way to regain the power and strength of audio, video, animations and interactive simulations, and to build those features into educational materials. These materials actively engage students by giving them the best possible presentation and explanations with whatever media are the most suitable to the task. Interactive multimedia implies multiple forms of communication, controlled, coordinated and integrated by the computer. The computer allows the individual user to interact with and control the flow of information. Instead of reading the information in a conventional linear way, the user is encouraged to pursue links from one topic to another following a uniquely personal trail through the information. The user becomes an active participant in the flow of the narrative, actively choosing material, and in some cases, modifying the content itself to suit his or her needs and interests.

In the past few years there has been a dramatic growth in the interest and possibilities of using multimedia in educational settings (Ferretti, 1993). However, Wiburg (1995) noted that although there are thousands of articles about multimedia, there is very little research. In addition, Wiburg continued, much of the research that does exist about multimedia has been conducted in other areas and is peripheral to the concerns of most educators.

Effective Use of Technology

There are many viewpoints on the competencies that educators need to effectively use computer technology in their classrooms. Teacher education organizations have proposed that educators should have, “The ability to integrate instructional technology into the classroom to facilitate interdisciplinary teaching and learning, supplement instructional strategies, design instructional materials, and enhance hands-on experiences and problem solving” (National Council for the Association of Teacher Education, 1992) and “demonstrate knowledge of uses of multimedia, hypermedia and telecommunications to support instruction” (International Society for Technology in Education, 1992). D’Ignazio (1993) stated that multimedia has a great

New Media — 665

671
potential for educators at all grade levels by bringing even “the driest areas of curriculum to life” and by turning the classroom in “an exciting studio-like area” (p. 490).

**Authoring Courseware**

Lockard, Abrams, and Many (1994) listed several reasons why teachers may find it advantageous to develop their own software. First, teachers may not find appropriate software. Educational software companies must develop software that meets the needs of many students in order to be cost-effective. Second, budgetary considerations may prevent teachers from purchasing a commercial software package. Third, educational software is not designed with specific students and individual needs in mind. Finally, teachers may have a personal preference for creating their own materials including the natural desire of experienced teachers to produce their own educational materials of all kinds.

Teachers are logical developers of courseware for their classrooms. They have a better knowledge of the content than do commercial software designers, and they bring to the authoring environment their knowledge of good pedagogy and teaching skills. Teachers also have the concrete experience of actually teaching the content. They have learned by experience what strategies work and which ones must be reinforced in multiple ways. Teachers understand the needs of their audience better than anyone else. Many teachers may actually prefer to develop their own materials just as they do with other classroom materials such as handouts and worksheets. Kearsley (1986) suggested that teachers should author their own programs in order to become better software evaluators. He stated that the ability to distinguish a good software program from another is one of the critical skills needed by software designers. He continued by adding that evaluation skills and design skills are mirror images of one another. Finally, teachers are the ultimate users of the software.

As early as 1984, researchers have cited the need of some teachers for producing their own software and have contended that software development is a valid topic for teachers to study at the graduate level (Young, 1984; Monahan, 1987; Overbaugh, 1994). In addition, Turner and Dipinto (1992) stated that hypermedia gave students new insights into writing. Using hypermedia caused students to view information as more than large streams of text, but more as chunks of information that were linked. Turner and Dipinto reported that the study indicated that “the time students invest in learning to use software and hardware not only gives them a powerful new medium of communication but may also give them new insights into organizing and synthesizing information” (p. 198).

**Multimedia Design Teams**

In spite of these compelling reasons for educators producing their own courseware, it is not reasonable to expect that educators will be able to produce professional looking courseware taking into consideration both the limitations of time and production capabilities. The range of skills needed to produce a multimedia project include a detailed knowledge of computers, information processing, graphic design, sound and video editing, and instructional design. It is practical, therefore, to view the development of educational courseware much like the development of commercial software utilizing the concept of multimedia design teams with specialists in the various production fields.

A design team usually consists of several individuals with specific talents who contribute in some way to the development of a shared goal. Martin (1995) stated: “A team refers to a small, tightly knit team of people intensely focused on meeting a specified objective that all members of the team are committed to accomplishing together.” (p. 65) In a successful and effective design team, each member feels a sense of trust, commitment, and responsibility for other members and a shared vision for team goals and objectives.

Multimedia design teams are, for the most part, organized around a project manager, an instructional designer, a graphic artist, an audio and video producer, a content writer and a programmer. Working for a client, the team develops learning materials that may include some form of computer-assisted software program, a manual or guide and a set of usually print-based teacher materials.

One of the most important factors in a team approach to courseware design is the interaction and communication among team members (Ally, 1985). Team members are required to work cooperatively and must learn to function as a unit. In spite of areas of specialization, team members must be able to communicate ideas and meanings effectively. As illustrated in Figure 1, there are many possible channels of communication.

![Figure 1. Team Communication and Collaboration.](image-url)
In the business field, design teams may spend several sessions learning to work collaboratively. Unlike the highly structured procedures of cooperative learning, a collaborative learning environment empowers the learners to actively seek knowledge. Teams become more autonomous as they learn to work, interact and nurture each other while working toward the team goal. Bouton and Garth (1983) cited the fact that through a collaborative learning situation, the learners are transformed from spectators to being involved in more complex interactions in an active learning process.

This study investigated some critical factors that enhance collaboration, communication and cooperation among team members developing educational courseware. This research has implications that will impact both students and faculty in the design and development of educational multimedia courseware. Current trends in educational research indicate that the delivery of multimedia materials will increase over the next decade.

Research Design

Objectives

Goals for this study included:
1. determining those behaviors which promote group cooperation and those behaviors which contribute in a negative manner to teamwork
2. soliciting from participants ways that positive behaviors may be learned and developed
3. examining solutions to problems which occur between members of a team
4. creating guidelines and suggestions for promoting positive team interaction
5. suggesting what role previous team experiences may have on group communication and behavior

Procedures

Procedures included a detailed literature review concerning effective team qualities in multimedia design teams including those used in the business field, pre- and post-team surveys, peer reviews, participant interviews and journals, and observations. Participants included 42 students in two graduate instructional technology courses, CUR 7327, the Design and Development of Instructional Packages during spring semester, 1996 and 1997.

The research plan began with an initial assessment of computer skills, multimedia skills and knowledge of team strategies based on two surveys completed by students the first night of class. The Computer Skills Assessment (Figure 2) asked students to rate their skills in such areas as proficiency in specific types of software programs and the ability to use hardware peripherals such as scanners and digital cameras. The Multimedia Skills Assessment (Figure 3) asked students to rate their skills in areas such as the use of specific authoring programs such as Macromedia Authorware and Director.
In addition, this survey asked students to rate their multimedia project experience in such areas as designing navigational structures, building a prototype and producing video.

**Design Teams**

Based on this survey and student interviews, each class was divided into design teams consisting of the following members: a project manager, a graphic designer, a videographer, a programmer and a content writer. During the 1996 semester, four teams of five members each worked with a different client to develop a multimedia project according to that client’s specifications over the course of the fourteen-week semester. During the 1997 semester, four teams worked on different sections of a large project for one client. The purpose of this project was to provide students with an introductory, but realistic, experience in developing a piece of software in a team environment.

**Design Process**

Students were assigned to different teams based on the skills analysis they completed on the first night of class and the instructor’s knowledge of each individual’s background. For the most part, students in this class had completed both the introductory instructional design course and overview of multimedia course.

The next few class sessions were spent on discussing team roles and developing competencies that would allow students to complete their part in the projects. Teams also met with their client to discuss and develop preliminary analysis and goals for the project. Students soon realized that working in a team and trying to develop a piece of software for someone else is a lot of work.

Communication began to develop both in class team meetings and through email. One student noted: “I remember all of us being polite to each other at first. However, we had a lot of creative work to accomplish and ‘polite’ wasn’t exactly what I had in mind from this team. But as soon as we got to know each other, our meetings became more open and lively.” Another member of the team reflected, “I found these discussions, sometimes heated ones, to be thought provoking and interesting. Ideas were put forth, discussed and then tested for consensus. We tossed a lot of ideas back and forth while we were trying to visualize how this product should look and what was needed to make it a reality.”

In addition to communication skills, one student noted in his journal, “I’ve noticed that listening skills are especially important on a project team ... there are times in our groups where people don't stop to listen to each other's ideas and it really slows progress as we discuss (debate) a single item over and over. It's much easier when everyone takes a turn speaking, others listen, the issue is out on the table and a decision is made.”

Some problems were encountered when quiet students were reluctant to voice their opinions: “I believe other (students) have been frustrated or have kept quiet because of the vocal nature of a few members of the class.”

Teams also foundered a bit at first trying to develop ideas and models for their projects. Members soon realized that decisions should be made by the team and not by individuals. It took most of the teams several weeks of meetings both as a team and with the client to develop a plan and direction for the projects. Some team members noted that success was related to early decision making. “We had to 'start from scratch' a few times, but those times were well justified - and were team decisions. It took us about two weeks before we settled on a direction. And we did not make a major change after that point.”

Some teams spent several sessions establishing team rules for discussion; this usually facilitated decision making and communication. Although University of Houston graduate students usually work full time and often commute as much as an hour to come to class in the evenings, team members met many meeting requirements by using email.

Many students felt apprehensive about time considerations, working in a team situation and being evaluated by their peers rather than just the instructor, “I fear that the amount of time needed for production will be very demanding. The team process and work is worth the course alone! I’m learning tremendous lessons. It is also a very positive experience with each problem, group interaction, individual interaction building a team spirit. I like this!” A student remarked, “I think everyone is ‘nervous’ because the expectations of the finished product is high – everyone wants to create something really good.”

**Student Resources**

Several different types of resources were available for student learning. These included the textbooks, *I Sing the Body Electronic* by Fred Moody and *Multimedia Making It Work* by Tay Vaughn. In addition Web pages for each class were developed and used as means for sharing information and progress on the projects.

**Figure 4. Web Site for CUIN 7327.**

Several students remarked on the Web pages in their journals noting, “The web pages have some interesting links and the material is organized in a logical and consistent
fashion... The pages are a good way to stay connected to the class when at work or at home - important in creating a 'community' because of job or personal schedules."

To access the pages used during spring, 1997:
http://www.coe.uh.edu/courses/cuin7327

**Project Presentations**

At the end of each semester, team members demonstrated their final projects in a special evening presentation. Although the content and quality of each project differed greatly, the goals of the class were clearly met - students experienced working in an authentic learning situation. Several teams exceeded expectations in functioning as a cohesive unit noting, "own weight and did not depend on someone else to do their job. We functioned as a team and not a collection of individuals. Our group rose to the highest definition of a team."

**Preliminary Findings**

A mid-semester and final survey on Project Team Attitude was completed by each member anonymously. This survey has been adapted from relevant surveys used in business (Systems One, 1996). In addition, students participated in both mid-semester and final peer reviews. Peer reviews asked students to rate such competencies as "Quality of Assignments," "Responsibility to Team," "Contributions to Team," "Attitude," "Teamwork," and "Overall Team Member" for each member of the team and to also rate themselves. Comments at this time included, "My group is very eager and positive - we feel a sense of 'group.' I still think we're showing our best selves - will be interesting as the timeline nears."

Direct observation of team meetings and interviews with team members were also conducted by the researcher at critical milestones for courseware development over the course of the semester. In addition, team members were also required to keep journals of their thoughts and feelings during team meetings and other development opportunities.

**Midterm Evaluations 1996**

Participants used a likert scale to rate their perceptions of their team health and well-being. Using a scale ranging from 1 – strongly agree to 5 strongly disagree, participants responded to such statements as:

- The goals of the team are clearly understood by team members.
- Team meetings are productive.
- I feel that I have been an important part of this team so far.

The highest disagreement among all teams was shown on statements such as, "The team is developing effective strategies to meet objectives." And "Team members are making efforts to get jobs completed." The ratings ranged from 2.65 to 1.85. These collective results were shared with the participants and strategies for facilitating better interaction and problem solving were addressed in a group discussion. At this stage in the project, there was a steep learning curve and many problems were being worked out, both with the clients and between team members. The overall attitude of the project teams ranged from 4 responses of excellent, 6 responses of very good, 4 good, and 4 fair.

**Final Evaluations 1996**

Similar evaluations were completed at the end of the semester. As in the midterm evaluations, one of the highest areas of dissatisfaction among all teams continued to be, "The team is learning to effectively address and resolve problems within the team." The most agreement among all teams occurred on such statements as, I feel that I have been an important member of this team so far," "Team members are making efforts to get jobs completed," and "Team members have been generally positive in their outlook regarding the project." The ratings ranged from 2.09 to 1.52.

![Peer Review Form](image-url)
Peer Reviews

Peer reviews (Figure 4) asked students to rate such competencies as "Quality of Assignments," "Responsibility to Team," "Contributions to Team," "Attitude," "Teamwork," and "Overall Team Member" for each member of the team and to also rate themselves. Consistently across all teams, team members rated their other members above average on most categories.

Discussion

Although many components of this research are still being evaluated and researched, it seems from a preliminary investigation that the areas of communication, collaboration and cooperation in a team environment are rich in experiences and nuances. Successful teams, as demonstrated in both project development and peer reviews, were able to work together and resolve problems quickly without any single person assuming a dominant or overpowering role. Teams that experienced some dissatisfaction with the team process typically did not form a cohesive group or work together to solve problems that arose. Although a leadership role is expected of the project manager, successful teams clearly developed a process for equal participation among team members. Further research is needed to explore other influences such as time constraints and different skill levels among members.

Email: smcneil@uh.edu
Integration” still seems to be the leitmotiv of most reports this year and probably the most sought after goal in current teacher preparation programs. Effective infusion and integration of technology in preservice teacher education are quite challenging undertakings as has been well documented in several papers submitted to this section. You will find papers here addressing the integration of technology into specific subject area courses, into methods courses, and others addressing infusion of technology across the curriculum. Some suggest specific approaches and others raise interesting questions regarding the perception students might have as to why technology should be integrated into the curriculum. Is the danger real that students might believe that technology does relieve them of their responsibility for learning foundational skills as reported by Edwards and Mosley? Progress on one dimension sometimes might lead to unanticipated negative consequences in another unless those involved grasp the complete picture and act accordingly (Wellburn, in press).

In order to achieve successful infusion of technology into teacher preparation, and in order to meet recommendations and standards laid out by ISTE/NCATE and other professional organizations, our profession has decidedly moved in the direction of curriculum renewal. Not surprisingly, several examples of curriculum renewal and reform at various institutions are described in this section at this time as well.

A third, very strong theme which emerged from this year’s submissions is the social constructive perspective shared by several instructors/researchers who believe that learners build a knowledge base through personal experience, exploration and reality construction. At a time when technologies become available which allow interaction and group collaboration, the constructivist environment is becoming more and more an appropriate educational consideration. The concepts espoused by most teacher preparation programs are in alignment with a constructivist viewpoint allowing students to “learn how to learn.”

Finally, the section concludes with some wonderful thoughts on the building of virtual communities. No doubt, our field and seemingly the whole world, has gone “virtual”! Consequently, new “virtual communities” are being created which obey their own rules but also share underlying principles and characteristics with traditional communities. If we want these communities to stay healthy, take on their own life, and serve a purpose, it is essential we learn about them and consider the nature of these new communities which are being created for the purpose of learning, or other endeavors.

Enjoy the readings.

Integration:

a. in specific subject areas Cooper (Texas Tech University) describes a course in Research and Evaluation in which written and electronically generated portfolios are compiled by preservice teachers and compared. Edwards (Purdue University) and Mosley (Bennett College) describe a “tests and measurement” course which attempts to increase preservice teachers’ higher thinking skills. Students’ perception of the use of technology differed from the instructors’ expectations. Jinkerson (Northern Michigan University) discusses the planning stages of a block format of elementary methods courses with a technology course in order to integrate the technology with the subject areas. Omorogie & Coleman (Jackson State University) describe a project to infuse technology training into core academic subject areas. Tejada (University of La Rioja, Spain) provides a critical analysis of the application of technology to music education.

b. into methods courses Prouty & McGrew-Zoubi (Sam Houston State University) describe efforts to have student teachers apply previously acquired technology skills to the implementation of a “methods” class. Shi, Ren, & Ma (Beijing Normal University) relate the development and implementation of Computer Assisted
Lesson Preparation System (CALPS) software for student teachers. Drier (University of Virginia) describes using manipulatives and a computer program to explore the concepts of probability, randomness and graphing in a mathematics education methods course.

c. across the curriculum. Maney, Perry, Brooks, & Foss (Miami University) discuss TEAM, their approach to beginning teacher technology preparation. They emphasize integration of needs-based technology training and real-world connectivity with inservice teachers. Maney & Brooks (Miami University) focus on alternative evaluation procedures to measure the effectiveness of one of the components of TEAM. Persichitte (University of Northern Colorado) describes the methods of a case study research project to investigate examples of "best practice" in the use of educational technologies in teacher preparation.

Curriculum Renewal
Bao, McKeel, & Stafford (Shippensburg University) describe an Urban Education Initiative and its multimedia presentation. Koenke (University of Illinois) describes an innovative program for elementary education (the Year Long Program) which has served as a pilot for redesigning the entire student teaching program. Powers (Indiana State University) describes how the ISTE/NCATE standards are being implemented and how they have been used as the basis for development of eight technology proficiency examinations for student teachers. Snider & Gershner (Texas Women's University) describe the curriculum renewal research project developing at TWU to align technology preparation efforts for student teachers with the NCATE recommendations. Waugh, Levin, & Buell (University of Illinois) discuss the development and implementation of a WWW-accessible Technology Competencies Database used to support student teachers' development of electronic portfolios illustrating mastery of the ISTE/NCATE standards.

Social Constructive Perspective
Edwards, IIChul Ahn, Mooney (Purdue University) describe how two computer labs were reconfigured to provide more "cognitive learning exercises" by using "scenario-based activities" in which students cooperated and came up with solutions/approaches to issues of management and instruction, in order to facilitate students' thinking about real applications of the technology. Ferdig (Michigan State University) suggest the use of a "story-based approach" to replace the more typical skills-based one, in which think-aloud protocols are used to help students develop their own realities about the connection between teaching and technology. Halpin (Mississippi State University) explores the use of the constructivist approach to learning technology and describes a program model which encourages exploration and discovery. Topper (Michigan State University) finds that the dialogue between instructor and learner takes on different dimensions when conducted within the teaching model that considers teachers as adult professionals who have their own ideas about teaching, learning, and technology.

Virtual Communities
Nonis, Bronack, & Heaton (University of Virginia) offer suggestions for building a "virtual community", based upon experiences gained in creating such a community for students at the Curry School of Education.

ELECTRONIC DIAGNOSTIC PORTFOLIOS: ADVANTAGES AND DISADVANTAGES OF THIS TECHNOLOGICAL APPROACH

Sandra B. Cooper
Texas Tech University

There is a current trend toward the integration of technology into instructional practices. What are the advantages for teachers in using technology? Mathies (1994) pointed out that technology can be employed by both the student and the teacher to improve performance and instruction. It is possible for teachers to enhance their instruction and attempt to lessen their workload by taking advantage of the capabilities of various technologies.

Purpose of the Study
The new elementary education program in a College of Education at a large university offers a course for undergraduates in Research and Evaluation. As part of this course, teacher education students collect elementary student work and develop a process of analyzing this information to make instructional decisions. In the section taught by the instructor/researcher, teacher education students are required to complete a Diagnostic Portfolio of the elementary student work analysis. In addition, this section focuses upon the integration of technology in the research and evaluation process. The combination of the two brings forth a research proposition for the instructor/researcher. What if the Diagnostic Portfolio were created and presented on the computer?

In this project, teacher education students will (1) design and create Diagnostic Portfolios either electronically or written, and (2) present Diagnostic Portfolios for peer and instructor feedback and to determine advantages and disadvantages of the two formats.

The data collection for this project attempted to answer the following questions: (1) What processes are required in designing and creating a Diagnostic Portfolio in a written format and in an electronic format using the computer? (2) What are the advantages and disadvantages of creating Diagnostic Portfolios in a written format or an electronic format using the computer?

Rationale
Chambers and others (1992) encouraged modern electronic classrooms to “block out outside stimuli and present situations as realistically as possible short of the use of virtual reality; thus projecting students into meaningful situations in which learning occurs faster due to the focus of attention.” Some advantages and disadvantages of teachers using technology for elementary student analysis could be determined from factors presented in the data collection and analysis of this project.

Relevant Literature Review
A short review of literature on the topic of elementary student analysis in the form of electronic portfolios indicated a lack of studies and information in this area. However, many analysts have recommended portfolios as a mechanism for integrating learning and assessment (Schon, 1987; Gardner, 1989; Wolf, 1989; Collins, 1990; Pearlman, 1991; Belland & Best, 1992; Paulson, Paulson, & Meyer, 1991). Pearlman (1991) reported that some Maine schools are piloting the use of computers and multimedia to develop “electronic portfolios” of K-12 students’ work.

McLellan (1993) described diagnosis as dynamic and on-going. The teacher must analyze at every moment the progress of the learners and adapt or customize the methods and other conditions of learning to meet the emergent needs of the learners. She indicated that diagnosis is based upon many kinds of information, including portfolios, summary statistics, and the teacher’s continuous assessment of the learner’s progress.

These two approaches provide a starting point for exploring new kinds of evaluation that are needed to support a new model of learning. McLellan (1993) recommended that additional research is needed to develop and refine instructional practices and technological tools that serve both a learning and evaluative function.

Data Collection
Teacher education students enrolled in a section of the Research and Evaluation course during the Fall semester, 1996 were the subjects of this study. All teacher education students were involved in the process of creating Diagnostic Portfolios as a requirement of the course, however, volunteers were sought to participate in the development of Electronic Diagnostic Portfolios by using the computer.
Informal interviews were conducted with 3 teacher education students from each group of participants which included the group who created written Diagnostic Portfolios and those who created Electronic Diagnostic Portfolios. Questions used during the interviews were developed to determine the process each group experienced during the semester as they created these Diagnostic Portfolios. These interviews were conducted at the end of October, 1996 and were audio-taped and transcribed for analysis.

At the end of the semester, all teacher education students presented their Diagnostic Portfolios to the class. At the conclusion of this presentation session, the teacher education students were asked to reflect on their processes of completing these Diagnostic Portfolios and compare their products with each other through discussion and a written survey. This presentation/reflection session was video-taped and transcribed for analysis. The written surveys were collected and analyzed qualitatively.

Data Analysis

A qualitative approach was used for the data analysis in this project. The transcription of the interviews were analyzed according to the delineation of categories that emerged from the statements made by the teacher education students about the processes involved in creating a Diagnostic Portfolio. The transcription of the video-taped discussion was analyzed according to the delineation of categories that emerged and identified as advantages and disadvantages (by being positive or negative in connotation) of the two formats used in creating Diagnostic Portfolios.

Data analyzed from the interviews and video-taped discussion indicated the advantages and disadvantages of using electronic portfolios. The results are given in Table 1.

### Conclusions

Using Electronic Diagnostic Portfolios was a unique and intriguing approach for the students in this class/study. Many were excited about the prospect of learning more about using technology, especially since they anticipated expectations of using technology when entering the classroom as teachers. However, in this process, there was a realization that using technology is more that just an innovative action, it is an extensive task.

In order to fully implement a system of electronic portfolios, a careful evaluation of equipment needed, software necessary, and available assistance is mandatory. In addition, teachers should start small (with a few students or with a few inclusions) and pilot this implementation to work through problems and to practice applications.

### Future Directions

Reporting assessment information to Parents in an important part of effective communication for classroom teachers. Developing a Diagnostic Portfolio for Parents could potentially serve classroom teachers well in presenting and sharing significant information about children in their classroom. However, in view of the results of this study, we need to consider the following questions. Is it effective to use the computer in the development of Diagnostic Portfolios? Is this a beneficial tool for classroom teachers? Would classroom teachers have the time to develop Diagnostic Portfolios for the children in their classroom?

Many educators are embracing the effort to integrate more technology. Before this big step, there needs to be careful consideration of the needs of those involved and the availability of equipment and materials needed to fully implement the technology.

### Table 1. Advantages and Disadvantages of Electronic Portfolios

<table>
<thead>
<tr>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Electronic Portfolios can be stored on a computer diskette and this takes up less space in the classroom</td>
<td>Scanning student work, pictures, etc. is difficult when the appropriate equipment and/or assistance is not available.</td>
</tr>
<tr>
<td>Information can be easily retrieved from the computer as you can “click” from one screen to another, as opposed to “flipping” through pages.</td>
<td>In addition, scanned work requires lots of memory and cannot be easily saved on one computer diskette.</td>
</tr>
<tr>
<td>A variety of formats can be placed on electronic portfolios that are more easily accessible and easier to share with parents. For example, photographs of student projects, video clips of group work, audio clips of a student reading, etc.</td>
<td>It is difficult storing a lot of information on a computer diskette.</td>
</tr>
<tr>
<td>Inclusions of various formats requires specific equipment, special expertise, and a larger capacity for storage.</td>
<td></td>

If I Teach … With Technology, They Will Learn! But What?

Gloria Edwards
Purdue University

Barbra Mosley
Bennett College

Is the notion that teachers will teach the way they were taught compelling enough to motivate those in higher education, who teach pre-service and in-service teachers, to change their instructional methods to use and model the use of technology (Baumbach, Kysilka, and McLain, 1989; Diem, 1989; Rutherford and Grana, 1995)? The answer for many may still remain something other than an absolute yes or no, even when (with all things being equal) the instructors possess all the necessary knowledge, positive attitudes, and skills to accomplish the task, including good, solid, computer skills. Less than a decade ago, one of the original arguments for inclusion of computers in educational environments was that “computers increase student engagement, add realism to instruction, promote skill mastery and understanding of principles, augment laboratory experiences, and encourage inferential thinking” (Johnston and Joscelyn, 1989, p. 2). Today, it remains one of the leading arguments promoting inclusion of computers in the curriculum.

One would get very little argument in suggesting that any good instructor enters the classroom well prepared to facilitate the learning process without technology. Therefore, with technology (and the technology of choice being the computer), that same instructor will in all likelihood be willing and eager to move students to a higher level of thinking and learning. The expectation is that by engaging students with computers, they will develop and demonstrate better problem solving skills, better analytical skills, better critical thinking skills, and better decision making skills … and the emphasis here is on the word “better.” But is this the perception students have as to why technology, and in this case the computer, is being integrated into the curriculum?

A Case For Integration

The instructor at a medium-size, southern university was excited about the prospects of teaching a Teacher Education core course, Tests and Measurements, to pre-service and lateral entry in-service teachers. Supposedly, students were not allowed to take Tests and Measurements until their junior year, however, from time to time, special arrangements were made for outstanding sophomores. The possibility for adding a technology component to satisfy mandated computer competencies was second only to the vision of restructuring the course to include (a) more group activities in which objectives would be written and matched to test items prior to test taking, (b) weekly “easy, nonsense” tests for data collection, analysis, and understanding of key concepts, e.g. reliability, validity, test-retest, equivalent forms, and (c) various ways of scoring and grading tests including the weighted method and use of the mean score. The technology component, as originally designed by the instructor, included the use of two computer applications, one simple to use statistical shareware package and SPSS for Windows. Presuming that students would have spent one semester crunching numbers in a basic statistics course, moving them to statistical packages would consolidate time, allow for more in-depth analysis of concepts, and facilitate the use of critical thinking skills during classroom discussions. And to get them accustomed to the weekly “easy, nonsense” tests which would be given during the first three weeks of class, the instructor took the 2 through 12 multiplication tables, eliminated the duplicates, and excluded all numbers times 1. A total of 66 multiplication items were then randomly assigned to two test sheets, each containing 33 multiplication table items.

A Method To The Madness

During the first day of class, Fall 1995, a syllabus was distributed, and the students were given in-depth information on the course, especially the use of “easy, nonsense” tests for data collection. The “easy, nonsense” tests would consist of information the pre-service and in-service teachers would have learned no later than the 5th grade, thereby a non-threatening environment in which to learn testing concepts would exist. And because each student would be taking the “easy, nonsense” tests, a sense of ownership would encourage participation for understanding test construction and test results. The intent was to facilitate
each student’s understanding of testing and to hammer home the point of test analysis and interpretation. Each week, students would be responsible for answering the question, “What do the test results mean?” and each student would analyze his or her own individual test score in isolation from class peers, and then, his or her own individual test score in relation to the entire group of test takers.

Following the distribution of the syllabus and detailed explanations of the course, a short survey was distributed and collected to gather basic information on each student. Then, the first “easy, nonsense” test of multiplication table items was distributed face down. Students were made to feel at ease and it was reiterated that the “easy, nonsense” test had nothing to do with the grading system for the course. This first “easy, nonsense” test would be a timed test and students were to complete, to the best of their ability, as many multiplication table items as possible in 30 seconds. Prior to giving the “begin” signal, students were given an opportunity to ask questions. The only question that was asked was, “Can we use our calculators?”

Of the 74 students enrolled in Tests and Measurement in Fall 1995, 64 were present for administration of the second “easy, nonsense” test of multiplication table items. Raw scores ranged from a low of 12 to a high of 33, with a mean score of 21.6 and a standard deviation of 5.7. Forty-three of the original 48 students who took the first test were present for the second testing. As a single group, their raw scores ranged from 8 to 30, and yielded a mean score of 16.0 with a standard deviation of 4.0 for the first test; and for the second test, raw scores ranged from 12 to 33, and yielded a mean score of 22.1 with a standard deviation of 5.3.

A Possible Problem

There may be a very serious problem ... a problem which was tracked with the help of the Educational Media Specialist from Fall 1995 through Summer 1997 via a number of the “easy, nonsense” tests. Because the Tests and Measurements course was meant to utilize statistical means for assessment, math-based “easy, nonsense” tests were used, both timed and untimed. And with each administration, more problems were uncovered. And the problems were not limited to the “easy, nonsense” tests. Problems surfaced on the survey which solicited basic student information. Each semester, students were specifically asked to provide their height in inches. Too many refused, crossing off inches, and substituting their height in feet and inches. Some admitted they did not know, noted such on their sheet, and left the answer blank. Others tried to figure out their height, but bizarre answers were the result, e.g. 2.5 inches, 4 inches, 5 inches, 144 inches, 300 inches. Students may have simply forgotten how to do basic math or the severity of the problems could mean that students lack mastery of foundational math skills generally taught prior to or no later than 5th grade.

More Problems

The multiplication table items and the conversion of feet to inches were not the only problems. In subsequent semesters, a number of other “easy, nonsense” tests were administered. The following items were extracted from sites on the World Wide Web and incorporated into two of the numerous “easy, nonsense” tests.

1. Question: Divide 30 by 1/2. Add ten. What is the answer.

2. Question: The price of an article was cut 20% for a sale. By what percent must the item be increased to again sell the article at the original price?

Preservice Teacher Education — 677
Both represent somewhat problematic items, however, they were specifically selected for that reason. They would lend themselves quite well for discussion of problematic test items due to wording. But the wording of the items were not the problem. Question #1, a fill-in item, was incorrectly answered by most students who thought the answer should be 25. The wording of the item was not the problem. They seemed baffled by the explanation to “invert the divisor.” Question #2, a multiple choice item, was incorrectly answered by most students who thought the answer should be 20%. Once again, the wording was not the problem. Students were shocked at the logic that to increase the article to its original price, the percentage must be higher that the percentage to cut the price.

**Even More Problems**

These problems were not limited to any one semester. They were recurrent every time the course was taught from Fall 1995 through Summer 1997. There is an old saying (author unknown) which goes something like this: “The first time it happens, it is an accident; the second time it happens, it is a coincidence; but the third time it happens, it is a habit.” Unfortunately, every semester most of the students consistently had problems completing the “easy, nonsense” math-based tests which consisted of items no later than 5th grade level. Table 1 documents the original problem over multiple semesters as identified by the instructor from the very first day the course was taught. Only the Fall 1995 students were given 35 seconds for the second administration of the multiplication table items, however, all students were strongly encouraged to review their multiplication tables prior to the administration of the second test.

**Addressing the Problems**

It is more than reasonable to assume that pre-service and in-service teachers, who rank as juniors, seniors, or graduate students in college, should know basic math skills. Or is it? If not, how will they conceptualize the sum of the squares versus the square of the sums for calculating standard deviation. The “easy, nonsense” test results were an indication of a more serious problem ... a problem which might travel with pre-service and in-service teachers as they entered the K-12 school systems ... a problem serious enough to be addressed immediately.

Remediation of basic math skills in higher education was prerequisite instruction for the Tests and Measurements course from Fall 1995 through Summer 1997. What originally was to be three weeks of basic statistics instruction consistently turned into three weeks of math remediation including the memorization of the multiplication tables. A total of 346 students took the course over a period of four full semesters and two summer sessions. The data changed very little from semester to semester, with additional math deficiencies surfacing with each new “easy, nonsense” test. Over the two years the instructor taught the Tests and Measurements course, almost 60% of the students entered without ever having taken a statistics course. And because a basic course in statistics was not a part of the Teacher Education program, most left with no intention of ever doing so.

One focus of the course was to provide a foundation for interpreting standardized tests results. Each test item was reviewed and explanations provided as to why the correct answer was indeed the correct answer. Most students felt the missed questions were trick questions. The truth was that the correct answer required higher level thinking skills. Whereas some students were able to make the connection, others simply dismissed the issue feeling that they simply were not good test takers.

678 — Technology and Teacher Education Annual — 1998
And What About Technology Integration?

The integration of computers in the course was well received by the students because most were "fearful" about math and the computer seemed to solve that problem. The technology component was altered somewhat to eliminate the use of SPSS for Windows which was above the heads of most of the students. A gradebook program was substituted in its place which satisfied the computer competency requirement and simultaneously gave the students a more down-to-earth experience in assessment. However, too many students entered and left the course believing that technology relieved them of their responsibility for learning foundational skills. Others quickly came to realize that sometimes technology will slow you down, especially when taking a timed test, and that the best of all worlds is to know ... really know the material. And equally importantly, some began to understand at least one possible reason for their less than desired performance on standardized tests.

It was encouraging to see the students anxiously await their group's turn to process the data, e.g. mean, median, mode, and standard deviation, on the computer. But it was sad watching them try to proof the answer for the standard deviation ... even after the computer supplied them with the basic elements for calculation. It is possible that some might perceive this two-year situation as an isolated case ... or even one which suggests more technology inclusion (probably computers) in the curriculum, especially to address the issue of remediation. As strange as it sounds, it is a success story with a very strange twist. The instructor and Educational Media Specialist are still very excited about teaching ... and will continue to teach with technology ... because they believe students will learn ... and that in time ... rising to a higher learning level will become a reality. But more importantly, both will continue to take a closer look at the attitudes of students when technology is integrated into the curriculum, because learning is also about change.

BLOCKING THE EDUCATION MEDIA & TECHNOLOGY COURSE WITH METHODS COURSES: AN EXPERIMENT

Lorana A. Jinkerson
Northern Michigan University

Beginning with the Fall 97 semester, the Department of Education at Northern Michigan University, located in Marquette, Michigan, started a block of elementary education courses. Included in this block of courses were: ED 310 Elementary Social Studies Methods and Materials - 2 credit hours, ED 311 Language Arts Methods and Materials for Elementary Teachers - 3 credit hours, ED 316 Elementary Reading Foundations I - 3 credit hours, ED 361 Special Education and the General Classroom Teacher - 2 credit hours, and ED 483 Educational Media and Technology - 2 credit hours.

The result is a total of 12 semester credit hours. This allowed students to take an additional content area course in addition to the block for a total of approximately 16 semester credit hours. The recommendation was made to students that they should register for each of these classes. ED 311 and 316 had been field based in Whitman Elementary School of the Marquette Area Public Schools for the past several years. In addition, a pilot blocking ED 311 and 316 with ED 310 had been implemented a couple of semesters earlier and continued. The addition of ED 361 and ED 483 to this block was meant to provide an integration of concepts from 361 and 483 into the 310/311/316 methods courses. This paper will discuss the planning stages for this blocked semester, the Fall 97 semester's implementation, the Educational Media and Technology component, and plans for the Winter 98 semester.

Planning Phase

Under the suggestion of Dr. James Hendricks, Head of the Department of Education at Northern Michigan University, four faculty members of the Department (Dr. N. Suzanne Standerford, Associate Professor of Language Arts; Dr. Lorana A. Jinkerson, Associate Professor of Educational Technology; Dr. Laura Hoffman, Assistant Professor of Language Arts; and Dr. Laura Reissner, Assistant Professor of Special Education) began discussing the possibility of blocking their courses for the Fall 97 semester. The suggestion from Dr. Hendricks came partially in light of an agreement between Bay de Noc Community College located in Escanaba, approximately 70 south of Marquette, and Northern Michigan University to begin articulation of course work that would allow Bay de Noc students to take 3 years of teacher education coursework at Bay and reside at Northern for the methods phase of their teacher preparation, essentially 2 semesters, and then return to the Escanaba area to complete the program through their student teaching experience.

Another concern that had been plaguing the Department was the separateness of many of our courses. The Department wanted to model to our prospective teachers not only how to work together, but also how to teach thematically through the integration of several subjects. Specifically, the following background was presented to the group as a basis for this work: the Department of Education faculty develop for and with prospective teachers and professional communities of practitioners the “norms” of the best possible K-5 teaching and learning practices; to the preceding end, the Department practice as a community of professional educators, e.g., capacities for “team” decision-making and instruction; and, the faculty develop as they proceed principles to guide their pedagogy and to guide the development of their content, e.g., “inquiry-centered” principles for teaching and learning together (faculty, prospective teachers, classroom teachers, administrators, K-8 learners, et al).

There was some apprehension among the faculty about ED 483, a new Educational Media and Technology course, that had recently been made a requirement for graduation. The Department did not want the course to be focused on just the “how to operate computers” or “how to run a specific program”. Rather the desire was that this course model to students how technology supports learning in all content areas. As a separate course, this was proving difficult. Likewise with ED 361, Special Education and the General Classroom Teacher. Each of these courses had developed a “technology of the week” or “disability of the week” format and students saw little connection to content and felt very frustrated trying to do assignments with no content focus or authentic utilization.
Other than some beginning discussion meetings held during the Winter 97 semester, the planning stages were conducted during the Spring 97 semester and continued through the Summer 97 semester. The four professors involved in these five courses and a group of professors who would later comprise the second semester of the block (e.g. math methods, science methods, children's literature, elementary reading instruction II) met formally four times over the course of the spring/summer to plan the block. The first meeting was an all day meeting. The other three were half day meetings. The Department paid a stipend to each participant for their time on these planning days.

The first meeting began with the general question, "To what extent can we develop and model a collaborative learning community which reflects: an integrated approach to learning and curriculum; a supportive learning culture within which students develop agency, reflection, collaboration, and culture; time for students to reflect and think more deeply about their learning experiences; and, assessment of common professional traits and qualities of students across courses and tasks."

Each professor listed the goals and objectives of their separate courses in the hopes of identifying common outcomes. Some of these included portfolios, lesson plans, walking journals of field experiences, e-mail projects, reading of children's novels, attending professional meetings, writing, weekly news logs, case studies, reflective articles, materials production, software utilization, software evaluation, and information access on the World Wide Web. A unifying theme was for the students to see the connection between "what they're seeing, what they're reading, and what they're doing."

The group discussed textbooks and other resources in an attempt to utilize some materials across the courses. In addition to reducing the amount of reading students would need to do, freeing up time to read more in depth and critically, dual use of materials would save students money. The faculty shared their separate syllabi from the previous Winter (97) semester and looked for ways to rearrange and/or combine topics to support one another's work. Using these syllabi, each faculty member made a list of their requirements, looking to consolidate assignments across two or more of the courses. Assignments were listed in three categories: blocked assignments, possible blocked assignments, and individual assignments for specific classes. Finally each faculty member revised their syllabi according to the topic schedule discussed and assignments to be shared.

At the final summer meeting of the block faculty, plans for the first day of classes were made. The overall goal was not to have all faculty attend all course times, but rather to have each course taught by the appropriate faculty member in a supporting capacity to the others. However, the decision was made that we would all meet with the group of students the first day of classes to explain the goals and working arrangements of the block. It was further decided that we would all meet a couple of times over the course of the semester with the students. Class lists were compared and notations of which students were actually enrolled in all five courses were made. Since this was a new program, some students had already taken one or more of the courses we had blocked together. Hence, there was not 100% overlap. The students in ED 310, 311, and 316 were all the same, but those in ED 361 and ED 483 were not. Overall, there were 13 students in all five courses. It was the hope that the Winter 98 semester would have a larger number of students enrolled in all five classes, and indeed the registration lists for the upcoming Winter semester support that goal. We predict that it will take approximately two years before all the students are in all courses of the block.

**Implementation Phase**

All four instructors attended the first meeting of the ED 311/316 class. Syllabi for all courses were distributed and an introduction to the concept and goals of the block was presented. Students were encouraged to provide feedback throughout the semester on this experimental program. Time was given for student questions.

The faculty had one meeting at approximately mid-semester to discuss how things were going, changes to make, and what needed additional work. Overall, the general impression at that time was that all was going well. There had been some glitches to work around and details to decipher, but all faculty had received positive feedback from students. At this meeting, 2 more sessions with all faculty present with the students were planned. The first was intended to be a feedback session, giving students a chance to address their thoughts, concerns, and suggestions for the remainder of the semester to all faculty at once. The final meeting between all the faculty and the students would be a time the practicing teachers with whom the students were doing their field experiences could express their thoughts, concerns, and suggestions. Both of these sessions were well received. Both students and practicing teachers verbalized their extreme satisfaction with the program, offering only a few suggestions for modification and/or improvement. Feedback from the students highlighted the collegiality of working together as a cohort across the classes, the ease and support of working with all four faculty including our flexibility in regards to assignments supporting several courses, and the connectedness of all to authentic practice.

Some typical student comments include: I think the block classes have been a great success and I would highly suggest to other students who will be taking their methods classes soon to enroll in the block courses; About the block classes I love them. I really have a great time and I am learning so much. Actually I come home some days with a headache because I have so much new information in my
copy of your log. For ED 483 specifically, respond a minimum of 3 times over the course of the semester noting technology observations include VCRs, overhead projectors, computers, video camcorders, recorded audio, the Internet, CD-ROMs, e-mail, teacher utility programs, etc.

Some possible questions to think about and respond to include: What technology is being used? Who is using the technology? What is being done with technology? How do the students react to the technology compared to similar non-technology work? What pieces of technology are in the classroom? How much technology is available in the class? Do you see ways the teacher could utilize technology in non-technology lessons? If so, what and how? If computers are available, how many students work on one machine at a time? Do you see changes in classroom organization and structure when technology is being used? If so, what and how? Do you see changes in student behavior when technology is utilized? If so, what and how?

A web site was set up for students in the block which included the syllabus, a listing of all assignment requirements, detailed instructions for producing them, and exemplary examples of each.

Revision Phase

As the end of the Fall 97 semester is upon us, the faculty are contemplating revisions for the Winter 98 semester, taking into account final comments to be collected from the students during exam week. These revisions will be discussed during the presentation and will also be available on the web site: http://www.nmu.edu/staff/Ijinkers/BlockW98.html

Preservice Teacher Education — 683

ERI
head; We do have our rough weeks but we all manage to get through them. I feel I can talk to or call anyone of you (meaning the faculty) at anytime and that goes the same for the students - we are so close. I've never had a class where the students and teachers were so close before; I think all the classes are going very well and I am getting the most out of them. They are really interesting and keep me on my toes. I am never bored; All of my concerns were brought up in the discussion we had last week which by the way was very good to have. It gave us all a chance to sit down and talk about our concerns as well as what we liked; I really enjoy being part of this block and it is a very good idea to have it. Thanks for giving me the chance to be in it.

Media and Technology Component

The majority of assignments in ED 483, Educational Media and Technology, were planned to be completed as part of a requirement for the other courses. There were only four assignments that were exclusively for ED 483. In previous semesters all assignments were completed solely for this class. As ED 483 had not previously had a field experience component, working with the other blocked courses that did have a field experience allowed the inclusion of assignments taking advantage of this experience. A concerted effort was made to integrate and support assignments in the other blocked courses with technology so students could apply the technology ideas in authentic teaching tasks. Prior to this arrangement little technology integration was taking place in the other courses. The following partial list of assignments for ED 483 illustrate the interrelationship of the assignments with those of one or more of the other courses.

Audio Tape

Select a poem or story to record with appropriate background music. May be combined with writing and performing poetry for ED 311/316 and/or social studies poem for ED 310.

Concept Mapping

Design a concept map with the inspiration program or other drawing program for the Rainforest Packet assignment (ED 310) or for ED 361 as instructed by Dr. Reissner.

Database

Design a News Log database with a minimum of 8 fields and 5 records for keeping track of your new stories for ED 310. Insert a header and/or footer labeling with your name and the assignment title. Print the database in list form, landscape mode. Sort the database on any one of the fields, change the heading and/or footer identifying what field it is sorted on, and print again.

Graphic Flyer

Use a program on a computer such as The Print Shop, a word processor or presentation program to design a handout, poster, or flyer you might use in a class. Include both text and graphics. This should follow all the design guidelines discussed in class as to text, graphics, and color. It must support one of your block assignments - suggestions include lessons, cover page for your portfolio, etc.

Hypermedia

Using a hypermedia package such as HyperStudio, HyperCard, or Linkway, design a project to support the novel you read that compliments Sing Down the Moon, or a ED 361 project as defined by Dr. Reissner. Other possible connections can be discussed with me prior to execution. A minimum of 5 cards is required. All design issues discussed in class should be considered. Incorporation of scanned image, Internet image, digital camera image, original computer graphic, etc. is encouraged.

Internet Graphic

Locate and save on your disk at least one graphic from the Internet to support your portfolio, word processing, hypermedia, presentation, overhead transparency, newsletter, graphic flyer, lessons, etc.. It must support one of the projects for the block classes. Be sure to jot down the address and date you downloaded the graphic. Convert to PICT format with the GIF Converter program. Resave on your disk. Finally, utilize the graphic in another assignment.

Internet Resources

Locate a minimum of one Internet site that could be used in conjunction with the Rainforest book, for your News Log, your American history characterization, with the story Sing Down the Moon, or with one of your lessons. Print out the Internet page, being sure the http address and the date of the printout is included. Write a paragraph explaining how the information will be used in your project.

Professional Development Event

Attend one professional development event such as Upper Peninsula Reading Association Annual Conference October 9 and 10, Seaborg Math and Science Conference October 10, a NMU SMEA meeting, a Marquette-Alger Reading Council (MARC) meeting, etc. Show proof of technology focus to get credit for ED 483.

Technology Lesson

Choose one or more of your lessons you plan for any of the block classes but integrate technology into the execution of the topic at hand, whether reading or social studies. Discuss with me your ideas before you implement. Think of all the various technologies we are covering this semester and which would best support the content you are trying to teach. Identify which of the State of Michigan K-12 Technology Outcomes are supported by your lesson.

Walking Journals

Using groups selected in ED 311/316, set up an e-mail discussion list to act as your walking journal of your field experience assignment. Include comments for all block classes. Be sure to include all faculty in your list so we get a
Technology Infusion: The Impact of Technology Infusion in Creating Quality Instructional Materials

Mike Omoregie
Jackson State University

Betty Coleman
Jackson State University

In the Summer of 1996, Mississippi Institutions of Higher Learning funded a proposal for the Jackson State University’s School of Education to implement the Technology Infusion Project for core academic subjects. The Project staff developed and operated a comprehensive multimedia computer training program to enlighten the participating School of Education’s teacher education preservice teachers on how to deliver instruction in English, the arts, geography, math, science, and history by utilizing technological tools. The Project goals and objectives were as followed: (1) to enhance preservice teachers with the knowledge of modern technologies that will enhance curricula in English, history, the arts, geography, math, and science at the K-12 level, and (2) to facilitate practical knowledge about technology infusion. The major objectives were to: (a) provide two weeks of intensive multimedia computer instruction to 20 selected preservice students during the 1996 summer semester, (b) provide 20 preservice teachers with knowledge on integrating modern technology in English, history, the arts, math, science, and geography curricula, (D) facilitate a structure for focused electronic discussions between the instructor and project participants, and (d) provide information on developing materials for English, history, the arts, math, science, and geography by using technological tools.

In order to serve twenty of the School of Education’s preservice teachers in the twelve-month granting period, the School requested funds from Mississippi Institutions of Higher Learning. Throughout the Fall of 1996, the TIP project staff continuously monitored the participating preservice teachers during their practical teaching experience to ensure that technology was being integrated in their daily classroom activities. Finally, the participating preservice teachers were provided with E-mail addresses to communicate with the faculty at the University while on practical field experience.

Research on Technology

As we approach the 21st century, technology must become the driving force in the delivery of instruction to today’s youth. Since the birth of microcomputers, the education community has recognized that redesign of teacher training is essential to the successful integration of technology in classroom instruction. While much has changed over the years, the need for teacher support and training has not. These components remain the key to successful implementation of technology in the classroom.

In schools across the nation, teachers continue to use calculators to average students’ daily test grades, and they continue to create lesson plans and homework assignments for students through the use of freehand. With today’s technological innovations, teachers should have skills that will enable them to use new innovations such as multimedia computers, digital cameras, scanners, in focus video projectors, in focus LCD panels, CD-recorders, video conferencing systems, and numerous software packages; i.e. Hyper studio, PowerPoint, Word Perfect, Netscape, and Microsoft works, to name a few. Many educators fear making massive investments in technological training. Their prior experiences with educational reform have led them to believe that the “new” revolution in computer use will pass in a few years like the so many other “new” revolutions in the past. As Decker Walker wrote:

It is impossible to predict how long computers-in-education will hold the spotlight of public and professional attention. Five years would be an excellent run; 10 years would be the best since progressive education. What concerns me, however, is not the length of the run but what will remain in the schools when the boom has run its course and a new act has captured the spotlight. When that happens, the fate of computers-in-education will depend on the instructional uses to which teachers and students can put their computers (Walker, 1983, p. 244).

Still others fear that the emphasis on technology may overshadow important efforts to develop basics in math, reading, communication skills, and science. In reality,
technology and the new demands of the technological age should lead educators to redefine these cherished basics and the ways in which they are taught. A considerable body of research has already revealed that computer technology can enhance the learning skills of at-risk students by developing critical thinking and problem-solving skills, as well as, encouraging collaborative learning. Further, systems can be implemented to facilitate interaction among parents, teachers and students; an outcome already known to improve school performance (Poiriot and Canales, 1993; Norris, 1994; Poiriot and Robinson, 1994). Nevertheless, the collective fears expressed by too many educators may partially explain an observation made by Gwen Solomon of the US Department of Education: “technology is everywhere but in the schools.”

The reluctance of teachers to fully commit themselves to becoming technologically literate must be addressed. For the public schools, teacher involvement is the key aspect for successful technology infusion process. After all, it is the teacher who develops and implements the actual lesson plans for classroom instruction. As such, the advice of Abrams and Many (1997) seems particularly relevant:

Teachers who have not yet decided to adopt technology personally should continue to be exposed to the possibilities, gently encouraged, and offered support; but, their participation cannot be forced. More will result from supporting the willing than from cajoling the reluctant. To try to interest reluctant colleagues, inquire as to the areas of their teaching that cause them the most difficulty. Explore the potential for technological intervention. If there is an acknowledged problem, that teacher may be more willing to consider a new approach. If not, try again next year. (p.377)

On a broader scale, successful integration of technology in the delivery systems of public schools will require support from the district office in a number of areas. These areas include technology coordination, planning, integration, teacher involvement, staff development, hardware configuration, facilities and funding for successful implementation of technology infusion (Lockard, Abrams & Many, 1997). Successful coordination of technology literacy programs in schools requires effective leadership to provide training seminars for classroom teachers and administrators. Teachers will also need access to resource persons in the district. Even with training needs and administrative support, teachers do not have the time to create individualized tools or make new technologies possible. Teachers may possess general ideas regarding these areas, but a specialist can help the teachers put their ideas into practice, either by creating software applications or by customizing existing technologies. Infusing technology in a school curriculum requires a carefully developed plan that includes a long-term view involving factors such a system-wide applications and major involvement of teachers/administrators (Lockard, Abrams & Many, 1997). One can not overlook the importance of articulation across grade levels because each teacher needs to know what students have previously learned to effectively plan for his/her own grade level. Finally, on-going staff development, appropriate hardware/software, appropriately equipped facilities, and adequate funding are all needed in any plan for successful technology infusion in the schools.

**Method**

The project was designed using the following phases: preservice teachers training workshop, and district students exposure program. The phase one entailed introducing 20 twenty program participants to the technology based training program developed to achieve the project goals and objectives. The technology based program entailed the following: Infusing Technology into the Classroom; Integrating Technology into English, reading, mathematics, science, and other core Curriculum; Introduction to Networking Systems (Windows NT & Novell NetWare*); Publishing an Interactive Multimedia Project; Image Creation; Word Processing, spreadsheet, & Database; Using Telecommunications tools in Education. After the preservice teachers had received instruction from the faculty involved in the project, they were asked to develop a multimedia project to represent their areas of specialties.

The final phase entailed the delivery of the technology based instruction in the classroom by the preservice teachers to students in the district schools. The preservice teachers utilized technological tools and materials which they were exposed to in delivery instruction in the following areas: English, math, science, geography, history, and arts. Periodically, participants were supervised and evaluated by site coordinators assigned by the director of Center for Excellence in Education in the School of Education.

**Equipment/Software used for the Project**

The project facilitators and preservice teachers employed the use of the following equipment: Networked Multimedia Computers, Digital cameras, scanners, printers, QuickCam Technology, Infocus Video Projectors, Infocus LCD Panels, Overhead Projectors, Presenter Tview, Television Sets, Sony CD-Recorders, Personal Video Conferencing System, File/Video Servers. HyperStudio, PowerPoint 7.0, Microsoft Works 4.0, Word Perfect, Student Writing Center, Microsoft Explorer, Microsoft Front Page, Windows NT, Novell NetWare, and Macromedia Freehand were used by faculty and preservice teachers during the two week session. Finally, for transmission, ISDN/telephone lines, and T1 connections were used for equipment connectivity.

The research design employed in the study was descriptive in nature. Based on the review of literature, the

Preservice Teacher Education — 685
researchers found no satisfactory instrument which met the requirements of this study. Therefore, a Likert Scale was developed to measure responses. According to Kerlinger (1973), developing a Likert Scale requires that numerous statements concerning the interest, attitudes, values or other personal characteristics are gathered. Statements developed representing relevant aspects of the variable to be measured were selected using expert judgment and testing with appropriate respondents. Five researchers determined whether a positive or negative response would be scaled higher. However, after the consideration of the aforementioned reasons, an evaluation instrument with twenty four questions was developed and administered to twenty project participants. The instrument addressed the importance of technology infusion in course curriculum such as math, history, arts, English and geography.

Due to the research component included in the project, the following questions were examined:

(a) does technology infusion play a significant role in developing quality instructional materials?
(b) does technology infusion play a significant role in the academic performance of students?
(D) does technology infusion play a significant role in the preparation of preservice teachers?

Results

In analyzing the preservice teachers’ responses and the data of district school students academic performance, the analysis revealed that technology enhanced following:

- Increased interaction between students and preservice teachers.
- Increased academic performance of students and preservice teachers.
- Increased computing skills of students and preservice teachers.
- Increased motivation of students and preservice teachers.
- Encouraged rapid feedback between university faculty and preservice teachers.
- Encouraged rapid feedback between teachers and school district students.
- Increased students’ interaction using the electronic mail enhance their writing skills.

In response to the three research questions, (a) does technology infusion play a significant role in developing quality instructional materials? Based on the data gathered, 95% of the preservice teachers agreed that technology infusion plays a significant role in developing quality instructional materials for school aged students and adults.

(b) does technology infusion play a significant role in the academic performance of students? Based on the analysis, the academic performance of preservice teachers and students increased by 75% in core academic subjects. 0

preparation of preservice teachers? Based on the data analysis, 100% of the participants agreed that technology infusion plays a significant role in the preparation of preservice teachers.

Implications

The evaluation results of twenty respondents revealed positive perceptions of technology infusion core academic subjects. The study calls for further consideration that would allow the analysis of perceptions of inservice and preservice teachers after the completion of similar technology training workshops. Consequently, it is evident that technology infusion as well as other technology application should be implemented in higher education and k-12 levels.

Equipment and software acquisition, faculty support, administrative involvement, and staff development are very important in the successful implementation technology infusion in the classroom. The research revealed that “Train-the-Trainer” model would be the best way to transfer technology from higher education to k-12 classrooms across the nation. In the State of the Union of January 23, 1996, President Clinton stated that he would ask the Congress to support the education technology initiative which calls for every classroom in America to be connected to the super-highway with computers, good software, and well-trained teachers. However, the success of the aforementioned initiative lies on the improvement of teacher education program across the nation.

686 — Technology and Teacher Education Annual — 1998
Even if a child of this age could abstract and understand certain aspects of writing and reading music, we believe living the music with all the body must be a fundamental and more important objective than providing him or her with theory and musical literacy through technology. The child needs live, sensory based experiences on which to build knowledge and skills that will permit him or her to develop cooperation, solidarity and a respect for values. Music education has a strong socialization component, which must be developed through relationships with other individuals, not next to a machine. But computers and digital instruments can be behind them, manipulated by the teacher, bringing them a greater timbral wealth than the one which customarily exists nowadays in the music classroom; giving them, through the compositions and arrangements accomplished by the teacher, a rhythmic guide for the pulsation that helps them develop their internal pulse, as well as a guide for the intonation.

This way, it is possible to work with music in a progressive manner with more difficulties added at each surpassed phase, according to a didactic principle which will offer them the possibility of assembling their proposals in collective compositions and release music class time which can be used by the teacher for greater intervention and interaction with the children.

Electronic instruments, computers and music software are potent and useful tools for the Music Educator. Music technology helps teachers in the elaboration of sound and written materials that will help the children move, sing, perform, dance or improvise, whatever the methodological approach the educator uses.

From the perspective of the integration of music technology in the Music Teacher curriculum, there are two conceptions: as a tool for the future Music Teacher and as a reinforcement of pupils' apprenticeship. Because it constitutes a very useful instrument for the didactic elaboration of music materials, it is a teaching tool. Music technology acts as a graphic and sound support in a predominantly active teaching environment in which classic elements of movement, speech, song, dance, improvisation, performance and dramatisation play a very important role. It is a useful apprenticeship tool because it provides training elements, permits immediate hearing which musically can be imagined, facilitates the approximation between abstraction and reality and aids in the acquisition of certain procedures related to the areas of Composition and Instrumentation.

In this work, we will do a critical revision of the uses of Music Technology, its application in Music Teacher Education and its possible applications in the classroom, specifically in compulsory education.

Music Technology and Multimedia in Music Teacher Education

Generally musical teaching, at least in its first levels would be fundamentally practical. This would be particularly true of offerings by universities in the training of music specialist teachers. General Psychology, the different Didactics or the different subjects inserted into the curricula of Primary Education would be applied by the future music teacher in his or her future professional context. If the music teacher, however, wants to make the best use of the contents and adapt these at the level of the group class, they will also need to apply the practical harmonisation, arrangement and instrumentation knowledge in order to elaborate his or her own didactic materials. In this manner, the teacher can be creative with the work, whether it is with simple melodic lines, popular songs or collective and individual compositions.

In first instance, the acquisition of the abilities and skills cited is the objective of Functional Harmony. This is the University of La Rioja's course where the knowledge of both managing of musical data processing and music technology is inserted (Tejada, 1997). Functional Harmony is an obligatory subject; it has 4.5 credits corresponding to the second course of the Music Education Teacher studies plan. With the amount of time available we take a predomi-
nantly practical approach where the acquisition of basic skills and abilities outweighs the learning of concepts and theoretical elements. The heterogeneity of the group, seen in the general lack of previous musical skills with which the pupils enters into these studies, is a second reason for applying a practical approach.

Functional Harmony consists of two differentiated parts though very imbricated. The first one, Foundations of Harmony, is approached through theoretical notions related directly with harmonic discipline, that is to say, construction, operation, relationships and chord links. Within this part exist some areas related to the Composition and Instrumentation that imply the creation of works and arrangements, constituting a hidden part of the curriculum.

In the other part, Musical Informatics, the contents deal with the communication between computer and MIDI devices and the managing of scores publishing programs such as Encore, sequencers, Master Tracks, and algorithmic programs such as Band in a Box. Music technology is used to form the harmonisations that the pupils create and permits them to explore in an intuitive way the parameters that the composer uses. With such technological tools, the pupils individually create popular song arrangements. In addition, they compose in groups while taking into account Didactics of Music.

Another important technological element used in Functional Harmony is the multitrack recorder device that has been employed for the first time in this academic year. The multitrack is used to record group compositions created by the pupils using real Orff instruments and, eventually, with some digital sounds. This is also used to record the musical arrangements accomplished for the subject Agrupaciones Musicales (Musical Groups). With a multitrack recorder, the pupils knows and approach the various problems brought up during musical performances in real time (i.e. timing and synchronization) and those which generate the accomplishment of a good recording (i.e. equalization, panning, mixing, etc.).

During the last two academic years we have been looking at the scarcity of previous training of the pupils that enter into this career. I have decided to use a series of aural training practices with the computer which employ a training program, Practica Musica, as a reinforcement of the apprenticeships in certain specific subjects: Lenguaje Musical, Formacion Vocal y Auditiva, Formacion Ritmica y Danza (Musical Language, Auditive and Vocal Education, Rhythmic Education and Dance). These practices are accomplished at the margin of those credits assigned to Functional Harmony. This includes the establishment of a second part of this subject as well as the implementation of such auditive education activities in the compulsary and obligatory subjects mentioned earlier.

The Internet, through E-mail lists, plays a complementary role in the subject in serving as a liaison with other foreign educational centers to exchange didactic materials elaborated by the pupils with both digital instruments and computers. These materials go from a simple melody to complete arrangements or arrangement sketches that modifies the pupils’ criteria. This active exchange of music materials helps us understand the differences in the music of other countries. The elaboration of this type of materials increases our knowledge of appropriate compositional techniques.

Music Technology has also been used in the preparation of both graphic and sound materials in the training of the future Early Childhood Teachers, Foreign Language Teachers and Physical Education Teachers, as well as in other subjects used in Music Education. The technology gives graphic and sound support during predominantly active teaching in which classic elements of movement, speech, song, dance, improvisation, performance and dramatization play a very important role. The teacher elaborates the sound materials and the pupils play, dance, sing and improvise on them. At the present time, there is a permanent seminar made up of music education teachers from all levels of teaching, whose objective is the creation of music educational materials with the help of technology.

Educational Multimedia

Nowadays, there exists a broad offering of courses, congresses, seminars, workshops and publications on multimedia and educational technology. Unfortunately, fewer of these possibilities are found in the actual classroom. Many teacher educators continue to believe that their work is reduced to the transmission of knowledge which their pupils collect. Even though some are using educational technology, too many continue in their old attitudes concerning the teaching-learning processes.

Some teachers who support the use of technology still disregard certain necessary processes before its integration which can result in forced implementation. While examining curricular blocks in which to introduce the technology, they attempt to insert technology in places where it might have the best or most striking results, when indeed we must reflect upon the role that technology is going to have in the educational intervention.

Multimedia can help some students to surpass their inertia such as that of taking notes from teacher’s lectures. This can eliminate the boredom produced by the mechanic repetition of exercises focused on acquiring aural skills or instrumental performance skills. This can be a motivational aid for the pupils. Thanks to its special treatment of the information, multimedia can “hook” pupils in the exposition of specific contents. It also facilitates the exposition of key issues regarding given topics and makes the question-answer strategy more dynamic (Barajas, Simo, 1994). For example, a video sequence inserted into a computer program can demonstrate a real orchestra with its instru-
ments, its placement, its timbres, the musical arrangement, etc. This can be more motivational for the pupil than teacher's words or the isolated sound of a cassette or disk.

The creation of a multimedia musical project need not be very complex nor costly, given the existing authoring tools currently on the market. This would permit us to adapt and personalize the instructional contents that we make available to our pupils. Educational multimedia in CD-ROM constitutes a magnificent resource at an educational library. The pupils can use it for looking up information in order to elaborate their work. In this way, technology reinforces the apprenticeship of a given topic (musical analysis, history of the music, musical forms, organology, etc).

At the University of La Rioja, we are using certain multimedia titles for the subjects Audiciones Musicales Activas (Active Musical Auditions) and Historia de la Musica (History of the Music) as a multimedia support of master classes. Such is the case with The New World Symphony, by A.Dvorak, Dissonant Quartet and The Magic Flute, by W.A. Mozart, Ninth Symphony, by L. Beethoven, Guide to the Orchestra for Young People, by B. Britten or So I've Heard, a recompilation of music and information from different historical eras.

A Critical Point of View

A recent virtual conference carried out on Internet outlined the possibilities that would exist if music technology had a role in elementary music education. This topic has provoked a strong dissent among the presenters. Leaving aside the difficulties of forming the nuances of the discussion, I will attempt to condense the main contributions, which, in my opinion, constitute the synthesis of what currently is thought about technology in music education.

Doug Goodkin, a known specialist in methodology Orff, was against these technologies arguing we spend our lives working to understand what the body, the voice and the imagination can be capable of making. Furthermore, we have limited musical instruction time throughout the primary stage, a short period in which to communicate to the students our knowledge of music as well as our love of this art form. Goodkin ask a number of questions: Is it worth the time that is devoted to learn the operation of the system, the time employed in teaching it and the time that is not devoted to something else? Can we justify the monetary investment in a computer in order to obtain the supposed quality from presentation when there is not even money to pay the music specialists that are needed in the schools? Are the children working about a screen in the same way they would work together in the creation of a dance or music piece? Citing Postman, while simultaneously articulating ideas from Marshall McLuhan, Goodkin asserts that the technologies are not neutral, but have implicit values, educational definitions, implications related to the social and emotional processes, that radically transform to the users without taking into account the content. New technologies are not added to those which came before but aggressively replace them. He also argues about the effect of the large amount of time that the children devote to television screens and the need for a greater relationship to the real world.

Another point of view is presented by musician and programmer Jeff Evans, creator of the auditive training program Practica Musica. He argues that by definition the art is synthetic. The real world is something that each child must experience, but would not have to concern us if the computer eliminates the pleasures of the natural world. The cybernetic world is built with the imagination, an intellectual construction. It has its own captivations which are not the same as those of reality while being themselves no less real. No programmed musical performance can rival the content of a live performance. Hearing one is different than hearing the other. Evans, however, does not reject the use of the ordering when it is applied to those tasks related to the objective of acquiring a deeper comprehension and appraisal of the music. His examples include the invention of new melodies which the students transcribe by hearing and the creation of an endless number of variations of chord progressions for identification. These tasks are more applicable to the education at higher levels than basic teaching but the principle is the same: the computer aids music education, it does not replace it. Therefore, programs could be used outside the class to help train ears and minds in the purely technical aspects of music in order to take advantage of limited class time. For Evans, the computer is another tool, something else to use.

I share the opinions of Goodkin on music education, but I do not reject those of Evans. From my experience with technological tools in classes for adults, I have found that they are a helpful complement to the acquisition of a series of objectives such as the ability to imagine the music and other aspects related to the music reading-writing.

On the one hand, to experience aurally harmonic exercises through use of publishing score programs in a theoretical way helps the pupils facilitate the approximation of concept and sound reality, that is to say, among elements of the music reading and writing and its sound decoding. To elaborate specific didactic materials with technological tools (play-backs for performing, improvisation and movement, composition of curricular musical materials and popular song arrangements that support the scholarly activities programmed by future music educators provides procedures directly to areas not inserted explicitly into the curriculum of the specialist. This is true in the case of Composition and Instrumentation. Furthermore, they help these potential music teachers while they reflect on the Didactics of the Music, in developing a critical ear in the...
technologies which can spark the musical imagination as well as those technologies which can spark the musical imagination as well as the exploration of sound.

Without a doubt, I believe that this is the greater advantage that musical technology provided by musical technology in the training of the future Music Education Teacher. Coinciding with the opinions of Jeff Evans, I see that the auditive training programs can save much of the time dedicated by professors, conservatories and high schools to the monotonous and repetitious tasks that auditive training brings, that is, in the technical aspects of the musical language. During class time, the computer can help pupils to reinforce the concepts given in the classroom, while the teacher can devote the time of class to interact with the pupils, dance, move, play the instruments or sing with them. In this type of program the pupils receive more individual attention.

Nevertheless, I do not see clearly the application of the technological tools in Primary Education as part of children's curriculum. I do not accept the use of the technology with these children because there is a world to discover in an active way before they are drawn into the musical literacy mechanisms, that the technology facilitates. In my opinion, many schools around the world still lack material and human resources to give an adequate musical education and there are still a high number of educational centers that lack instruments or do not have specialists. Even where there are few of the problems of a material type, there are academic difficulties, including the small amount of time devoted to music in the curriculum.

Even if a child of this age can abstract and understand certain aspects of music reading and writing, I believe that it is fundamentally important to live music with all the body. This is a more important objective than providing students with theory and musical literacy through the technology. The child needs some tangible musical bases, lived and sensed, on which to build knowledge and skills that will help in developing values of cooperation, solidarity and respect. Music education has a strong socialization component which must be developed through relationships with other people, not with a machine. Computers and digital instruments can be in the background, manipulated by the teacher, providing a greater timbral wealth than that which customarily nowadays exist in the music classroom. This will give them, through the compositions and arrangements created by the teacher, a rhythmic guide to the pulsation which will help them to develop their internal pulse, as well as a guide for tuning. All of this will make it possible to work on musical pieces in a progressive way, with difficulties added to each surpassed phase, offering the possibility of assembling their proposals in collective compositions. A certain amount of class time can then be used by the teacher for greater intervention and interaction with the children.

Conclusions

From the perspective of school practice, technology is a very useful didactic resource in the music classroom. Electronic instruments, computer and music software constitute potent tools for the Music Educator. That technology will help in the elaboration of sound and written materials that will serve the children while they move, sing, perform, dance or improvise on whatever the methodological approach the educator uses. From the perspective of the integration of music technology in the Music Teacher curriculum, this has two sides: as a tool for future Music Teachers and as an element of reinforcement during the training of pupils. It is a teaching tool which constitutes a very useful instrument for the didactic elaboration of music materials. It is a useful apprenticeship tool as it provides elements of training, permits immediate hearings that can be musically imagined, facilitates approximations between abstraction and reality, and helps in the acquisition of certain procedures related to the areas of the Composition and the Instrumentation.

The elaboration of materials would necessitate the addition of music workstations for the music educator in each center of Primary and Secondary Education. These workstations would, at a minimum, have to consist of a computer, a MIDI keyboard synthesizer, and a score editor program. The keyboard synthesizer would serve not only as part of the teacher's workstation, but would add other instrumental possibilities to the classroom. A device with a very rich timbral range and a source of sound effects can be most helpful in the attainment of various objectives of music education.

Footnotes

based elementary science program adopted in local districts. The discs contained single frame pictures and diagrams, as well as very brief film clips. Some of the film clips had audio, but most of the discs did not. A large binder of teaching materials and prepared scripts was available. The materials were adaptable to any grade level by changing the language used in the script at the discretion of the teacher. Although most of the preservice teachers had no experience with videodiscs, they found them quite easy to use and manage. The major difficulty was locating the player and the materials at the schools as most teachers did not use either. Another videodisc program used in elementary classrooms was Science Sleuth by Tom Snyder Productions. This videodisc had a very different presentation mode. Students used a problem-solving approach to a scenario presented early in the disc, and the video stopped periodically to give them opportunities for discussion.

Although most preservice teachers had observed PowerPoint in use, they had not learned how to access it on the network nor how to develop slides for their own purposes. After presentations and experiences in the laboratory, PowerPoint became one component for a Methods class presentation on a conflict area of the world. Next, preservice teachers used the PowerPoint software to develop a lesson or lesson component for their field based teaching in the classroom.

HyperStudio became the required format for presenting a prepared set of mathematics cards for teaching metric measurement in the field based classrooms. Preservice teachers learned to create additional stacks of math cards, as well, and used these with their assigned students.

**Assessment**

The data from all participants - the preservice teachers, the classroom students, and the public school mentor-teachers - gave evidence of high evaluations of the performance of the different groups. Weekly reflections, pre and post interview data, portfolio assessments, the actual technology products, classroom students’ and preservice teachers’ self assessments and product assessments triangulate to give valuable in-depth information for ongoing and summative assessments of the technology emphasis in this Methods semester. These process and product data were qualitatively evaluated by graduate students (inservice teachers) and other instructors outside the instructional team with high scores on all measures used - a team prepared Likert-type scale and a program analysis.

**Afterward**

This major emphasis on the technology component for the Methods semester involves a large segment of the allowable hours within the Methods blocked courses for the teacher-in-training. Also, major logistic planning for use of the computer laboratory for initial teaching becomes a crucial component. The technology emphasis, however, continues to get high priority from the assessments of all participants. The input from student teachers and from the inservice teachers in the field also supports this focus. With major advances in the availability of technology in public schools and in teacher training institutions, our abilities to touch the world and our willingness to do so can only grow.

Preservice teachers excitedly share their e-mail messages from their assigned elementary students with variations of "Look at this question!" to "How will I ever find this information?" These preservice teachers in their Methods semester are exchanging questions and answers with the students from the classrooms where they will soon be teaching. Weekly e-mail messages from third and fourth graders ("What are fish scales made of?" and "Is fog the same thing as a cloud?") send these university students to a variety of sources as they prepare the interchange for their classroom keypals. The immediacy of a young student waiting for a reply offers excitement and motivation (Poling, 1994) as this methods section begins its final semester with university classroom instruction and field based teaching experiences before the student teaching experience.

Felt Need

Although technology projects had emerged in earlier semesters and students were required to participate in a technology literacy course, interview data showed that preservice teachers at this small southwestern university fit into a generalized ratio of 1/3 for each category of experienced, moderately experienced, and inexperienced users of computer technology. With this information and a new computer lab facility, the Methods team of three professors planned technology interactions with e-mail, videodisc, Power Point, and Hyperstudio to prepare preservice teachers to use the technology to implement an integrated six day teaching unit in their public school classroom during the semester. In addition, each preservice teacher used the Internet to pursue information for assigned research papers, for small group papers and presentations over current educational topics, as well as for locating answers to the questions of their keypals.

Another need was defined by the independent school districts who participate as partners with the teacher education program for field based experiences. Representatives from these districts function as a Board for input and planning. These districts had begun to purchase and equip their schools with computers, networks, software, and presentation facilities only to see them used on a very limited basis. Even though inservice had been provided in buildings where the equipment was located, there was ongoing concern from school district representatives that teachers found it difficult to plan and implement appropriate materials for this technology use in their classrooms. The Board requested and fully supported the planned Methods instruction and the field experiences with the strong emphasis for preparing future teachers to access, use, and facilitate the technology that was available in schools.

Theoretical Background

Various research based experiential models of learning (Bandura & Schunk, 1981) support components of motivation, observation, instruction, and presentation as learners acquire new technical skills. In addition, a constructivist approach (Merrill, 1991) to provide levels of assistance as needed to maximize learning, to scaffold, and to operate in the "zone of proximal development" (Vygotsky, 1986) undergirded the instructional team's planning and implementation of the technology goals for these preservice teachers. If a preservice teacher had experienced technology only as an end unto itself in earlier interactions, during the Methods semester, technology use would become a tool for instructional support, hopefully as commonplace and as transparent to the content and skills being learned as a piece of chalk, overhead projection marker, or a transparency.

Demonstrations, Applications

Planned sessions on technology use in the computer lab built upon learners' earlier experiences; however, parameters for the assignments were broad enough to allow the preservice teachers wide variations in their personal interpretations and applications for classroom use. The first aspect of technology to be instructed was e-mail because it would be an avenue of frequent use between the university students and instructors as participants shared reflections about Methods' issues from class time and field experiences. It was important for preservice teachers to experience e-mail as a service technology for information exchange, much as one would use a telephone. And most were able to do so; however, some still found themselves distrustful enough to share that they kept a hardcopy of each interaction.

The videodisc technology used by students was in the form of Windows on Science by Optical Data, a technology...
APPLYING COMPUTER IN TEACHERS’ CLASS PREPARATION ACTIVITY

Shi Shuen  Ren Yufeng  Ma Demin
Beijing Normal University  Beijing Normal University  Beijing Normal University

Computers in education can play a role in helping teachers prepare their class-teaching activities as well as assist or guide the students’ learning (Shi, 1995). Much attention has been devoted in recent years to Computer Assisted Learning, whereas less to the Computer Assisted Teaching to a degree. Nowadays advanced information technology, and in particular the computing technology, have been widely accommodated into the pre-service teacher education in China. But there are still a considerable amount of in-service teachers who have only a little, or even no experience working with computers (Shi, 1995). This paper examines the application of a CBE (Computer Based Education) system from the teacher’s side and depicts with discussion the effect of one Electronic Class Preparation System that aims to help teachers of the Chinese Language in senior-middle school. The conclusion we drew is that several factors have an impact on one information technology’s application and popularization. Among these factors that will have to be considered are (1) the user’s (i.e. the teacher’s) psychological acceptance to and his or her previous experience with the information technology, (2) the relevance of the information technology in solving specific problems, (3) the cost and accessibility of the information technology.

Introduction
Advanced information technology is currently particularly amenable to use in education and training, as a stage in the development of the technology itself (Cotterell, Ennals, & Briggs, 1988). It is recommended (Owen & Rowlands, 1992) that teachers in the ‘information age’ should a) make confident personal use of a range of IT devices and key applications; b) critically evaluate applications of IT in their subject specialization; c) plan and manage teaching experiences making appropriate use of IT; d) evaluate the changes in teaching and learning made possible by IT. So advanced information technology needs to be embedded in the whole of a student’s experience in teacher education.

In China the term “teacher education” generally denotes the pre-service and in-service education for those who are (to be) teachers. The pre-service teacher education is provided by the postgraduate schools of normal universities, teacher colleges (under-graduate), professional teachers colleges, and normal schools. The in-service teachers can take further study at the teacher’s advancement colleges or through radio-TV programs, correspondence courses, TV universities and spare-time colleges.

China’s teachers colleges, normal universities and institutions of education train teachers in specialized subject-matter areas generally based on the curriculum of secondary schools. In recent years, there have been great changes in the provision of programs at many normal universities and colleges. In addition to the subject matter areas corresponding to the curriculum of secondary schools, these universities and colleges have also established many new specialized courses, according to the requirements of social development and construction and the growth of science, technology, and education. These new courses are not exclusively designed for training teachers and include such offerings as Computer Science, Radio Electronics, Educational Technology, Information and Library Science, etc (Yang, & Lin, & Su, 1988). These courses are important to help teachers (or tomorrow’s teachers) gain the experience of IT usage and then make confident personal use of a range of IT devices and key applications in their teaching career. But we have to point out that although there is some good practice to be found in teacher education institutions, provision is patchy, and that all the elements of good practice were never found together in a given institution. The lack of resources is thought to be a main barrier (The Teacher Today, 1990). Another problem is that tomorrow’s teachers are currently being educated (albeit inadequately) in the use of yesterday’s technology, and this is clearly inappropriate (Langborne et al., 1989).

On the other hand, despite the rapid development in the past few years, neither pre-service nor in-service programs of teacher education have meet the needs of elementary and secondary schools in either quantity or quality, while the proportion of unqualified teachers in elementary and
secondary schools is exceptionally high (Yang et al., 1988). According to present regulations, completion of an undergraduate program is the minimum standard for the preparation of senior middle school teachers. However, a large number of schoolteachers currently in the classroom have not met this standard. There is great demand for in-service teacher education at every level.

All in all, the prominent problems in the current teaching staff are low academic degrees, outmoded knowledge, inability to grasp and use advanced techniques and teaching mediums, etc.

Background

The advancement of computing technology gives rise to the performance/cost ratio of the computer, and this in turn has encouraged more and more middle schools in China to establish (micro)computer laboratories. At first computers were mostly IBM/PC 386 or its compatible, which are still in use now. But the majority of computers in middle schools today are PC486 or above. At the same time as the hardware is available, many people realize the need for software or courseware. Teachers and trainers in non-computing subjects have waited for the technology to deliver its promised benefits in a manner that might benefit education and training in their area. Some of them have been disappointed because the results do not live up to initial hopes and expectations. One problem is the common belief that the power lies in the technology, rather than the proper usage (Norman, 1987). Some researchers (Cotterell et al., 1988) have pointed out that in education and training we do not aspire to perfection: we seek to enhance our understanding and that of our students and trainees, equipping them to deal better with problems in the real world. We believe that advanced information technology, and in particular computing science, can offer some powerful new tools with which we can cast new light on old problems in teaching and training (Shi, 1995).

Computers can be used as a teaching resource, which both supposes and facilitates the adjustment of teaching method to the learning processes of pupils. Teachers can use the computer as a tool in their practice. Nowadays classroom teaching is the main organization form in teacher's vocational practice in China. So we believe that the quality and efficiency of the classroom teaching influence the quality and efficiency of the whole education. In order to improve the quality of teaching teachers we must fully prepare each lesson (or lecture). Considering its noticeable ability in information processing it is possible for the computer to play an important role in helping teachers in their classroom in teaching preparation activities. Computers and their applications can also be utilized by teachers to assist with record keeping and paperwork (Langhorne, Donham, & Gross, 1989). With necessary peripherals it can produce some kinds of teaching materials such as handouts used in the classroom, overhead projector transparencies, etc. Furthermore, the computer's large amount of storage capacity and quick information retrieval can provide great convenience to the teacher's looking up of information in their lesson (lecture) preparation process.

Now let's examine a specific example of a computer assisted lesson (lecture) preparation system.

The Computer Assisted Lesson Preparation System (CALPS)

This CALPS is designed to run on the Chinese platform of Win3.x/95. So its appearance and user-interface accord with standard Windows style. This can benefit those users who have experience with Windows applications. The main interface when CALPS has started is shown in [figure 1].

The main interface consists of title bar, menu bar, general library function panel, special library function panel, browsing function panel, status bar and content display area. As a whole, the CALPS can be divided into two parts: General Library and Special Library. The General Library is both a toolkit and a database. It provides an Electronic Dictionary that contains about 7,000 common Chinese characters with phonetic alphabet, explanation and pronunciation [see figure 2].
• "writers and their works" which contains the works, biography, comments of writers involved in the textbook;
• "text material" which contains some versions of Chinese Language textbook used in senior-middle school;
• "reference examination" contains large amount of test papers.

The CALPS provides search menu command for the user to navigate the General Library and bookmark menu command to mark up the information found.

The special library function panel has two push buttons. The button on the above leads to the "outline prompt", where the user can read the syllabus, teaching goal, teaching requirement, contents of textbook, writing instruction, questions which should be paid attention to during instruction, literacy basic skills, and basic knowledge instruction requirements, etc. By clicking the other button ("contents of unit") on the special library function panel, the user can get into the interface with "unit course options". The unit options comprises courses within the unit, target requirements, test for this unit, and extracurricular activities recommended.

The course option consists of "lesson preparation guidance", "collection of data", "teaching method prompt", "teaching notes samples", "intensive research", "feedback and summary". In concrete, "lesson preparation guidance" comprises twelve items: a) teaching goal requirements; b) key and difficult points; c) introduction of the author; d) background of the writing; e) key words; f) grammar and rhetoric; g) paragraph comments; h) thesis; i) characteristics of writing; j) relevant knowledge; k) exercises; l) multimedia selection guidance. By clicking the mouse the user can select one item to see its detailed contents. The "collection of data" unit provides information about the authors, background of the day, word explanation, grammar and rhetoric, paragraph structure, relevant knowledge, exercises and tests, and multimedia data. Using the "intensive research" and "feedback and summary" unit the teacher can enhance understanding of knowledge, sum up teaching experience and raise vocational proficiency, cultivate the ability to do educational research (the user’s guides, 1996).

For the convenience of the user, the CALPS provides several assistant functions, including giving comments, defining bookmark, index, page down/up, enlarge/reduce font size, changing color and printing. So the teacher who has experience using Windows applications can master the CALPS quickly.

Assessment and User Feedback

The CALPS emphasizes the teacher’s leading role in the teaching and learning process and lays stress on bringing the initiative and creativity of teachers into full play. Its contents closely adhere to the syllabus and give prominence to the key and difficult points of teaching. Providing full support for the whole process of teacher’s teaching activity, it is helpful to the teacher in producing effective teaching notes, broadening one’s view of teaching, and forming his or her own teaching ideas, to achieve the teaching goal at the end.

To install the CALPS, the computer hardware should meet the following demands (the user’s guides, 1996): PC386/40 (486/66 or the above are recommended); 4MB 0(8MB or the above are recommended) memory; double speed CD-ROM driver; 16-bit sound board; hard disk 5MB free.

These requirements are not very high. But the fact is that there are a considerable number of computers in schools in China that can not meet the demands, especially the demands for CD-ROM driver and soundboard.

Some researchers (Rothan, Clerc, & Simonnet, 1988) pointed out that there remains a gap between the few teachers who use educational or professional software and sometimes even write their own programs, and the wavering majority who still feel uneasy at the idea of appropriating new technological tools. Training teachers to use computers in their classroom is a difficult problem for schools. Teaching with a computer is a skill. For teachers to develop skill, there must be opportunities for practice, both guided and independent (Gardner et al., 1988). It is also argued that one step toward making teachers feel comfortable with the computer as a teaching tool is to assist them in learning to use it as a personal tool. (Langhorne et al., 1989). A noticeable characteristic of the CALPS is simplicity of operation. Users can do almost everything only by clicking the mouse button. This conforms to the character of the user, i.e. the teacher. Teachers who have Windows operation experience need no special instruction to use it. The simplicity is also an advantage for those teachers who have no experience in computer usage. The teachers can acquire experience while using CALPS. Because they have had classroom experience, which can help them to make judgements about the educational desirability of IT usage, they can produce effective pedagogical sequences using the computer in their subject areas (Knupfer, 1993). It is obvious that the provision of in-service teacher education is often more expensive and much more difficult than pre-service owing to the fact that, in addition to the resource problems shared with the pre-service sector, high substitution costs may be incurred if teachers have to be relieved from normal teaching duties for the duration of courses (Gardner, Fulton, & Megarity, 1988). The CALPS is so easy to use that it can even be mastered by self-teaching. This can save much time and money.

Considering the contents provided by the CALPS, we could find that the data are abundant, plentiful, and convenient to use. Using the CALPS, a teacher does not need to
loop up other materials for data. This can save a lot of time and effort. Taking advantage of multimedia, the CALPS also provides text recitation with video, giving a vivid presentation of the text (see figure 3).

Just as everything has two sides, the simplicity of operation appears to be monotonous. The whole CALPS behaves like a database. With respect to the slowness when it runs on computers such as PC80386, and considering the fact that there are teachers who prefer to write notes or make plans on paper rather than ‘think on the screen’ (using the computer as a word processor), such a large, slow data base is not comfortable to use.

**Conclusions**

Advanced information technology needs to be embedded in the whole of a student’s experience in teacher education to enable them to make confident personal use of a range of IT devices and key applications. In-service teacher education should be appointed the task of giving the teachers experience in IT usage. The aim is to enable teachers to produce pedagogical sequences using IT in different subject areas. Considering the cost of in-service teacher education, some computer programs with self-taught characteristics are preferred in China. Specifically through the use of the CALPS we can draw the following conclusions:

Information technology, especially computer technology can benefit the teacher’s classroom teaching preparation activities to a considerable degree, with limitations set by several factors such as: a) the user’s (i.e. the teacher’s) psychological acceptance to and his or her previous experience with the IT, b) the relevance of the IT in solving specific problem, c) the cost and accessibility of the IT.

EXPLORING PROBABILITY WITH PRESERVICE TEACHERS USING DOMINOES, DICE, AND TECHNOLOGY

Holly Lynne S. Drier
University of Virginia

As part of their mathematics education methods courses, preservice teachers need to experience effective mathematics instruction. This instruction needs to address mathematical understandings of concepts, a variety of instructional methods, and how to use manipulatives and technology to facilitate mathematical learning. The use of dominos, dice, and a computer-designed program can provide this experience and enhance the exploration of probability concepts and pedagogy in preservice mathematics methods courses. This paper highlights an innovative and integrated probability unit used to introduce preservice elementary teachers to the use of technology to enhance the exploration of complex concepts such as randomness, probability, and graphing. The unit was originally developed by the author and Paula White, an elementary teacher whom the author co-teaches with several times a week. The unit has been used in first and third grade mathematics classrooms as well as an elementary mathematics methods course.

By utilizing concrete experiences with familiar objects (dominoes and dice), the power of random generation, and visualization of data, this unit of study enables preservice teachers to gain insight into experimental and theoretical probability through discovery activities. The connection between the physical dominos and dice and the computer program is an essential aspect of the exploration. Students can begin their exploration with physical objects and use the computer program (designed in Oracle Media Objects) to extend their exploration and make the organization and analysis of data more efficient. This unit also creates a forum to discuss pedagogical issues of implementing a unit which:

- spans objectives across several mathematical content strands (i.e., probability, statistics, computation, estimation, patterns, number sense),
- addresses the National Council of Teachers of Mathematics (1989) four broad goals of problem solving, communication, reasoning, and connections, and
- incorporates effective use of technology.

For example, the exploration begins with each student randomly picking a domino from a double-six set (without the pieces that have a blank side). Each student should have a different domino (21 possibilities). If there are more than 21 students in the class, some students can share the same domino identity. For this purpose, the same as since they are just a rotation of one another. The domino set will only contain one of the pair (2,1).

Students become familiar with their domino identity and are oriented to the computer program by a demonstration on how to use the “domino maker” (see Figure 1) to pick a specific combination of dice and make a matching domino or to randomly roll a pair of dice that creates a corresponding domino. The “flip” feature can be used to show students how their domino appears in reverse order. Students who have a double ( ) notice that their domino looks identical when rotated but that all other dominos look different when rotated. This leads to a discussion that students with “double” dominos can only make their domino one way while all other students have two ways to make their domino.

The exploration continues with students physically rolling two dice in the classroom until they roll the combination of numbers that represent their domino identity. This quickly becomes a tedious and time-consuming task. Students are also not able to keep a visual representation of each number combination in front of them. This level of abstraction can be difficult for students.

However, using the computer-designed program allows the students to see the dominos that correspond to each roll of the dice and provides a work space for the students to sort the dominos by characteristics chosen by the user (see Figure 1). The students can randomly generate combinations in the program until their domino identity appears. The counter within the program automatically keeps track of the number of dominos created so that the students can quickly analyze the data. After several experiments,
students will notice the pattern that "doubles" take longer to appear during a random generation of two dice.

![Image of dice and dominoes]

**Figure 1:** Example of sorting the dominoes by the first side

The students can also sort the dominoes according to the sum of the two numbers in the combination. As they do this, they get practice with their basic addition facts and soon realize that the sums range from 2 to 12 and that many sums have different number combinations that total the same amount (i.e., the sum of 6 can be made with the pairs 1,5 5,1 2,4 4,2 and 3,3, where 1,5 is a distinctly different from 5,1).

By using the computer program, students can sort the dominoes according to sums in such a way that actually builds a visual pictograph that leads to analysis of the distribution. The pictograph shown in Figure 2 shows the results of 75 rolls of dice. The corresponding dominoes were then sorted by their sum in the columns of the bar graph. Organizing the data this way leads nicely into a discussion of which sum is more likely to appear and why. Thus, experimental and theoretical probability can be discussed in a concrete way for students to understand! Repeat experiments will allow students to compare their results and make generalizations.

The powerful interplay between real objects and the computer representation of those objects provides a wonderful scenario to allow both preservice teachers and students to experience probability issues in a meaningful exploration. Preservice teachers are able to learn probabilistic concepts, different methods of instruction, and how to use manipulatives and technology as tools for teaching and learning.

At the Curry Center for Technology and T-eacher Education, our goal is to educate preservice and inservice teachers on effective and appropriate uses of technology in all curriculum areas. The probability unit is an example of how technology enhances students' experiences with concepts that would be too time-consuming to explore with paper and pencil. This probability exploration represents only one of many projects being developed for this purpose. For more information on the computer program or the probability unit, please contact the author.

**Figure 2:** Sorting the dominoes by sum and creating a pictograph of the distribution

Using the Stages of Concern Questionnaire as an Ancillary Tool to Evaluate the Effectiveness of the TEAM Approach

J. Kevin Maney  
Miami University  
Douglas M. Brooks  
Miami University

This paper focuses on alternative evaluation procedures to measure the effectiveness of one of the components of the Technology in Education Adoption Model (TEAM), the computer module of EDT 343 Media and Technology For Teaching, at Miami University and Partners in Learning, a successful Ohio SchoolNet Prototype in Oxford, Ohio. In addition to standard course/workshop evaluation forms, Stages of Concern Questionnaire (SoCQ) data have been systematically collected since the inception of TEAM which indicate the approach used to teach pre- and inservice teachers is also effective in reducing their Stage 2 Personal concerns. Since Stage 2 Personal concerns are a source of teacher resistance to the adoption of education technology, it is critical that those concerns be significantly lowered during pre- and inservice professional development. In addition, 343 students consistently show gains in Stage 4 Consequence concerns and Stage 5 Collaboration concerns which indicate that they are beginning to focus more on effective uses of technology and how technology will impact their students and less on the actual mechanics of using technology. These are desirable outcomes from a TEAM perspective because they indicate that the technology is becoming more “invisible” for pre- and inservice teachers. In other words, pre- and inservice teachers begin to focus more on teaching with technology and less on how to use it, an indication that they have adopted education technology. Combined with consistently high student ratings of the EDT 343 computer module and Partners in Learning “playshops,” the SoCQ data suggest that an authentic approach to learning technology is effective for both pre- and inservice teachers. Moreover, in K-12 contexts, the concerns identified by the SoCQ can also be found in the different stages of teachers' instructional evolution as identified by Apple Classroom of Tomorrow (ACOT) research (Sandholtz, Ringstaff, & Dwyer, 1997). Consequently, SoCQ data can be used to help identify where teachers currently fall within an instructional evolution continuum and help planners to create unique professional development opportunities that meet the concerns of the participants and provide them with methodologies appropriate for their particular stage of instructional evolution. With appropriate and effective professional development opportunities, teachers are more likely to use and integrate education technology into their respective courses of study.

Background and Context of TEAM

In the state of Ohio, two state technology initiatives, SchoolNet and SchoolNet Plus, are being advanced. The goal of SchoolNet is to hardwire every classroom K-12 for network access while the goal of SchoolNet Plus is to provide one computer workstation for every five students in grades K-4. Together both initiatives represent a $500,000,000 commitment by the state to infuse technology into K-12 education. Moreover, new state licensure standards that take effect in 1998 require that each teacher candidate demonstrate an ability to integrate technology into curriculum and instruction. Combined, these events provided the context and rationale that led to the development of TEAM at the School of Education and Allied Professions. Miami University, Oxford, Ohio.

TEAM Goal, Theory, and Empirical Foundations

The goal of TEAM is straightforward: to systematically provide multiple opportunities for undergraduates to use and integrate technology into curriculum and instruction so that as inservice teachers they will: (1) be more likely to adopt education technology; (2) be prepared to use SchoolNet/SchoolNet Plus resources as powerful tools to support and enhance teaching and learning; and (3) meet new state licensure requirements.
The theoretical constructs of TEAM are derived, in part, from the model of instructional evolution developed from ten years of research in the Apple Classroom of Tomorrow (ACOT) project (Sandholtz et al., 1997) as well as the Concerns-Based Adoption Model (CBAM) developed by Gene Hall and associates (Hall, Wallace, & Dossett, 1973). The ACOT model provides an empirical framework in which to discuss the process of technology adoption whereas CBAM’s Stages of Concern Questionnaire (SoCQ) provides a statistically valid and reliable instrument to measure pre- and inservice teachers’ concerns about technology throughout the adoption process. Used together, the SoCQ and the ACOT model help document the effectiveness of TEAM by providing both quantitative and qualitative data.

**ACOT’s Model of Instructional Evolution**

For more than a decade, the ACOT project studied the effects of technology on teaching and learning. In the process, researchers developed a model of instructional evolution through which teachers progress as they adopt and integrate technology into the curriculum: (1) Entry: Teachers focus on technical issues, learn how to use the technology, become greatly concerned about time, and face typical first-year teacher problems, e.g., discipline, resource management, and personal frustration; (2) Adoption: Teachers show more concern about how technology is going to be integrated into daily instruction; (3) Adaptation: Technology becomes thoroughly integrated into traditional classroom practice and student productivity emerges as a major theme; (4) Appropriation: This is more a personal milestone and a turning point for teachers in which they come to understand technology and use it effortlessly to accomplish real work (invisible technology); and (5) Invention: Teachers experiment with new instructional practices and explore new ways to interact with their students and other teachers. Teachers also begin to question old practices and speculate about the causes for change in their students’ work (Sandholtz et al., 1997).

**Overview of CBAM**

The Concerns-Based Adoption Model (CBAM) was developed by Gene Hall and associates (Hall et al., 1973) and posits that change is a process, not an event, and understanding the point of view of the participants in the change process is critical (Hall & Hord, 1987).

As a result, CBAM identified four clusters of concerns through which school personnel progress related to the change process. These concerns are: (1) Unrelated concerns, those which have nothing at all to do with the innovation under scrutiny; (2) Self concerns, those which deal directly with the person’s perceived ability to handle the innovation; (3) Task concerns, those which relate to the actual use of the innovation and indicate that the decision to adopt has been made; and (4) Impact concerns, those which go beyond usage concerns and focus on the effect of the innovation on others (Hall, George, & Rutherford, 1979).

From this model, the SoCQ was developed which contains seven different Stages of Concern and addresses how teachers or others perceive an innovation and how they feel about it. Using the Stages of Concern, Hall and associates concluded that it is possible to predict the most likely concerns profile (Figure 1) for a teacher about to embark on a change effort.

![Hypothetical Teacher's Concerns Profile](image)

For example, if no unusual information is known about the innovation or the teacher, then the prospective users of the innovation are assumed to have typical “non-user” concerns. In other words, their concerns will be more intense at the Stage 0 Awareness, Stage 1 Informational, and Stage 2 Personal levels and relatively less intense on the Stage 4 Consequence, Stage 5 Collaboration, and Stage 6 Refocusing levels. In addition, if Stage 2 Personal concerns are not resolved but are further heightened, then the entire evolution of the change process and the potential for the arousal of higher stages of concern are endangered (Hall & Hord, 1987).

**TEAM Description**

While TEAM is operationalized in four different courses offered by the Department of Teacher Education (EDT) at Miami University, only one course, the computer module of EDT 343 Media and Technology For Teaching, is described here. In this module, students are first exposed to education technology over a seven week period. The main instructional objective is to provide students with authentic contexts in which they learn how to integrate technology into the curriculum and to use technology to enhance student learning. Toward that end, students are divided into interdisciplinary/intergrade teams and are required to plan, peer teach, and evaluate a problem- or
project-based unit (or part of a unit) of instruction that uses technology to support and enhance learning. During the first 4 1/2 weeks students are given “need to know” instruction in word processing, database, network and web conferencing resources, an electronic gradebook, and multimedia production tools (digital photography, audio and video digitization, web-based multimedia resources, and scanning). Students are also introduced to constructivist learning and instructional design models and asked to use the above technologies within these approaches to teaching and learning. During the last 2 1/2 weeks student teams are each given 300 minutes of class time to peer teach their lessons and must demonstrate their ability to use the technologies as both productivity and learning tools to accomplish their stated instructional objectives. All lessons are videotaped and students are asked to analyze their performance after they have completed their teaching obligations. This approach allows students to learn necessary teaching and technology skills within authentic contexts, much like inservice teachers do. For example, peer teachers use ClarisWorks word processor to create their lesson plans and instructional handouts and create databases to use as classroom management and instructional tools. Internet, web, and multimedia resources are integrated into ClarisWorks slide shows that peer students create and present as part of their assigned tasks during peer teaching. Peer teachers use an electronic gradebook to record and report grades and attendance data to their students. All students are also required to use Internet e-mail to “ask an expert” about teaching content and to use Conferencing on the Web (COW) to ask SchoolNet teachers about teaching strategies related to using technology. To offer prospective employers a glimpse of their teaching with technology skills, student teams digitize video of their teaching which is then published to the web along with other relevant data about the lesson and themselves. Using this approach offers two main advantages: (1) students learn how to properly use technology within authentic educational contexts; and (2) skill development is embedded in these activities rather than through a direct instructional approach. Evidence of the effectiveness of this approach to learning technology comes from: (1) pre/post Stages of Concern Questionnaire (SoCQ) data; (2) COW entries and class discussions that pertain to the adoption of technology; and (3) course evaluation data.

This same approach was also successfully used during technology “playshops” which were conducted during the summers of 1996 and 1997 at Talawanda City Schools, Oxford, Ohio, a successful Ohio SchoolNet Prototype, in which teachers were trained to use SchoolNet and other technology resources. During the first Playshop (1996), whole group instruction was used only once at the beginning of the two week period to help participants develop a “Big Picture” about using SchoolNet and consisted of a demonstration on how a typical teacher might use SchoolNet resources in his or her classroom. Teachers then went to their respective classrooms and used the district’s telecommunications server and network to participate in simulations where they defined potential uses of networks and technology and began to develop technology-based resources for their respective courses for the coming school year. This same approach was used the following summer only it was expanded to meet building-level needs by conducting “just-in-time” mini-workshops based on participants’ stated needs, both for their classrooms and for their buildings. Consequently, teachers not only learned how to use SchoolNet resources, but they also began to learn when and why to use these resources. In other words, learning to use technology was done within the context of their specific jobs, thus giving participants a better feel for how they might begin to use technology. Evidence of the success of this instructional approach came from: (1) pre/post SoCQ data (which was also used to help develop the learning activities for the playshops); (2) positive feedback from playshop evaluations; (3) increasingly positive messages posted on the telecommunications server as the playshops progressed; and (4) the fact that many participants stayed and worked long after they were officially dismissed each day.

Discussion

To help evaluate the effectiveness of both the computer module component of TEAM and the playshops, multiple indicators were and are used in addition to standard course/ workshop evaluation data. These indicators include students' reflections posted on COW and pre- and post-surveys of the SoCQ. Students take the pre-SoCQ via the web during the first day of the computer module which gives them and the instructor some immediate baseline data about their concerns dealing with education technology. At the end of the module, students take an identical online post-SoCQ which gives them a chance see how their concerns about education technology have changed over the seven week period. The pre/post data are then analyzed to look for significant differences within individual stages and to create composite class concerns profiles. This procedure was also used during the previously discussed playshops.

As teams begin to teach in the EDT 343 computer module, a predictable pattern emerges. The first two teaching teams are terribly concerned about using technology in their lessons and tend to neglect good instructional practices such as informing learners of the lesson’s objective or having learners recall needed prerequisite knowledge and skills. Questions that their peer students ask them are typically “how to” kinds of questions and usually both peer teachers and students are more concerned about using the technology rather than completing their lessons or assignments. However, since all students get their skill development through repetition and practice within the context of
the lessons peer taught, by the time the last two teams teach, questions begin to shift from technology-related issues to teaching and learning issues. Curiously, students consistently report that not enough time is given in class for skill development, yet most students agree that by the time the last team has taught, they are no longer concerned about how to use the technology and are more concerned with how the technology will impact their students. The SoCQ data typically confirms this phenomenon by indicating that many students begin to lose their Stage 2 Personal concerns about teaching with technology and increase their Stage 4 Consequence concerns, an indication that students are beginning to focus more on the impact of technology rather than the technology itself. However, there typically isn’t much change in Stage 3 Management concerns which deal with the students’ concerns about being able to use technology. Perhaps this can be explained by the fact that most students start with a “non-user” concerns profile with its attendant relatively low Stage 3 concerns and by the time they take the post-SoCQ, they have mastered using the technology and are simply not very concerned about this aspect of it. To test this hypothesis, the SoCQ would have to be given right before student teams began their teaching when their “how to” concerns are at a peak.

Students’ progress is also consistent with the ACOT model of instructional evolution developed by Sandholtz et al. (1997) because students typically demonstrate Entry and Adoption level concerns about focusing on technology, learning to use it, and integrating technology into their lessons. Moreover, students are usually very concerned about the time it takes to teach with technology and most display personal frustration with the process, all typical Entry level concerns of teachers. As more teams peer teach, however, these concerns diminish and both peer teachers and students generally begin to become more productive in using the technology (Adaptation) and use it effortlessly to accomplish real work ( Appropriation). Because Invention level behaviors are embedded in the course requirements and because there is simply not enough time for students to really display authentic behaviors typical of this stage, it is difficult to determine whether any of them ever reach this level. After all, seven weeks just is not long enough to really change students’ beliefs about teaching and learning although many students show gains in Stage 4 Consequence concerns and Stage 6 Refocusing concerns which indicate that they are thinking about how technology impacts students and different ways it can be used other than what was introduced to them in the computer module.

Quantitative and qualitative results from the computer module evaluations are also consistently positive and students, for the most part, indicate that they plan to use technology when they become inservice teachers. However, there are consistent complaints about not having enough time to learn all the technologies introduced in the computer module nor do students feel comfortable about their ability to perform basic troubleshooting functions when the technology does not work. This indicates that while students significantly reduce their high Stage 2 Personal concerns, those concerns still persist at a relatively high level.

In general, however, these are desirable outcomes from a TEAM perspective because the Concerns-Based Adoption Model posits that relatively high Stage 2 Personal concerns can act as a significant barrier that prevents teachers from adopting and using an innovation. Moreover, the increasing Stage 4 Consequence concerns indicate that 343 students are becoming less concerned about their ability to use the technology within teaching and learning contexts and more concerned about how the technology will impact their students, an indication that students have made the decision to adopt and use technology in their professional careers.

SoCQ data can also be used to measure the progress of inservice teachers related to technology adoption. As teachers begin to adopt and use technology, their concerns need to shift from Personal concerns to Impact concerns to reduce potential resistance to the adoption of education technology. SoCQ data can therefore be used to ensure that this phenomenon happens by identifying the current concerns of teachers and helping planners develop relevant professional development activities which address these concerns. While this obviously takes more planning and preparation, school leaders will find that overall satisfaction with professional development activities increases because the concerns of all participants are being addressed. This also helps explain why some teachers find particular professional development opportunities a waste of time while others find the same opportunity richly rewarding.

Conclusion

TEAM offers a systematic approach to preservice teacher education in the area of technology adoption and utilizes the power of network technologies to connect preservice teachers with inservice teachers, an approach endorsed by the Office of Technology Assessment (1995). The model recognizes the importance of learning technology within the context of authentic educational experiences and attempts, through a series of courses, to provide students with multiple opportunities to teach with technology instead of simply teaching them how to use technology. This goes well beyond the standard practice of technology training found in most teacher education programs today and can serve as a useful model for other interested faculty. Moreover, TEAM uses an integrative approach to technology adoption. There is no “technology ghetto” supported in this model and empirical data suggest TEAM is effective in accomplishing its objective of encouraging preservice teachers to adopt technology in their entry-year and beyond. TEAM also has a web presence at http://www2.eap.muohio.edu/TEAM/ which interested parties
can access to learn more about this approach to education technology adoption.

EXAMPLES OF BEST PRACTICE IN THE USE AND INTEGRATION OF EDUCATIONAL TECHNOLOGIES FOR K-12 TEACHER PREPARATION

Kay Persichitte
University of Northern Colorado

During 1996, a team of three researchers from the University of Northern Colorado were selected to conduct a study for the Research and Information Committee of the American Association of Colleges for Teacher Education (AACTE). The focus of that research effort was to investigate the adequacy of the technological infrastructure for information technologies (e-mail, Internet, distance education) at individual Schools, Colleges, Departments of Education (SCDEs) as well as across a large sample of SCDEs. Results clearly indicated that: (a) an overwhelming majority of respondent SCDEs had adequate infrastructure to support the use of information technologies and (b) over 95% of the respondent SCDEs had faculty and students who were using information technologies (Persichitte, Tharp, & Caffarella, in press; Tharp, in press). While these results were satisfying for their potential impact on the preparation of preservice teachers, the researchers were further interested in the actual uses (both quantitative and qualitative) of multiple educational technologies. Thus, the same researchers found themselves engaged in the study which is the topic of this paper.

Many recent reports and research projects have identified a gap in the readiness of novice teachers to effectively utilize educational technologies within their classrooms for curricular or instructional purposes (e.g., National Commission on Teaching and America’s Future, 1996; Office of Technology Assessment, 1995; American Association of Colleges for Teacher Education, 1997; Awbrey, 1996). The purpose of the case study in integration of educational technologies is two-fold. First, to document and analyze factors, both positive and negative, associated with the integrated use of educational technologies within SCDEs. Secondly, to develop configurations (rich descriptions) of best practices of technology use and integration to serve as models for preservice teacher program revision and revitalization. Site visits were conducted at the University of Arkansas at Fayetteville, Graceland College in Iowa, and the University of Virginia Curry School of Education. [At the time of this printing, site visits were still in progress. Preliminary results of the data analysis will be presented at the SITE 98 Conference.]

Research Questions

The following research questions were used to guide the study and to develop the interview protocols.

RQ1: What are the characteristics of preservice teacher faculty, students, curricula, and programs which would currently be considered examples of “best practice” in the use and integration of educational technologies for the preparation of K-12 teachers?

RQ1a: How have these best practices evolved?
RQ1b: What documentation and/or artifacts lend support to the effectiveness of these best practices?
RQ1c: What are the “secrets” and the cautions which should be shared with other SCDEs as we strive for improved preservice teacher preparation in the use and integration of educational technologies?

RQ2: What are the resultant impacts of these best practices on preservice teacher performance during: (a) field experiences; and (b) student teaching?

RQ2a: How has the use and integration of educational technologies within the preservice teacher preparation program(s) affected the SCDE related to planning for, maintenance of, and meeting user demand with existing infrastructure?
RQ2b: How has the use and integration of educational technologies within the preservice teacher preparation program(s) affected the preservice teacher faculty and curriculum?

Research Design

This study is a qualitative, case study analysis of three AACTE member SCDEs. The three teacher preparation institutions were selected by the Research and Information Committee of AACTE. Specifically, the research team (Persichitte, Caffarella, & Tharp) employed an empirical phenomenological observation method; gathering perceptual descriptions from people who are involved in the actual experience of preservice teacher education in combination.
with the integration of educational technologies. All data collected were documented, transcribed as necessary, and reviewed by each institution prior to any presentation or publication of results. Data were triangulated for each institution with observations, interviews, and concerns survey data (Hall, Dossett, & Wallace, 1973).

During the site visits, we observed: (a) SCDE classrooms, (b) SCDE computer/media lab facilities, (c) two or three methods classes, and (d) other general access to campus information technologies. At each site, we interviewed: (a) three to five teacher preparation faculty, (b) the lead administrator in the professional education unit, (c) three to five teacher education students (variety preferred; e.g., differing stages of their program, non-traditional student, elementary/secondary), (d) two to four teacher education students who were student teaching, and (e) two recent graduates of the SCDE who are now classroom teachers. The third set of data which we collected was concerns survey data. We asked that all those who consented to interviews complete the survey. The paper survey required about thirty minutes to complete. These surveys were sent out in advance of our site visit. In general, we informed the host institutions that we were interested in visiting with faculty and students who have demonstrated high interest in further integration of educational technologies within their professional endeavors or who have become role models among their peers for continued technology integration efforts.

Data Analysis

Data other than the concerns survey data will be coded for electronic analysis using QSR NUD*IST, a software application designed for the manipulation and analysis of ill-structured data. Observation data will be used to develop an in-depth description of the degree of integration of educational technologies (both in amount and type) and the naturalistic/environmental variables which were most salient within each institution. Cumulative analyses will focus on: (a) providing suggestions for strategies and interventions ("best practices") to facilitate the further integration of educational technologies within preservice teacher preparation, and (b) presenting one or more implementation models for SCDEs characterized by similar environmental variables. The interrelated elements of the systems under consideration in this study are complex and must be viewed with attention to the dynamic nature of educational technologies and the contemporary external influences on teacher preparation. The phenomenological approach combined with the site visit will allow the researchers to maintain a systems perspective for this study.

Summary

This research effort is an attempt to look beyond issues of access to technology; to instead, focus on identification of exemplary uses of educational technologies within SCDEs. As trained educational technologists, we agree with Hall and Hord (1987) when they write, "For schools to improve, teachers must change. For teachers to change, there must be appropriate and promising practices and procedures (i.e., innovations) that they develop or adopt, and, when necessary, adapt. Student achievement and other desired outcomes are enhanced when teachers improve their practices and use more effective instructional resources" (p. 5).

Effective and efficient utilization and integration of educational technologies will not occur without substantial investment by both the individual classroom teacher and the SCDEs which prepare them. In a description of the Apple Classrooms of Tomorrow (ACOT) project, Sandholtz, Ringstaff, and Dwyer (1997) say that, "[T]echnology by itself was not the silver bullet. In fact, it added another layer of complexity, a whole new set of things for already overworked and stressed teachers to learn and manage...Its [technology] use in instruction and learning changed as teachers themselves changed" (p. 36). Hopefully, the results of this research project will provide a foundation upon which other SCDEs can build as more external communities move to hold SCDEs ultimately accountable for the improved education of the children in our public schools.

Acknowledgements

Special thanks to the American Association of Colleges for Teacher Education for their support of this research effort. Special thanks, also, to Graceland College, the University of Arkansas at Fayetteville and the University of Virginia Curry School of Education for their hospitality and willingness to share. Finally, thanks to Wes Leggett, a doctoral student at the University of Northern Colorado who served as a research assistant for the data gathering.

Preservice Teacher Education — 705

Kay Persichitte is an Assistant Professor of Educational Technology in the College of Education at the University of Northern Colorado, Greeley, Colorado 80639. Voice, Office: 970 351-2913, Fax, Office: 970 351-1622. E-mail: persi@edtech.UNCo.edu.
One of the major challenges facing the educational profession during the 1990s is the improvement of education in urban areas. Currently, approximately 39% of Latino American children and 46% of African American children live in poverty (National Center for Education Statistics, 1994). With large concentrations of minority children in urban areas, providing quality education to students in urban areas during the 1990s and beyond is an especially challenging proposition. Nevertheless, urban school districts have more difficulties in recruiting teachers than do other districts. According to the findings of Choy, Henke, Alt, & Medrich (1993), districts having 20% or greater minority enrollment found it harder to find qualified teachers. For inner city schools, teacher shortages are three times higher than for other districts (Darling-Hammond, 1990).

In spite of the shortage of qualified teachers in urban areas and eagerness to enter the teaching profession on the part of the preservice teachers, education graduates so often are reluctant to seek careers in urban areas because of real and imagined fears. The Urban Education Initiative developed at Shippensburg University is one of the programs to address these concerns.

The Urban Education Initiative was a partnership program between Shippensburg University and the York City School District of Pennsylvania. The purpose of the program was to have teacher education majors become more sensitive to the special needs of all students and to become more aware of the unique educational challenges and opportunities that presented themselves in many urban schools.

Forty nine teacher education seniors participated in the program in the spring of 1995. Apart from spending 4 days in 7 elementary schools in York, they also visited William Penn High School, the Crispus Attucks Community Center, the Spanish American Center, the Health Education Center, and attended multiple professional development programs conducted by the York City Personnel. It was a one-week intensive training program highly spoken of by all participants. This research was used as a partial evaluation tool to assess the effectiveness of this program.

Purpose of the Research
The purpose of the research was to assess the impact of the Urban Education Initiative on the SU students' perceptions of city schools. These perceptions of SU teacher majors were indicated by 12 variables that included their perceptions of personal safety, relation to minority children, management of classroom discipline, children's health, school supplies, personal vehicle safety, children's hygiene, teacher salary, AIDS risks, physical building conditions, relationship with colleagues, and relationship with parents.

Research Design
The design of the research was a Quasi Single Group Pre-and-Posttest. The subjects were 49 preservice teachers from the Shippensburg teacher major seniors. The instrument was a self-designed survey questionnaire that consisted of 3 parts: The first part collected the background information about these students, which included the kind of schools they attended prior to Shippensburg University and how many days they had spent in urban schools. The second part solicited their perceptions about urban schools as indicated in the above mentioned 12 variables, and the last part asked about their general comments about the program. The 12 variables indicating their concerns about city schools were measured by a modified Likert scale consisting of Very Concerned, Concerned, Undecided, Little Concerned, and Not Concerned, and a dichotomous scale was used in the last variable to ask about their willingness to accept a teaching position in an urban setting. The pre survey was conducted a week before they went to York, and the post survey was completed 4 days after they returned to the University.

Results
Forty five usable questionnaires were collected from both surveys, achieving a return rate of 92%. Among the participants in the research, only one person who had spent
above 40 days in an urban school prior to Shippensburg University. 35 people had fewer than 5 days, and over half of the group never visited an urban school.

The collected data was processed by the SPSS statistic program. Descriptive and inferential statistic procedures were used to analyze the data. Paired t-tests were calculated to find the statistically significant changes of their perceptions as indicated by each variable before and after they participated in the program. Of the 12 variables computed, 5 demonstrated a statistical significance between the pre and post surveys at .001 level, and 1 variable was significant at .05 level. The means and standard deviations of the 6 pairs of variables that were tested significant are reported in the Table 1.

Among the differences found, the change of perceptions on Personal Safety in an urban school headed the list with $t_{(44)} = 6.44$, $p < .001$. Figure 1 illustrates this change of perceptions on Personal Safety:

![Figure 1. Students' Change of Perceptions on Personal Safety (n = 45)](image1)

This significant change of perceptions on personal safety was followed by their change of perceptions on Relation to Minority Students, $t_{(44)} = 4.64$, $p < .001$; Safety of Personal Vehicles, $t_{(44)} = 4.51$, $p < .001$; and Management of Classroom Discipline, $t_{(44)} = 4.48$, $p < .001$. Figure 2 and Figure 3 illustrate the findings of the pre and post surveys on students' change of perceptions on Relation to Minority Students and Classroom Management:

![Figure 2. Students' Change of Perceptions on Relation to Minority Children (n=45)](image2)

In the above figures, the data in the post survey wiped out the first category (Very Concerned) in all three variables, and demonstrated a drastic change of their perceptions of personal safety, relationship to students, and management of classroom discipline in an urban educational setting. This radical change of perceptions was also reflected in students' perceptions of personal vehicle safety in urban areas.

Table 1. The Means and Standard Deviations of the Six Significant Pairs of Variables
Other significant differences were found on Salary, $t(44) = 3.63, p< .001$ and Colleague Relationship, $t(44) = 2.25, p < .05$. No statistically significant difference was indicated in the student perceptions regarding children's health conditions, school supplies, children's hygiene, AIDS risks, physical facilities, and relationship with parents.

For the sake of clarity and brevity, the writers combined the "Very Concerned" and "Concerned" answers into a large group and compared its size and intensity in the pre and post tests. Figure 4 illustrates a significant reduction of students' concerns with working in an urban school after they participated in the program.

**Summary and Discussions**

The findings from the pre and post surveys were quite interesting. Data from the pre survey indicated that the students involved in the Urban Education Initiative had little experience in urban schools. Most of them had never been in an urban classroom prior to the program. Moreover, the pre survey data indicated that many of the university students involved had a number of significant concerns that could possibly discourage them from seeking employment in urban schools. Post survey data indicated their concerns were significantly abated in 6 of the 12 variables that measured levels of concern. This Urban Education Initiative had exerted a great impact on their perceptions of personal safety, relationship with students, managing an urban classroom, vehicle safety, salary scale and relationship with colleagues in an urban educational setting.

Though the program also had some positive impact on student perceptions of school facilities and AIDS risks, its influence was not statistically significant. It had practically no impact on their perceptions of relationship with parents. This phenomenon might partly be attributed to the fact that, during the program week, these students had no chance to work with urban parents, and how to relate to and work with urban parents will make a very interesting topic for our future research.

Only one variable (school supplies) showed a slight negative direction. 40% of the participants was concerned about the school supplies in the pre survey, and this percentage of concern increased to 42% in the post survey. This negative increase was possibly influenced by what they saw in classrooms and a few stories they heard about school supplies during the week, and it was not statistically significant.

Due to the fact that the sample was relatively small and not drawn randomly from a larger population, in spite of the significant differences that existed in the perceptions of the preservice teachers between the pre and post tests, the result of the research was not generalizable to more students. Nevertheless, the findings were very significant to the students who participated in the program and to the Teacher Education Program of Shippensburg University. One of the most encouraging aspects of the post survey data was the comments of participants. All of them indicated that they thought the project was very helpful and should be continued. 28 students made enthusiastic entries in the last open-ended item. Their comments and remarks offered an overwhelming endorsement of the effectiveness of the program.

Multimedia Presentation of the Research

This demonstration was first created by using Macromedia Director 4.0, which was a movie composition program where movies were composed from elements that were either created on or imported into the Director. During the Urban Education Week, the researchers took 70 photos and kept ample notes. Based on those photos and interviews, the researchers designed the multimedia presentation by using the Paint, Cast and Score Windows of the Director. For the software conformity and convenience of the presentation at the 9th SITE Conference, they converted it into a Power Point presentation. The finished product contained 40 screens, twenty scanned pictures, 3 movie clips, 4 research figures, some music and many hypertext pages. Though some animations were lost in the conversion, many of the designing principles and major features were quite similar. Some of their suggestions are as follows:

1. Overall design of the presentation

   The overall design of a multimedia presentation is critical. The designers not only have to consider what they want to present, but also what messages the audience will get from viewing the hypertext screens. Very often the audience are drawn toward the dazzling electronic bells and whistles. The designers need to spend much time at the beginning of the project selecting the most effective approaches.

2. Readability of the screen

   Readability of the screen is very important, because the bulk of the information will be obtained from these screens. It can be achieved by selecting appropriate font size, content words and the number of headings. The recommended font for the opening page may be set at around 40 points with each page containing no more than 6 lines. It is unnecessary to write the detailed information on the screen. When the presenter reads the 5 to 6 essential words in a line, the readers will be able to fill in the rest of the information. For general purposes, using templates is often a convenient shortcut.

3. Import digital images

   The Macromedia Director and Microsoft Power Point employ different ways to import graphs, charts, pictures, and videos, but the methods are more or less the same, namely, cut and paste, insert or import. Spending some time on the software, one will get used to them quickly. It is the creativity and depth of the project and selection of images that will take the bulk of one's time.

4. Avoid screen clutter

   Because multimedia software enables the designers to use all fancy tools with great ease, it is important not to distract the readers by using too many dazzling digital images or music. Sometimes, excessive use of transitions and special effects many make your presentation too "cute."

Consequently, the ultimate purpose of the presentation is compromised.

5. Logical reasoning vs. nonlinear nature of multimedia presentation

   The definition of the multimedia is any combination of data, digital movies, animations, graphics, text, and sound delivered on a computer. It is a highly nonlinear environment. Therefore, the designer need to balance the logical and sequential presentation of main content pages with temptation of overwhelming effects. 6. Navigation control

   It is important that the presenters should designed the demonstration in a way that they can navigate the demonstration with ease and can change the length and direction of each screen at will.

Selecting and designing a multimedia presentation is a never ending learning process. In preparing this project, the researchers tried Macromedia Director, Authorware, Asymmetric ToolBook II, and finally landed on Microsoft Power Point. They might have just scratched the surface of the capacities of these multimedia software, but one thing is clear, that a multimedia environment has certainly made their presentation more effective and, therefore, made their research more accessible to more of their students and colleagues.

WE'RE DANCING AS FAST AS WE CAN: TECHNOLOGIES FOR A YEAR-LONG STUDENT TEACHING EXPERIENCE

Karl Koenke
University of Illinois
at Urbana-Champaign

Catherine Thurston
University of Illinois
at Urbana-Champaign

Matthew Stuve
University of Illinois
at Urbana-Champaign

Preparing student teachers to be able to use technology effectively in today's classrooms is a critical role for teacher education institutions. Over 200,000 new teachers enter the profession each year (President's Committee of Advisors on Science and Technology, 1997), with a 50% turnover of the teaching force approximately every 15 years. Nevertheless, technology is not a major component of the teacher preparation experience in most colleges of education.

The Office of Technology Assessment (OTA, 1995) found that most technology instruction in colleges of education is teaching about technology as a separate subject, not teaching with technology across the curriculum. The majority of teacher education faculty do not model technology use to accomplish objectives in the courses they teach, nor do they teach students how to use information technology for instruction. Seldom are student teachers asked to create lessons using technology (OTA, 1995). In fact, currently, just 32 of the 50 states require courses in educational technology for obtaining teaching licenses (CEO Report, 1997).

Although Illinois is one of eighteen states still not requiring technology courses for certification, the College of Education at the University of Illinois at Urbana-Champaign has been integrating technology into the student teaching experience within an innovative program for elementary education, the Year Long Program (YLP). Now in its fifth year, the technology initiative within the YLP was jump-started in 1993 by a project funded by the National Science Foundation called Teaching Teleapprenticeships. The YLP has evolved into a permanent component of the teacher education program in the College of Education and has served as a pilot for redesign of the entire student teaching program.

The one constant feature of the YLP has been adaptation to change. While the program has gradually become institutionalized, the technology infrastructure has changed, the teaching methods have changed, and the syllabus has changed. This paper will describe this change process which has been central to the success of the program.

Overview of the Year-Long Project

The YLP is a model elementary teacher education program based on collaboration between the University faculty members and local public school teachers. It is considered unique because it integrates extensive classroom experience and methods courses within the final year of teacher preparation and asks classroom teachers to play a strong collaborative role in training, advising and evaluation of the preservice teacher. These cooperating teachers are known as the Advisors. After the first eight-week session in the Fall, the Advisors arrange at least two classroom visits and follow-up conferences with their Advisees during the second eight-week placement and during the Spring semester. Additionally, they participate in all student teaching evaluation conferences throughout the year.

The preservice teachers enrolled in the YLP participate in three separate classroom placements. During the Fall semester there are two eight-week placements of two and one half days per week in the classroom. The placements are usually within the same school, but at different grade levels. The first placement also includes a full week in the classroom as school opens. This is done so that classroom organization and beginning-of-year activities can be experienced. As the YLP preservice teachers grow in experience they are entrusted with more classroom responsibilities, take a larger role in planning, and teach more frequently and for longer periods of time.

When the preservice teachers enter the Spring semester, they are placed in another school, at yet another grade level. The Spring placement, which lasts the whole semester, is for two and a half days per week until the end of February; then the preservice teachers spend full time in the classroom and attend a weekly seminar in the evening with instructional team members.
The four integrated methods courses, all of which require class time for a semester and a quarter, follow: 1) Language and Literacy (L&L), which integrates three traditional courses, reading methods, language arts methods, and children’s literature, is nine credit hours. 2) Curriculum and Instruction (C&I), which integrates general elementary methods and technology, is six credit hours. 3) Social Studies methods, which has been expanded so that further study of and experience with diversity could be given its place in teacher preparation, is four credit hours. 4) Science methods, which has a constructivist focus, is three hours. (Math methods is required prior to entering the YLP.)

Since technological literacy is viewed as an integral part of what it means to be a teacher, instructional time is provided for training in the use of technology in education, and assignments within the methods classes require use of computers and relevant peripherals and software.

**YLP Students’ Use of Technology in their Courses**

During the year-long program our students are working intensively to experience the classroom and to gain further theoretical insight and—to the best of their ability—fuse the two; they are asked to use their computers in all of their methods courses. Generally, they must monitor email from all instructors. We have separate reflector lists for faculty, graduate assistants, and students. We fuse the three to create the general list. Instructors send assignments, require assignments, and send changes to the semester plans as a minimum.

As a part of what is called a general elementary methods course the students are asked to write three reflective journal entries weekly; monitor email communication from their instructors, supervisors, and other students; complete technology surveys of the classrooms in which they are placed and send the results to the instructor via email; write a unit of four or more lessons using the word processor and any other tools they deem necessary; browse the web for resources for the unit; browse the web for five sites of use to them as teachers and review what they have found; review multi-media software which may be used in their classroom or in the building of their units; and create an ideal third grade class. That means drawing the room using an appropriate tool, writing lessons, creating a schedule, and describing their classroom organizational strategies including building of community. At least one lesson is to incorporate the use of technology.

Finally, as part of the general methods, selected teachers speak to the students regarding their teaching. One such teacher not only showed the projects that her students had created on PowerPoint, but discussed the differences between teaching based on units and teaching based on projects. Students were able to see how second graders could use the scanner, camera, and computer to create pages and hear about the philosophy of teaching that underlies projects as a method in elementary school instruction.

**Impact**

On the basis of surveys of the YLP graduates of 1996 and 1997, we can say that some our graduates are highly involved with technology as a part of their professional lives. It is not possible to claim that the experiences with computers, peripherals, and software provided during the YLP are the only cause of this involvement, but we can claim partial credit for the following:

Via email, we are still in communication with 9 graduates of 1997, 3 graduates from 1996, and 1 graduate from 1994. These messages are both personal and professional communications. The graduates are located in Japan, California, Texas, some small towns, the Chicago suburbs, and the local Champaign-Urbana area. Although a very few of our graduates choose to teach in the City of Chicago, none of them are communicating with me via email. The YLP graduate who is currently teaching in Japan has sent detailed information about her experiences and has volunteered to be a resource for any of this year’s class as they implement their units this spring. Others have responded several times regarding their teaching and recommendations for the further enhancement of the program.

The local email traffic is usually regarding graduate courses or involvement in the teaching and mentoring of our current YLP students. However, most recently, a 1997 graduate located in the Chicago suburbs asked for help in creating a unit in Spanish (she teaches middle-school Spanish among other things).

The survey of the 1997 grads indicated that 26 of the 40 graduates (65%) are first year teachers; an additional 5 are full-time as aides and/or subs (77.5% are then known to be in the field of education); 4 are in industry/business; and we have not heard from five. We hope that one or two more will pick up the survey that was mailed to their parents’ homes and respond during the winter break.

In terms of the involvement of the 1997 graduates with technology as a part of their careers, the survey revealed that

- one is training to become—next year—the technology mentor for her school,
- one has successfully written a proposal to get more CDs and drives for her room,
- one has written a proposal for more technology for her room,
- one has taken the lead in getting his school wired,
- numerous graduates have commented that they are seen as technologically savvy and that older teachers seem to admire their knowledge and willingness to create instructional opportunities for children,
- numerous graduates have written about the hardware in their classrooms.
• some graduates have written about the infusion of technology in their teaching,
• some graduates have made recommendations regarding the technology training of future elementary and middle school teachers, and
• one graduate referenced her school's web page and then footnoted it with the warning that it was not really slick.

The graduates of our program are also complaining about the lack of modern technology in their rooms and schools. The graduates yearn for equipment that allows the use of the Internet and web. We will continue to include a small workshop on writing of proposals in our Spring semester as one of our contributions to changing our schools.

**Technology Infrastructure:**

It is important to situate the technology infrastructure of the College of Education within current trends in educational technology. In a May 1996 survey of schools of education, only 45% of faculty regularly use computers or TV with VCRs for interactive instruction during class periods (Zehr, 1997). Furthermore, the same study found that 53% occasionally used some electronic technology to present materials in class. Surprisingly, the report found that 58% of schools of education do not have any classrooms wired for the Internet. These data indicate that, despite our best intentions to prepare future teachers for technology-rich classrooms, teacher education institutions may not be practicing what we teach.

Yet, in programs like YLP, we have sought to overcome some of these shortcomings by looking at the cumulative technology profile of the student teaching experience. The technology profile of the YLP consists of many components, which include:

1. Mobile computing in the form of laptop computers.
2. Access to advanced computers in the College computing lab.
3. Awareness of and guidance on how they use computers in their placement classrooms.
4. Encouragement on the use of home computers.
5. Information servers for on-line resources.
6. Coordination of University computing resources.

Central to the technology strand of the YLP is the idea of ubiquitous access to computers for communication. This was a goal of the Teaching TeleApprenticeships (TTA) project. TTA provided laptop computers (with support from Apple Computer, Inc.) to YLP and other teacher education students to facilitate e-mail communication between the student, his or her faculty advisor, and cooperating teachers. The PowerBooks are Macintosh 145 models with Microsoft Works (donated by Microsoft, Corp.), Eudora, and Netscape. They have dial-up connectivity to the students' free campus PPP access at 14.4 kbaud. In the first two years, the PowerBooks only had 2400 baud modems and 4 MB of RAM. But with advent of the Web in 1995, we added more RAM and replaced the modems. One of the practical benefits of the PowerBooks is that whenever there was a technical problem with them, the student could bring the unit to the TTA office where there were graduate students to either fix the problem or swap the unit.

Although we are using the same basic PowerBook that we started with in the Spring of 1993, their use has changed over the years. For example, since Eudora was developed at UIUC, we were free to install it on all the PowerBooks. Eudora's client architecture fit nicely with the TTA model of anytime access to e-mail. Students could stay in the familiar Macintosh operating system to check mail on their University Unix account without having to learn Unix, or having to have the continuous connection of a telnet session. In the Fall of 1995, the University went to on-line course registration, which meant that every student had to know how to use telnet to enroll in courses. At the same time, the campus computing office implemented an improved Unix e-mail application for telnet access called Pine. These two developments, on-line registration and Pine, caused a migration away from Eudora to Pine.

A parallel development at this time was the growth in networking in the placement schools, University residences, and in the College. Since Pine centrally stored all their mail in mailboxes just like Eudora AND they could access from all their contexts, the shift in student preference was based on factors not of our design.

These changes influence how the PowerBooks and other infrastructures were perceived and used by the students. The College has two computer labs that are available to the YLP students. Of course, the technology of these labs has changed in five years, from being mostly LC-class Macintoshes in 1993 to now include advanced PowerPC Macintoshes and Pentium-class Windows machines with plenty of multimedia hardware and software.

Since the capabilities of the technology had changed, so did the contexts for using it. In the first two years, the PowerBooks were the infrastructure. It had everything the students in the first two years wanted in a computer. They toted the infrastructure with them into all contexts of their teaching experience: school, university, and home. The use of the computer lab has changed to included advanced multimedia and new methods for projection. During the two years (1995-97) when the lab and the College curriculum was beginning to include multimedia and the Web capabilities, some of the YLP students often made negative comments about the old black-and-white, slow, no-CD-ROM PowerBooks we were asking them to haul to their University classes.

Much of the need we were addressing in 1993 was the lack of access to computers in the K-12 schools. During the first few years of the TTA project, the PowerBooks we
provided our students were often the only computer in the classrooms where our student teachers were placed. Of course, more classrooms have computers now, albeit with varying degrees of sophistication and support. Most YLP students report having an adequate computer in their cooperating classroom, almost all with Internet access. When we consider these developments, we see why the students felt the PowerBooks were “underpowered”.

But this year, we are noticing yet another shift in the modes of computer use. We have recently introduced two PowerBook printing and networking docking stations in the basement of the College. We were surprised to see how the YLP students made use of these. We had envisioned that they might use the network connection to browse the web and send e-mail in a quite space away from the lab. What we found was that the students did not care to use the network in these small study carrels but instead just used them for studying, writing on the PowerBooks, and printing. In this way, it became apparent that this most recent cohort of YLP students are employing different modes of computer use in different contexts. Not every student uses all modes the same, or at all. But the main point is that they are making personal decisions about how they computers. This is an emergent indicator of increasing skill, confidence, and acceptance with technology among the YLP students over the past five years.

To summarize, the technology infrastructure of the YLP changed from being a portable infrastructure used in multiple contexts to include multiple modes of computer use that varies by the context. All of the contexts in which the YLP students are using technology have changed significantly over the past five years. We have been dancing as fast as we can to keep up with these changes. But what is more important is how the YLP students have adapted to these changes and, because of the increase in incoming skills and their selection of preferred modes of computer use, they have determined how technology will be used in the YLP. In other words, we have adapted to them and their changing skills, beliefs, and experiences more than the technology.

**Methodology**

In the five year history of the YLP, the modes of instruction have changed dramatically. The initial group of students received very little instruction on how to use of the applications on the PowerBooks. There were a few whole group sessions of basic instruction, but for the most part, the laptop computers were distributed to the student teachers who were on their own to be able to use them. The major focus was on the use of email to facilitate communication between the professor, the teaching assistants, the supervisors, the cooperating teachers and the student teachers. The one experimentation involved electronic journaling. This effort was not successful in the first year because the instructors did not place limits on the amount of text submitted, and the instructors quickly became overwhelmed with the quantity of email received.

After the first year, the faculty and supervisors involved with the course asked for assistance from the technology faculty and graduate assistants involved with the TTA project. The course was structured to allow for one hour of technology instruction every Friday, and a team-teaching model evolved, with the YLP faculty meeting weekly with the technology faculty to plan sessions for the students. The “standing” approach evolved in the second year of this initiative. At this point, however, instruction was still geared to those who needed help the most, for those most insecure with the technology.

By the third year of implementation, the methodology, driven by student demand and comments the students made on semi-annual evaluations, had changed drastically. In addition to presentations made to the whole group, lecture style, the students had more hands on experiences in the Instructional Computing Lab. Instruction included uses of email but by this time expanded to use of the web, multimedia software exploration and evaluation, and other related topics. Student evaluations called for more hands-on experience with technology. The College Computing Lab thus became a place where the students could experiment with multimedia.

By the fifth year of implementation, the methodology had changed again, with more topics of instruction, more small group work, and multiple choices of topics on given Fridays. The faculty and staff had recognized the great range of technology competencies among the student teachers, and instruction accommodated this diversity. Fewer whole group presentations were made; the students more often were able to select from several topics on a given Friday with instruction geared to differing abilities and interest. On a given day, clusters of students could be working on the web, on specific software packages, creating multimedia, learning how to use a digital camera, et. al. In addition, the faculty brought in guest speakers who were technology using elementary teachers from local schools. The local teachers’ modeling of the use of technology proved to be an extremely effective means of presenting new ideas to the students.

By the fifth year, then, the student teachers experienced a whole range of mini workshops, most of them set up around small group instruction which was hands-on. The students themselves selected and suggested topics to the instructors. In the 1996-97 school year, workshops were characterized as being ability-grouped, hands-on, wired (i.e. connected to the Internet), taught in small groups on a variety of platforms, and offered on dual platforms. It became important to offer instruction on software on both the Mac and PC platform whenever possible.
A sampling of topics from workshops during the 1996-97 year includes the following: Microsoft Works and Wizards, HyperStudio, scanning and digitizing, evaluation of educational software, acceptable use policies and ethics, creating slide presentation with PowerPoint, resumes, reference materials on CD-ROMS, creating personal web pages, and using different methods of projection in the classroom.

**Institutionalization**

What began as a small pilot project within TTA has evolved to an institutionalized methods course which is serving as a model for curriculum redesign in the College of Education. Microsoft, as part of its College of Education Partnership, donated software earmarked for teacher training to both the PowerBooks and the College Instructional Computing Lab. Faculty and TTA research assistants worked in conjunction with College faculty from the Department of Curriculum and Instruction to team teach the technology component of the YLP.

The NSF funding of TTA ended in the summer of 1996. In the fall of 1996, the College established an Office of Educational Technology, created with non-recurring funds from the Chancellor’s Office, to support faculty development and provide assistance in integrating technology into course work. During its first year, the OET staff worked closely with the YLP course as well as with several other methods courses (math methods, science methods, English methods.) At the College level, faculty began to plan for teacher education redesign—a means of reworking the teacher education curriculum beginning in 1998 to allow forstranding of technology on an infuson model into all the methods courses. Also in 1996, two faculty members began working on a technology competencies database - a matrix they were piloting to track a student’s use of technology across all courses taken in the teacher education experience.

In 1997-98, the OET received permanent funding from the campus. It is continuing to focus on faculty development and integration of technology into the curriculum. Staff and faculty are gathering data on uses of laptops vs. desktops, student computer use patterns, and researching what other institutions of teacher education are doing to support student computer use in order to project an expansion in the future. Teacher education redesign is fine tuning its planning, with beginning implementation still scheduled for 1998. The Curriculum and Instruction Department has purchased a mobile multimedia unit for use by students and faculty in the department. This consists of a mobile cart outfitted with a high end computer with CD ROM, a color printer, a scanner, and a digital camera. This cart is housed near the department on the third floor of the building to give faculty and students more immediate access to these tools.

**Conclusion**

The success of the Year Long Program and its technology integration strand can perhaps be judged by the impact its has had on its graduates as well as the impact it has had as a model for future development in the teacher education curriculum at the University of Illinois. The participating faculty and staff’s ability to adapt quickly to the numerous changes that have occurred in the hardware, software, network infrastructure, student experience, methodology, and course curriculum have been critical. A team approach, with curriculum and instruction faculty working hand in hand with instructional technology faculty and graduate students, meeting weekly to plan the technology integration component of the course, has been a significant factor in this group’s adaptation to change.

Preservice Teacher Education — 715
Developing a Need for the NCATE/ISTE Standards for Pre-Service Teachers

Susan M. Powers
Indiana State University

Classroom instruction is undergoing a transformation. The push for this change emerges not only from reform and standards movements, but also from the sheer volume of information that must be relayed to students. Teachers are becoming information brokers as they work to relay needed information on to students and not always from a position of knowledge and authority. This move also makes the classroom more student-centered (Barron & Goldman, 1994). This change can and should be supported by information technologies. The pressure for teachers, particularly new teachers, to be proficient with information and instructional technologies is growing.

As pre-service teachers look to enter the workforce, they are beginning to find that their ability to demonstrate proficiency with computer technologies affects future employment possibilities (Davis, 1997). At the same time, college and universities who seek accreditation for their teacher education programs face a need to be able to demonstrate that their programs, faculty and graduates reflect these standards as well as be able to perform at a competent level. Specific performance criteria (ISTE, no date) have been developed by the International Society for Technology in Education and adopted by the National Council for the Accreditation of Teacher Education (NCATE). The foundation standards for all teacher education students include the following core principles:

A. Basic Computer/Technology Operations and Concepts. Candidates will use computer systems to run software; to access, generate and manipulate data; and to publish results. They will also evaluate performance of hardware and software components of computer systems and apply basic troubleshooting strategies as needed.

B. Personal and Professional Use of Technology. Candidates will apply tools for enhancing their own professional growth and productivity. They will use technology in communicating, collaborating, conducting research, and solving problems. In addition, they will plan and participate in activities that encourage lifelong learning and will promote equitable, ethical, and legal use of computer/technology resources.

C. Application of Technology in Instruction. Candidates will apply computer and related technologies to support instruction in their grade level and subject areas. They must plan and deliver instructional units that integrate a variety of software, applications, and learning tools.

Lessons developed must reflect effective grouping and assessment strategies for diverse populations. (ISTE, no date).

All colleges and universities that are accredited by NCATE must ultimately demonstrate compliance with these performance standards or risk losing their accreditation. Realistically however, schools may not attempt to meet the standards until the date for re-accreditation looms on the horizon. The reasons for avoidance are diverse and may range from a lack of knowledge about the new technology standards to a lack of faculty interest in and abilities with technology. It therefore becomes important to build a grassroots demand for the inclusion and integration of instructional technologies in order to meet the needs of students.

Building Student Demand

There are multiple ways this campaign can be achieved. Individual faculty members could be the impetus by undertaking the task of teaching technologies in their own classes, i.e., make technology an integral part of assignments and class. Another choice would be to have educational technology courses attempt to cover all aspects of the standards in a cursory fashion (given the expanse of the standards). Another possibility is to expose the students to the standards and have the students create a demand for the inclusion and integration of all standards in the teacher education program. This final option is the focus of this paper.

At Indiana State University, all students do complete a series of technology competencies as part of their coursework in the 5-12 program. The competencies are an integral part of the teacher education program and success-
ful completion is required to move forward. These competencies provide basic introduction to use of the Internet, and presentation software. A handful of students develop more in-depth skills on their own or through other classes. Therefore, the majority of students do not have skills that would match with the standards described above.

**Proficiency Exams**

To build the student support and interest in these instructional technologies, an optional program was developed (Powers, 1997). Eight proficiency examinations were created which cover the major topic areas of word processing, spreadsheets, data processing, electronic communications, desktop publishing, instructional applications, presentations/digital imaging, and concepts and societal implications of instructional technologies. Students can select any of the eight proficiencies, read the requirements to achieve competency on that standard, and then sign-up on-line to take a proficiency exam. The students then sit-down with the proctor and are asked to “perform” on demand. For example, as part of the word processing proficiency exam, students would be asked to complete the following:

- create a file;
- save a file;
- retrieve a file;
- modify text styles;
- include headers and footers;
- create and modify a table;
- modify page layout;
- insert graphics; and
- complete a simple mail merge.

If the student can successfully complete each of these skills, they pass that proficiency exam. Students then receive a certificate of completion along with a letter explaining the proficiency exam on departmental letterhead stationary. The benefit for students is that these artifacts can then be placed in a student’s professional portfolio as a demonstration of proficiency to superintendents and principals while interviewing for professional positions.

**Reality of Meeting Proficiency Levels - Students and Faculty**

At present, the technology component in the secondary education program covers relatively well two of the eight competencies: electronic communications and presentation/digital imaging. With some minor additional work, the majority of students in the program could successfully complete both of these proficiency exams. With only two of the eight covered, a big hole remains in the compulsory instruction. Students can achieve several of the competencies partially and sometimes fully through electives offered in throughout the university.

Going back to building a grass roots case, plans are in development to begin offering workshops to students to assist them in the development of these technology skills. Before the first offering of any workshop, the demand from students has already been significant as the students themselves recognize deficiencies in their knowledge base. As workshops increase the skills of those students who participate, students who are not able to participate in extracurricular workshops due to family and job constraints will begin to insist that these skills become an integral part of the teacher education program. The already developed workshops will then provide a core set of instructional materials.

There is an additional base level purpose for the development of the technology proficiency exams. By breaking up the standards into eight separate proficiencies, the skills themselves become manageable, not only to the pre-service teachers, but also to the in-service teachers who take graduate courses through the department, and more importantly, to the faculty who teach within the department.

The ISTE/NCATE Unit Guidelines state:

**Faculty Qualifications**

Higher education faculty are knowledgeable about current practice related to the use of computers and technology and integrate them in their teaching and scholarship.

**Resources for Teaching and Scholarship.**

Faculty and candidates have training in and access to education-related electronic information, video resources, computer hardware, software, related technologies, and other similar sources.

Media, software, and materials collections are identifiable, relevant, accessible, and systematically reviewed to make acquisition decisions. There are sufficient library and technical staff to support the library, instructional materials collection, and media/computer support services.

**Resources for Operating the Unit**

Facilities and equipment are functional and well-maintained. They support computing, educational communications, and educational and instructional technology at least at the level of other units in the institution. (ISTE, no date).

These guidelines place a high burden on faculty members in teacher education institutions and raise the bar to a level not currently being met by a majority of faculty members. By creating proficiency examinations that are possible to grasp in small units, workshops, and potentially proficiency exams, can be offered to teacher education faculty in order to upgrade their own skills and abilities. The continued assumption is that if faculty also have the same proficiencies, the technology will become an integral part of the teacher education program. Many researchers have shown the benefit that integrated media and technol-
ogy can have on helping teachers develop new models of teaching and learning (Barron & Goldman, 1994).

Conclusion

President Clinton articulated a vision of “Four Pillars” to support technology literacy which include hardware, connectivity, digital content and professional development. The recent School Technology and Readiness Report (STaR) by the CEO Forum (1997) indicates that schools have markedly increased the ratio of students to computers, as well as increased Internet access. However digital content and the professional development pillars are still missing. Superintendents and principals are right now seeking to fill these voids by hiring new teachers who are proficient with instructional technologies and can help train established school faculty and model the inclusion of digital content (?, 1997). Anything a pre-service teacher can do to communicate that they are proficient and competent with technologies, such as through certificates of proficiency, will enhance their employment opportunities and the ability of the schools to meet this need.

The standards cover many areas of technology. However, as reported in T.H.E. Journal (Davis, 1997), none of the skills are out-of-line with the needs and demands of employers, including educational employers. Building demand from the marketplace is just one method of finding room in the curriculum for instructional technologies. This program has just left the development process and is now entering implementation. Students are showing interest in the exams and signing up to participate. Hopefully, the technique will prove successful in this pre-service program.

ENRICHING MIDDLE LEVEL PRESERVICE TEACHER TRAINING THROUGH THE INTEGRATION OF TECHNOLOGY

Melanie Green
Appalachian State University

Jeradi A. Cohen
Appalachian State University

E ducation clearly is and will continue to be impacted by new and emerging technologies. In 1996 President Clinton challenged America's schools to ensure each learner would become technologically literate by the dawn of the 21st century and further stated that "every classroom in America must be connected to the information superhighway with computers and good software and well-trained teachers" (Winters, 1996). In the School Technology Users Task Force Report (N.C., 1995) basic technology competencies were established for all preservice teachers to ensure that educators in the future can integrate instructional technologies into student learning. Attainment of these competencies would enable educators to deliver effective teaching and to enhance overall professional productivity.

According to the Office of Technology Assessment (1995) 5.8 million computers are available in America's elementary, middle, and secondary schools. Students continue to exhibit high levels of interest in technology as a result of their varied experiences with technologies. Yet, teachers continue to fail to integrate technology into instructional planning. Lack of teacher training and limited access to technology (Becker, 1994, Lucas, 1976) are cited as reasons for limited use of computers in classrooms. No longer can the 1300 colleges and universities across the United States ignore this issue. These institutions must be in the vanguard of change and provide a technology enriched curriculum that will adequately prepare preservice teachers for meeting the challenges that lie ahead.

Purpose
The purpose of this study was to assess the basic and advanced technology competencies of middle level educators in a preservice training program. Results of the initial survey were used to diagnose the skills of these university students and to determine areas of weaknesses to target for remediation in the ensuing methods courses. Additionally, these preservice teachers were given the opportunity to gain the proficiencies needed to pass the state mandated technology competency surveys. A questionnaire of ten opened items required written narrative responses. Semi-structured, exit interviews were also included in the data collection process.

Participants
Eleven students enrolled in the Middle Grades Program in the Reich College of Education at Appalachian State University were selected to participate in this study. Three of the students were seeking certification only and eight were undergraduates pursuing an undergraduate degree in Middle Level Education. In this cohort of students, four were preparing to teach language arts and social studies, three were preparing to teach mathematics and science, two were preparing to teach social studies and science, and two were either a science concentration only or a social studies concentration only. Their current schedule included an intense ten weeks of methods courses followed by a six-week internship in a middle level school. All students were scheduled for a sixteen-week student teaching experience the next semester. Ten participants were female and one was male.

Instruments
The Survey of Basic and Advanced Technology Competencies (N.C., 1995) was selected for data collection. This instrument contained 113 questions ranging from basis skills to more complex technological practices. The items were divided into the following categories.
1. Computer Operations
2. Setup, Maintenance, and Trouble Shooting
3. Word Processing/Introductory Desktop Publishing
4. Spreadsheet/Graphing

Preservice Teacher Education — 719
5. Databases
6. Networking
7. Telecommunications
8. Media Communications
9. Multimedia Integration
10. Curriculum
11. Subject Specific Knowledge
12. Design and Management of Learning
13. Child Development
14. Social, Legal, and Ethical Issues

Students were asked to indicate familiarity to the 113 items by checking yes or no to each one. This instrument was used for preassessment at the beginning of the semester and as a postassessment instrument to determine growth at the end of the semester.

The Student Technology Questionnaire allowed students to respond to the following questions.
1. How do you think technology will influence your role as an educator?
2. Are you aware of the technology competency requirements for education majors? If so, how did you acquire this information?
3. List below the previous/current courses in your teacher education program that have included opportunities to practice and/or apply the technology competencies. Describe the expectations for application in each course.
4. What procedures will you follow in acquiring the information necessary for you to master those competencies?
5. How could the College of Education facilitate your mastery of these competencies?

Students were also asked to respond to this survey at the beginning of the semester and at the end of the internship experience which followed the ten-week block of methods courses.

Results and Discussion
The results of The Survey of Basic and Advanced Technology Competencies pretest revealed students were most proficient in Word Processing/Desktop Publishing and Spreadsheet/Graphing with over 90% responding positively in these areas. However, only 9% of the participants had previous exposure to multimedia integration.

Traditionally, teacher education institutions have been slow in integrating authoring programs in hypermedia (Reehm, 1994). Yet, it has been determined to be a powerful tool for teachers in the areas of instructional presentation and student engaged learning (Blanchard & Rottenberg, 1990, Reinking, 1997, Sholten & Whitmer, 1996).

Figure 1. Comparison of Pre- and Post Survey Results by Category
To address this area of weakness, the methods professor and the university technology specialist revised the course syllabus to incorporate a training session for hypermedia use. Hyperstudio was selected as it was readily available to the students in an open computer lab, after their training. Students were introduced to the program and were given suggestions as to how the middle level educator might incorporate its use in content area instruction. As a total group assignment, the middle level preservice teachers created a hypermedia stack on “Interdisciplinary Teaming” to display their knowledge of the use of this software. Sound effects, fading, and buttons were added to the stack. Limitations included time for the students to create further nonlinear programs relative to other content areas in methods courses.

Post test data revealed growth in all fourteen competency categories. Students indicated the most significant growth in the area of Multimedia Integration. Initially, 9.09% of the students felt competent in this area. At the conclusion of the course, 72.72% expressed increased confidence in their abilities and knowledge in Multimedia Integration. Other areas where more than a 30% increase of growth was noted included Database, Networking, Media Communication, and Curriculum.

The narrative responses in The Student Technology Questionnaire indicated that all respondents were aware of the tremendous impact technology will play in their future role as educators. The majority of the students have had two or more previous courses in computers and in related technologies. Only two of the eleven surveyed were unaware of the computer competency test required of teacher education graduates in North Carolina. All respondents felt a need for further workshops, seminars, personal study, and integration of technology into methods courses, internships, and student teaching to prepare for the examination. One key need indicated by students was for more availability of computers in university classrooms and in labs. As middle level educators, students felt participating on an interdisciplinary team would be an asset to them when new technologies emerge. Collaboration and peer teaching will improve overall instructional planning and the integration of technology into all content areas. All students planned to exit the university as change agents in their future teaching assignments. The majority surveyed indicated a willingness to be not only an advocate for technology in the classrooms, but to petition administrators, local governing agencies, and businesses to seek additional funding to acquire needed technologies if classrooms had outdated or limited resources.

Exit interviews conducted with the students confirmed their earlier perspectives. These interviews occurred after a five-week internship in a middle level classroom. These preservice teachers were able to articulate in detail ways in which they see technology impacting classroom instruction and their performance as a teacher. For example:

As an educator, technology is a great resource. I was amazed to discover a sample text (book) in my classroom that had an accompanying CD. I could not believe that my (cooperating) teacher had not checked out what was on the CD. When I checked, I found a wealth of varied information. Technology will influence me as an educator. But I think it will happen a little bit at a time. I learned Hyperstudio and scanning techniques among other things. As an intern I am seeing very little of these in practice. I am glad that I learned what I did but it will be a few years before the school system implements all of this technology.

Technology can reinforce concepts that are being studied. Personally, I am considering graduate studies in technology education because I feel that our students need to understand technology and be able to use it if they are going to be successful in today’s society.

Conclusions

At the conclusion of the internship experience, results indicated 72.72% of those surveyed expressed knowledge of Multimedia Integration. Significant growth was documented in all other areas of the basic and advanced competencies during the semester. Students expressed positive attitudes regarding the new emphasis on technology as well as the diagnostic and prescriptive efforts made collaboratively by the preservice faculty member and the technology specialist at the university. Students exited the semester with a higher level of confidence in all technology related areas. Additionally, they acknowledged the challenges of technology integration faced by classroom teachers due to the limitations of equipment, training and support. They emerged with a strengthened desire and increased knowledge to be a change agent in their respective schools of employment.

Preservice Teacher Education — 721
A DYNAMIC MODEL FOR TECHNOLOGY INTEGRATION IN A LEARNING ORGANIZATION

Sharla L. Snider
Texas Woman's University

Vera T. Gershner
Texas Woman's University

This project relates to the redesign of the teacher education program to address the technology proficiencies desired by the schools, recommended by the National Council for the Accreditation of Teacher Education, and delineated by the professional technology associations. This project encourages faculty to explore new technologies and provide a model of technology integration into curriculum delivery. This research effort identifies the basic technology proficiencies of approximately 400 Texas Woman's preservice teachers and presents the curriculum plan which evolves from the findings. Additionally, this project provides a baseline of data and planning which can serve as a foundation for ongoing research related to educational technology.

Introduction

In these times of rapid technological change the schools have needs for teachers who utilize diverse technology productively, who can contribute to campus and district technology planning, and who integrate technology into the curriculum. This includes the use of advanced forms of hypermedia, optical data, and global connectivity. These goals are congruent with the Texas Woman's University strategic plan and require an accurate assessment of our current curriculum for preservice teachers. Therefore, a new program design is evolving which reflects the guidance of the literature and the goals of the society.

Curriculum Development

The field of educational technology is struggling to move beyond measuring teacher attitudes surrounding technology or acquiring hardware and learning basic programming skills to educational productivity and curriculum development. The National Council for Accreditation of Teacher Education (NCATE, 1997b) in its description of preparing for the 21st Century classroom emphasizes the need for a vision of a teacher education program which fully utilizes information technology. Such a vision requires major adaptations: (a) greater understanding of the impact of technology on our society, (b) new roles as authority over knowledge moves beyond the teacher and the classroom, and (c) the emphasis on the ability to organize and interpret information and assess quality of information and sources in a reflective and critical manner.

In order to accomplish such a vision, preservice teachers must participate in formal courses designed to encourage the development of teachers as fearless users of technology (NCATE, 1997a) and at the same time offer an integrated and collaborative program which seeks to encourage this development through meaningful activities within authentic context. Some of these courses will encourage risk taking and lifelong learning through instructional delivery in non-traditional ways such as distance learning and on-line classes. NCATE further recommends that stimulating effective utilization of technology through a vision and plan would include integration across all areas of curriculum in the teacher education program.

Across the nation, professional development schools link teacher education institutions with field training in K-12 schools. Barker (1995) describes the Professional Development School (PDS) at Western Illinois University implemented with a large AmeriTec grant. The critical components are: (a) distance education technology linking to the public school; (b) a teacher education curriculum that integrates instructional delivery, communications, computer application and resource development; (c) the linking of technology resources to curriculum development and various teaching strategies; (d) training faculty to model integration of technology, and (e) acquisition of the technological resources for faculty and students at both university and school sites. Such a vision is congruent with the mandate for Texas professional development schools.

Within the design of a Professional Development School (PDS) Model at the field-based setting, inservice teachers recognize the need for changes in the preparation of preservice teachers (Fisher, 1997). The students must be able to concentrate on advanced educational technology skills. They must be able to examine curricular issues involving instructional technology within their programs of study. The value of technology in the schools is dependent upon the preparation of the teachers. Their preparation is
dependent upon the teacher education program as designed and implemented by the faculty.

At the university level in the PDS, specific technology issues continue to be revisited. As faculty shape the teacher education curriculum, key factors must be in place. Faculty must engage in active collaboration in planning for the systematic, ongoing integration of technology. They need to model a multi-faceted approach including critical thinking and reflection (Parker, 1997). They also need to ensure that students' prerequisite skills are in place (Rodriguez, 1996). This may involve a foundations course in educational technology, distance learning, local workshops, individual mentoring, field trips, learning buddies. The required facilities and materials must be available. Instruction must be focused, hands-on, and lead to success.

"If the role of teacher education programs is to produce teachers who are able to use the new computer technologies, we must take our preservice teachers from where they are when they enter and advance them to where the technological society needs them to be" (Sheffield, 1996, p. 52). Performance-based programs are measured in terms of competencies or proficiencies (Buhendwa, 1996; Flowers, 1997; Woodrow, 1991). Thus, educational needs at all levels can only be reached when our preservice teachers are able to model the desired proficiencies identified in educational technology programs designed around an integrated teacher education vision.

Design and Refinement of Dynamic Program Model

This project relates to the redesign of the teacher education program to address the technology proficiencies desired by the schools, recommended by the National Council for the Accreditation of Teacher Education, and delineated by the professional technology associations. The project encourages faculty to explore new technologies and provide a model of technology integration into curriculum delivery. These efforts are reflective of the Texas Woman's University strategic plan as it relates to the preparation of future teachers. Several of the strategic plan's major goals call for incorporating technology into higher education instruction and delivery. This project addresses college and institutional goals in relationship to technology and preservice teacher education. Additionally, this project provides a baseline of data and planning which can serve as a foundation for other funding and ongoing research related to educational technology.

Identifying Need

This research effort identifies the basic technology proficiencies of approximately 400 Texas Woman's preservice teachers, compares the differences in proficiencies between two teacher education programs, and presents the curriculum plan for educational technology which evolves from the findings. The dependent variable is the Basic Technology Competencies for Educators (BTCE) developed by the research team at University of North Carolina at Charlotte (Flowers, 1997). Independent variables include the alternative programs, and three levels of experience. The quantitative part of this study uses an ANOVA repeated measure design, and MANOVA for interactions for independent variables.

The Basic Technology Competencies for Educators (BTCE) is a self-report summated rating scale which is divided into nine-competency domains: (a) basic computer operations skills, (b) setup, maintenance, and troubleshooting of equipment, (c) word processing, (d) spreadsheets, (e) database, (f) networking, (g) telecommunication, (h) media communication, and (l) social, legal, and ethical issues. Within each domain five items are given. The fifth item is a summary for that dimension.

Flowers (1997) used the 207 skills identified by the Association for Educational Communications and Technology (AECT) and the International Society for Technology in Education (ISTE) as the foundation for the Basic Technology Competencies for Educators (BTCE) which is the measure selected for this research. The nine-dimension, 45 item scale uses a four-point scale documenting degrees of competency: (a) non-user, (b) extensive assistance, (c) minor assistance, (d) proficient user. Ten scores summarize the total technology competency score and each of the nine domains.

The validity and reliability study of the BTCE supports its psychometric qualities as an instrument to be used for assessing teacher education programs or conducting research (Flowers, 1997). Three classic methods were used to provide evidence of validity: content validity, criterion-related validity, and construct validity. Two types of reliability were examined: stability and internal consistency. Test-retest reliability coefficients range from .73 to .93. The internal consistency, for the total test score and each domain was measured using Cronbach's alpha which ranged from .87 to .97 indicating high internal consistency. Thus, the total score and all the domains have adequate homogeneity.

Program Integration: PreService Teachers

Needs Assessment Findings: Based on the findings from a preliminary needs assessment examining the preservice teacher population at Texas Woman's University a program model addressing four basic areas: (a) Foundations; (b) Connectivity; (c) Productivity; and (d) Integration has been designed and will continue to undergo refinement based on research findings from the Preservice Teacher Technology Proficiency Survey.

Foundations

This program component will address knowledge of computing systems, developing basic skills of computer
operation, examination of the evolution of technology and encourage users to begin to think with technology. Additionally, The social, legal & ethical issues pertaining to using technology in an information society will be addressed. An overview of University technology resources including The Information Technology Service provisions for students and Information Technology Library Services will be provided. This program component will be conducted at the pre-Intern level.

Connectivity

This program component will provide students at the Intern I level the information and skills needed in relationship to connecting on campus as well as remote access issues. Both the University system, Venus, and the use of a World Wide Web browser, Netscape, will be utilized by students as they are involved in various e-mail and connectivity projects including tele-mentoring, e-mailing assignments to liaisons, and communicating with other field-based participants through web-pages, electronic bulletin boards, web-based forums, and list-serves. Managing electronic documents and issues of netiquette and confidentiality will be examined.

Productivity

This program component will provide students at both Intern levels I and II the necessary skills for teacher productivity. Intern I will focus on word processing, data base and spreadsheet. Intern II will focus on advanced skills for teacher productivity and integration into curriculum. The use of desktop layout, managing graphics, and presentation tools will be addressed.

Integration

Integration as a program component is delivered at both the Intern II level and the Resident level. Intern II will focus on learning theories and technology integration models, the examination of student technology tools (tutorial, simulation, exploratory, problem solving, and multi-media) and integration into various curriculum areas. Advanced forms of media including optical technology, internet resources, and related multi-media hardware and software will be utilized in the creation of student projects. The use of global classrooms, on-line education, and distance education will be included. Additionally, students will learn networking skills, set-up and maintenance skills, and participate in planning for technology at the campus level.

Educational Technology Mentor Team: A team of technology mentors will be established within each of the three CCPDC groups (Intern I; II & Residents). These teams will be trained on:

Intern I:
- Netscape
- Venus
- Claris Works: WP; SS; DB

Intern II:
- Claris Works: Slide Show; Desktop Layout
- Power Point
- Hyper Studio

Residents:
- Web Page Editors
- Advanced Forms of Multi-Media Hardware

Tech. Teams:
- Establish Tech. Teams within each of the three CCPDC groups. These teams will operate according to the cooperative learning model with specific role assignments, one of which will be the team leader. During certain technology seminars the technology mentors will work with team leaders on various pieces of software. Team leaders will disseminate skills and information to individual groups.

Tele-Mentoring Project:
- Tele-mentoring partners will be established among the three CCPDC groups. This project will support the evolution of advanced use of technology and facilitate the development of reflective teaching practices.

Educational Technology

Organization for Pre-service Teachers: This student organization will provide support for those students who are interested in advancing in their use of technology tools and learning to think with technology.

Role of Technology Seminar Leaders:
- Technology Seminar Leader will function in the following roles in the instructional delivery process:
  - train educational technology mentors
  - construct tech. teams
  - facilitate team projects:
  - provide additional resources
  - provide necessary background knowledge
  - make connections to the field site
  - facilitate and encourage communication and provide for individual development through the effects of and with technology through a tele-mentoring project, student technology club and the use of a web site for instruction.

Indicators of Student Achievement:

Intern I:
- Students will produce documents related to the development of Teacher Productivity Skills. These documents will include a parent letter, student data base, and grading spreadsheet designed for individual field placements.
- Students will describe the use of technology at their respective field sites.

Intern II:
- Students will produce documents related to the development of advanced Teacher Productivity Skills. These documents will include a newsletter and the use of presenta-
Students will describe the use of technology at their respective field sites and include a plan related to recommended modifications for a future technology plan. This plan will include the evaluation of software located at each field site and a plan for implementation at the classroom level.

Residents:
Students will design student projects using advanced forms of media including internet resources. These projects will be implemented at the respective school sites utilizing tools mastered in the previous intern experiences.

Students will describe the use of technology at their respective field sites and include a plan related to recommended modifications for a future technology plan. This plan will include the evaluation of software and technology resources located at each field site and a plan for implementation at the both the classroom level and school wide setting.

Program Integration: University Faculty

Needs Assessment Findings - A purposive sample of current faculty identified perceived critical needs in the areas of Productivity, Connectivity and Integration.

Productivity
A first priority that included Power Point presentations, creation of a personal Web Page, and the development of multimedia presentations. Special training sessions will be scheduled by the Information Technology Services (ITS) for CCPDC Academic Faculty. These sessions will be offered during Monday seminar times when liaisons do not have field schedules. The liaisons will develop Power Point presentations for routine use in classroom instruction. A second instructional goal is development of personal web pages for use in classroom instruction and communication with preservice teachers. When liaisons have developed these two skills and begun to use them routinely in classroom instruction, they will participate in training to extend their multimedia presentations with more advanced media tools, i.e., the cameras, optical technology, laser disks.

Connectivity
Use of the WWW, connecting with students, and connecting with peers in the global community. This includes establishment of forums, chats and listservs, using Netscape or Eudora to send class messages and manage e-mail files, and using a personal web page to communicate with students. Faculty currently have E-Mail available for routine campus communications, and many use a service provider at home for additional service. However, they perceive a need for training to support the use of forums or chat rooms as part of electronic class discussions, of training to manage more efficiently responses to student E-Mail, and management of accounts.

Integration.
Integrating technology into the curriculum as taught in the university, and as taught in K-12 education. This also includes the use of advanced forms of media such as optical technology, scanners, video and sound, digital and document cameras, and interactive laser disks. Of special interest because of its integral place in the TWU Strategic Plan is the need for training in distance education. The University is committed to the development of more on-line courses, participating in global classrooms, and extending its video conferencing. To date, a number of courses have been taught successfully, and video conferencing between our Denton/Houston/Dallas campuses is routine. Faculty need training in use of Internet resources to use with various content areas at various levels as well as use of appropriate CD-ROMs and content-specific software. The evaluation of software and of the teaching/learning processes are an intrinsic part of the training in this area.

Program Integration: Mentor Teachers

Conduct Needs Assessment
Mentor teachers have identified their need for more technology training. Approximately 360 mentor teachers are involved each semester. The eleven school districts in CCPDC vary in training provided and in their platform choice. The mentor training needs to provide a series of choices, some of which would be sequential. The training could be conducted by university, district, or service center personnel. The annual needs assessments need to be completed in January so that plans can be made for summer training, and the schedule for the next year established. A subcommittee of the advisory counsel needs to direct this activity.

Collaboratively Plan Yearly Schedule
In order to involve district personnel, the yearly schedule needs to be established and publicized in the spring, prior to the design of school calendars. The yearly schedule requires a recognition of district variations in schedule, class size, training resources, and rotation and sequencing of sessions.

Implement and Evaluate Training
The training will be routinely evaluated and reviewed by the technology committee for modification, repetition, and rescheduling. Evaluation is standardized, reviewed by the committee, and used as a basis for revision and enhancement.

The Technology Competencies Database: Computer Support for Assessment, Teaching, and Portfolio Management

Michael Waugh
University of Illinois

James Levin
University of Illinois

James Buell
University of Illinois

The teacher education programs at the University of Illinois in Urbana-Champaign have no single, foundational course in instructional technologies. Rather, we work with our instructors to infuse relevant and appropriate instructional technologies into each course in our teacher education programs. Recently, NCATE adopted the ISTE-developed standards that identify the critical instructional technology concepts/topics that should be included in all teacher education programs. Given the distributed structure of our approach to incorporating technology into our programs, we felt the need to develop a software tool that would assist instructors in situating specific technology experiences within a series of courses. In addition, we needed a system that would enable instructors to collaborate effectively in assessing students’ competence regarding each standard. Further, we wanted a system that would provide student access to their records and an easy means of submitting evidence in support of their attainment of the required skills and experiences.

To meet this need, we developed the Technology Competencies Database, a World-Wide Web-based software tool that will enable a group of faculty to collaborate more effectively in providing technology experiences to their students. The TCD is a FileMaker Pro database running on a Macintosh computer that is also a World-Wide Web server. Students and Instructors interact with the system at any time of day and from any location using any web browser software.

The TCD contains individual records for each student and enables them to submit statements and materials in support of their attainment of the ISTE/NCATE standards (which we refer to as the Technology Competency statements). These submissions are accessible by the students’ instructors; and the students and instructors may exchange messages regarding the competency statements, the students’ submissions and any additional work which will be required by the instructor.

The students’ submissions and the faculty responses are all preserved in the database and can be sorted in various ways to provide the faculty with reports regarding where each competency is addressed in each program and, most importantly, what kinds of activities each faculty member is accepting as evidence that each competency has been met.

The TCD system may be very valuable in helping us to ensure that each student is being held to the same standards of performance. In addition, it will help us to demonstrate where and how each technology competency is acquired by our students. Further, it will allow the students to create an electronic portfolio of their technology expertise.

Introduction

Thirty-two states already require technology training as part of their certification requirements for teacher licensing (Zehr, 1997). In line with this trend, the National Council on Accreditation of Teacher Education (NCATE) is adopting comprehensive guidelines for what teachers in training ought to learn about uses of educational technology (Guernsey, 1997; NCATE, 1997). Although a requirement for the “technology competencies” is not yet in place in all states, teacher educators know it is only a matter of time until they appear, in part because of the rapidly increasing funding for classroom-based learning technologies. In such an environment, it is perhaps not surprising that instructional technology is growing rapidly in importance among teacher education programs.

One way to deal with technology competencies is under way at the University of Illinois at Urbana-Champaign (UIUC). We developed the Technology Competencies Database (TCD), a web-based resource being implemented in the undergraduate education program at the College of Education. In the fall semester of 1997, 57 senior-year undergraduates majoring in elementary education are being introduced to the TCD as part of their coursework. The TCD offers students a chance to tell their professors what...
they know about aspects of educational technology, and gives the professors the chance to award credit to the students for their knowledge.

This paper describes a formative evaluation study of the process of implementing the TCD in our teacher education programs. Technical, educational and social issues relevant to the innovation are described, with attention given to the views of diverse stakeholders including teachers, students and the TCD designers. Conclusions and recommendations appearing in the study deal with a broad range of implementation issues within and beyond the immediate context of use.

Overview of the ISTE/NCATE national standards

NCATE is a Washington, DC-based coalition of 30 national organizations that sets standards for education schools and accredits about 500 teacher training programs nationwide (Bradley, 1997). Recently, the International Society for Technology in Education (ISTE) recommended technology content guidelines to NCATE for programs in educational computing and teacher preparation. The ISTE guidelines encompass five general areas: 1) recommended foundations in technology for all teachers; 2) educational computing and technology literacy - endorsement; 3) secondary computer science education - endorsement; 4) secondary computer science education - bachelor’s degree, and 5) educational computing and technology leadership - advanced program (ISTE, 1997). NCATE adopted these guidelines for use in the accreditation of teacher education programs beginning in the fall of 1998. The first area, “recommended foundations,” lists eighteen competencies which all teacher education programs should address. These are divided into three categories: Basic Computer/ Technology Operations and Concepts, Personal and Professional Use of Technology, and Application of Technology in Instruction. (A list of these competencies appears in the Appendix.)

In mid-September 1997, an NCATE task force released a 32-page report warning that new teacher graduates are not being adequately prepared to use technology in their teaching (Bradley, 1997; Guernsey, 1997). This report urges that technology topics be integrated fully into the curricula of teacher training courses, rather than being ignored or treated as an optional add-on. In addition, the task force report urges NCATE to work with other professional organizations to encourage education schools to use modern communications technologies, and to identify and promote examples of exemplary practices. Among other recommendations, one particularly relevant to the efforts described in this paper is a suggestion that teacher education programs post student portfolios for electronic review (Bradley, 1997).

Teacher Education at the University of Illinois

The TCD project is taking shape at a time of major change in the College of Education at UIUC. In fall 1998, two redesigned teacher education curricula (elementary and secondary education) will begin which will include both classroom work and extensive internship experiences in the public schools. All majors in elementary education will be placed in public schools as student teachers for their entire senior year. Secondary education students will not graduate as education majors at all—instead, they will be majors in the subject areas of their specializations, and will meet state certification requirements by minoring in the College of Education. These secondary education students will spend an intensive final semester engaged in two field placement settings—one in the middle grades and the other in high school.

Throughout this redesigned curricula, technology is to be a recurring strand within a spiral curriculum; junior- and senior-year students will explore educational technology issues as part of at least four courses within the College’s curriculum. (The other recurring strands are “diversity,” “special populations,” and “evaluation.”) Such an approach requires that students be made aware and encouraged to explore educational technology use in a systematic yet highly fluid manner. This need has led to our development of the Technology Competencies Database.

The Technology Competencies Database

For the past three years, senior-year students majoring in elementary education in the College have had the option of enrolling in the Year Long Program (YLP). The YLP served as a pilot program for our newly redesigned elementary education curriculum. Students in the YLP spend two to three days a week teaching at public schools in the fall semester, and move to a five-day-per-week placement in the spring. In the spring of 1997, 40 YLP seniors were introduced to the Technology Competencies Database (TCD). Based on their experiences with the TCD, we modified the program and used it with another group of 57 YLP students in the fall of 1997.

The TCD works by linking a server-based database program to a web interface, allowing users to update, change and delete information via web-browsing software. At present, the resources in place are a Power Macintosh computer used as a server, FileMaker Pro 3.0 database software running on the server, WebStar 2.01 server software, and a WebStar add-on called Lasso, which allows information to be passed between FileMaker Pro and Internet web browsers.

Using the TCD via web-browsing software, the students described how they met some of the competencies laid out by NCATE and ISTE. They may also have provided a link to a web page with supporting information. The instructor
uses the TCD to respond to the students’ descriptions, either by awarding credit or by requesting additional information. In addition to providing these means for individual student-teacher interaction across the network, users also can see successful completions of various competencies by the students; the result is a system which grows more useful as more users contribute to it, with standards that are operationally defined through use.

**Purposes of the TCD**

The TCD is intended to give students a way to communicate their experiences with instructional technologies to the faculty, and for the faculty to assess the students’ accomplishments in these specific aspects of instructional technology. While many of the students’ experiences might be gained through participation in courses in the teacher education program, this mechanism will also permit students to earn credit for experiences gained through other means. Due to the large number of students in our programs and our need for multiple faculty to have simultaneous access to the students’ records of performance, we felt that an on-line mechanism for student-teacher interaction and record keeping would prove to be the most efficient, effective and convenient means for infusing the technology strand through the courses in our programs.

We see the TCD as a mechanism that can provide some essential structure to independent learning. One participating faculty member has suggested that the TCD might be made more flexible by having students nominate areas of technology expertise themselves, rather than responding to the list of competencies provided by ISTE/NCATE. Even in its present form, the faculty involved see the TCD as representing a portfolio approach, in that students are in control of the content they submit, and that they are creating a coherent summary of their work which may be used later as evidence of achievement.

**Analysis of the Spring 1997 TCD pilot study**

During the spring semester of 1997, 13 competency areas were included in the TCD. These were the original set of standards recommended by ISTE/NCATE. (Changes made by ISTE/NCATE in mid-1997 resulted in 18 rather than 13 standards.) In the spring 1997 version of the TCD, students were rated as having achieved at one of three levels of accomplishment for each of the 13 competencies; in general, Level 1 represented basic familiarity with a competency, Level 2 indicated that the student had used the competency with elementary-school sessions, and Level 3 showed that the student teacher had made the competency an integral part of an extended set of lessons in the elementary school (Levin, 1996).

An evaluation of the TCD implementation in spring 1997 revealed strengths and weaknesses (Moore, 1997). On the positive side, students reported high interest in using the TCD, particularly because they thought it would prove useful in job searches. As negatives, students listed the slowness of the system (it has since been made considerably faster to use), and the long waits many of them experienced between submitting information and receiving any response from their instructor.

Analysis of the TCD responses following the Spring 1997 semester showed that of the 40 students in the YLP, only seven had successfully completed any of the competencies. Eight students had submitted descriptions which received no response from the instructor, and five students had neglected to respond to the instructor’s requests for additional information about one or more of their descriptions. Furthermore, only 25 of the 39 competency/level combinations had been attempted by any of the students.

These findings led to substantial revisions in the TCD over the summer. The TCD was updated to reflect the new 18-competency version of the NCATE standards, and the three-level performance distinction was eliminated. In the current version of the TCD, students are asked to describe a single level of completion for each of the 18 competencies; the instructor is given the choice of withholding credit pending more information, awarding a rating of acceptable, or awarding a rating of exemplary/outstanding.

**Evaluation of the Fall 1997 TCD trial**

In the fall of 1997, formative evaluation techniques were employed to seek an understanding of the diverse viewpoints of the various stakeholders involved in the implementation of the Technology Competencies Database project. Through these efforts, we gathered information from students and faculty members via surveys, personal interviews and direct observations. We then used this information to modify the design of the TCD throughout the semester. Although this departs from traditional research designs in which evaluators refrain from direct interference in the projects they are examining, we felt that the benefits of a hands-on approach outweighed any purity of purpose that might otherwise be achieved; that is, it was reasoned that if the purpose of evaluation is to inform practice, the greatest benefits would be achieved by applying the information gained as soon as possible, so that participants would not have to continue dealing with inefficiencies which might easily be remedied. Among the changes which resulted from this approach during the semester were improved instruction sets and programming changes to maximize the speed of interacting with the database.

The evaluation conducted during the fall consisted of four main phases: 1) participant observations at the time of students’ initial introduction to the TCD; 2) distribution, analysis and collection of surveys given to the students at the time of introduction; 3) interviews and discussions with a faculty member participating in the TCD project; 4) interviews with two students who used the TCD extensively. Each phase will be discussed below.
Introduction of the TCD to students in fall, 1997

The students were introduced to the TCD in late September. At that time, forty students submitted responses for at least one competency area. This occurred despite remarkably slow response times from the network, owing to the large numbers of simultaneous users on what is essentially designed to be a one-at-a-time database program. (Particularly slow were page updates, which are made when users submit new information to the database. Each took about 20 seconds, so in cases where as many as fifteen users submitted requests almost simultaneously, the last requests in the sequence would take nearly 300 seconds, or five minutes, to be processed.)

Thirty of the 57 students returned surveys which were distributed to them at the time of their introduction to the system. In these surveys, they were asked to write briefly about their likes and dislikes regarding the TCD, about what changes they would like to see, about anything they found confusing, and about how they thought the TCD might be useful to them.

Fourteen students said they liked the way the overall operation of the TCD, with five reporting that it was user friendly, seven commenting on its ease of navigation, and two commenting that the directions were self explanatory. Four respondents commented favorably on the efficiency of using the TCD: one called it “effective,” another reported that it was “not very time consuming,” one appreciated being able to use it “on my own time,” and one remarked favorably about being able to provide a narrative description of abilities.

The negative comments from students largely fell into two major categories. There were seventeen complaints about the speed of the system, and twelve about the wording of the competencies themselves. One respondent commented that it was difficult to decide what to write about, and another complained, “it’s just another thing to do.” Similarly, suggested changes included twelve requests that the standards be rewritten to make them less confusing, and four requests for faster programming. One student suggested that designers might explore “a more specific way of testing these skills,” rather than relying on self-reporting by the students. In writing about what they found confusing, sixteen students commented on the language of the descriptions (They did not understand the wording of the competency statements); four others were confused and irritated by a programming error which brought up an incorrect response page (the error was fixed immediately after the session).

Finally, in responding to how the TCD might prove useful, seventeen students commented that they hoped to show their records in job interviews or as a part of portfolios for potential employers to see. “It will make me more marketable,” wrote one. Eleven responses dealt with personal goals; three students said the TCD would encourage them to learn more about computers, five saw it as a tool for self-assessment, and three said it helped them to realize what they didn’t know. One student wrote that “meeting future national standards” was a useful goal.

Changes resulting from the survey responses

As a result of the students’ responses, two independent efforts were made to clarify the intent of the standards. The instructor of the YLP group prepared one set of descriptions to help the students understand the competencies. He distributed his comments to the students on paper. In addition, the authors of this paper also paraphrased and revised the statements and added these to the TCD via hyperlinked text. This duplication of effort was in part due to lack of communication between the authors and the instructor, but it resulted in the creation of two good sets of plain-language descriptions which may be combined for even better results. By going through this process, the instructor became more aware of the standards he would actually employ in deciding how to award credit to students.

Discussions with the YLP course instructor

Following introduction of the TCD, the programmer met several times with the students’ instructor to show how the system could be used efficiently, and to explore areas where the TCD might be improved. In general, the instructor spoke quite favorably about the TCD’s ease of use, and about what it has enabled him to learn about his students’ abilities. However, he expressed concern about finding ways to devote time to the task of marking responses. He devoted considerable effort to the job at times, as can be seen in e-mailed comments: “I worked for about 45 minutes on 10/15/97 to react to all YLP in section #2, who had responded to standard #1. I did not count, but I estimate 15-20 students in section #2 had noted something on some standard. I did not really refer to the responses I had created when reacting to section #1. Also found that I gave only one exceptional grade. Maybe I am becoming harder to please. The constant rereading of the standard and student responses certainly helps clear things up.” Several days later, he wrote, “I have worked on standard #1 since 1:00 PM or so-Jim Buell dropped in and coached as I started. I then went on to do all YLPs’ standard #1. That is, all of those who had entered something for standard #1. It is now 3:30 PM. I have not left my chair, but have had a steady stream of phone calls, visits, and secretarial interruptions. It is my opinion that I can get quite a bit done in a short amount of time if I stay w/i one standard and do this after hours. ... There are several do-it-agains and 3 exemplary judgments. They differ, but should have in common more than we asked for.”
Through these efforts, the instructor completed the evaluation of one of the eighteen competencies for the thirty students who had attempted it, within four weeks of the time the students were introduced to the TCD. However, those thirty submissions were just one-fourth of the 120 which students had submitted up to that point. Owing to other demands on his time, the instructor was able to advance little in the task over the following month. By late November, nearly all students were still waiting for responses to descriptions they had entered as much as two months previously.

Problems to date

As solutions are being found to problems associated with access speed, information collection and usability, a key problem regarding feasibility of use has been discovered. It has become obvious that faculty will have a difficult time providing the optimal level of individualized feedback to students that the TCD is capable of enabling. The success of the TCD initiative will depend upon our discovering several acceptable models for assisting instructors in managing the effort involved in evaluating student submissions. Designers, instructors and users all agree that having one professor evaluate fifty-seven students in eighteen different competency areas is proving to be an unrealistic task.

Future directions

This raises interesting questions about the role of evaluation in a student-centered resource like the TCD. At least one faculty member has considered the idea that students themselves be required to evaluate, or pre-evaluate, one another’s completions of the competencies. However, students who have been presented with this idea have responded that they do not believe they would be qualified to judge one another’s work. An alternative strategy might be to devote the time of a teaching assistant to this task; this, in fact, was suggested by two students interviewed for this study.

Summary

The convergence of calls for technology competencies and the need for improved assessment motivated the development and implementation of the Technology Competencies Database. We see this as a way to help students acquire a wide range of expertise with educational technologies, while at the same time providing them with the tools to support the students’ development of electronic portfolios illustrating their expertise. While we have developed a system that supports students in their submission of evidence supporting their expertise, we still need to develop additional tools to help faculty evaluate these submissions in a timely, and efficient manner.

Introducing the Technology Competencies Database matrix

Recently, the International Society for Technology in Education has drafted several sets of competencies for teachers in training. The first set of 18 competencies, “Foundations,” is intended for all undergraduate education students. The National Council for Accreditation of Teacher Education has accepted the ISTE standards as goals for all teachers in training.

As part of your teacher training, you will have ongoing opportunities to assess your level of achievement in these competencies. You will be using the Technology Competencies Database (TCD) matrix, an information-gathering resource that runs on College of Education’s web server. Using web-browsing software, you will be able to correspond with your instructors to describe how you have met various competency requirements, and to seek their approval. The TCD will let you build a personal record of your accomplishments, which may be of great use to you in later job searches and resume-building. The TCD will also help your teachers to lead a course that takes full account of your current knowledge and needs.

The TCD matrix is still in an evaluation phase. Throughout the course, we encourage your comments and suggestions about how to adapt it to suit your needs and interests.

Using the TCD matrix, you will be presented with descriptions of each of the 18 foundation competencies, and will be requested to write online about how you have met any or all of these. Supporting evidence may be given in the form of a URL, pointing toward your own home pages. Instructors will then have the opportunity to evaluate your efforts. Credit may be awarded in the form of a “gold-star” (or, for outstanding efforts, a “double star”); alternatively, you may be asked to refine your descriptions before credit is awarded.

Although you will use web browser software to build your personal matrix of competencies, you should get started with the process by looking over the competencies on the other side of this paper. Check off any competencies which you already have, and jot down a short description of how you have met them. Soon, you will have opportunities to enter this data into the TCD, so your teachers can see your answers and evaluate them.

Here’s how to get started using the TCD matrix:
1. On a computer connected to the Internet, start a web browser program (we recommend Netscape 3.0 or higher)
2. Go to the following site: http://lrs.ed.uiuc.edu/tcd/
3. Log in, using your network ID and the TCD password you are given by your teacher (if you would like to use a different password, please tell your teacher; do not select your network password, however - at present, the TCD matrix is less secure than the university’s system)
4. From the matrix (pictured on other side), select a competency to write about.
5. Write about how you have satisfied the competency; give detailed answers, and consider putting evidence onto a personal home page for your teacher and others to see.
6. Submit your answer for your teacher to evaluate; optionally, you may also send e-mail to your teacher.
7. Return to the TCD matrix regularly, to check your progress and to write about additional competencies.
## Technology Competencies Matrix for Joe Test

**Name:** Joe Test  
**Network ID:** j-test  
**Educational Program:** example

### Foundations Competencies

1. Professional studies culminating in the educational computing and technology literacy endorsement prepare candidates to use computers and related technologies in educational settings. All candidates seeking initial certification or endorsements in teacher preparation programs should have opportunities to meet the educational technology foundations standards.

#### Group Description

1. Candidates will use computer systems to run software; to access, generate and manipulate data; and to publish results. They will also evaluate performance of hardware and software components of computer systems and apply basic troubleshooting strategies as needed.

<table>
<thead>
<tr>
<th>#</th>
<th>Competency Description</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.1.1</td>
<td>Operate a multimedia computer system with related peripheral devices to successfully install and use a variety of software packages.</td>
<td>✪</td>
</tr>
<tr>
<td>1.1.2</td>
<td>Use terminology related to computers and technology appropriately in written and oral communications.</td>
<td>✭</td>
</tr>
<tr>
<td>1.1.3</td>
<td>Describe and implement basic troubleshooting techniques related to using a multimedia system with related peripheral devices.</td>
<td>✪</td>
</tr>
<tr>
<td>1.1.4</td>
<td>Use imaging devices such as scanners, digital cameras, and/or video cameras with computer systems and software.</td>
<td>✭</td>
</tr>
<tr>
<td>1.1.5</td>
<td>Demonstrate knowledge of uses of computers and technology in business, industry, and society.</td>
<td>✭</td>
</tr>
</tbody>
</table>

#### Group Description

2. Candidates will apply tools for enhancing their own professional growth and productivity. They will use technology in communicating, collaborating, conducting research, and solving problems. In addition, they will plan and participate in activities that encourage lifelong learning and will promote equitable, ethical, and legal use of computer/technology resources.

734 — Technology and Teacher Education Annual — 1998
Educational reform initiatives aimed at integrating technology into the curriculum are well at work in institutions of higher education across the country, with computers being the technology of choice. As more and more K-12 teachers are required to change their teaching methods and teaching styles to include technology, educators within teacher education programs are being asked to alter their methods and styles of preparing teachers, specifically to include teaching with technology. To facilitate this change and to structure computer-based activities, teacher preparation programs tend to use either the International Society for Technology in Education (ISTE) Foundation standards or the Association for Educational Communications and Technology (AECT) program and learner guidelines. (ISTE, 1997a; ISTE, 1997b; ISTE, 1997c; Wiebe and Taylor, 1997). However, as curriculum strategies are developed to address the issue of educational reform for technology inclusion, a word of caution is in order. Whether the chosen strategy for change consists of an isolated computer course, the concurrent attachment of a computer lab to existing courses, and/or the option to use and model the use of technology in established teacher education courses, what you do not want is for the integration of technology to mimic the training environments of business and industry.

Viva La Difference!

There are many lessons to be learned from business and industry training environments. However, it is crucial to remember that the focus of training in business and industry is short-range instruction for equipping employees with new skills that will be applied immediately once they return to the job. Teacher education programs may have a short-range need to impart basic computing skills to its students. However, the focus of their computer-based activities must go beyond short-range, step-by-step skill development to include long-range transfer of learning and transfer of training. This is necessary because (a) each year, more and more students enter higher education with basic computing skills, (b) the majority of the students will not go immediately to the teaching job, and (c) the steps students are taught to perform computer skills are subject to change over time as software is upgraded. And although the creation of isolated word processing-, spreadsheet-, database-, graphic-, presentation-, and telecommunication-based documents (which is the norm) serve to improve or reinforce basic computing skills, they accomplish little towards preparing teacher education majors for the K-12 classrooms of the 21st century or helping them understand the big picture of instructional computing.

The Big Picture

One of the original arguments for inclusion of computers in educational environments was that "computers increase student engagement, add realism to instruction, promote skill mastery and understanding of principles, augment laboratory experiences, and encourage inferential thinking" (Johnston and Joscelyn, 1989, p. 2). If this is still the case, and many believe it is, then learning through supplemented computer-based instruction is the true goal to which the development of basic computing skills becomes prerequisite for teacher education majors who will ultimately use the computer as both a management tool and an instructional tool. Using the computer as a management tool requires that users develop and demonstrate better problem solving skills, better analytical skills, better critical thinking skills, and better decision making skills. Using the computer as an instructional tool requires the same cognitive skills as using the computer as a management tool, however, such skills must be fine tuned to help develop the corresponding skills within the students being taught. The real challenge is to teach and to reinforce these skills to teacher education majors while simultaneously showing them how to integrate the technology into the range of curriculum they will be teaching.

Preparing For The Challenge

Realizing the challenge before us is not unique to any one institution of higher education, faculty and teaching assistants within the Educational Technology Program at Purdue University began working together on a project to transform the computer labs for two of its highly populated
courses into environments which facilitate more cognitive learning experiences through scenarios-based computing activities. In preparation for the change and to better understand the students in attendance, both courses were to be taught as usual during Fall semester 1997, however, the strategic collection of data was planned as a means of justifying the future changes.

An initial data collection instrument was designed and distributed early in the semester to gather profiles of current students (Appendix A). Approximately 30 days into the semester, a second instrument was distributed to solicit student feedback regarding on-going computer activities and projects (Appendix B). Throughout the semester, the largest populated computer lab was closely monitored by the instructors and the teaching assistants with discussions of problem areas taking place via email correspondence and weekly staff meetings. Approximately 10 weeks into the semester, one learning activity was administered specifically to gather information as to whether or not students were making the integration connection between classroom lectures and computer-based activities (Appendix C). The final data collection instrument was distributed at the end of the semester to assess the learning experiences of the students. As such, the information provided the foundation for pilot testing the use of scenario-based activities.

**Why Scenario-Based Computer Activities**

The scenario-based computing activities were designed with a four-fold purpose in mind, specifically to allow
1. faculty to closely correlate the required computer component of the course to learning which takes place through the class lectures and textbook.
2. faculty and the teaching assistants to use instructional computing to teach and reinforce the educational skills which need to be developed, i.e. problem solving, analysis, critical thinking, and decision making.
3. pre-service teachers to use cognitive skills to help them learn about computer use and solve problems related to computer use.
4. pre-service teachers the opportunity to create a living portfolio which contains examples of instructional computing projects they understand and can implement within a curriculum.

Scenario-based computer activities incorporate the day-to-day work situations encountered by in-service teachers with the possibilities of effective computer use. Doing so provides pre-service teachers with an opportunity to focus on (a) the management and instructional duties faced by in-service teachers and (b) technology integration issues within the classroom. It also forces them to think about each task in relation to what they might actually face sometime in the future. The instructions for each scenario-based computer activity solicits questions from the students that are necessary to clarify the situation. Failure to ask questions may result in obstacles for resolving the problem, however, questions are entertained throughout the activity.

Data files are provided for each scenario so that students focus primarily on the task and not on data entry. Additionally, since resolution of each situation could differ from student to student, collaboration is facilitated. Ultimately, each scenario requires that students think about and discuss computer use relative to (a) what needs to be done, (b) why the computer becomes the medium of choice for the specific scenario, and (c) exactly how the computer will be used. Then, and only then, do the students use the computer to perform the necessary management task(s) or instructional task(s).

This curriculum strategy will be demonstrated during the poster session so that attendees can see why it does a better job of preparing teacher education majors to integrate the technology than the basic computing skills method. To experience scenario-based computer learning first-hand, interested individuals will have an opportunity to participate in solving the following scenario-based computing activity and brainstorming the development of a new activity.

**A Mini Management Scenario-Based Activity**

Approximately 876 students attend Smith High School in the urban community of Anytown, Your State. In an attempt to increase school security within the district, the superintendent of schools implemented a picture ID card/barcode scan system within each high school. Students gain entry into the school by scanning their ID card at the monitor station that simultaneously documents the date and time of entry and departure. Over the past six weeks, the system has worked extremely well so well, that a suggestion was made to eliminate the 20 minute homeroom period and redistribute that time into the current block scheduling periods. To test such a possibility, each homeroom teacher was asked to match the manual attendance records of their students for a two week period against the computerized records of entry and departure for the same time period. As one of the 47 homeroom teachers, you must verify the records for your students and provide a report of its accuracy to the school principal within the next seven days. The principal is also interested in hearing your thoughts about using the picture ID card/barcode scan system to eliminate homeroom period within the report.

**Abbreviated Scenario-Based Activity Instructions**

Since each teacher is responsible for accessing the computer database located in the main office and requesting a printout of his/her students for the designated two-week period, five 1/2 hour training sessions were scheduled to
brief teachers on obtaining a computer printout. The training sessions will take place this week on two mornings before home room period and three afternoons following the last class period. You have the option of attending one or more of the session and/or using the self-instruction sheets to learn the system. Feel free to collaborate with other teachers, however, each teacher must submit a typed report no later than 5:00 PM next Friday. It is important for you to remember that the database you will be accessing contains sensitive and confidential information in addition to the full name of each student, complete ID number, full home address and telephone number, complete parental/guardian information, complete high school schedule for the current school year, and all entry and departure information for the school year thus far. You do not need a printout of every piece of information, just your students and the dates and times of their entry and departure during the designated two week period. Are there any questions?

As such, the completed scenario-based computer activities lend themselves toward preparing pre-service teachers to interact with the realities of their future work environment and prepare themselves accordingly. Pre-service teachers should find that responding to real-world situations is fertile ground for learning, understanding, and reasoning through the process of computer use. And equally important, computer use is no longer a luxury, but a necessity (Thomas & Knezek, 1997)

As computers become prevalent in every part of our daily lives, so does the need for training on how to use those technologies. Because of this increase in need, demands have also been placed on schools to educate our children and make them "technology literate." However, prior to educating our youth, efforts must be dedicated to preparing teachers who can harness the educational possibilities of using computers in the classroom. One of the most difficult tasks any undergraduate teacher preparation program can face is trying to help educators become comfortable with computers while still preparing them for the ever changing and flexible technologies of the 21st century. Over the course of the past five years I have either taught or been a part of numerous teacher technology-training programs in Elementary schools, Middle schools, High schools, and Universities across 2 different countries. Time and time again I am presented with training programs that show teachers how to memorize steps in order to become experts in particular software. The problem is that with the speed of changing technologies, expertise turns into frustration as memorized steps become chaff in the wind. This is readily apparent in undergraduate pre-service programs where students learn technology skills but find that they can't integrate the skills (or can't remember the steps) upon graduation and placement. There are cases where teaching specific skills inspires some teacher education students to adopt a technology mindset to approaching curriculum planning. However, for the most part, this transmission model of technology adoption fails.

A Narrative Solution

Stories have been used to educate since the beginning of time. And recently, there has been a resurgence of interest in a narrative approach to educating our youth by educational researchers (McEwan & Egan, 1995; Heath, 1994; Egan, 1986). McEwan and Egan (1995) introduce their edited book with, "We begin with Barbara Hardy’s celebrated observation that we ‘dream in narrative, daydream in narrative, remember, anticipate, hope, despair, believe, doubt, plan, revise, criticize, construct, gossip, learn, hate and live by narrative”, in order to argue for the importance of narrative in education. In regards to teachers, there has also been an effort to capture their thoughts, feelings, and philosophies through a narrative approach (Jalongo & Lillard, 1980). Finally, the use of stories has even infiltrated the computer and technology realm (Murray, 1997; Gesture and Narrative Language). What can be learned from the above research is just how important stories can be both as a teaching approach and research methodology in education and educational technology.

In trying to create a pre-service teacher and technology-training program, it is possible to combine the three approaches to narrative. John Shotter points out the following,

This, I think, is where Wittgenstein’s (1953) work is of such importance: for he draws our attention simply to the role in our ordinary, everyday social practices, of us drawing each other’s attention to aspects of our own ongoing practices, especially to its crucial role in us learning our social practices in the first place.

Therefore, if we adopted a dialogical or narrative approach as the actual autobiographical teaching method (combining all three of the above uses), we would help the pre-service educator become aware of their own feelings and thoughts about computers and education. This narrative methodology, rather than a completely skill-based program, affords students the ability to understand their own process of coming to know how to integrate changing technologies as a tool in education rather than a fixed landmark based on software instructions. These stories, told by the teacher through the process of learning about technology, would reveal a detailed picture to the researcher, teacher, and student herself of the development process a pre-service...
educator goes through on her way to learning how to use technology in the classroom.

Method

In March of 1997, I was approached by a pre-service student who was interested in learning more about technology. She was going to look for a job over the summer and felt like the market demanded technology skills that she did not have. It was about this same time when I became very interested in the narrative approach and so, with her permission, set out on a quest to teach her about technology in a storied manner.

We decided that we would meet as many times as we could prior to her leaving to find a job. I agreed to tutor her but asked if she would be willing to help me learn more about how to teach technology to an audience such as the one she originated from. I informed her that the process would include audiotaped sessions, weekly journals from her, and a beginning and ending interview. However, I also let her know that failing to meet any of these needs would in no way jeopardize her tutoring sessions.

Finding out about technology

We met throughout April and May of that year for about 1 hour to 90 minutes a session. I spent most of the time teaching her how to accomplish certain tasks (e-mail, browsing the web, creating web pages), but left enough details out to reinforce my constant reminders that the process was more important than the details. During those sessions, in order to help both her and me understand the processes she was going through, I asked her to "think aloud" during the sessions. Meaning, I wanted her to talk through whatever she was doing—both the actual mechanics of what she was doing as well as her thoughts about how she would or wouldn’t use the technology. I was trying to get her to determine where technology fit into her philosophy of teaching. Initially, she was nudged into doing so by my continually asking questions about what she thought she was learning and how she thought it might impact her teaching. However, as time passed, she became more and more comfortable with the think-alouds. As I reviewed the audiotapes, I was amazed at the shift from the initial tape to the final tape. My voice could be heard through much of the tape in the beginning. However, towards the end of our sessions, one wondered whether I was even in the room. I owe this to the fact that she was becoming more comfortable with technology and more importantly with her story about technology.

Another important component besides the think-alouds was the weekly journals. Three important notions became evident in the journals. First, technology was frustrating to her (as it is to most teachers learning about computers for the first time). Early entries were comprised of: "I still feel pretty overwhelmed about what the possibilities are in the this crazy computer world." and "I found our meeting frustrating..." However, later entries showed a developing sense of learning how to use technology: "I also found a sense of patience that is necessary as I begin learning my way around." and "I'm starting to understand at a more connected level."

Second, the agenda that I had started out with was by definition very loose. I wanted to be able to structure our sessions around initial basics (surfing the web, using e-mail, etc.) but I also wanted to have time to encourage her interests and her thoughts about computers. I found that she not only followed her own interests but started asking her own questions about teaching and teaching with technology. "Our sessions remind me of how haphazard learning can be. If we stuck to the outline we create at the beginning of the session, we'd be missing out on a lot of the discussions we've been having. It can be scary from a teacher perspective to stray from the plan, but do teachers always know the best way to proceed with a subject?" What initially began with, "I am interested in..." turned into "I really want to learn how to create a webpage. We should look at some classroom web pages to see the kinds of things they have on them."

Finally, it became evident through our sessions that she was learning more than just skills, but seemed to be rewriting her story of how she viewed herself in relation to technology. She reported that she moved from being afraid of computers to being willing to try different things out. It is through this process of learning and telling narratives about that learning that the student changed her own narrative on her view of technology and philosophy of teaching.

Implications for Pre-service Education

Although my case study was only an N of 1, I believe that it has some important implications for preparing teachers to be technology literate. First, as with any class, there must be an agenda with objectives of what should be learned. However, if we can move away from skill objectives to focus more on the teacher coming to her own understanding of technology in the form of how it changes her story, we may be teaching them how to use tools rather than just which way to turn a screwdriver. Therefore, successful programs will focus on teacher exploration of their own interests whether that is with a supercomputer or a calculator.

Second, my case study was unique in the sense that I was able to have constant dialogic interaction throughout the learning process. In a classroom of 20 students, that isn't always realistic. However, as we change our pedagogy to focus on the teacher as facilitator of knowledge rather than master of the class, we realize the importance of using classmates in learning objectives. This would include working on technology collaboratively and having one of the partners facilitate think-alouds while the other explores.
Journals can then help communicate between the observed, the observer, and the educator. Journal topics would focus on what the students learned about the other person as well as their own views of technology. Using Shotter and Wittgenstein’s ideas mentioned above, students become aware of their own social processes and in turn their own story about technology. As my subject replied, “I, too, would like to have some documentation about my learning process.”

Finally, when asked about what makes a technology expert, many students reply that it is the ability to walk into most technology situations and not necessarily know everything that is happening, but not being afraid to try. It is very rare that anyone states a technology expert is someone who knows everything there is to know about “X” software. In the ending interview, the student in my case study reported that she still gets frustrated over not being able to do certain things with technology. However, through discoursing about technology and its relevant uses to her ideas of pedagogy, she has gained a persistent attitude, a willingness to try, and has started to overcome the fear of computers that dominated her earlier story. When teaching pre-service teachers about technology, many programs force students to adopt their story of what technology should be used and how it should be used. In the end, students drop those stories as easily as one forgets a joke. However, we may be able to facilitate the creation of the educator’s story through discourse and dialogic interactions about the processes they are going through in learning about that technology. As they go into the workplace, technology is not an add-on but a central component of their philosophy of pedagogy.

Future Research

The findings in this paper are based on preliminary analysis of audiotapes, journals, and interviews with a preservice educator as she learned about computers and how they can be used in her classroom. Future research includes a more complete analysis of the transcripts to not only examine more closely the teacher’s story, but also the dialogic interaction between the researcher and the educator. I hope that this analysis will provide more information about how teachers realize and conceptualize technology in their stories as well as how those dialogic interactions could be reproduced in the classroom. Finally, I also hope that this and future research will shed light on more effective ways to teach teachers about technology by using a narrative approach.

The purpose of this technology training model for preservice (those in training) and inservice (practicing) teachers was two-fold in order to address technology integration into the pre-college classroom and preservice teacher education programs. The first purpose was to provide inservice teachers the essential training for integrating technology as an instructional tool. Simultaneously, a model for preservice teacher education instructors was being developed to assist with the integration of technology into the methods courses across the curriculum. The question to be answered was whether technology training should include learning the basics of how to use a computer (e.g. using a wordprocessor or spreadsheet) and then how to integrate specific applications into the content or can both be addressed simultaneously? This paper describes the logistics of the training model designed to investigate the effectiveness of training teachers how to integrate technology based on the constructivist philosophy that learning occurs and is transferred when based on the participant’s own exploratory and discovery experiences.

Background

A teacher’s decision to implement technology in the classroom is guided by many factors including accessibility to equipment, educational objectives, students’ diverse needs, and the teachers’ vision and expectations regarding the contribution of the new technology to achieve local, state, and national educational goals and objectives. Researchers during the past decade have provided evidence demonstrating the effectiveness of computer-assisted instruction in the classroom for improving students’ ability to learn (Duplass, 1995; Kaput, 1992; Kulik & Kulik, 1987; Liao, 1992; Niemiec & Walberg, 1987; Niemiec & Walberg, 1992; Ryan, 1991). The current curriculum reforms in math, science, language arts, social studies, and technology education in our precollege classrooms have required essential training of preservice and inservice teachers. The integration of technology in the precollege classroom is upon us and as a result, the proper training of teachers must include modeled instruction using technology for teaching specific concepts that can be transferred into the teachers’ real classrooms of instruction. Research has shown that technology instruction not linked to subject matter is not valued by the learner (Schmidt, Merkley, Strong, & Thompson, 1994) and this model was developed to address both theory and application simultaneously. In other words, the teachers will learn the logistics of using a computer through applicable, exploratory training that could be transferred into the precollege classroom. Furthermore, the preservice and inservice teachers worked together on interdisciplinary, multiple grade level teams. For example, an elementary preservice teacher was a team partner with an inservice ninth grade science teacher and an elementary preservice teacher was a team partner with a preservice secondary mathematics teacher. Because each of the groups of teachers (preservice and inservice) was currently completing a different phase of their career, the exploratory environment encouraged valuable interactions between the teachers and their learning was complemented by the interdisciplinary teamwork.

It is essential to provide training across the curriculum at the undergraduate level in order to prepare preservice teachers to enter schools with the needed technology training. Similar training is needed at the graduate level to provide training as technology continues to change for inservice teachers returning to complete their graduate work or receiving re-certification. On a national level, technology began as an essential tool in the business world. As changes occur in our society, the curriculum in our schools must also adjust in order to produce students who have the foundation to use computers as problem solving tools as they pursue a college degree and function in the technology-based workforce. Therefore, it becomes a necessity to prepare teachers in all curriculum areas how to use technology as an instructional tool and to know when it is appropriate to use technology to involve students in active use of the computer without inhibiting essential skills such as reading, writing, computing, and communicating.
1. Experimental and observational projects

The teachers gathered data from experimental and observational projects and used appropriate computer applications to analyze the data, interpret and communicate the results. There were a series of these projects for different disciplines. An example of one group’s experimental project was to study the effect of the height and slope of an incline on a toy car’s speed. They ran 20 independent trials, recorded their data, and used the spreadsheet to produce line graphs. Then, they hypothesized what would happen if the slope and/or height was increased. A whole group discussion of how and why the graph changed was initiated and the teachers concluded by brainstorming how they could expand this activity and apply the same concepts in other subjects. Many more of the teachers’ ideas surfaced because of the discussion than would have occurred if the teachers had not explored and discovered for themselves. After each group had presented, a whole group discussion was necessary to summarize how the lesson “fit” the curriculum objectives. Finally, the groups exchanged lesson plans.

2. Layout of computer-based classroom and laboratory

The teachers designed a computer-based classroom and laboratory layouts with a minimum amount of technology resources and the typical classroom features: 5 computers, 1 television, sitting for 30 students (they chose whether tables or desks), 1 blackboard, and 1 teacher’s desk. The layouts were produced using drawing software of their choice. A written explanation accompanying the layout included cost, justification for classroom layout, and uses of the computer-based classroom. A majority of the teachers placed the computers on tables and located them separate from the students’ desk. Their explanation was that it was important to not only teach students by using the computer, but to emphasize to the students the importance of knowing when it is appropriate to use technology. Therefore, they did not want the computers on the students’ desks at all times for their convenience. This was an indication that the teachers were beginning to transferring from the training their own philosophy of how to “fit” technology into their already existing curriculum and their own philosophy of teaching.

3. Mini-grant proposals

It is essential for all teachers to remain current with the ever-changing demands by providing them with the grant writing skills needed to continually update the resources in their classroom as technology continues to improve. The teachers wrote a mini-grant for supporting a technology-based classroom.

4. Interdisciplinary instructional modules created by teams of students

Using state and national curriculum objectives, the teachers developed single subject and interdisciplinary computer-based activities. These activities preceded the teachers’ interdisciplinary, multimedia lesson modules that were presented to the class.

5. Development of a technology plan

The teachers located outstanding schools’ technology plans from across the nation in preparation for developing their own technology plan given criteria and including state-of-the-art technology. The research component included interviews of teachers at different grade levels (in person or via the Internet) and administrators.

6. Persuasive presentation

The teachers prepared a PowerPoint presentation to address the following scenario: Suppose your school has $10K to spend. Prepare a persuasive argument to convince your colleagues and the parents that the money should be spent on technology for the classrooms in the school. Provide specific examples, cost, logistics, and computer specifications required for ordering. The purpose of this project was to assist the teachers with their communication of technology issues as they prepared to return to their schools and use technology as an instructional and training instrument. One important aspect was to build their confidence in their ability to first, use technology in front of a group, and secondly, be able to correctly “talk” the language.

Results and Conclusions

Based on the teachers’ evaluations of the experience, they received valuable experiences and felt confident returning to their classrooms and implementing similar projects with their students. The overall rating of the experience by the 26 teachers was 4.8 out of 5.0. A random selection of fourteen of the teachers was made and telephone interviews were conducted as preliminary data as to whether the teachers have begun to implement the skills they learned. All of the teachers were able to describe at least one application they had implemented thus far. A content analysis was conducted on the teachers’ implementation responses and those could be summarized by the five categories shown in Table 1 (the teachers could give more than one response).

The follow-up interviews indicated that the teachers were transferring the technology skills learned in the workshop into their classroom. The most impressive result was that 13 of the 14 teachers responded that they were taking the initiative to explore and discover how to use the computer applications discussed during the training session. This response prompted a second question as to why they felt their exploration was necessary after having just completed the ten-week training session. Overall, the
Given this current emphasis for computer integration into precollege classroom instruction, the concern arises whether the use of computers as an instructional resource should be taught in a separate course or integrated into the current courses in much the same manner as other subjects, such as mathematics, are integrated and taught based on hands-on, exploratory methods supported by the constructivist philosophy. When an educator speaks of integrating technology into the K-12 classroom, the immediate thought is the effect of computers on the “learning” of subject matter. However, who makes the decisions on computer specifications, software purchases, computer layout in a laboratory or classroom, funds for upgrades and expansion as technology changes? Aren’t these issues also pertinent to the integration of technology in our schools? The answer is yes. Therefore, there are many ethical and legal issues that must be addressed by the teachers and these issues must become part of producing a computer literate teacher for the 21st Century.

Model for Technology Training

The model described in this paper was designed to incorporate the critical components teachers need to integrate technology into the classroom as an instructional tool for teaching across the curriculum as well as the theory and knowledge needed to support their teaching philosophy. One unique feature of this model was providing interdisciplinary training involving preservice and inservice teachers across grade levels (K-12). Observations indicated that the pairing of the inservice and preservice teachers across subject areas was one of the most valuable aspects of the computer training model. Eleven teachers (6 preservice and 5 inservice teachers) participated during the first year pilot study and twenty-six teachers (12 preservice and 14 inservice teachers) participated during the second year of implementation of the revised training model.

Description of the Interdisciplinary Experience

The planning of the computer training model began through a grant from the Mississippi State Department of Education. A pilot of the model was planned during a five-week period of the summer of 1996 based on input from an advisory committee consisting of teachers and administrators from the public schools. The goal for the model was to provide preservice and inservice teachers the opportunity to work together on exploring, discovering, and communicating how technology should be integrated in a practical way into the curriculum. An emphasis was placed on fitting technology to the curriculum already present in the school as opposed to fitting the curriculum to the technology (Niess, 1990). Based on the feedback from the eleven teachers, the model was revised and implemented again during the summer of 1997. One of the major revisions was the time period for the training. All of the teachers recommended that the training be extended over a long period of time because they did not feel enough time was allowed for exploration, reflection, project expansion, or discussion during the five week period. During the second summer, the model was implemented in a 10-week period and this adjustment was sufficient time for the teachers to reflect on their work and apply the learning theories discussed in class. The objectives of the training model were for the teachers to:

1. Identify current issues in mathematics, science, social studies, language arts, physical education, and foreign language that affect the selection and use of technology,
2. Plan lessons and design instructional activities that integrate technology using a direct and constructivist learning strategy based on state and national curriculum standards,
3. Apply appropriate use of specific kinds of instructional software and technology using either a single subject or an interdisciplinary approach,
4. Match specific kinds of instructional software and technology tools to classroom needs and design a computer-based laboratory and classroom, and
5. Identify appropriate funding sources and prepare a proposal for obtaining and using technology resources in the classroom and persuade others of the validity of their ideas.

The importance of creating this model was to provide teachers across different grade levels (K-12) and subject matter the opportunity to receive technology training that could be transferred across the curriculum and determine the effectiveness of technology training designed to teach both theory and application simultaneously. If teachers are expected to provide their students a problem-solving environment in the classroom, teachers must feel confident in their ability to use computer applications as tools for solving problems. Therefore, it was essential to train teachers as we would want them to integrate technology into the precollege classroom through hands-on exploratory and discovery-based projects that were supported by the constructivist philosophy for teaching. As a result, the teachers explored and discovered for themselves and were forced to acquire any basic computer skills that they did not have prior to the training experience. Throughout the training sessions, the instructor modeled how to provide students the opportunity to explore and discover through interdisciplinary lessons taught using appropriate technology-based ideas. As follow-up, practical applications that the teachers could transfer into their classrooms were assigned as projects. It was the combination of the projects that provided a valuable technology training model that could be used by any individual desiring to learn how to integrate technology into the classroom as an instructional supplement. A summary of each project is provided below:
teachers responded that either they wanted to learn because they had acquired just enough of the basics to give them confidence to continue, or they were integrating technology-based lessons into their curriculum and working with the students as they explored and completed their assignments. When asked if it had been necessary to teach the students “how” to use the computer prior to giving an assignment, all of the teachers responded “no” because the students could learn the basic skills as they completed their assignments.

Table 1. Content Analysis of Fourteen Teachers’ Follow-up Interviews

</table>

These preliminary results indicated that technology training designed to address theory and application simultaneously can be an effective approach for preparing teachers to return to their classrooms and actually implement the computer skills learned and provide students the opportunity to explore and use technology appropriately. Furthermore, the teachers were comfortable talking about their ability to “fit” technology into their already existing curriculum. They did not consider the use of technology as a “burden” or something that was required above and beyond their normal lesson planning. In summary, the teachers were trained to learn the logistics of using a computer as an instructional tool through applicable, exploratory training and they were transferring that same constructivist philosophy into their classrooms with their students. The tracking of these teachers will continue and include follow-up surveys, interviews, and classroom visits in an effort to determine in more detail their philosophy on integrating technology into the classroom and how they continue to expand on their lesson ideas for using technology as an instructional tool.

Acknowledgement

This project was supported through a grant by the Mississippi Department of Education, Jackson, MS.

CO-CONSTRUCTING PRACTICES OF TEACHING WITH TECHNOLOGY: WORKING COLLABORATIVELY WITH TE INSTRUCTORS ON TECHNOLOGY ADOPTION

Andrew Topper
Michigan State University

Current conceptions of technology literacy or competency tend to argue for a functional view of proficiency (ISTE, NCATE, etc.) These standards often consist of a laundry list of functional skills that teachers are required to demonstrate before they are judged to be competent with technology. While these standards have helped teacher preparation programs develop assessment programs that measure specific functional skills and expertise, they are often disconnected from the context in which technology serves a useful pedagogical purpose.

Teachers who pass these functional competency requirements can be said to exhibit simple or functional skills associated with a variety of technologies, but there is no guarantee that these same teachers will use technology in pedagogically appropriate or meaningful ways when they encounter these technologies in their own classroom. What represents a more appropriate target for future teachers is some demonstration of adaptive or pedagogical uses of technology within a specific subject area, which I believe requires thoughtful consideration of pedagogical choices in the context of actual classroom practice.

The MSU college of education has been struggling with this issue and recently a group of faculty members and graduate students have been experimenting with a program to implement a stronger pedagogical focus for technology in the teacher education (TE) program - i.e., integration of technology into teaching across the teacher preparation program. To this end, we have been examining the nature of teacher preparation in support of technology adoption, and learning from our own experiences trying to facilitate and support these efforts in the past.

In this paper I will report on some of our initial findings on these and related issues in an attempt to offer alternative ways of conceptualizing teacher technology competencies that hopefully will result in more meaningful uses of technology by K-12 teachers when they have access to technology in their own classroom.

History of the MSU approach

MSU has developed and implemented a variety of support mechanisms to help graduates of their teacher preparation program meet the state requirement for technology competency. The state of Michigan requires that all student teachers be competent with technology, so MSU has an obligation to ensure that its’ students meet these legal requirements. In the past, the college of education has taken steps to infuse technology into the teacher education program, including hiring graduate students to teach specific technology workshops, developing technology requirements resources for students, and discussing the integration of technology within the TE program. But it is safe to say that these efforts have met with only limited success in the past and the reasons why illuminate some of the problematic aspects of a functional approach to technology literacy.

Initially, technology education was to occur within two hours of class time each week and was to be provided by faculty or staff from each TE team. This made the goal of embedding technology in curricular contexts very difficult and resulted in a focus on a small set of generic tools which could be used in a variety of educational settings instead of a contextual technology use approach.

As a result of these constraints, very little attention was paid to curricular-specific technology. A change in focus also occurred when necessary funding for faculty training and support was not forthcoming in the second year of the program. This led to a perception within the teacher preparation program, both on the part of faculty and students, of technology as an additional task and not an integral part of learning to teach. This was reinforced by providing technology classes that focused on functional skill development towards meeting the technology requirements.

Later, technology coaches (also called mentors) were hired by the college to support students learning to use technology and to assess their technological proficiency in five areas: e-mail, Internet, word processing and presentations, database and spreadsheet, and subject-area software.

Preservice Teacher Education — 745
To understand why these perceptions became prevalent, we need to examine the nature of learning from a specific theoretical perspective, as well as question our own assumptions about TE students and technology.

**Theoretical perspective**

I hold a social constructivist perspective on learning which argues that learning occurs through participation in social interaction. This perspective stresses the importance of social interaction as providing opportunities for individuals to share their ideas through language, observe and critically review other ideas, and develop a shared sense of understanding within a supportive social context. Within this perspective, instructors, faculty members, and students are all viewed as adult learners who make sense of their experiences through their own beliefs and ways of knowing. These individuals bring their own assumptions about and experiences with technology to their learning and my focus is on helping them co-construct new teaching practices with technology.

I believe our eventual goal is to develop a TE program where technology is seen as a necessary and integral part of learning to teach by respecting the knowledge and expertise the TE instructors bring to their work. This is accomplished by developing collaborative relationships with TE instructors, working together on problems or ideas of interest, and engaging in stimulating conversations about technology in a variety of settings. The essential component here is to provide support in the form of ongoing collaborative work that draws on examples of technology use in TE programs and helps instructors see what these methods might look like. Exposure to and discussion about these kinds of experiences which are contextualized in classroom practice might help their students see the connections between their subject areas and possible uses of technology.

Supporting TE instructors in their thinking, talking, and teaching with technology is initially more difficult and less productive (in the short term) than alternative methods but we believe will eventually leading to a fundamental change in the TE program. This collaboration recognizes the interdependence between the TE instructor and the techguide and respects the knowledge that both bring to the relationship. The techguide brings extensive technology experience, having thought about how technology might be supportive of educational goals, and the TE instructor brings practical classroom teaching experience as well as pedagogical and subject matter knowledge. Together, the TE instructor and the techguide form a team that is bigger than either one individually.

**Field Experiences with TE instructors**

**Deb Smith: Secondary Science TE401 - E-mail and spreadsheets**

Deb and I met in a Macintosh lab a few days before she was going to be demonstrating how to use e-mail to send attachments for her TE401 students. We sat down and went through each of the steps as I helped guide her. She also wrote down the steps to document the process for her own students. As a result of that session, Deb felt confident that she could demonstrate for her students how to use e-mail as part of her regular class communications. She planned to use e-mail as a tool for communicating with her students, for encouraging them to share amongst themselves, and for sending her required coursework for grading.

As luck would have it, when she held her class in the very same Macintosh lab, we had nothing but technical trouble from the start. Somehow, the version of e-mail program we had used had been removed from the LAN server and I spent 20-minutes hunting down another copy. When I found it, we scrambled to update the descriptions only to find out that the version we were now using wouldn’t work on the computers. I spent another 15-minutes tracking down another version of the software before calling in another faculty member to help us with this problem.

Although we had lots of problems using technology, and the unforeseen problems, Deb kept a good attitude about the whole experience and managed to make the best of a bad situation. I think this experience actually helped her students realize that technology doesn’t always work the way we expect it to, a valuable lesson in itself. Deb was able to use the same Mac lab later in the term for a spreadsheet demonstration that went much better. Afterwards, she wrote about her teaching experiences in an e-mail she sent to me:

> "There were the usual server crashes, disk problems, etc. — mostly because when we made the Eudora disks originally, Yong came in and used his account, remember? So, many of their disks apparently had Yong’s email address on them, and when they tried to sign on, of course the machine wanted his password. But we got that straightened out, with Deepak’s and Tim Smith’s help, and several other TEC guides who came over for short periods of time to help us.

I think the seniors were intrigued by the possibilities that Clarisworks showed them for spreadsheet representations, and played around a lot of different graphs and charts. And my in box is full of email and attachments from them today, so I’d say that they all accomplished getting that checked off! :)

Thanks for your continuing support and help, both in helping me learn new things and in making it possible for my students to do the same.”

You can see from this e-mail that Deb is feeling more comfortable with technology herself, is especially grateful for the support she gets from the technology guides, feels she has learned a lot, and is also confident she is helping her students learn and meet the technology requirements. Deb
successfully modeled pedagogical uses of technology for her TE students, including dealing with the uncertainties often associated with classroom technology use, and is part of an ongoing discussion about the practical value of technology in Science teaching.

**Lynn Brice: Elementary Social Studies TE401: Collecting Primary Sources in a DBMS [URL=http://rorschach.educ.msu.edu/TechReq/TE401_9/]**

Lynn Brice and Tim Smith developed a database assignment for Lynn’s TE401 class (Section 9, Fall 1997) where their students helped construct a database to organize their annotated bibliographies of useful social studies references. Rodney Williams and myself worked with Lynn and Tim on this project, supporting them before, during, and after their students met in a Macintosh lab as part of their regular class time.

The social studies references were collected from a variety of sources, including books and the World Wide Web (Web), and gathered into a single database for distribution to all students in class. The students met in a Macintosh lab and learned about databases, designed the database for their annotated references, and used the Web to locate potential references.

Tim created a document describing databases and how to create them in ClarisWorks 4.0. Lynn used this assignment to help her students satisfy the database technology requirement (simple or fundamental use) as well as optionally to satisfy the e-mail and Web requirement (simple or fundamental use). Students could e-mail their Web bookmarks or database entries to Lynn or Tim, satisfying the e-mail requirement as well as the Web requirement. Before Lynn brought her students to the computer lab, she wrote about her own plans for using technology, sharing her pedagogical rationale for the assignment and her perspective on the use of technology in her teaching:

"Thank you for all your help on getting this arranged. I have e-mailed Rodney about what we (Tim Smith and I) have planned for Friday. Tim is going to walk the group through using the database on Clarisworks. We plan on setting up the fields on Friday and then having the students enter on diskettes their three sources to the database. Tim has it figured out how this will work. We were thinking that the students could send their formatted database entries to me as e-mail attachments and then I can cut and paste the database (and Tim will do the same) Then, we will give each student the full database on diskette. We should have a little under 100 entries.

The second half of our time on Friday, I would like to have students look at one or two websites that are from bookmarks I have. I would like to briefly look at two of these sites together and then have the students do some browsing for their unit topics. I think it will be immensely helpful to have you and Rodney there to help them learn to make bookmarks and how to store them on disk. At least get them started on the bookmark tech requirement and get them started on researching their unit topics.

WE are meeting Wed after class. Tim will be there around 12:30-1:00. We typically meet over at XRoads and then head over to the tech lab. I'll look for you to see if you and/or Rodney can join us. I just want to say thanks again. It is a little overwhelming at first to think about how to make this technology stuff happen when, basically, I don't know much more than my students. It is immensely helpful to have Tim, Rodney, and you coaching me as well as the students. I also like having both of you there so our students know you and know who they can go to have their tech requirements checked off independent of 401."

Lynn later shared her own beliefs about how important it is to connect technology use to subject matter concerns: "Using these in 301 is OK with me. But I do have one thought. My intention for the technology things we've done is to have them tied closely to the subject matter. As this was my first go around with these particular activities, next time will be refined in that direction. Although these assignments are pretty generic, I do have several other that are specific to social studies and don't think they would be easily used in 301 (for example using spreadsheet to convert historic prices to contemporary equivalents, which I did not do this semester). My thought is that were I to teach 401 or 402 again, I would want to reserve these technology assignments for my syllabus, having put in the time and all to design and incorporate them. Does that make sense? I get the feeling that the most difficult requirements to accomplish get left for 402. I would be unhappy if I were teaching for 402, had these activities ready to go, know how to do them, and then find they were already done in 301. This is not really about using the ones we did on Friday in 301. I think as the program develops these things will be predetermined for instructors maybe. In any case, I have no problem with passing them along. But you might also want to ask Tim Smith about the database one because much of it was his design."

You can see from her e-mail that Lynn articulates her beliefs about how the TE program itself should change to support better technology integration across sections of TE courses. This is a good example of how technology is
viewed by her in the service of some larger pedagogical goal. In this case, Lynn is conceptualizing a spreadsheet as a tool for "convert(ing) historic prices to contemporary equivalents," a pedagogically useful way of using technology.

Conclusion

Based on this work, and related research within the MSU college of education, we are moving towards a new goal for teacher preparation at MSU: helping future teachers develop the necessary expertise, dispositions, and attitudes to support their own generative learning around and with technology, and learn to use technology appropriately to serve some useful pedagogical end. In order to understand this process, we need to critically examine our own teaching practices and the assumptions we make about the nature of learning, teaching, and the role of technology.

I believe that building collaborative relationships with TE instructors, respecting the knowledge and expertise they bring to these interactions, and supporting their efforts to construct their own practices of teaching with technology will ultimately result in the fundamental changes described above. There is no doubt that this change will be difficult and time consuming, but this approach is also consistent with social constructivist views of learning that I hold which shape my own understandings of the intersection of technology and teaching in the work I do with staff at the college of education.

WEB-BASED DISCUSSIONS: BUILDING EFFECTIVE ELECTRONIC COMMUNITIES FOR PRESERVICE TECHNOLOGY EDUCATION

Aileen Nonis
University of Virginia

Steve Bronack
University of Virginia

Lisa Haton
University of Virginia

According to Turkle (1995), "In cyberspace, we can talk, exchange ideas, and assume personae of our own creation. We have the opportunity to build new kinds of communities." Technology and teacher education at the University of Virginia's Curry School of Education has included programs such as the Technology Infusion Project (TIP), which promotes collaboration and communication between preservice and practicing teachers in area classrooms. Advances in technology have provided the impetus for exploring additional modes for increasing communication among preservice teachers. As is the case in many educational technology classes at other schools of education, electronic communication initially centered around the use of electronic mail. Every preservice teacher has access to a university e-mail account for communicating with other students and instructors. For the most part, e-mail has increased communication, however, this has been limited to interactions mainly between students and the instructors. Although students were encouraged to communicate with one another to share ideas and ask questions, few took advantage of this resource.

To increase the level of interactivity among peers, students were required to participate in weekly electronic newsgroup discussions, with the hope that these "discussions" would encourage class members to engage in thought-provoking dialogue. More often than not, student responses to the newsgroup resembled individual "reaction papers," rather than ongoing discussions of issues and perspectives. Although students found e-mail helpful in communicating with instructors outside of class, most found class discussion on the discussion group time consuming, and of little worth.

The gaining popularity of the World Wide Web has provided us with some solutions. What has evolved is a unique system for learning about various educational technologies and their professional implications through Web-based collaboration and communication with like-minded peers and professionals. This system, Curry CONNECT, enables the type of electronic communication that is essential for providing successful technical and instructional support, facilitating discussions of current and relevant topics about technology in schools, and fostering the development of an emergent professional community whose members are comfortable with incorporating innovative uses of technology in their teaching practices.

Through the CONNECT site, our goal is to create an environment for open communication on topics of common interest for the students involved in a number of educational technology courses. By creating a virtual community we are opening the lines for collaborative learning (McQuail, 1995) so that large numbers of students and instructors are able to discuss issues without the normal constraints of time and place (Cutler, 1996).

This new medium for class discussion has the potential to change the definition of social roles and lift constraints on the current order of the situation. The ability for a number of participants to read and respond simultaneously establishes a forum in which every participant has an equal opportunity to be heard (Rosenberg, 1992). One of the greatest challenges to overcome in completing this task is to ensure that students are prepared to use the technology. While the opportunity is present for all members of the group to have an equal voice in the discussion, this cannot occur if they lack the technological knowledge to perform the operations required to submit their own contributions.

The technology currently used is primarily Web-based, due to its familiarity and accessibility among students in the current class. Students access this "central" location for core materials, such as the course syllabi, school maps, educational Web sites of relevance to the week's topic, and online forms for filling out weekly progress reports. Resources, readings, and threaded discussions are also linked into the site. This concentration of activity served as a first step toward establishing an on-line class community. While creating a virtual class space was simple enough, we were more concerned with ensuring sustainability. What follows is a discussion of the critical elements we believe are necessary for supporting electronic communities.
Sustaining Effective Electronic Communities of Discourse

Relying heavily on student feedback, we are now able to offer a better understanding of what constitutes effective and ineffective uses of electronic discussions. This feedback has informed the assumptions upon which the suggestions offered in this section are predicated. One such assumption is the importance of a group of like-minded peers and professionals, and the role such like-mindedness plays in the formation of an on-line community. A recognition of the concept of community with which we are working is essential to an understanding of our notion of successful web-based discourse and, therefore, must lead this discussion.

When a group of like-minded individuals gathers to share resources and to strive toward a common good, a community is said to exist (Dewey, 1927). Web-based discussions that succeed are the direct result of a concerted effort put forth by members of such communities. This effort is most often provided thorough the amount of meaning and thoughtfulness embedded in individuals' participation in the discussions, themselves. It has been our experience that, without proper attention to the importance of community, student participation more resembles individual "reaction papers," rather than carefully considered discussions of issues and perspectives. Therefore, fostering a strong sense of community among discussion participants is essential to success.

Effective electronic communities of discourse occur when three fundamental realms of consideration are adequately addressed. First, the intended consequences of the discussion must be explicit and generally agreed upon by those involved. Second, discussion designers and facilitators must be cognizant of the essential attributes of effective on-line discourse. Finally, careful regard must be given to the facilitative structures requisite for sustenance and appropriate progress of the discussion. These realms of consideration are discussed more thoroughly in this section.

Intended consequences

People often view new processes, tools or ideas in terms of solving old problems before learning that, while these new technologies may make the old problems irrelevant, new problems or issues often emerge (Kay, 1992). For example, a typical on-line discourse model involves a conversation between people discussing common issues that begins face-to-face and is then continued via an electronic medium. This model has time and again exhibited an initial stage of general optimism about the successful continuation of the discussion, followed by an overwhelming lack of response and conversation continuity. Similar patterns of response historically have existed among preservice students in technology and teacher education courses. Little attention has been given to the intended consequences — that is, the constructs which emerge from pedagogical and cognitive considerations that directly impact those who are participating in the discussion.

The same can be said of web-based discussions and their use in teaching education. Being cognizant of the intended consequences means recognizing the need to get to the essence of what we want to accomplish. To achieve this recognition requires an analysis of the pedagogical effects enabled by the technology and of the cognitive residue which occurs as a result of the participant interactions. Success is more likely when both participants and instructors are aware of and agree upon the intended consequences they desire the web-based discussion to produce.

Attributes

The most obvious fallacy associated with web-based discussions lies in the assumption that discourse via the Web is really the same as discourse as it occurs in a classroom. It is not. There exist unique attributes associated with web-based discussions which enable certain communicative endeavors and hinder others. An understanding of these inherent characteristics is essential. Successful implementation hinges upon how well the following attributes of on-line discourse are addressed: (1) convenience; (2) familiarity; (3) accessibility; (4) meaningfulness; and (5) focus.

Convenience suggests that unnecessary barriers to usability and understanding are avoided. The principle of familiarity requires that the discussion group incorporate as many common symbols and metaphors as possible. In fact, these two attributes guided the decision toward web-based discussion groups and away from newsgroups. Again, relying on student evaluation and feedback, newsgroups have proven ineffective due to the cumbersome nature of the still-developing newsreaders and to the unfamiliar nature of the metaphors employed. Accessibility refers to the availability of the technologies and resources necessary to fully participate in the discussion. Web browsers are becoming increasingly available and are commonly found on most computer lab machines, which makes web-based discussions more accessible than those relying on plattform-specific or proprietary software. Convenience, familiarity, and accessibility are meaningless if they do not combine to enable meaningful communication that would otherwise be inaccessible. Face-to-face discourse among members of a community is spatially and temporally bound. Web-based discussions allow members to extend the parameters and continue discourse in a meaningful manner. Finally, the most contentious and potentially problematic attribute which requires attention is focus. In this sense, the conversations which occur within a Web-based environment must be focused predominantly on the dialogue content, and not on the technology that makes such dialogue possible.

As a result of these considerations, we have adopted a model that strives for a state of "transparency," in which a
blending of technology and professional practice context-building create a more efficacious environment in which the problem of participation is largely dissipated. Telephone use serves as one example of such a model. One rarely gives a second thought to picking up a receiver, dialing a number, and speaking to a person in the next building, state, or country when the need to talk with that individual is felt. We use the telephone, when appropriate, because it is convenient, accessible, we are familiar with its operation, and - most importantly - it enables meaningful communication which would otherwise be inaccessible. Like the telephone, effective Web-based communication is such when the technology is used in a natural, transparent manner that maintains focus more on the dialogue content between students and less on technological methods that make such dialogue possible. The format of class discussions in this arena have been restructured to reflect this understanding.

**Facilitative Structures**

Simply creating a discussion area, however, is not sufficient. Sustained dialogue is predicated upon certain facilitative structures. These structures may be grouped according to environmental, social, motivational and expectation factors.

**Environmental conditions**

Environmental structures include factors that enable a comfortable and successful atmosphere for on-line communication. For example, successful discussions are always grounded in areas of professional relevance — in this case, to preservice educators. To facilitate this, instructors pose "talk topics" around which conversations begin. Examples of such topics have been: "The Computer Delusion" (Oppenheimer, 1997), "Acceptable Use Policies," "Technology Standards," and "Technology and Equity." These talk topics encourage participants strive for depth as opposed to breadth of topics (only four topics per semester are introduced). Also, creating an environment where students can relate personal experiences to the issues at hand is essential. Such an environment encourages buy-in and a higher level of participant ownership in the medium.

Finally, the availability of adequate technical support is always a mitigating factor in the success of any on-line endeavor.

**Social factors**

Social structures are integral to success, and refer to factors that encourage collegiality and meaningful interaction between peers within the group. Our most successful web-based conversations are the ones in which we employ a "moderator" whose responsibilities include responding to students' comments and questions, as well as raising provocative issues for further discussion when needed. For example, Curry Connect combines students from four separate classes to participate in four discussions throughout the semester. Therefore, each instructor takes a turn as moderator for one discussion.

We have found our greatest success when we employ what we refer to as the "Cocktail Party" metaphor. It is essential to note here that we do not view a discussion as a singular event — that is, we do not assume that each discussion group is a simply one conversation in which all participants are equally engaged in all strands. Rather, we recognize that each discussion group is actually comprised of several mini-discussions, all occurring simultaneously. Each mini-discussion is represented by a particular strand or thread in the discussion group, similar to the pockets of conversation which naturally occur at any social gathering where relatively large groups gather. Therefore, much like the hostess at a cocktail party, the moderator's job is to circulate among the various threads and "stir up the pot" or ask and answer questions when necessary.

**Motivational issues**

Motivational structures involve those factors that address the issues of control and ownership. For many, these structures provide the most difficult barrier to initiating successful web-based discourse. Questions which often arise with this factor are: Are discussions graded/compulsory? If so, how are they assessed? The answers to these questions will dictate who is perceived to be in control of the discussion group, and will have a definite impact on the quality of the participation of those involved. For example, compulsory participation ("You must post two times each week.") obviously places the instructor in control, whereas participation which is not mandatory ("You are encouraged to participate on-line; however, you may hand in a word-processed analysis instead.") allows for a more negotiated sense of dominion. In addition, these issues lead to the question of ownership — another factor which must be explicit and decided beforehand. Those discussions which are highly controlled by the instructor are also perceived as "owned" by the instructor. However, those discussions that are allowed to evolve more naturally — where the instructor is viewed as an equal member of the community — generally result in a higher sense of participant ownership.

**Expectations**

Finally, expectation structures involve those factors that address the issues of outcomes and demands. Successful web-based discussions suggest that the more explicit these structures are, the more comfortable the participants will be. For example, the instructor's expectations of the quality of the discussion postings must be clear from the beginning. If, for example, participants will be held to some type of standard of discussion quality, that standard must be explicitly shared at the outset. In addition, students must understand and be comfortable with the facilitation role the instructor chooses to adopt. The importance of this comfort level is heightened when the nature of the on-line medium brings focus to those students who may have an inordinate
fear of the technology or of communicating in a public way. It has been our experience that technological fears are more easily mediated. However, there is no worse feeling than crafting a discussion response, offering it to the group, and receiving a deafening lack of replies. In this sense, the facilitative role of the instructor must clearly guide him or her to seek out these situations and quickly provide a reaction.

Conclusion

Recognizing the important role each of the fundamental realms of successful web-based discussions plays will likely increase the probability that your discussion group will succeed, as well. Intended consequences, essential attributes, and facilitative structures are all essential, and combine to create an environment where meaningful and satisfying discourse between groups of like-minded peers can not only occur, but also have distinct educational value.

We realize that relying on technology is not always the best solution and affirm the importance of maintaining personal relationships; however, we also believe that in some circumstances it is desirable to develop electronic communities which further enrich students' experiences and opportunities to grow.

Kay, A. (1992) Keynote presentation to the National School Board Association's Technology and Learning Conference in Dallas, TX.
Beginning teachers are often ill prepared for the varied applications of technology in their classroom. The Teacher Technology Portfolio Program is a unique preservice program that combines the infusion of technology throughout the curriculum with the development of a reflective portfolio on technology in education. The program was initially tested with student teachers. Subsequently, every student in the department was required to begin a portfolio to be completed by the end of their student teaching semester. Based on initial evaluation results, a long range plan for continued revision and implementation of the project, training and support for faculty, and acquisition of necessary materials was developed.

Introduction and Background
It is apparent in the field of education that the preparation of teachers to effectively use and apply technology is lacking. Many local, state and national agencies have indicated a need for teachers, both at the preservice and inservice levels, who are better prepared in the area of technology (Lee, 1996; Northrup & Little, 1996; U.S. Congress, 1995). This viewpoint has been supported by accrediting agencies such as the National Council for the Accreditation of Teacher Education (NCATE) which has implemented new guidelines for teacher preparation including standards for technology (Thomas, 1994). There is continued discussion in the field on the best method for preparing teachers, such as using stand alone courses on technology versus the integration of technology into education courses, using a constructivist perspective versus a behaviorist perspective, or incorporating experiences in student teaching or clinical settings (Bosch & Cardinale, 1993; Thurston, Secaras, & Levin, 1996; White, 1995; Willis & Mehlinger, 1996). The Teacher Technology Portfolio Program was developed in response to these issues raised by cooperating satellite school districts, department graduates, students, and the field of education about teacher preparation and competence with technology.

Elmhurst College is a small, 4-year liberal arts college in the Chicago land area. The Department of Education includes programs in Early Childhood Education, Elementary Education, Secondary Education and Special Education. The Teacher Technology Portfolio Program integrates instruction on technology and modeling of instruction with technology throughout the course work in each of the teacher training programs. Preservice teachers begin their portfolios in their introductory courses or their first education course in the department with opportunities in methods courses to build technological competence; investigate curriculum and technology connections; and develop and implement activities that integrate technology. The Teacher Technology Portfolios are finalized during the professional, student teaching semester.

Development of the Program
Initially, faculty in the Department of Education determined the need for a method of infusing instruction on technology throughout the major courses. The idea of using a portfolio approach that would reflect a student's growth in knowledge and application of technology was proposed and approved. A three person departmental committee was formed to develop and monitor initial implementation of a portfolio approach.

Input requested from several departmental advisory councils, composed of administrators and teachers from surrounding local districts, indicated a strong need for new teachers, as well as veteran teachers, to have both basic and advanced technological competence and the ability to apply that competence in the classroom. Based on this input, the technology committee decided to survey students, assess their current knowledge, and then plan a course of action.

Using the text, Instructional Media Technologies for Learning (Heinich, Molenda, & Russell, 1989), the technology committee formulated a survey which was administered to both those students just entering the department's sequence of courses and those students about to student teach. (That text has since been revised and a 5th edition, 1996, is available). Students were asked to rate their skill proficiency in each of a number of areas by indicating previous acquisition of the task, ability to learn the task in the current clinical setting, or the need for an
opportunity to learn the task on campus. The survey was strictly competency based and did not ask the students to assess their ability to integrate their technological competence into the curriculum.

At this time, guidelines for the portfolio were developed. Portfolio requirements included the development of a reflective statement regarding technology and education, the development and implementation of lesson and unit plans with artifacts integrating technology, and the documentation of mastery of basic and advanced competencies with a variety of instructional technologies. Using the results of the survey a list of basic and advanced competencies, as well as forms for documenting the acquisition of the competencies, were formulated and included. Also at this time, an advisory council specific to the Teacher Technology Portfolio Program was formed with the specific function of providing evaluative feedback and advice for the continued implementation of the program. The council is comprised of members of the college community, department alumni, students, and practitioners.

Time lines were also developed for an initial pilot test of the program in the spring of 1996 with students entering their professional student teaching semester. A series of on campus workshops were planned using the data from the survey to support the student teachers in their attempts to build competencies and complete the portfolio. Workshops were planned primarily in areas relating to computer use, telecommunications, and multimedia. Faculty were asked at this time to begin including technology activities within their course syllabi and to list the Heinich text as an optional text for students to purchase. In order to begin supporting faculty members in their endeavors, the technology committee proposed and received a small mini-grant to provide a series of full and half day workshops for full time and adjunct faculty with a focus on training in areas of technology and steps for integrating technology into their courses.

Implementation of the program for all students in the Department of Education was scheduled for Fall, 1996. Plans for the fall included continued workshops supporting those students entering their professional student teaching semester and expected to complete a portfolio. A series of mini-courses was developed and offered to both student teachers and all other students. Education faculty were required to include the Teacher Technology Portfolio in their syllabus with opportunities for students to build competencies, to develop and field test activities with technology integration, and to reflect upon their experiences.

**Evaluation, Revision, and Future Plans**

During the pilot test of the program in the Spring of 1996, the student teachers were asked to complete seminar/workshop evaluations and a survey at the end of the semester about the portfolio process. Completed portfolios were assessed for number of competencies attained, number of lessons utilizing technology with artifacts, and the completion of a reflective statement on technology and education. Overall, the student teachers indicated a sense of the importance of learning to use and apply technology in the classroom. Although a variety of workshops at beginning and advanced levels were offered during student teaching seminars, many of the student teachers felt a lack of preparation to complete the portfolio satisfactorily. As well, a number of the students commented on the lack of technology in their field placements and therefore, the inability to implement the required lesson or unit plans.

Also during the spring, steps for preparing faculty to begin integrating technology into course work and supporting documentation of the student portfolios were begun. Results from a needs assessment, attitude survey, and the all-day workshop evaluation were compiled and indicated the same sense as the students regarding the importance of using technology as well as an equal need by the faculty for more adequate training on a variety of issues in order to be better prepared to infuse technology into their courses.

Based on the results from the pilot test and faculty evaluations, several revisions were made in preparation for the implementation of the program with all students in the fall, 1996. The portfolio guidelines were the first to be revised. Despite the fact that the student teachers were submitting technology portfolios, many completed portfolios were handwritten or typewritten. Specific instructions (with the requirement that all items must be completed on a word processor) and sample elements were developed. A bibliography of available library resources, procedures for documenting competencies from previous clinical or work experiences, and an evaluation checklist for the students to complete prior to final submission were also developed and included. Next, the supporting workshops for student teachers were revised to include a more specific focus on integrating technology into the curriculum, more hands-on, and some sessions for those students who were still fearful of technology. Additional stand alone mini-courses were developed and offered on basic instructional technology and using ClarisWorks for teacher productivity. Finally, plans were made for follow-up training for the faculty at the end of the semester and in the spring, 1997; improving the system for access and use of existing instructional software; and the printing of the portfolio guidelines and placement of them in the campus bookstore for purchase by the students.

Despite the fact that the faculty in the department have indicated the importance of and supported the need for this initiative, many still feel lacking in their preparation to actually implement technology in their courses. Others have expressed the desire to have the program more focused with clearer direction on what competencies and activities are expected in what courses. Stepping back and evaluating what has been completed so far, the realization that perhaps...
the program has attempted too much too soon seems clear.
A long range plan with phases of implementation has been
developed with start up in the fall, 1997. The phases of
implementation in the plan build upon a growing level of
expertise in varying areas of technology by the faculty (and
subsequently the students) with opportunities for training
and the acquisition of necessary resources, materials and
hardware to support the phase. Each phase focuses on a
specific area of technology, such as productivity software,
telecommunications, or presentation software, and includes
objectives and competencies synthesized from several
sources (ISTE, 1996; Northrup & Little, 1996; Todd, 1993).

Conclusion
The Teacher Technology Portfolio program represents a
major initiative with the Department of Education at
Elmhurst College to infuse technology throughout the
course work of the preservice teacher and to provide an
opportunity for continued reflection about the integration
and application of technology into the curriculum. The
program is designed to produce teachers who can use the
technology available in the schools and effectively integrate
that technology into their units, lessons, and activities. The
program is attempting to achieve the goal of preparing new
teachers to effectively use technology. "Technology is the
catalyst, but the chemical starters for such fundamental
changes are teachers highly skilled in technology, with a
deep understanding of curriculum and a knowledge of how
children learn" (Lee, 1996, p.12).

At St. Mary's University of Minnesota, preservice teachers upon leaving the teacher education program are developing their own menu driven computer portfolios. Included in these computer portfolios are such items as text casts of philosophical beliefs, voice casts of effective teaching strategies, and digitized videos of actual teaching performance. This capstone project allowed preservice teachers an opportunity to both self reflect and assess their recent student teaching experiences. This computer portfolio project utilized Macromedia Director as an education software tool in the development of the preservice teacher's own portfolio. The use of this powerful software development program was viewed both by instructors and preservice teachers as a very valuable learning tool in preparation for teaching with technology. By having preservice teachers authoring their own electronic portfolios, it provided them with a greater understanding of how technology can be implemented into their future classrooms.

This project was not without some challenges. Some of the most problematic technical issues that students had to overcome were: dealing with limited disk storage capacity, finding a balance between quality of video output and file size constraints, producing a usable end product for a job search, and creating CD-ROM versions of portfolios.

The process of preservice teachers developing their own computer portfolio however had many positive outcomes. First, these preservice teachers benefited by reflecting upon their student teaching experience as they compiled their own effective teaching characteristics. Second, the end product became a very valuable instrument in the student's job search. Third, the opportunity to author their own computer portfolio provided students with an increase capacity to infuse technology later in their classrooms.

The development of a computer portfolios through the use of Macromedia Director was an extremely valuable learning opportunity for our preservice teachers. Many of the preservice teachers spoke of their intent to take their new found knowledge of technology and apply it directly to their classrooms. In the end, both future teachers and their students will benefit directly from this process.

Value of Portfolios

My observations of students striving to put in place their most exemplar pieces of work along with writing and rewriting their most current philosophical foundations revealed a sense of value portfolios have upon my student teachers as they prepare to enter the profession. Their portfolio in the end represented, in essence, a capstone to their preservice teacher education. The pride of their accomplishments are now exhibited through their portfolio.

Furthermore, the reflection needed to successfully complete their portfolios provides a springboard to future development. They came away from this experience knowing that while they have made great strides in becoming solid young teachers, they still have much to experience and work towards in becoming outstanding teachers.

The value of creating a portfolio that will be shared with others makes the nature of this portfolio not only an individual possession but also a public document. This development of a publicly shared portfolio requires people to be active, socially responsive, and willing to transform his or her teaching from a private to a public experience (Schram, Mills, and Leach, 1995, p.71). By having students preparing a portfolio with one of the intended outcomes being its use in their job search, the portfolio becomes extremely public with regards to the quality of their personal teaching experiences.

The value of having students develop a portfolio for use in a job search makes this experience not only an exercise in reflective teaching, but also a very meaningful exercise tied to improving their opportunities for a job. This added component of producing a portfolio not only for their and our programs sake, but for others, resulted in preservice students placing even more emphasis upon the quality of their portfolios.

Determining the Portfolio's Content

There are undoubtedly a multitude of items that could be included in a preservice teacher's portfolio. Thomasena Adams (1995, p. 569) referred to the items that were to be collected to rest solely on the assessment information that is needed to respond to specific and general questions about
proached this question of what students needed to include in their portfolios by setting forth a set of standards that students should be able to demonstrate through evidence collected in their electronic portfolios. The major emphasis of our students' portfolios were to but forth their highest quality work which demonstrated the standards of knowledge, organization, and teacher effectiveness.

Because of constraints in data storage, students were restricted to selecting only the best pieces of evidence to be included in their electronic portfolios. They also were expected to maintain a more traditional portfolio which would contain additional evidence of meeting these standards of teacher effectiveness. Perhaps one of the most important factors I discovered in having students complete a computer generated portfolio was to allow them to determine how they were going to demonstrate their mastery of effective teaching. When preservice teachers are given the responsibility to demonstrate the standards based upon their analysis, synthesis, and evaluation of their evidence, it forces them to reflect upon the quality of teaching and learning taking place in their classroom.

**Developing the Portfolios with Multimedia Director**

The utilization of Multimedia Director as the software foundation for our students' portfolios was based upon the belief that it will better prepare our students to be more effective in infusing technology into their own classrooms. Perhaps one of the most beneficial uses of Multimedia Director is its value in producing a diverse set of multimedia applications for use in the classroom. Teachers who are well versed in Director can take advantage of this software with their students to teach them how to produce their own multimedia presentations.

The interactive capabilities of Multimedia Director script language allows for students to develop menu driven programs that are very user friendly. While this does require time for teaching students how to effective utilize the powerful tools Director has to offer, the benefits of this knowledge far exceeds the time requirement. With this project however, I choose to assist the students by providing them with a template which included the scripting needed to complete their portfolio projects. This was done to meet a time requirement that didn't allow for the necessary teaching of scripting versus time needed to develop their portfolios.

Students had access to a PowerMac lab (Mac 7500/100 with video input capabilities). To digitize their teaching videos, they utilized Apple Media Conferencing by recording into the self view window video clips from their teaching experiences. Since digitized video clips require large amounts of data storage, students who were planning on sending their electronic portfolios on 1.3MB disks with their resumes, choose to record their videos at one frame per second and set their sound preferences at a six to one compression. Videos were saved as quick time video files which were easily imported into a Director cast member for later use.

Students also scanned in images with the use of Photoshop. They then added any enhancements to those images and saved them as PICT files which Director utilizes. Students with images saved in a variety of other formats, utilized a graphics conversion program to place all images into PICT files before loading them into Director cast members.

Text cast members were either copied over to Director or composed right in the text cast page. Students were encouraged to compose utilizing a word processor before copying them over to Director because of the access to spell checkers in most word processing programs.

**Positive Outcomes of the Project**

I found three very distinct benefits from having students complete their own computer generated portfolios. First, these preservice teachers benefited by reflecting upon their student teaching experience as they compiled their own effective teaching characteristics. Second, the end product became a very valuable instrument in the student's job search. Third, the opportunity to author their own computer portfolio provide students with an increased capacity to infuse technology later into their classrooms.

By engaging the students in developing their own portfolios, it required them to analyze what they had accomplished during their student teaching experience. They came away from this process with a clear understanding of how they were effective in the classroom and teaching areas they needed to refine in the years ahead. The work they did in developing their philosophy statements/beliefs further defined their understanding of what makes them effective in the classroom. Without spending considerable time reflecting upon these areas, the portfolio would have simply become a series of video clips and meaningless documents for others to view. The importance of communicating clear philosophical beliefs and following those beliefs up with documented evidence makes a truly significant difference in the quality of the portfolio.

I have little doubt that the technological expertise the students demonstrated with their computer generated portfolios had a very positive impact upon their securing job offers. While I did not conduct follow up interviews with school administrators who hired these students, several students returned from interviews with comments directly related to how impressed the interviewers were with their computer generated portfolios. In many cases, the use of computer generated portfolios sends a subtle, but powerful message that the educator who is applying for this job is computer literate. A knowledge base that many districts are seeking candidates with.

---

Preservice Teacher Education — 757
Included in this exercise were two teachers who had returned from their first year of teaching to complete the masters degree program. On several occasions, they made repeated comments about how they intended to incorporate Multimedia Director into their curriculum when they return to school. They were coming up with specific examples of how they could involve their students in a multimedia project and their beliefs that multimedia presentations are an important skill for students to master.

**Traditional versus. Computer Generated Portfolios**

Both types of portfolios have benefits and drawbacks. The strength of the traditional portfolio is that one is often looking at original documentation with an unlimited supply of materials. While the materials may be cumbersome to page through, and at times locate, access is generally available.

With a computer generated portfolio, the ease at accessing video clips with a click of the button is truly user friendly. Making duplicates of the portfolio is very easy and can be done at a minimal cost. However, it does require that the user has access to compatible equipment. The other drawback is the data storage limitation that a computer generated portfolio presents. Students wishing to utilize a 1.3 MB disk will only be able to record approximately one minute of video at one frame per minute to be include in their portfolio, those utilizing a CD-ROM disk will be able to record over 600 MB onto their disk. While the CD appears to be the answer to the storage demands of digitized videos and images, producing one for every application is both expense and time consuming.

One case study dealing with evaluating electronic portfolios found it to be clearly superior to paper portfolios because the ease of accessing the information (Bushweller, 1995, p. 19). The majority of computer generated portfolios developed by our students took between five and ten minutes to review. A time frame that should work well for school administrators reviewing teacher applications. These computer generated portfolios were produced for either Apple or PC's and required no special software for most computers before running.

**Summary**

Our students experience with building computer generated portfolios resulted in a very meaningful end product which allowed self reflection, a very user friendly product, and improved knowledge base in technology. As technology becomes more prevalent in our classrooms, the need to take advantage of utilizing computers for portfolio development is even more valuable. The limitations of data storage capacities faced by students today is quickly diminishing as access to larger storage devices become more available. In the future, the questions educators will be asking themselves isn't if they should utilize electronic portfolios, but how they should utilize them.

David Jackson is an Assistant Professor in the School of Education at Saint Mary's University of Minnesota, Roger Bacon Center, Rm 118, 1165 W. Broadway #76, Winona, MN 55987-5152. Office phone: (507) 453-5492; Home phone: (608) 248-3148 Email: djackson@mps.org
Being a college professor in the waning years of the twentieth century is indeed exciting. We are challenged to incorporate technology, to increase the literacy skills of our youth, and to prepare literacy teachers for the next millennium. The eleven articles in this section highlight the increasing importance of weaving technology into our curriculum as we prepare tomorrow’s literacy teachers. The authors have examined the use of technology in their own college classrooms, their own certification programs, and novel ways of using the newest literacy tools to enhance the reading, writing, listening, speaking, viewing, and presenting skills of elementary, middle, and high school students.

Most educators are enamored with the idea of technology, recognizing that it is an integral part of our culture, and have incorporated it within their daily teaching lives. The first paper in this section investigated the attitudes of college professors about the use of technology. Neilsen and Kiley present their findings on attitudes toward computer use in college settings. Given the positive outcomes, they discuss the importance of not only providing college professors and students with technology, but also with the technical support, including faculty workshops.

Inservice teachers seeking Masters’ degrees will find innovative programs at several colleges and universities. Kahn’s article provides a look at an exciting new Master’s degree program that combines a Master’s in applied technology with coursework for reading certification. Realizing the potential impact of technology on reading, Chestnut Hill College set out to create a degree program that prepares teachers to utilize technology to teach reading and to assume technology leadership roles in their schools. Enns and Auten describe the changes that were made in graduate education at the University of St. Thomas (St. Paul, MN). This new Masters’ degree, based on standards established by the International Society for Technology in Education, prepares teachers to be creative, responsible, and to construct new ways of thinking.

While the foundations of new programs are pivotal, how we include these innovations within our graduate and undergraduate programs are also important. We know from experience and from research (most of it reported at this conference!) that it is essential to incorporate technology within our methods classes. Several papers in this section describe exciting and authentic classroom contexts for teaching literacy theories and research through technology. Peel and Ledford use children’s literature with preservice teachers to make connections to geography and to the Internet. Focusing on Native American culture, they demonstrate how a children’s book can teach history, values, and culture through the framework of the five themes of geography. They also provide the reader with several websites as resources that will add a technological dimension. Using quality children’s literature is also the focus of the first of two articles written by Rader. She reports on the successes she has had at the University of Mississippi. Preservice and inservice teachers learned about using children’s literature, the writing process, and various software programs to enhance literacy skills. She discusses the importance of determining story patterns and text structure as a foundation for developing individual stories, complete with graphics and computer enhanced illustrations. In the second article, she reminds us of the motivating nature of Language Experience Stories, updated for the new millennium via the use of technology.

Self-reflection is an important concept in the professional growth of teachers. If this process is ignored, we are no longer able to improve, and consequently become ineffective in our teaching. Given the rapid advances of technology, it is critical that we examine the technological elements in our college classrooms. Long and Reehm offer specific examples of readily available software to enhance reading and writing instruction in the language arts classroom. Their paper is based on experiences gained while teaching a summer reading/writing program for Reading Specialists. They stress the importance of teacher monitoring and using the appropriate software that will enable each reader to succeed. Hence, a variety of software is made available to their students to help them determine which
application will best suit the needs of children as they become competent, fluent readers and writers. Williams reflected on her own teaching practices as she examined assignments and class activities in her language arts class over a three-year period. Concluding that the use of technology evolved due to the changing needs of preservice teachers, she advocates the need for reflexive examination of teaching practices. This reflexive evolution requires continued dialogue between students, professors, and school personnel.

As we prepare teachers to work with children, we become aware of the difficulties that face today's classroom teachers. The wide range in cognitive and behavioral abilities, coupled with the complexities of economic and cultural diversities can be frustrating to some. Two authors in this section weave the concept of cooperative learning with technology to better meet the needs of elementary school children. Zhang examines the integration of technology as a means of meeting the needs of mainstreamed learning disabled students into a fifth grade classroom. Through this collaborative experience, preservice teachers are also provided with an authentic classroom experience. Silvia, Antonella, Luisa, and Mario's study examines students working in cooperative groups to explore their environment and to share the information they discover with students in Italy using an interactive software application, Our World. The final article in this section offers us suggestions to use with all learners. Taylor discusses some of the technology innovations available to reading teachers as they work with students in their classrooms. Multimedia, reading environments provide electronic supports for children as they develop reading competencies. These electronic advancements are seen as supplements to the printed texts in the classroom. With teacher support and guidance these electronic texts can facilitate children in the process of becoming independent, life-long readers.

The articles in this section provide a kaleidoscope of uses for technology and motivate us to reflect upon how we use technology in our very own teaching lives. We believe that using technology within authentic contexts better prepares our students to teach tomorrow's children.

Kathryn I. Matthew is an assistant professor in the College of Education at Louisiana Tech University. 318-257-2676 and kim@vm.cc.latech.edu

760 — Technology and Teacher Education Annual — 1998
As the new millennium approaches, nations are recognizing the necessity to harness technology efficiently. The need for a well-prepared work force demands that teachers and their students are technologically literate. Regretfully, funds have not been readily available for the purchase, and installation of computers, or for appropriate staffing and maintenance. Additionally, some college professors, despite expertise within specific academic areas, may lack specific skills when using technology. This paper focuses on one college’s efforts to provide adequate computer resources and technical assistance to their faculty during the spring of 1997.

Larsen (1983) reported that only 25 percent of 200 college chemistry faculty nationwide used computer-based instruction in their classes even though 68 percent were familiar with computer-based education. Lillard’s (1985) study of 200 K-12 Pennsylvania teachers indicated that attitudes towards computer use could be predicted both from the respondent’s level of knowledge of computers, and willingness to use computers. Of the 144 University of Illinois faculty surveyed by Jacobson and Weller (1986), those over 40 years of age used computers more skillfully and more often than colleagues in their 30’s. However, five years later, Harold’s (1992) study of 171 professors of adult education across the nation found a significant negative relationship between age and computer use (older faculty used the computer less and experienced greater computer anxiety). Hawes (1992) study of 96 faculty of a New Hampshire college found significant differences between r computer anxiety). Terry and Geske’s (1990) study of a 21 member faculty teaching journalism and mass communication found that the level of use was affected by how the participants obtained assistance for computer problems. The reason most cited for lack of computer usage was the respondent’s lack of information. Conroy (1991) reported significant differences between Maryland secondary teachers of required and elective courses; those who taught the electives used their computers more often. The study of Ohio universities by Faseytian and Hirschbuhl (1991) found highly significant differences in computer usage between those who required student use of computers in their course work and those faculty who did not require student computer use. The technological orientation of the faculty’s discipline was a significant predictor of computer usage stages of concern and levels of computer experience, and interest in learning new software and discipline groups. Shifflett, Richardson, Ghiassavand, Plecque, Verduzco, and Thomas (1993) examined the faculty of the California State University system and found that so few faculty members used computers to communicate with each other or to access information services, that the integration of computers into the classroom would take a considerable amount of time. When Broom (1994) investigated the faculty in the University of Georgia system, the significant factors for predicting instructional use of computers were use of e-mail, and the faculty member having been employed in private industry.

Procedure
The participants for this study included 120 faculty members at a private liberal arts college in York, Pennsylvania. The college enrollment is approximately 3,400 from Pennsylvania, New York, and Maryland. Almost 75 percent of the faculty have doctoral degrees. Since 1995, a local electronics communications network was created for faculty use of e-mail, voice-mail, and access to the Internet. Classrooms and laboratories were also equipped with LAN drops. Faculty have been provided with computer workshops since 1996.

The participants were invited to complete a 41-item questionnaire modified from Lillard’s (1985) study. Questions were developed to determine if attitudes towards computers were affected by knowledge about computers, gender, number of years teaching, or by subject matter. Fifty-five usable surveys were returned by 22 female and 33 male respondents. Twenty-six taught technical course (Biology, Physical Science, Computer Science, and Nursing) and 29 taught non-technical courses (Behavioral Science, Business Administration, Education, English & Humanities, History & Political Science, Music, Art, Speech, and Communication). Six of the respondents taught at the college level for 1-5 years, seven taught at the college
level for 6-10 years, 21 taught 11-20 years and 21 had more than 21 years of college teaching.

**Data analysis and findings**

The questionnaires were collected and analyzed by a series of analyses of variance (ANOVA) using SPSS 4.1 (Statistical Package for Social Sciences) to determine statistical significance at the .05 level. No significant differences resulted between attitudes toward computers as instructional tools and knowledge of computers. However, the value was very close to significance. Almost 90 percent of the respondents owned computers; nearly 93 percent had attended seminars and workshops; and 76 percent supported the college's efforts toward greater computer access and technical assistance to faculty. No significant differences resulted between attitudes toward computers as instructional tool and gender, number of years of college teaching experience, and subject matter taught (technical or non-technical). These respondents' perceptions of computers as instructional tools were very positive. Almost 90 percent did not feel that computers were cost prohibitive; and almost 93 percent felt that computers were useful as instructional tools.

Attitudes toward how computers will affect teaching were also positive. Almost 96 percent felt that colleges should use computers in their instructional programs; 85 percent felt that computers can improve the quality of education for the students; 95 percent said that the colleges should purchase computers for instructional use; 91 percent agreed that implementation of computers for instruction should be encouraged; and 100 percent felt that students should have access to computers in colleges. How computers in the classroom affected students brought about more positive attitudes. Sixty-seven percent did not feel that computers caused students to be isolated for each other; another 86 percent thought that computers help students learn; and almost 78 percent did not feel that computers dehumanize colleges. Personal perceptions dealing with computers in general were also very positive. Seventy-eight percent enjoyed working with computers; almost 74 percent did not feel apprehensive about learning how to use computers; and 91 percent did not feel that using computers required a strong background in mathematics.

**Implications**

The very positive attitudes of this faculty toward computer use in their classrooms provide evidence that, given the equipment, training, and technical support, faculty welcome assistance to master this vital learning tool. Continued research is justified to ascertain whether those positive attitudes continue; whether faculty computer use will be limited to word-processing or will develop into more sophisticated applications. Ascertaining levels of anxiety by as faculty attempt more difficult tasks and levels of teacher-student collaboration via computer might well be examined. Additionally, faculty may be surveyed regarding their present and future use of this valuable educational tool. Failure of the faculty—at any level—to maintain competence and to continue to develop computer expertise will be detrimental to American education.

PREPARING A NEW PROFESSIONAL: APPLIED TECHNOLOGY AND READING CERTIFICATION

Jessica Kahn
Chestnut Hill College

The Education and Applied Technology Departments of Chestnut Hill College have collaborated to create a new strand in the Master's in Applied Technology degree program. This strand combines the coursework for the Master's in Applied Technology degree with coursework in Reading Certification. This degree program builds on the demonstrated strengths of our two departments and acknowledges the value of technology in the reading/writing/language arts curriculum. Graduates of the program should be highly sought after by schools and school districts seeking to infuse technology and literacy throughout the curriculum. This program is the only one of its kind in the state of Pennsylvania, and response to it has been enthusiastic.

Currently the Education department at Chestnut Hill College offers Master's programs in Early Childhood Education, and Elementary Education, as well as early childhood, elementary and secondary certification. Our Applied Technology Master's program offers a strand designed for educators, as well as strands in leadership and in instructional design. Each of these programs attracts well-qualified students and prepares them, according to the mission of the College, to be leaders in their fields.

This program was created because we are aware of the powerful synergy created by the informed incorporation of technology and software into educational practice. Students in the Education department at Chestnut Hill are encouraged to take courses in Applied Technology, and a significant number of Master's candidates in Applied Technology have simultaneously become certified through the Education Department. Our two departments share a constructivist philosophy of education, in which whole language strategies and integrated learning are stressed. In all our programs students are encouraged to design and evaluate practice in terms of sound pedagogical theory. As students cross-register, their appreciation of the relationships among curriculum design, educational practice and technology widens and deepens.

Our own pedagogical judgments suggested that the creation of a Master's degree in Applied Technology with state certification in Reading would acknowledge and finalize the relationship between powerful technologies and sound literacy theory. Believing that literacy is a multifaceted, complex process, we have designed a program, based on a working relationship between our two departments, to prepare school leaders for the future. We began accepting candidates for this combined program in the 1996-97 academic year. We continue to accept new candidates and to design new courses, in which literacy development and technology use are reconceptualized.

This program targets certified teachers who seek to further enhance their performance in the classroom, and/or as leaders within their schools or districts. Teachers who already have Master's degrees in education will find an opportunity to refine competencies, increase income, and explore new professional challenges. The program has been designed specifically to provide expertise and state certification in reading, in conjunction with competence in the uses of all forms of technology, especially in the language arts curriculum.

Program Rationale

The link between the reading/writing curriculum and technology can be powerful. For developing readers and writers, technology can scaffold and support emerging literacy, through the use of multisensory approaches and timely feedback. Research has demonstrated the ways children’s perceptions of the writing task change when the tool is changed from pencil-and-paper to word processing, "writing in light" (Kahn, 1988; Cochran-Smith, Paris & Kahn, 1991). New reading software, including CD-ROM storybooks and game formats about literature, changes the ways children experience books and reading. Instrumental reading in text-based computer games invites children to read for authentic purposes. Computer conversations via email involve children in timely reading and writing activities with peers and mentors (Jody & Saccardi, 1996). Moreover, teachers become aware of the wide spectrum of literacies their students possess and of the necessity to assist students to refine those literacies.
This degree program combines technology with the best reading/writing techniques. Currently the move in schools is away from self-contained labs and towards the presence of technology in every classroom. This degree program will graduate a new kind of reading specialist, who understands the contributions of technology to the reading/writing curriculum. Children with reading and writing difficulties will be better served by this new professional. Children can learn to read using CD-ROM storybooks and learn to write using word processing rather than pencil and paper. New research suggests that reading difficulties can be minimized or eliminated through judicious use of software, and numerous studies document that students write more and write better using technology (see Cochran-Smith, 1991 for an extensive review of these studies).

**Goals of the program**

In our proposal to the state of Pennsylvania, we identified the following goals of the program:

1. To prepare teachers to serve as technology experts in their schools;
2. To prepare teachers to serve as reading specialists in their schools;
3. To prepare teachers to work with classroom teachers, facilitating the integration of technology across the curriculum, especially in reading and writing;
4. To prepare teachers to identify the research and pedagogical issues involved in the use of technology in the English language arts.
5. To prepare teachers to use technology in reading and writing to assess and evaluate the progress of all students, including those “at risk.”

We designed this program, therefore, for certified teachers who bring to their coursework strong foundations in teaching and a wide range of classroom experiences to share with their colleagues in the program. We seek those candidates who wish to assume broader leadership roles in their schools, and help them develop the expertise in technology and reading to enable them to do so.

**Designing the program**

In creating this master’s level program, we had to deal with issues concerning the integrity of the degree. The existing Master’s program in Applied Technology was a 12 course, 36 credit program - how then to add the necessary courses for Reading Certification without making the program too ambitious to be attractive? Let me walk you through our reasoning and show you how we have conceived this program.

Currently, students in the Education strand of the Master’s program in Applied Technology take the following courses:

**Technology core**
- Video Communications
- Online Communications

**Education core**
- Learning Theories
- Technology in a content area (language arts, social studies, math, science or the arts) Professional Issues and Curriculum Development
- Technology in the Curriculum

**Research core**
- Statistics
- Research Methods

**Electives**
- Choose two from the following courses: networking, presentations, authoring languages 1 & 2, advanced video, multimedia presentations

Our rationale for the original degree program in applied technology is to prepare classroom teachers to be leaders in their profession, using technology to enrich and enhance the curriculum. It is our contention that critical pedagogy extends to and applies to the use of technology in schools. We are committed to maintaining the integrity of the degree, insisting that all of our graduates be able to think about curriculum; analyze other people’s research; design and conduct their own research; and develop ways to integrate technology into the curriculum. We could not award the degree without having all our students demonstrate the same competencies.

So, how could we develop a program that added reading certification without creating an unwieldy, overburdened list of courses? We spent a semester talking about the profession we hoped to educate, and the likely candidates for this degree. Those discussions were helpful in defining our population and tailoring the program to their educational histories.

In order to be a reading specialist in Pennsylvania, one must possess Instructional I permanent certification, which is awarded after 3 years of satisfactory teaching, and completion of 24 semester hours of post-baccalaureate study. As an aside, most teachers opt to complete a 36 credit Master’s in Education, since there is a significant difference in pay at the Master’s level. Therefore, we reasoned, anyone who would enter our program would have accomplished this already, since they could not be certified without Instructional I permanent certification. That caused us to look at our courses and decide which of the Applied Technology courses might be duplicated somewhere in the 24 semester hours required for Certification.

We identified three courses that would probably be included in any master’s program in Education: Statistics, Research Methods, and Learning Theories. In addition, we eliminated the technology in the curriculum seminar, since those issues would be covered in other courses (we had a
precedent for this in the Leadership strand of the Master's in Applied Technology, which only had one semester of seminar). So the technology core is kept intact, the education core is focused in the English language arts, and we assume that the candidate has already taken learning theories and the research core in their previous master's degree coursework. This enabled us to add four courses in reading, to meet Pennsylvania competency requirements and two electives.

Our program is, then, structured in this way:

**Technology core**
- Video Communications
- Online Communications
- Modes of Thinking
- Seminar

**Education Core**
- Technology in the English language arts
- Professional Issues and Curriculum Development

**Reading Core**
- Reading and Writing in the Elementary School
- Reading and Writing in the Secondary School
- Building Literacy Competencies
- Evaluation and Assessment

**Electives**
- One from the technology core:
- Advanced video, Presentations, Networking, or Authoring languages
- One from the education core:
- Problems of Development or Inclusion

The program begins with Technology in the English language arts, a course that has been an offering of the Master's program in applied technology since 1991. The course begins by examining the NCTE/IRA standards for the English language arts. Students read Frank Smith's (1997) *Reading without Nonsense* as well as *Learning to Write Differently: Teachers and Children Using Word Processing* (Cochran-Smith, Paris & Kahn, 1991). These two books give a perspective on whole language values and practices, a perspective that is continued throughout the course. Other texts include *Technology, Reading, and Language Arts* (Willis, Stephens, Matthew, 1996), *Spelling in Use* (Laminack & Wood, 1996) and *Computer Conversations* (Jody & Saccardi, 1996). Each was chosen because of its explicit articulation of the connections between language learning theory and methodology.

The second level of this course is entitled Professional issues and Curriculum Development. It is a requirement of every graduate student in the education strand of the Master's in Applied Technology, taken after a discipline-specific course such as Technology in the English language arts or Technology in the Math (Science, Social Studies) Classroom. This course prepares graduate students to become resource persons in their schools, with expertise about the research literature, mastery of observation and evaluation techniques, and the ability to plan and conduct workshops for their colleagues. The assignments are identical for students in each discipline: an annotated bibliography; an observation of students using technology; and the planning and conduct of a workshop for adults. In this way, we afford scaffolded experiences for our students and help them to develop knowledgeable perspectives concerning roles of technology in the English language arts.

The program's new courses in reading are designed and taught by a member of the education faculty who is a reading specialist and adjunct faculty members who will take responsibility for regularly teaching one particular course in their areas of expertise. We see our program offerings as unique in the state, not only meeting the requirements for state certification, but also conceptualizing a specialist who understands the various forms of literacy our students must possess, has expertise in the design and evaluation of research about reading and writing, and understands alternative forms of assessment (portfolios, holistic scoring, etc.) well enough to teach it to classroom teachers.

We assume that our students have taken a course in children's literature and if they have not, we strongly urge that they do. In addition we require a new course entitled Building Literacy Competencies in which our graduate students examine multiple symbol systems, multiple intelligences, and assemble materials (both print and non-print texts) to help children learn to read. What can we learn from fiction? from textbooks? How do we learn it? What do movies teach us? What information can be gleaned from maps and charts, signs and logos? We argue that there are many ways to know the world and that students need to develop expertise in each of those ways. While the reading list for this course is under development, it will certainly include *Mind in Society* (Vygotsky, 1978) and selections on the nature of literacy.

We offer two courses in methodology: Reading and Writing in the Elementary School and Reading and Writing in the Secondary School, since reading specialist certification covers grades kindergarten to twelve. Each of these introduces a wide variety of strategies for helping children become literate, and provides the graduate student with tools to use in the practicum. We expect that many of our graduate students will do their practicum assignments within their own schools, under the supervision of their building reading specialists, but some of our students may prefer to work in a reading clinic during the summer, either at our campus or on a neighboring college campus.

The fourth reading course addresses the issues of diagnosis, evaluation and assessment. During this course, our prospective reading specialists will be assigned children whose assessment and programs they will design and administer. Throughout the program the focus will be on discovering children’s strengths, rather than documenting.
their weaknesses. Our intent is to help children use their learning styles and their strengths to develop proficiency in the use of symbol systems.

The final seminar will be formatted in an unusual way. The goal of the seminar is to prepare a reading specialist to evaluate a reading program, both qualitatively and quantitatively. This created a scheduling problem for us, since we are committed to research extended over time. Our solution was to stretch the seminar over two semesters, to provide that extended time for research. The seminar will meet in September and early October to help graduate students formulate their research questions, review the appropriate literature and design their projects. Then, from mid-October to late February, our graduate students will conduct their projects, collect and begin to analyze data, and fine-tune their proposals, while in contact with the professor. The class will meet again in March and April to provide support as students interpret and organize their findings for publication. The course is a three-credit course, spread over two semesters, a format that enables us to do meaningful research in real world settings.

Summary
This program has been designed to combine coherent theories of literacy acquisition and development with the judicious use of various technologies and media. Our goal is to prepare a professional with expertise in several areas: in dealing with individual children; in creating and implementing curricula; in working effectively with classroom teachers; and in designing and critiquing research. Towards these ends we have created assignments and readings that enable our graduate students to move into positions where they can help classroom teachers reconceptualize literacy and literacy instruction.

The University of St. Thomas (UST) recognized the need to include technology in degree programs in the late 1970's just as the first Tandy and Apple IIe computers found their way into classrooms. By 1981, UST offered students a Learning Technology Master's Degree program, a professional growth degree with emphasis on models of learning; instructional design and evaluation; and technology's role in design, delivery, monitoring and evaluation of educational programs. From the mid-1980s to 1995, over 500 teachers throughout the state of Minnesota participated in this degree program. After an intensive review process, the Organizational Learning & Development Program of the University of St. Thomas recommended that in order to maintain a timely, state-of-the-art program, it was necessary to redesign the degree structure and curriculum offerings of the MA in Learning Technology. The task was accomplished in early 1997. A new cohort of eighteen students began their studies in Learning Technology in the summer of 1997.

Master Of Arts Degree in Learning Technology
The Master of Arts Degree in Learning Technology is designed for professionals who provide leadership in educational applications of technologies. The program focuses on the integration of information technology, models of learning and instruction systems design, and preparation that lead to proposed certification or licensure in information technology in Minnesota.

Reflective Active Participation
The program is a cohort model that asks the participant for an active engagement in the learning process leading to the presentation of a professional portfolio and an internship project. The program model provides a cadre of support for each cohort including an advisor for course participants, a mentor for course instructors, and a design team to ensure the alignment of current research, course instruction, and participant reflective response. The program recognizes adult learners as reflective professionals in search of meaning as they experience the ever-changing technological applications for teaching and learning. Adult learners who are seeking professional growth in their teaching and administrative positions need to understand and demonstrate the essential skills of technology as well as communicate, plan, design and implement innovative changes in classroom, school and community settings. As adult learners respond to course requirements and reflect on meaning-making moments, they will realize a transforming process that will lead to the construction of innovative professional thought and practice.

Assessment and Professional Development Planning
This course is offered throughout the degree program in three one-credit increments at the beginning, middle and end of the course of study. It focuses on the organization of a digitized portfolio that includes a professional assessment of technology skills based on standards established by ISTE. The course presents a dialogue on the process of assessment leading to the mastery of technology skills needed for professionals who provide leadership in educational applications of technology. This dialogue is embedded in actual problem-solving activities that can only be resolved by active engagement with technology. Through collaborative learning process participants form their own assessment format and design a strategic plan to accomplish their goals.

Synchronous and Asynchronous Reflection
Throughout all course work, participants will recognize the integration of technology infused in instruction, presentation and assessment. Instructors and participants must engage in discussions that include opportunities for e-mail interactions, web site discussions and video conferencing. All course work must demonstrate synchronicity through integration and interactivity, but also asynchronicity that encourages participants to diverge and engage in dialogic conversation through innovative technological advancements. Note in the sample excerpt of the ISTE standards how participants engage in this reflection.
Effective methods courses assist pre-service teachers in developing strategies for instruction and in understanding the value of subject integration in facilitating their students' development of concepts. When teaching pre-service teachers, including an example to illustrate concepts such as integration provides a concrete application to connect theory to practice, as well as ideas for lessons to be taught in elementary classrooms. Since reading is a major focus in all elementary classrooms, pre-service teachers can certainly relate to examples which use literature to integrate a variety of subject areas. By providing an illustration for class discussion which incorporates Internet resources, teacher educators are modeling technology integration as well. Teacher educators must model lessons which use technology in Internet references for lesson preparation, student activities using Internet resources and databases if we expect beginning teachers to see technology as a viable tool in their classrooms. The following example provides a model for discussion in pre-service classes as well as a unit for instruction in elementary classrooms by integrating language arts and social studies through Internet connections.

The values of using multiethnic literature with elementary children are many. Lessons can address issues faced by minorities, similarities in human experience, artistic contributions in arts and humanities, respect for diverse value systems, geographic and historical facts, sociological change and social sensitivity. Studying a group of people by addressing these issues allows students to connect history and the present, and to consider events and situations from a viewpoint different from their own. McGowan, McGowan, and Lombard (1994) suggest that linking literature and social studies complements reform efforts in the social studies curriculum arena to encourage student engagement, subject matter integration, global awareness, social participation, and the formation/application of significant ideas.

Literature of Native American cultures provides an excellent vehicle for identifying and understanding tribal traditional values and beliefs and a source for integrating numerous content areas into lessons (McGowan & Guzzetti, 1991). Often, students acquire superficial views of Native Americans by being introduced to certain stereotypic components of their cultures. This can be avoided by studying the culture through literature such as folk tales, which provide students an opportunity to understand the central values of the culture and how these affect everyday lives (Franklin, Roach, & Snyder, 1993). A selection of literature which allows students to consider events from a different viewpoint, to reflect on the impact of a particular historical event, and to connect the past and present is Death of the Iron Horse (Goble, 1987). Goble’s beautifully illustrated folk tales is based on a specific factual event involving a train derailment by the Cheyenne people and their attempt to protect their land. In the book, Goble uses words and pictures to illustrate the similarities as well as the unique qualities of the culture and creates images that denote the way of life, artifacts and symbols, and traditions. The story reflects the cultural values of living in harmony with nature and emphasizing group and extended family needs rather than individual needs. The story portrays differences in cultural values placed on material possessions and the limited impact of the Cheyenne people’s heroic attempts to stop the changes brought by the invasion of their lands.

One strategy for using Death of the Iron Horse to teach history, values, and culture of a particular group of Native Americans is to focus on the five themes of geography: location, place, relationships within places, movement, regions/neighborhoods (Joint Committee on Geographic Education, 1984). These themes provide a framework for gathering information through a variety of sources, including the Internet, about the past and present. Suggestions for addressing the five themes of geography through this literary selection follow.

Connecting Literature and The Five Themes of Geography

1. Location: Position on the Earth’s Surface describes where specific points are located on the earth’s surface and where certain points are in relation to others.
   • Use maps to locate the home of the Cheyenne nation discussed in the story.
Plot the westward expansion of the railroad.

2. **Place**: Physical and Human Characteristics
   - Identifies the distinctive characteristics of areas (physical or human) that distinguish them from other places.
   - Collect information about the climate of the Great Plains.
   - Discuss implications for the natives who lived there: housing, clothing, agriculture.

3. **Relationships within Places**: Human-Environmental Interaction
   - Characterizes the ways people react to and sometimes change their environment.
   - Compare and contrast the viewpoints of the tribespeople and the white men concerning the advantages and disadvantages of the railroads expanding westward.
   - Find passages from the book which illustrate the tribespeople's respect and concern for the environment.

4. **Movement**: Humans Interacting on the Earth
   - Characterizes how people travel from one place to another, communicate with each other, or rely on products, information, or ideas from other places.
   - Compare and contrast how Native Americans and White Men communicated and traveled.
   - Discuss differences in values placed on products/material possessions.

5. **Regions/Neighborhoods**: How They Form and Change
   - Classifies areas that display similarities of selected features (landform, climate, natural vegetation, religions, land use, culture)
   - Identify changes in the region that occurred following the coming of the railroad.
   - Examine how the Plains Indians live today; investigate occupations, government structure, schools, family or national traditions.

**Internet Resources**

The Internet can be used as a valuable resource for teachers and students engaged in these activities focusing on the five themes of geography. Native American and environmental websites provide resources for gathering factual information about regions and people. The following websites are useful resources to further expand children's perspectives of history, culture, values, and traditions.

- **Multicultural Bibliography**
  - http://falcon.jmu.edu/~ramsey/mulnativ.htm
    - Includes links to bibliographies of Native American literature by genres and regions of North America; provides teacher resources and reference materials.

- **Index of Native American Resources on the Internet**
  - http://hanksville.phast.umass.edu/misc/NArources.html
    - Provides links to art, archaeology, music, and history of Native Americans; supplies a rating of each of the sites.

- **World Wide Web Links to Native Americans**
    - Provides an index of resources on the Internet as well as the Bureau of Indian Affairs.

Preservice and inservice teachers enrolled in elementary education classes at the University of Mississippi during the spring and fall semesters of 1997 learned first-hand how to use children's literature to integrate reading, writing, and multimedia technology. Selected trade books and children's literature selections provided writing prompts for students' own stories that were composed and illustrated online, using word processing, paint, and presentation software applications.

Method

Students enrolled in EDRD 350 Computer Technology and Reading Instruction, EDRS 557 Computers in Education, and EDEC 553 Language Concepts and Literature in Early Childhood were instructed in technology, the writing process, and elements of story structure in children's literature. In an attempt to provide these preservice and inservice teachers with authentic opportunities to integrate children's literature and the writing process with technology, practical applications were established. Several stories, based upon students' understandings of story patterns and structures were selected as writing prompts. These included The Important Book (Brown, 1990), Together (Lyon, 1989), Brown Bear, Brown Bear, What Do You See? (Martin, 1996), Polar Bear, Polar Bear What Do You Hear? (Martin, 1997), If You Give a Mouse a Cookie (Numeroff, 1985), and If You Give a Moose a Muffin (Numeroff, 1991). Some of these books provided opportunities for students to create online stories, while others were more suited for paired writings, illustrations, or for whole class composition.

Writing and illustrating as individuals, as partners, and as groups

Although The Important Book was written by Margaret Wise Brown in the late 1940's, it has remained one of her most beloved children's classics. The author focused on what was important about several things that are familiar to most children, describing the attributes of a common item, always ending with the pattern "but the important thing about a ... is that it is..." This story pattern was quickly recognized by students. They were provided time to reflect on what was important to them and why. The next step of the writing process required computer time. They composed their text in Microsoft Works and illustrated them using Microsoft Paint. Both text and drawings were then copied and pasted onto pages or slides in Adobe Persuasion. The resulting product was the publication of the students' work— "Our Important Book" online.

The story pattern of Together (Lyon 1989) focuses on corporation and collaboration. After listening to, discussing, and experimenting with the language pattern and structure of the story, preservice and inservice teachers worked in pairs to compose original text and illustrations for their own online versions.

The two highly popular books by Bill Martin Jr. (Brown Bear, Brown Bear, What Do You See? and Polar Bear, Polar Bear, What Do You Hear?) also provide story patterns that allowed preservice teachers to follow a similar procedure for writing and illustrating stories online. Finally, two books written by Laura Joffe Numeroff, If You Give a Mouse a Cookie and If You Give a Moose a Muffin, provide delightful stories with more complex patterns and structures.

Lessons Learned

Preservice and inservice teachers learned how to share quality children's literature with children, using it as a writing prompt to create stories that may be published online. They also discovered that this process approach to writing may be constructed for individuals, for pairs, or for small and large groups. Additionally, they learned valuable file management and transfer skills by working with multiple applications. Most important, however, they actually integrated reading, writing, and multimedia technology by using simple, fun children's stories.

Preservice Teachers’ Achievement and Attitudes in Creating Language Experience Stories

Jan Rader
University of Mississippi

Traditionally, language experience stories (LESs) have been used as a means of teaching children to read and write. "Young students typically dictate experiences to their teachers, who print them on paper, recording the students’ exact words. These experience stories then become the basis for reading instruction (Rader, 1997, p. 797) Older students print or word process their stories, adding drawings, photographs, clip art, or other graphic images for illustrations. The resulting SE are not only meaningful but also highly motivating since they provide an opportunity for students to express themselves, writing about their personal lives and experiences to share with others.

The Language Experience Story Project

As part of their course requirements for EDRD 350 Computer Technology and Reading Instruction at the University of Mississippi, 97 preservice teachers were assigned LES projects. The participants ranged in age from 19-46 with an average age of 23 years. (See Table 1 for gender and ethnicity information.) Each preservice teacher was required to follow the writing process (prewriting, drafting, editing, revising, proofreading, and publishing) and desktop publish a LES, using photographic images for illustrations. Preservice teachers were required to produce their LESs in duplicate—one for themselves and one that would be placed in a software library housed at the college of education.

Procedure

Preservice teachers received several class periods of computer technology instruction that included formatting skills for their LES notebooks. These skills included how to create covers (portrait orientation) and spines (landscape orientation), modification of font faces, types, types and sizes, and the development of text boxes, borders, and graphics. In addition to the basic skills needed to successfully complete this assignment, students were also required to obtain and learn about e-mail accounts. This process allowed the students the opportunity to communicate with each other and the instructors.

At the end of the semester, the participants were asked to complete a 20-item questionnaire targeting their levels of comfort using the computer, technological skills, and knowledge of the writing process before and after the project. (See Figure 1 for questions.)

Language Experience Story Questionnaire

Directions: Now that you have completed your LES, please provide the following information and answer the following questions to the best of your ability.

1. Name
2. Age
3. Gender
4. Ethnicity
5. The title of your LES is...
6. Before you began your LES, what was your level of comfort using the computer? (Rate your comfort level on a scale from 0-10 with 0 indicating no comfort using the computer to 10 indicating complete comfort using the computer.)

Reading, Language Arts and Literacy — 773
7. After you completed your LES, what was your level of comfort using the computer? (Rate your comfort level on a scale from 0-10 with 0 indicating no comfort using the computer to 10 indicating complete comfort using the computer.)
8. Before you began your LES, what was your level of computer technology skills? (Rate your computer technology skills on a scale from 0-10 with 0 indicating no computer technology skills to 10 indicating expert computer technology skills.)
9. After you completed your LES, what was your level of computer technology skills? (Rate your computer technology skills on a scale from 1-10 with a 0 indicating complete comfort using the computer to 10 indicating complete comfort using the computer.)
10. Before you began your LES, what was your level of understanding the writing process in education? (Rate your understanding of the writing process in education on a scale from 0-10 with 0 indicating no understanding of the writing process in education to 10 indicating complete understanding of the writing process in education.)
11. After you completed your LES, what was your level of understanding the writing process in education? (Rate your understanding of the writing process in education on a scale from 0-10 with 0 indicating no understanding of the writing process in education to 10 indicating complete understanding of the writing process in education.)
12. List as many of the computer technology skills that you have learned during this project. Use the back of this paper as necessary, Provide explanations as needed.
13. Please consider the costs of completing this project in time and money. First, how many hours did it take for you to complete this project? Secondly, how much money did it cost?
14. Do you plan to share your LES with the students when you are in the schools?
15. What are some of the things that your LES teaches?
16. What grade level or range applies to your LES?
17. When you desktop published your LES, how much did you use the school of education computer lab, your own computer, or other computer facilities? (These figures should add up to 100%.)
18. Please write five sentences explaining your feelings about the LES project.
19. Have you shared your completed LES with others? If so, what were their reactions?
20. Do you plan to create other LESs with your future students?

Figure 2. The Language Experience Story Student Questionnaire.

**Results**

The questionnaires were collected and compared using paired samples t-test. Results indicated statistical significance for all three comparisons. Participants reported a mean level of comfort using the computer of 5.76 at the beginning of the class and 7.91 at the conclusion of the semester, with a mean difference score of 2.87. The paired samples t-test indicated that there was a statistically significant difference at the 0.01 level \[t(96) = 11.98; p < 0.00\]. On the level of computer technology skills, participants reported a mean of 5.66 prior to the experience and 8.36 after completing the course, with a mean difference score of 2.61. The paired sample t-test indicated that there was a statistically significant difference at the 0.01 level \[t(96) = 15.53; p < 0.00\]. Finally, on the level of understanding the writing process in education, the participants reported that their mean levels of understanding were 5.04 prior to instruction, and 7.91 after, with a mean difference score of 2.87. The paired sample t-test indicated that there was a statistically significant difference between preservice teachers’ understands at the 0.01 level \[t(96) = 12.90; p < 0.00\].

On the open-ended questions, the participants reported over 80 computer skills learned in the duration of the study. The top six are: how to work with text boxes and borders for photographs (74); how to change the page orientation and create a notebook spine (40); how to work with fonts, including resizing (36); how to insert graphics and clip art (35); how to create a cover page (18), and how to insert page numbers (15). Participants reported that it took from 4-96 hours (average of 16.5 hours) and cost $10.00-120.00 (average $34.00) to complete the LESs. It should be noted that several preservice teachers chose to purchase special paper, software applications, and hardware components in order to complete their projects. Overall, (89.69%) the participants reported that they would definitely share the LESs with future students, with the remaining preservice teachers indicating that would most likely share the project.

The topics of the LESs included animals or pets (34), specific literary (22) or mathematical (14) skills, cooperation (14), and love of friends (9) and family (9). The targeted grade level ranged from preschool to middle school with the majority of preservice teachers writing stories for kindergartners, first and second graders. The projects were developed using the computers in the college of education computer lab (78%), on personal computers (18%), or on other computers (4%).

Each preservice teacher wrote five sentences responding to the project. These comments were analyzed and classified as either all positive (5 positive sentences), mostly positive (3-4 positive sentences), mostly negative (3-4 negative sentences), all negative (5 negative sentences), all negative (5 negative sentences), and no response. Findings revealed...
41 all positive responses, 49 mostly positive, 4 mostly negative, 0 all negative responses, and 3 no responses. An analysis was made of the negative comments categorized as mostly positive and mostly negative. Here, 16 participants felt the project was time consuming; 16 felt the project was expensive; 11 became frustrated using the computer; 9 wanted more structure; 7 found the assignment stressful, tedious, difficult, demanding, or tough; 4 perceived the process as a lot of hard work; and 3 felt that using the writing process was tedious. Other individuals reported difficulties with specific components of the assignment. Specifically, problems with the hardware (no color printer, difficulty with camera) with personnel in the computer lab or the public access to children’s photographs.

The preservice teachers indicated that this assignment was valuable, both in its approach to teaching computer technology and literacy processes. An added benefit was the personal motivation for these novice teachers. The participants were asked to report on how they shared their stories, and others’ responses to the LESs. Here, the positive comments were overwhelming, with most stating that they were great, cute, super, educational, creative, funny, or priceless. Finally, most of the participants (88.66%) indicated that they planned to create an LES with their future students. The remaining participants indicated iMaybei (6.19%), iProbablyi (2.06%), iNot Sureli (2.06%), and iIt depends on the grade I teachi (1.03%).

Conclusions

Since the LES project increased preservice teachers levels of comfort using the computer, computer technology skills, and understanding the writing process in education, it was concluded that it was a beneficial assignment. In addition, 87 percent of the preservice teachers planned to share and 89 percent planned to create LESs with their future students. It was also concluded that the LES project should be continued in future sections of EDRD 350 Computer Technology and Reading Instruction. Based upon student feedback, a computer trouble-shooting component will be added to the class. Future additions to the assignment will be the development of online LESs, with publication on the Internet.

The author wishes to thank the preservice teachers enrolled in EDRD 350 Computer Technology and Reading Instruction during the spring 1997 semester for their wonderful LES projects, as well as the computer lab graduate assistants for their help in compiling the data for this article.

Adapting Computer Software to Address Specific Needs of Problem Readers

Shirley A. Long
Eastern Kentucky University

Sue P. Reehm
Eastern Kentucky University

Literacy instruction has changed radically in recent years based on changing theories of how learning takes place. Teachers have incorporated whole language, writing processes, and literature based instruction in elementary classrooms to replace previous literacy programs that relied on basal readers and a focus on skills/subskills. This change is reflected in the recently published Standards for the English Language Arts (NCTE/IRA, 1996), which advocate new roles for teachers in the language arts classroom. These new standards have also expanded the definition of language arts from the traditional areas of oral language (listening, speaking) and print language (reading, writing) to include a third area of media language (viewing, representing). Thus, leaders in the field of language arts have acknowledged the profound influence of new computer technology tools on the teaching and learning of language in elementary classrooms.

There is a need for a similar change in the role of reading specialists. The advent of advanced computer technology and the development of a new generation of computer software programs has heightened this need. New forms of assessment are now available, and are becoming available on computer software (Hasselbring, Goin, Taylor, Bortge & Daley, 1997; McEneaney, 1992). New versions of literature such as interactive storybooks and writing tools such as children's versions of word processing have implications for teaching reading comprehension and writing composition. Other new software programs allow drill and practice on supporting subskills for reading and writing (e.g., word recognition, word meaning, spelling, punctuation, grammar) in entertaining formats such as interactive computer games.

There are, however, practical problems with using software for teaching. Unsupervised learning, even with complex software, may not be educational. Students play just for entertainment in interactive storybooks (Matthew, 1996) and fail to learn new words by attending to the print that accompanies the iplayi setting. They work with skill and practice software by trial & error instead of thinking and using strategies, thus focusing on iwinningi rather than learning.

Teachers must therefore tailor software use and practice to specific needs of struggling readers and writers. They must first identify needs, select specific software to fit those needs, then supervise closely as students interact with the software. They must monitor and coach, and evaluate with observational checklists in different types of literacy software.

One role of the reading specialist in an elementary school is to provide a isafety neti for those students who have difficulty in literacy tasks in the regular classroom. This can be accomplished more easily with technological tools now available. Reading specialists who are familiar with software programs and ways to tailor their use can help classroom teachers provide specific instruction beyond ipull outi and ipush inii or inclusion times with struggling literacy learners. For this reason it is important for teachers who are working toward the reading specialist certification to gain experience in working with elementary children as they use computer software.

Program Description

The Summer Reading/Writing Program (SRWP) conducted at Eastern Kentucky University for the past three summers involves experienced classroom teachers who are completing state certification as Reading Specialists. Elementary students in the program are identified by their regular classroom teachers or by parents as needing additional help in the reading/writing process. The program is an intense five-week program in which teachers spend two and a half hours each day with students either individually or in small groups. Over a period of three summers, a total of 32 teachers and 95 students in grades one through eight have been involved in the program. Teachers have used a variety of instructional strategies and materials under the supervision of a university professor who specializes in the field of language arts. The focus has been on creating a rich whole language environment and on engaging students in actively read, writing, listening, speaking, and thinking. A workshop format, along with language arts games and learning center
activities, has been used to allow individuals conferencing and tutoring time.

Computer technology has been used in all phases of the program from initial diagnosis of developmental levels of literacy to remediation of reading/writing difficulties. Several software packages have been examined and evaluated for use in the program. Two software packages used in the area of diagnosis were Assess A and Assess B. Software used for reading included Living Books, Accelerated Reader, and for reading skill development, Spell It 3 and Word Attack 3. In the area of the writing process, Storybook Weaver, Student Writing Center and Read, Write, and Type were used.

Teachers in the program used the software initially as prescribed within the manuals. However, the lesson plans and materials provided with the software were designed for general classroom usage. They included thematic unit connections and activities for a variety of content areas as well as general suggestions for reading, writing, and skills development. Teachers in the program found themselves sifting through the support manuals looking for activities designed to focus on specific needs they had identified. They found that they needed to design their own specific ways to use the software in order to meet the needs of the struggling readers in the SRWP. As they became more familiar with individual student needs and with the capability of the software, they adapted the software usage to better fit the needs of the particular students. Four programs in particular seemed to lend themselves to use in this way. The following discussion outlines specific techniques designed for students using these four programs.

Models Developed for Specific Use

At the end of the program, teachers reflected on their experiences and described some of the specific adaptations used and the effectiveness of each adaptation for particular needs. The four programs used most by the teachers were Living Books, Storybook Weaver, Spell It 3 and Word Attack 3.

Brderbund’s Living Books are designed to allow primary level students to listen to a book read aloud as text is highlighted on the screen. Students can play inside each page of the story by clicking on objects in pictures to see and hear animated characters do a wide variety of things. Students can also choose to click on words to highlight and hear them read aloud, and to hear and see the text in English or Spanish. The teachers reported that they adapted the Living Books program to help primary students with word recognition and comprehension. Students used the software with partners to do choral reading and paired reading in order to develop reading fluency. Teachers helped them develop comprehension strategies through guided reading activities such as making predictions and asking comprehension questions. They helped them develop word recognition skills by having them locate specific words or words containing specific phonic elements. A good technique that emerged was to require the students to do the read me mode before they were allowed to switch to the iplay inside the story mode. This encouraged students to focus on comprehension of the story and on reading along with the highlighted and spoken print rather than on the animated features. Teachers monitored these readings and enhanced comprehension by discussing stories with students before, during, and after readings. They also paged back through the stories to highlight a variety of sight words, phonic elements, punctuation, and the use of context clues to predict words and strengthen students’ use of word recognition strategies.

MECC’s Storybook Weaver Deluxe CD is designed for students age six to twelve, and allows students to create their own interactive storybooks with title page, text and illustrations. It has text to voice capability so that students can have their stories read aloud by the computer. Students can design illustrations using choices of background, foreground, objects which can be made larger or smaller, and can be given sounds and changed in color. Teachers found that this program worked well with primary students as a tool for invented spelling. This specific usage developed phonemic awareness and phonic skills. Especially useful was the feature of this program that converts text to speech. This feature allowed students to identify misspellings by hearing words pronounced the way they were written. Other ways teachers adapted this program were to have students create story maps before writing and use teacher created story starters based on specific student interest.

Two programs used extensively by teachers in the program were Spell It 3 and Word Attack 3. These programs were designed to focus on spelling and word meaning, with choices of ability levels ranging from primary to adult learners. Spell It 3 consists of a choice of game formats that present words in meaningful context, apply spelling rules, distinguish between correct and incorrect spelling, develop short term recall of spelling words, and develop editing skills for identifying errors. Word Attack 3 also has a choice of games formats designed to develop meaning vocabulary using context clues and dictionary definitions. Older students seemed to gain most by adaptations of the two programs. Teachers developed individual word lists based on analysis of student work samples. The computer programs then generated game activities to develop spelling and word meaning from the word lists. Types of word lists based on grammar were also used (i.e., nouns, adjectives, verbs). Students enjoyed working with a partner and prompting each other for specific strategy use.

Conclusions

Beyond making gains in the specific reading skills outlined above, students acquired competencies in the computer environment. For example, they became adept at using the keyboard, finding and clicking on particular options on the screen, and finding favorite pages in a book.
In the process of using the computer packages, they learned specific sight words such as quit, stop, options, restore, close, yes, and no.

Teachers gained confidence in their ability to tailor available software to specific students' needs. They discovered ways to exploit peer teaching by having students work in pairs at one computer or in small groups using one computer program under close teacher supervision.

The adaptations of software usage designed by these teachers should continue to be refined. Research is needed to determine and document the effectiveness of each technique. However, the potential uses of technology for struggling literacy learners are highly promising. The teachers in this program have shown that creative adaptations for specific needs of students are effective as well as motivating.

THE REFLEXIVE EVOLUTION OF TECHNOLOGY IN LITERACY COURSES FOR PRESERVICE TEACHERS

Nancy L. Williams
University of Houston

These are exciting but challenging times for teacher educators. As we strive to prepare teachers for the twenty-first century, we are confronted with both the public's anticipation and fear of the rapidly approaching third millennium. Many educators have heard the voices of the business sector concerning the quality of future workers, who must have the appropriate skills and the flexible creativity to function in a post typographic world (Boyette & Cohn, 1991). The recognition that future students and teachers must be proficient in technology prompted the institution of basic computer classes within teacher certification programs throughout the country. The evolution of these courses over the past decade has been exciting, and with the advances in hardware, software, and the limitless possibilities of the Internet, many educators anticipate the positive direction of teacher preparation. Regretfully, along with this anticipation, a critical public also voices fearful concerns about the literacy levels of our students. Witness endless newspaper articles and list-sery dialogues that again raise the ageless battle cry for phonics first instruction, correct spellings, even in young children's first drafts, and the dissonance between college professors' ideals and the real world. In a pre twenty-first century world where a strong economy prevails and no major wars dominate the evening news, it is not surprising that legislators in several states promise changes in state curriculum and in colleges of education, particularly in the area of literacy, and changes that are not particularly progressive nature.

The challenge for educators then, is to establish teacher preparation programs that are innovative, progressive, and are successful. Such changes must not be made because the legislators demand it, or because change is good. These arguments are no better than the premise of traditionalists that change is not needed because it has always been done this way. What is needed is a reflexive evolution of programs. This process requires the participants to reflect upon the events and to make changes, or not to make changes, based upon that reflection. This reflection is influenced by a number of variables including the students, the site based context, knowledge bases, belief systems, and political and economic factors. As the rapid advent of technology has increasingly played a critical role in the professional development of teachers, it is important to review the use of technology within methods courses. Through such a process, university professors can better plan courses for preservice teachers, courses that include technology within authentic contexts, rather than to use technology for technology's sake (Conklin, 1997). The purpose of this study then, is to examine the evolution of the use of technology in a preservice teacher literacy course. Specifically, the study focuses on the reflexive evolution of the use of technology in Reading and Language Arts in the Elementary School during a three year period (1994-1997) as it progressed from a one hour traditional campus based course to a three hour field based course.

The Milieu, Course, and Method

As this course evolved from a one credit university based course to a three credit field based course, several changes have occurred. In the fall of 1994, preservice teachers at the University of Houston were prepared for elementary classrooms in a very limited way. Due to previous Texas legislation, education courses were limited to 18 hours, relegating only a third of those hours to methods courses. This resulted in a one hour language arts class which met four hours each Monday morning for five weeks. The course was also taught at the university, and offered no opportunities to work with children. In the following spring, the course was field based, allowing opportunities to work with children, and met for the entire semester; however, students still received only one credit. The following fall (1995), with the sunsetting of the previous legislation, education courses were limited to 18 hours, relegating only a third of those hours to methods courses. This resulted in a one hour language arts class which met four hours each Monday morning for five weeks. The course was also taught at the university, and offered no opportunities to work with children. In the following spring, the course was field based, allowing opportunities to work with children, and met for the entire semester; however, students still received only one credit. The following fall (1995), with the sunsetting of the previous legislation, the course was combined with a three hour reading course and was field based along with science, math, and social studies methods. It remains part of the PUMA (Pedagogy within Urban Multicultural Actions) today. In the current context, students are assigned to a cluster that is determined by the
students' request for elementary or middle school setting, or by geographic areas. These site-based environments have provided opportunities for students to practice theories of learning in public elementary and middle school classrooms under the supervision of both university and public school teachers. Consequently the preservice teacher is at the elementary/middle school site on a daily basis and becomes a member of that elementary or middle school culture.

Approximately 25 students are enrolled in each of the six clusters and are in their last semester before student teaching. The classes are representative of the students within the college of education; they are predominately female, white, and are in their early twenties. Several students are male, African-American, Hispanic, or Asian, and may be older students seeking a career change. They also vary in their area of specialization, (reading, early childhood education, health, math, bilingual education, history) and in their familiarity and access to technology. While many of the students own or have access to a computer in their home, others have limited access to computers and may have only basic understandings of technology.

The reflective inquiry was structured by using Smyth's questions (1992) as a framework for critical reflection: 1) Describe- what do I do?, 2) Inform- what does this mean? 3) Confront- how did I come to be like this? and 4) Reconstruct- how might I do things differently? Specifically, the questions guiding the analysis were: 1) How have class activities and assignments regarding technology changed as a result of the evolution of the course?, 2) How will these changes impact the future of technology assignments within a field based course?, and 3) Will these changes encourage preservice teachers to utilize more technology in their future classrooms?

Using syllabi, course materials, and data collected from previous studies, (Matthew & Williams, 1994; Williams & Matthew, 1995; Williams, Tyson, Hilton, Kimbell-Lopez, & Granger, 1997) I completed a grid listing all the technology assignments made in the course from the fall, 1994, through the fall, 1997. Other artifacts from the course and the previous studies were also analyzed, including survey questions and field notes about student presentations and interviews. A reflexive narrative (Ruby, 1989) was then written to document these changing decisions. Finally, the data was compared to determine the evolving trends of technology within this field-based course.

Findings and Conclusions

The assignments regarding the use of technology changed greatly over the past three years. When the course remained on campus, one of the major concerns that the students raised was the lack of classroom experience. They voiced interest in the writing abilities of elementary and middle school students and were curious about developmental spelling in young children's writing. As a result, a HyperCard program, Stages of Children’s Writing Development (Williams & Matthew, 1994) was developed. This software was used on a weekly basis during class time in the computer lab. In this assignment, students worked in pairs to review the stacks which coupled literacy research on early writing with authentic examples of student writing. After the students spend time navigating the stacks, they were to analyze a sample of student writing, offering suggestions for teaching.

During the following semester, students were field based and did not have access to a computer lab. In the infancy stages of the PUMA program, there were few computers that were designated for university students' use when they were at the elementary school site. Through the use of a laptop computer, I was able to bring the HyperCard program to the site where students interacted with the program during a workshop approach. Due to the limited availability of computers, the assignment was not graded. By the following semester, progress had been made regarding the access to computers. The site where I taught had a power Macintosh and a printer. An LCD panel was promised, as was internet connection. Along with the laptop computer, I was able to continue using the HyperCard stack as an assignment, along with the presentation of educational software programs. Again, time and access to multiple computers prohibited the effectiveness of using this technology assignment as a grade. By spring 1995, we had been connected to the Internet. The HyperCard program was again used as a class activity. However, due to the added opportunities of working within authentic contexts, the students were now engaged in literacy events with elementary and middle school students which provided them with more authentic understandings of students’ abilities as writers. It became apparent that this program was not as effective in a field based course.

Prior to the start of the fall 1996 semester, the entire PUMA faculty was informed that each site now had a designated computer and was challenged to incorporate more technology into the curriculum. The five instructors for Reading and Language Arts in the Elementary School met to discuss the development of a common syllabus, and how to integrate technology into the course. Although we were all proficient with technology, our abilities and experiences varied. As we all recognized the changing and differing needs of our students, and held a constructivist belief about teacher preparation in general, and in computer literacy specifically, we decided to assign a technology project. This assignment allowed the student to create teaching materials, or to plan and implement literacy events with their students, that would require the use of technology. We provided class time for students to work together, to have access to the computer, and to share ideas through a process approach. The students defined technology to include computers, videos, and audio tapes. We continued this approach for the spring semester. During both semesters, students were also exposed to technology through mini-lessons, “surfing the net,” and the examination of software.
As this course has evolved, the use of technology has indeed changed. When the course was limited in time and place, the controlled assignment fit the needs of the students nicely. Lacking opportunities to observe children engaged in the writing process, they were happy to have the vicarious experience through a primitive virtual reality. As students became more involved in truly authentic field-based activities, the need for the information contained in the HyperCard diminished, and the need grew to develop literacy materials that could be used in the classroom. This was evidenced in the quality of their assignments, and in the nature of their comments. When the class was held on campus, the students enjoyed navigating the stacks, and did a good job of analyzing the student writing samples. They lacked the enthusiasm, however, that the field-based students had when they presented their technology project in class. These students were allowed ownership over the class assignment. They created innovative big books, software programs, and other teaching aides that were professionally constructed. Overall, students in all sections of this course enjoyed using technology as a means of learning about the literacy events of elementary and middle school students. However, some students were hesitant about using technology. Although students' computer proficiency increased over this three-year period, some students still turned in handwritten assignments, and were reluctant to take a leadership role when working with technology during class activities. Students who had computers at home, for example, tended to submit class assignments complete with graphics, decorated computer paper, and wrote longer, more thoughtful comments. They appeared to have more pride in their overall work when compared to students who submitted handwritten assignments, complete with misspelled words, incomplete sentences, and an overall lack of professionalism.

As teacher educators progress in the preparation of tomorrow's teachers, it is critical to incorporate technology within authentic and reflexive experiences, despite the difficulties faced when moving courses from the university to field-based settings. The opportunities that these elementary and middle school settings offer preservice teacher as they transfer from student to teacher are priceless, but many of the amenities that afford the university student may not be available to the average elementary and middle school teacher; despite the national cry for equal access to technology. Many universities may have the necessary equipment and teaching materials to illustrate the potential for using technology to engage students in literacy events. Therefore if preservice teachers are encouraged to use technology within the confines of the university, but are not able to use it during their field based experiences, it is unlikely that they will continue the practice as inservice teachers. Based on the premise that that technology continue to play a pivotal role. From this self-reflection I have discovered that the most effective use of technology is determined by the educational context. Given the university setting, where experiences are limited, the structured format provided the students with an image of literacy development of elementary school students. Once in a field-based setting, students do not need to be provided with this image, and consequently, such assignments are not meaningful. Allowing the students to have a voice in their control over the implementation of technology not only assists them in the development of meaningful teaching materials, but also provides them with the opportunities to become more proficient in the use of technology. Finally, it models for them, the way we would like them to teach their students. Therefore, as this course continues to evolve, based upon self reflection and oral interactions with other reading and language arts professors, as well as the other methods teachers involved with the PUMA program, I intend to continue using technology both in class presentation of materials, and in assignments. It is only through such constructivist approaches that preservice teachers will become more comfortable with using technology as an integral component of planning literacy events for elementary and middle school students.

Finally, students in this course have expressed the optimism that they will also use technology in their own future elementary and middle school classrooms. This information is encouraging, given the limited exposure to computers that they experienced during their field-based assignments. As these new teachers enter the next millennium, they are becoming far more prepared to teach tomorrow's children through technology. Hopefully, they will meet the challenges that are being made by today's society, and that they will be equipped to prepare their students to be literate, flexible, and creative, allowing them to be productive in this new post typographic world.

Haley states, “Collaborative working is pervasive in our society, indeed, society can be conceived as an organization to assist the utilization of our respective knowledge and expertise. Hence, collaboration occurs within a social context, . . .” (1996). Collaboration between inservice teachers and preservice teachers is crucial to enhancing school children’s learning and teachers’ professional growth. However, effective management of this instructional method is complicated by the high level of social intelligence required to work in a group. A successful collaborative endeavor rests heavily on the structure and organization of the instructional model, and the shared initiatives of the participants. Further, since collaborative work can often make the impossible possible, one must spare no effort in realizing successful collaborative ventures.

Classroom Problems
In their 1992 book, Modern Elementary Curriculum, Shepherd and Ragan discuss the mainstreaming of all students into elementary classrooms, including students with learning difficulties. A gap between needed services and available funds resulted in the Regular Education Initiative (REI), a proposal from the US Office of Education. This policy has initiated a reexamination of the delivery system for special education with an emphasis on the least restricted environment and equal educational (Shepherd & Ragan, 1992). REI assumes that: a) students are more alike than different, b) good teachers can teach all students using the same basic techniques, and c) all students can be instructed and managed effectively in the regular classroom. However, many inservice teachers have expressed concerns and frustrations in meeting the various needs of students ranging in intelligence and social behaviors.

Models of Collaboration
One highly successful model of collaboration often used in the classroom is that of peer interactions. Based on the work of Piaget, who argued that children greatly benefit from coordinating their thinking with that of their peers (Piaget, 1928), many teachers promote collaborative modes within their instructional framework. Although many studies report the advantage for learning within peer interactions, other research has suggested that young children do not engage easily with the demands of academic collaboration (Crook, 1995, p. 542). These observational studies of informal class groupings indicate that pupils may not readily or deliberately adopt collaborative modes of working. In practice, such work may proceed more as a cluster of parallel initiatives among the participants, albeit initiatives converging on a shared goal (Crook, 1995, p. 543). Given the findings of this research, we should not become overly discouraged, and therefore dismiss the use of collaborative learning, but rather consider ways to assist young children to master the process. According to Vygotsky’s zone of proximal development, individual learning is mediated through either adult guidance or collaboration with a more capable peer (Vygotsky, 1978, p. 86).

Thus, it is reasonable to conclude that the limitations of peer collaboration may be overcome by guidance provided by mature, capable and motivated adults who practice recent academic advances. In particular, Collaborative work between inservice teachers and preservice teachers, together with the help of technology, shows great promise in helping to address these concerns. Indeed, technology has already begun to provide means for creative and individualized instruction for the full academic and social range of students, without sacrificing the general curricular requirements of the class as a whole.

Recognition of Possible Assistance
As state and federal regulations forbid students to remain in classrooms or in computer labs without adult supervision, the necessary individual instruction becomes more complicated. Many schools approach this problem by putting a few computers in the classroom. This allows some students to work individually, while the teacher is free to meet the needs of the rest of the class. However, this is more an expedient than a solution, as the mere presence of the teacher does not automatically guarantee individualized student instruction. In addition, because many inservice teachers lack adequate technological literacy, and are constrained by multiple class preparations, the problem of designing individualized instruction integrated with technology becomes acute. Given this context, the possibility of LD students receiving efficient classroom instruction through technology is minimal.
Experienced supervision for students in the technology rich classroom is not limited to young students. Preservice teachers, although eager to be in the classroom, often lack a clear understanding of planning and implementing authentic learning events. As teacher certification requirements in Kansas include more than 100 hours of classroom involvement, preservice teachers are provided with opportunities to assist inservice teachers. Regrettably, all too often, these experiences are simply empty hours. This may be the result of inappropriate communication among the college supervisor, the classroom teacher, and the preservice teacher. The purpose of this article is to present an outline for a more highly structured environment which allows for better communication among the participants in teacher preparation.

Project Design, Procedure and Logistics

A specially designed collaborative learning project patterned on the "Vygotsky's zone" model (Vygotsky, loc. cit.), was carried out in an elementary school. Participants included an inservice teacher, three preservice teachers, the author (as an educational technologist), and five LD students with written language deficits. Using a computer program, the major goal was to help LD students develop writing skills. A sub-goal, however, was to provide preservice teachers with experience using computer technology, especially as it applies to providing individualized instruction to students with special needs.

This year long project was motivated by a fifth grade teacher who was struggling to teach writing skills to mainstreamed students with written language deficits. The proposed solution was to augment the instruction with technology; yet there remained at least two logistical difficulties: (1) finding appropriate educational software, and (2) providing supervised computer instruction, thereby conforming with state mandates. To address these difficulties, free software, which had been used successfully in the past with LD students (Zhang, Y., Brooks, D.W., Frields, T. & Redelfs, M., 1994-1995), was introduced to the participants.

The three preservice teachers were then recruited and instructed in technology and techniques of providing writing opportunities for these elementary school students.

Using this software, the fifth grade teacher redesigned a writing curriculum which included three 20 minute periods per week for the participating LD students. During this time, they practiced writing using computer technology in a supervised lab. The students engaged either in either free writing or composing according to a specific topic. Most of the assigned topics centered on issues related to their personal experiences. At all times, at least one preservice teacher worked with the LD students. Most of the time there were two or even all three preservice teachers in the lab, working one-on-one with the LD students. They helped them to recognize the potential of using computer technology to improve writing skills, and motivated them to help offset occasional periods of frustration. The author supervised the process, served as the technical advisor, and facilitated communication among the participants of the project.

Computer Program

The software selected was ROBO-Writer, a HyperCard stack developed over a three-year period through a close collaboration between classroom teachers, students, researchers, and software developers. The objective of this software program is to assist beginner writers and their teachers. (Brooks, D.W., Zhang, Y., Frields, T. & Redelfs, M., 1994-1995). HyperCard is an application for the management of small amounts of text, graphic, and sound information. It can be used to create and store words in clickable lists. ROBO-Writer has four features that make it especially active for writers with learning disabilities in primary grades. There are carefully designed, teacher editable lists of words arranged alphabetically; oral feedback is provided; words selected from internal lists as well as those typed in as free responses are pronounced. Nearly all the features are icon-driven; aural help is provided for all student-used features. This free software is available at the sight of http://www.cci.unl.edu.

Benefits for Preservice Teachers

In preparation for this project, the participating preservice teachers engaged in a pre-project preparation session. They become familiar with the computer software and the purpose of the project. They were also apprised of the special needs, including backgrounds, and current academic performances of the LD students mainstreamed into the classroom.

The experiences that the preservice teachers gained during the process varied widely as they differed in technology backgrounds, personal interests, attitudes and identification with the project. In order to document these differences, the participants were invited to record their experiences and perceptions in a journal.

One preservice teacher believed in the whole child philosophy, was technically proficient, and was ready for the challenge that she was to face every time she worked with the LD students. She maintained frequent communication with the author, expressing concerns, excitement, and discussing effective strategies. In her journal entries, she noted a keen appreciation of the real and potential applications of technology in the classroom; furthermore she felt that she had developed a variety of valuable skills in working with young students who have special needs. She provided individual instruction in writing, and tried different motivational strategies for writing, and for staying on task. She expressed appreciation for the opportunity to work with students in a real classroom setting and the valuable experiences gained through the process. However, one of the three preservice teachers was not very enthusiastic about his involvement. His participation in the project was merely to
fulfill the 20 hour field experience requirement. His journal entries revealed a general lack of interest in the project even though he did carry out his portion of the responsibilities.

All three preservice teachers responded to a follow-up questionnaire with positive reflections about the program, the project design and the process as a whole. They learned to perceive the impact and potential of using instructional technology, and to be more analytical about selecting technology. Additionally, they responded positively to working with mainstreamed students. They indicated that they better understood LD students’ special difficulties, and learned to try different strategies. The most beneficial outcome for these three preservice teachers was that they experienced real challenges within a classroom setting. They all felt that the structured, task oriented project was very important in assisting them to become a well prepared professional, and superior to classroom observations.

Discussion

By the end of the school year, all the participating elementary students gained a sense of self-confidence and heightened enjoyment in writing. Specifically, they learned to express their feelings in writing, and were able to better identify their strengths and weaknesses, and were able to cultivate individual differences.

The findings of the present collaborative project indicate that: (1) the students themselves saw great improvement in their writing skills, and (2) the preservice teachers were afforded a hands-on training experience. It is anticipated that through such project, preservice teachers can not only experience authentic classroom experiences, but also assist the literacy development of elementary school children.

Conclusion

This project further documents the emerging importance of technology at all levels of education. Furthermore, it establishes two levels of collaboration. The first includes a mentor, an inservice teacher and preservice teachers and leads to an effective and structured model for teacher preparation. The second level involves collaboration between the students and the more capable peers, which leads to enhanced student performance. Indeed, we feel encouraged by the fact that through this structured environment, students with a variety of disabilities were able to engage in collaborative behavior.

Finally, while this project is not intended to be a specific blueprint for a collaborative model, we anticipate that it will guide other models. We hope that it has helped to isolate, amplify and analyze those aspects of team cooperation.

In the most common school practice students (and teachers) are seen as consumers (and transmitters) of culture. A factor of dis-equilibrium in such a system is introduced when students (and teachers) become involved in the production, accumulation, and circulation of ideas that can be eventually appropriated or critically rejected by other members of the community, as it is the case in the scientific community.

An external audience constitutes a powerful "constraint" to the class practice: a) it questions the social value of the outcomes of the activities, to select what to make public, b) it requires argumentation, c) it creates awareness of alternative ways of pursuing the same goals, d) it demands confrontation with other standards of validity and of quality, and e) it makes one more responsible and proud of one's own achievements since they become shared resources. Based on these assumptions, we designed an educational context where the software Our World is a component.

Educational research is making significant progress in the comprehension of the principles which can guide the teachers in the organization and management of communities of learners (Brown & Campione, 1996; Lamon Secules, Hackett, Bransford, Goldman, 1996; Ligorio & Caravita, 1994; Scardamalia, Bereiter, & Lamon, 1994; Salomon, 1993). Consistently with the socio-constructivist theories, these studies have confirmed that action strategies, thinking strategies and communication strategies depend on one another for their development and growth, and require a social context. Recursive elaboration is motivated by the circulation of products in a community where expertise is distributed and where products must be integrated in order to achieve a higher level of complexity.

**Written Composition and Knowledge Organization**

In school, the students comply with their teachers' requests and write reports to demonstrate that they have actively participated in their class activities and have achieved learning goals. Text composition is intended for the re-production of knowledge (content knowledge, performance skills).

The school reinforces the idea that to write means to use the correct words, rather than to learn how to use one's own words; it does not suggest that words are schematic approximations of comprehension, which can be continuously readjusted along with the changes of meanings produced by situated interpretation and communication. No wonder, then, that evidence from several studies indicates that students of any age lack the abilities that expert writers use, such as the ability to plan and of revise texts at a deep level (Beach & Bridwell, 1987; Bereiter & Scardamalia, 1987; Hayes, Flower, Schriver, Stratman, & Carey, 1987; Piolat, 1988).

The purpose of our research project is to determine the extent of the development of these abilities (even at early ages), when the educational environment creates the conditions for the students to exchange meaningful, informative documents within a community larger than their class. In the learning environment that we are observing, collaborative writing and class discussion are viewed as effective situations that support children in cognitively demanding tasks such as producing informative texts for external readers, revising them, and evaluating documents produced by other children (Keys, 1994). We are monitoring these processes and their influence on knowledge organization. We are also wondering about the status that peers vs. adults
may have as information sources. Additionally, do children see documents produced by peers as worth reading and useful to their work.

Environmental Education and Information Exchange

An important goal of Environmental Education (EE) is to make students aware of the many components, variables, and constraints that shape every environment in which we actively and passively participate and to promote questioning about this interplay. The software Our World invites school classes all over Italy to contribute the outcomes of their explorations in the environments where they live to a library. The sharing of this resource makes comparison possible: children are confronted with the many ways of viewing the environment when the contexts are different and when people take different approaches. Emotions are involved when children can feel that they are entitled to interpret their environment and when they realize that they share similar experiences and questioning with others. Private experiences get transformed into objects that can be shared in social interactions. Essentially they take the features of information. Information is not an entity but it emerges and it is defined within the sender-receiver relationship in specific systems, in finalized contexts.

Method

Our project fits into a nation-wide project sponsored by the National Department for the Environment (Italy). It is currently taking place in a group of elementary schools in Rome and in three other towns. The software Our World provides the students with the organized structure of a database where they can store their documents; its very friendly pictorial interface facilitates the documents retrieval but it also conveys messages consistent with the ecological domain. The documents filed in the library are written texts which may be accompanied by images. Contributors are requested to follow simple editing rules and to submit their documents to an editorial board which is responsible for the database implementation and for sending feedbacks to the authors.

The library is split into five databases labeled as: Phantasy, Research, Law, Publishing, Institutions. This subdivision suggests that a range of approaches are possible when dealing with environmental issues and marks the difference in content and literary genre of the outcomes of the investigations. We are now working on a new version of the program for the Internet, that will allow communication among schools and other territorial institutions.

The pedagogical guidelines discussed with the teachers provided the following activities:

a. integrating writing with the inquiry activities (taking notes, keeping drafts, using metaphors, summarizing protocols.....) and the with the construction of knowledge;

b. fostering reflection on criteria for selecting ideas when the class is engaged in writing documents addressed to an external audience (informative, original, argumentative, ...);

c. calling attention to the rhetorical features of the text, in the respect of personal expressive modes; d) supporting revision by modeling interventions on the text’s structure and cohesiveness; e) promoting critical reading of documents retrieved from the database; and f) integrating this kind of information within the class work.

The data presented here concern critical reading. It has been collected in five 4th grade classes that we are monitoring. The documents submitted to children’s attention dealt with environments which had been investigated by the readers. They were presented as documents received by the editorial board to be evaluated and filed in Our World. Paper copies were handed out and children read them silently before engaging in a class discussion which was audiotaped. Discussions lasted one hour or more.

Results

The class discussions that followed the reading of the documents were very lively and engaging. For the teachers also, who expressed positive remarks on this activity which was quite new to them: they underlined how insightful it had been for addressing significant contents of EE and how it might improve children’s ability of composing written texts.

In each class the discussion was started with questions about comprehension, such as: “Do you have questions about this document? Did you find something that you did not understand?”

The majority of children’s questions had to do with the clarification of words’ meaning; words or expression which were not familiar to them (in some case because they had a regional connotation), local names identifying places, scientific names of plants and animals. The informative value of difficult words and in particular of scientific terms has been a controversial issue in almost all the discussions. The conflicting views can be summarized as follows: a) when you do not know a plant or an animal, their scientific name does not help you to identify them when you explore an environment; if you find them mentioned in a text you expect to understand which kind of plants and animals they are from the text itself; and b) if you do not know the scientific denomination you cannot retrieve information or pictures, you cannot search on vocabularies or manuals.

The suggested solution was that scientific denominations should be accompanied by short descriptions in parenthesis, or as a note, for example, “otherwise children who live in town... how do they know!” This is helpful and might enhance the motivation to look for more information or for the animals and plants themselves; “you might want to check if the description is truthful.”

Reading, Language Arts and Literacy — 787
The counter-arguments were that the text might become too long, might be boring, and/or it might lose focus. Here the students remarked: "the discourse cannot deal with too many issues, you must select", "if you describe the whole country and then you end up not talking about the topic you had chosen...then you lost what was important!!"

Additionally, students were concerned about understanding words imbedded in the text. "Difficult words are understood when you read further on in the text". Finally, few children raised issues concerning the clarification of claims in the text. In these cases their remarks originated from the experiences that they had carried out in the class, which suggested discrepancy of observations, or the need of more details.

Text relevancy was then discussed with the children. They were asked whether the document that they had read was interesting to them and why. The texts were valued as interesting in all the classes. Children offered a wide range of pertinent arguments which revealed an attentive reading and which are significant for assessing the educational value of exchanges among students. The judgments, however, were not unconditional. Trivial information was detected and limitations were also put into evidence. In addition, children appeared to be sensitive to the age of the authors. We exemplify here the main types of justification that were expressed.

"it is important, it is written by children who live there, because they know better, they can describe the place in a way different from what you can find on books, even easier to understand...perhaps. Though, if you search on books, probably you find the same things that they also have written"

"it helps you to know new words; they have used the right terms.... we did not know them, then we have asked you and we now understand their meaning"

"it helps you to understand the life of their school, what is alike between our school and theirs"

"I did not know anything about newts and here it is well explained"

"it can be useful because we can work and discuss on similar things"

"the text is effective but I am not interested in the content.....every person knows that already"

"we should not forget that the authors are second grade pupils: they have done even too much!"

Through effective questioning the adult who was leading the discussions was able to evaluate the content of the documents and to identify their informational core. In this respect, we must also take into account the peculiar features of these texts. They had been produced by non-expert writers and the textual structure did not always make clear the relationships between the main focus and the additional comments. This part of the discussion was introduced with a set of questions such as: "What information the authors wished to communicate with this document? What is the main subject? Can you guess an outline that these children followed when they composed the text?"

It was evident that these issues were at the edge of the fourth grade students' ability as critical readers (the inference of the outline in particular). Some children were more skillful than other ones in dealing with them. In general, the title of the document was used as the main cue for answering. The lack of consistency between title and content of one text was pointed out by two classes. Some children focused their attention on descriptive details or on the narrative component and were not proficient in extracting the core content of the message. Some children added personal interpretations. But interesting statements such as the following, called for the adult's attention and raised further discussion.

"the document made me understand that our pond is different.....very different from that in Tuscany"

"the stream is the main topic, plants are second in importance. The writers added the plants because these plants were typical of their country, so it was natural for them to specify it"

"I think that they made hypotheses about man's impact on the course of the stream"

"this text tells what our schools have in common"

"it is as if the text is a narrative at first, and is descriptive, then it starts giving more information"

"first they chose the title and then they chose what to say"

"this text treats many topics: it first lists things that get transformed in school, then it summarizes them and this makes the title"

"their outline was the image......they say what they talk about"

Finally, the discussion dealt with eventual changes to modify the documents. "Is any information lacking? Do you suggest modifications?" Children did not produce many responses. However, some of them were very sensible and representative of the cognitive processes that are promoted by the discussion. Expansion of the informative content of texts was proposed by some children.

"they (the authors) should have better described the difference among the two species.....how you can recognize them......they write about the colour but do not say anything on how these animals look like. By
reading the title “Newts and their environment” you expect that the authors describe just everything. We might search on the database if there is information about newts, if there isn’t and we find it in books, we might file it in the database, so that everybody gets to know what a newt is”

“they have described everything... they say that they have explored the pond, but they don’t tell us about their actual impressions...” “I would suggest them to add more emotion, because the sentences here are just descriptions”

“they should have given information on how to reach that place”

“they should have added whether those plants were living in the water or close to the water”

“why the park should be improved? We might ask them how they want the park to be improved. They do not tell if their park is dirty, if it needs more places for playing or if it has no grass....”

Suggested modifications mainly focused on elimination of obvious details or of places and people. These were viewed as irrelevant for readers who do not belong to the same community and as useless since they cannot be found within a universal vocabulary.

Children’s comments about these textual features, brought into evidence problems very relevant to the environmental domain and offered the teacher an opportunity for mini-teaching. One of the young writers expressed concern about deciding which were the significant components of a given environment that should be included in the document. Other problematic issues were: the relationship between structural and functional dimensions of built environments and how to decide where to set the borderlines of an environment.

**Discussion**

Although, our data is descriptive and exploratory, we consider these initial findings promising. They are supportive of our predictions about the educational potential of the learning environment that can be created with the support of technological resources such as Our World. Children are motivated readers of peer’s writings. Information produced by peers, just because it is not so complete and structured and unique, can be viewed by students as a more manageable than information contained in books. It is felt as closer in expression and in subject, it is empathically accepted, and it can be more freely criticized since its source has less authority.

The relationship between familiarity and novelty was confirmed as an interesting aspect of the exposure to informative messages. Children valued the content that could be related with their previous experiences. They were interested in the novel elements that enable them to acquire deeper or more specific knowledge related to those experiences. On the other hand, they liked to be surprised and by new perspectives. When exchanges take place among students who share final projects the many ways of perceiving, exploring, describing, modifying, and valuing the environment becomes informative.

Children appear to be critical readers and sensitive to trivial or irrelevant content. Teachers therefore must create the conditions that make the exchange fruitful. Among these the most important are: to engage the students in authentic investigations of the reality which they perceive, as they perceive it and to offer guidance in recursive processes of elaboration. This guidance enables the students to progressively obtain more significant levels of interpretation.

Collaboration among children makes possible performances that individual activity might not produce. As children write together they mutually support their cognitive work by raising questions, by offering explanations, and by modeling text processing. It was evident that the critical reading can go beyond the actual content of the text if the teacher is ready to capture the sometimes fleeting ideas that underlie tentative wording of problems.

According to Strickland (1994), "Even before they enter school, at least one-third of the nation's children are at risk for school failure." (p. 328). Although, a number of variables such as social and economic conditions attribute to this statistic, undoubtedly, reading deficiency is a contributor to school failure. In fact, "There is no skill more basic to success in school than reading ability" (Taylor, 1994, p. 592).

Wood (1996) posits that, “As long as a third of America’s public school students in grades four through twelve can’t read, efforts to save the nation with flatter taxes, balanced budgets, welfare reform, more policemen, or line-item vetoes are in vain (p. 50). Therefore it is critical that teachers apply successfully what is known about teaching and learning to enhance reading instruction.

Schools in general have always been challenged over innovative instructional ideals and traditional methods (Hillerich, 1991). Reading instruction particularly has recently come under fire in many states (Harrington-Lueker 1996), partly as the result of poor test performance on national exams and national statistics on literacy generally. Consequently, an atmosphere has been created for the scrutiny of effective classroom practices.

Nature of Innovations
Technological advancements have had a dramatic impact on the design of conventional reading instruction. Technology-based networks have ignited interest and use of computer-based representations of information and knowledge (Barker 1996). In addition to traditional books and basal, these included the Internet, electronic books, talking books, audio or recorded books, CD-Rom books, multimedia books and cyberbooks (Barker, 1996, Treiltin, 1996; Bergeron & Bailin, 1996; Owston, 1997; Carbo & Cole 1995-1 Yopp 1995-, fiarritigtori.-1,Lieker 1996-1 and Bigelow 1997). Application of these tools is supported by the fact that reading improvement can only be facilitated if schools go beyond traditional curriculum development approaches and integrate strategies that align all aspects of organizational behaviors and activities that support student improvement (Feirsen, 1997).

The most traditional pathway to reading instruction has been through the use of narrative texts read to and with children. As more technological developments advance in terms of information sharing, communication and learning, educators need to broaden literacy development options rather than view them with intimidation (Cali-ney, 1997). Multimedia technology, for example, reflects diverse methods and philosophies of instruction that have been the pillars for teaching and learning (Cazet, 1996). Computers are now part of mainstream education (Moodie, 1995), and children are attracted to and motivated to use them in the process of learning (Guthrie and Richardson, 1995). This coupled with the documented benefits of educational technology (Van Dusen and Worthen, 1995, McCarty, 1995, Cronin, 1990, and Cazet 1996-1 Wepner, 1990) establish the basis for widespread use of technology in teaching children to read and develop literacy skills.

Interactive CD-ROMs that share playful and appealing features of interactive storybooks are currently being used in reading classrooms to augment traditional instruction. These CD-ROMs include activities that address specific reading skills including phonics, comprehension, and word recognition. They incorporate animated characters, music, sound effects, color graphics, and lessons representing various levels of readability. Such programs are highly motivational and include features such as highlighted text and digitized voices to provide feedback, while enhancing visual as well as auditory discrimination skills (Cazet, 1996).

A number of software programs have been developed and published for widespread use in reading classrooms. Oehring (1991) conducted a teacher’s choice survey of software and categorized various software by subject area, and reported the teachers’ favorites along with reviews and strategies for each. Allen (1995; 1996) and Cazet (1996) identified some of the most popular software used in schools to enhance reading instruction. Cole (1997) reported on a comparative analysis of selected software for the K-3 curriculums. These programs and other interactive, multimedia programs supplement traditional printed material used for reading instruction, and have transformed instruction and the teacher’s role in classrooms.
Everhart (1996) discusses six ways to use the World Wide Web to augment reading instruction including allowing students to compare and contrast two reading hour experiences where students select a story and read it in the traditional format, then access the same story by way of Internet to identify the differences and similarities in the traditional versus the non-traditional modality. The assumption is that because of the more interactive nature of the Internet experience, students will favor it over the traditional i-node.

In a review of studies comparing the use of conventional books to electronic books, Barker (1996) reported evidence to support the merits of using electronic books over conventional, paper-based formats. He further identifies ten different classes of electronic books including talking books, which contain audio-narrated pages of text- cyberbooks, which rely upon the use of virtual reality techniques to create simulation experiences that foster interactivity, and multimedia books, which are combinations of video, pictures, animations, sound and text.

Conclusion

Books, nonprojected technology-based tools for instruction (Heinich 1996), have been a primary mechanism for teaching and learning in educational institutions throughout the world—in schools, colleges and universities. They have been and continue to be excellent resources for reading instruction. However, contemporary investigations, based upon previous researchers, have generated innovations for the development of new paradigms for instruction (Strickland, 1994) that have great implications for the selection and use of aids for reading instruction. Consequently, dramatic technology-based instructional changes are taking place in reading classrooms throughout the country. Although traditional books will probably always augment reading instruction, current technology allows for instruction far beyond the use of conventional books.

As computers become common place in the classroom setting, research in the field follows suit. As a result, findings become more powerful, more noteworthy and more consistent. This year’s research section of the 1998 SITE conference offers a plethora of interesting and noteworthy sections. The papers in this section have been organized into four categories for your convenience: Attitudes Toward Technology, Technology Integration, Teaching and Learning Styles, and Research.

The Attitudes Toward Technology section was broken down into three areas: preservice teachers, inservice teachers and other.

**Preservice teachers**

Hutchinson and Mitchell discuss the experience of preservice teacher teams engaged in a collaborative project with elementary students. The purpose of the project was to further preservice teachers' technology knowledge, provide an environment to connect theory and practice, and offer preservice teachers an opportunity to personally experience technology integration and collaboration in an elementary school setting.

Sadera and Hargrave investigated preservice teachers’ preconceptions about the role of the computer in learning and teaching. Their research was based on several factors which were believed to influence preservice teacher attitudes toward computer integration.

Sheffield researched preservice teachers’ basic computer literacy over a four year period. This research shows that over time the subjects’ computer literacy has increased.

Stephen examined the effects of differences in teachers’ and students’ perceptions of computers in a fourth grade classroom.

Valmont studied teachers working with an education college and their familiarity with and use of various technologies. They were asked to comment on the level of school support related to technology they perceived and what they believed their preservice teacher education students already knew about technology and what they should know.

**Inservice teachers**

Christensen and Knezek explored ten subscales forming the teacher attitudes toward information technology questionnaire.

Dawson investigated the differences between the amount of money spent on computers and the way they are typically used in instruction. They sought to identify instructional uses of computers by elementary teachers and factors that may contribute to these uses.

Kurubacak and Akbaba researched the possible factors influencing teachers’ negative attitudes toward computer use in the classroom.

McKenzie, Davidson, Clay and Kirby’s study seeks to validate inservice teachers’ ability to obtain information regarding technology use.

Vasu and Atkins developed an instrument to assess teachers’ knowledge and classroom usage of technology. Use of this instrument can result in more appropriate staff development and a corresponding increase in the effective integration of technology.

Zhao and Rop reported on a study that investigated the issue of educational applications of technology integration. This resulted in a long list of both internal and external factors, ranging from technical skills to availability of educational software.

**Other**

Liu, Johnsen and Chandler investigated the difference in computer attitudes between American and Chinese students at four levels. A linear trend between computer attitude and computer achievement was found between subject groups.
Technology Integration

Cox-Cruy and Scollay explored a new position created in all Kentucky school districts, the district technology coordinator. A mixed methodology design was used to examine the various roles and responsibilities of Kentucky district technology coordinators.

Dirksen, Naylor, Coffland, and Bauer examined data gathered from a cross section of Idaho’s school districts and teachers. They found that teachers have taken the initiative of expanding one or two ideas into a plethora of ways to use technology in their classroom and curriculum to challenge their students.

Dobson also examined a new breed of technology competent professionals and discussed how they have the power to change the world of teaching and learning.

Ekhaml, Beggs, and Ruskell explored the use of laptop computers and their impact on how teachers teach and what students accomplish.

Pan discusses his concern that inadequate involvement of teachers using technology and the lack of proper technology integration in the schools may be one reason that the use of that technology in schools has been unsatisfactory. He suggests that university teacher education programs should take the initiative to provide the public schools and teachers with the opportunities to gain technical skills and knowledge. He also addresses the issues and concerns related to this type of approach and presents his a proposal for its success.

Teaching and Learning Styles

Batchelder and Tucker examined a model of distance learning based on social constructionist principles that may help distance learners become active participants in their own learning process.

Hara, Bonk, and Angeli analyzed the use of on-line discussion and electronic conferencing discourse in two educational psychology courses. The initial findings indicated that students made use of both electronic discourse and face to face classroom instruction to create a convenient and flexible learning space.

Underwood and Cavendish discussed a teaching approach being trialled in the UK using large scale semi-intelligent teaching packages. This paper discusses the changes in social dynamics of the classroom and possible causal events leading to those changes.

Worthington and Henry examined computer anxiety and other issues dealing with teaching and learning with technology.

Research

Johnson and Liu address differences between preservice elementary and secondary students attitudes toward the subject disciplines of math, science, language, and social studies.
Most teacher training institutions are currently facing the overwhelming task of preparing preservice teachers for technology enhanced classrooms. There is significant pressure to graduate students that are knowledgeable about technology and equipped to use it effectively in the classroom. This paper relates the experiences of preservice teacher teams who were engaged in a collaborative project with elementary students. The purpose of the project was to further preservice teachers’ technology knowledge, provide an environment to connect theory and practice, and to offer preservice teachers an opportunity to personally experience technology integration and collaboration in an elementary school setting. The preservice teachers’ responses to this project were highly favorable towards collaboration and technology integration. However, these teachers also learned the obstacles they may face in attempting to effectively integrate technology as a teaching and learning medium.

Technology Training and Preservice Teachers

In recent years, teachers and teacher training institutions have been impacted significantly by the growth of technology in education, and this trend is not likely to change. The Report to the President on the Use of Technology to Strengthen K-12 Education in the United States (1997) suggests that more extensive and more effective utilization of computers, networking, and other technologies is crucial to the improvement of K-12 education in the United States (p. 6). In order to achieve this goal, the report suggests that “teachers will have to master a variety of powerful tools, redesign their lesson plans around technology-enhanced resources, solve the logistical problem of how to teach a class full of students with a smaller number of computers, and take on a complex new role in the technologically transformed classroom” (p. 47). Yet, many teachers today still do not receive adequate training or adequate time to accomplish such mastery.

As would follow, most teacher training institutions are facing the overwhelming task of preparing preservice teachers to be technologically literate and to effectively integrate technology and their future teaching. This occurs concurrently with decreased budgets and a mandate to reduce the number of hours in preservice teacher education programs. John See, in the May 1997 issue of The Computing Teacher, explains that in the four phases for successful teacher training in technology, teachers must first become aware of what technology is available, be shown effective applications and see how to integrate technology, before they are ready to refine what and how they teach” (cited in Hutchinson, 1996). Institutions are thus continually challenged to restructure preservice teacher curriculums to include the necessary computer skills training and provide opportunities to apply these skills in teaching situations.

This paper will present a case study that explored the experiences of preservice teacher teams in a technology-based collaboration with elementary school students. The purpose of this project was to further preservice teachers’ technology knowledge, provide an environment to connect theory and practice, and offer preservice teachers an opportunity to personally experience technology integration and collaboration in an elementary school setting.

Our goal is to relate how this experience affected the preservice teachers’ feelings toward technology and its integration with their future teaching. We will focus on the collaborative efforts involving the preservice teacher teams, as well as the collaboration between the preservice teachers and the elementary students. We feel that this field experience has revealed many of the rewards and obstacles teachers encounter in the daunting challenge to fully integrate technology as a teaching and learning medium.

Background

The College of Education at the University of Central Florida has been struggling since the late 1970s to meet the challenge of preservice teacher technology training and integration. Taking a learner-centered approach, faculty have rejected “the specialized study of computers, favoring an exploration of the computer’s role throughout the curriculum” (Hutchinson, 1997). Preservice teachers are
now required to take the *Technology for Educators* course, however infusion of technology is the goal in each undergraduate course.

Funded by an Apple Partners in Education-2 grant awarded in 1995, the University and Altamonte Elementary School formed a partnership to provide technology experiences for both students and teachers at both institutions. The College of Education and the elementary school acquired a variety of technologies including Power Macintosh LC 5200’s, Newton Message Pads, QuickTake cameras, color scanners, and a variety of software. One university faculty role in this continuing partnership is to serve as a teaching resource for a newly restructured K-5 program at the elementary school. The restructuring of the new program included the creation of learning communities. One community, the Vision Center, is comprised of approximately 120 fourth and fifth grade students, combined in four multi-age classes to create a “school within a school.” This community provides a practicum for unique field experiences for volunteer preservice teachers.

The preservice teacher volunteers are recruited from the *Teaching Strategies I* EDF 4321 course that has a field experience requirement of twenty hours volunteer work. Technology performance requirements are infused throughout the course. All class assignments must be completed on a computer to demonstrate word processing skill. In addition, students are required to learn how to use the university e-mail system, use a software package to produce a resume for their portfolios, and create a web page using HTML authoring software (i.e., Claris WebPage or Netscape Composer).

Since the grant award in 1995, several collaborative projects have been implemented between the University preservice teachers and the Vision Center students at Altamonte Elementary School. To introduce the elementary students to multimedia projects, the students created autobiographies using HyperStudio, a development program. The preservice teachers served as reviewers for the completed projects. Next, teams of preservice teachers and elementary students worked on an interactive map of the Central Florida area and electronic field trips, also created using HyperStudio. In each of these projects the preservice teachers had regularly scheduled times when they would work with their teams in the Vision Center. They enriched the resources of the public school by locating additional resources for their teams, helping to edit written work, and serving as creative consultants.

The creation of a Web page for the school was another collaborative project undertaken by the Vision Center students and University preservice teachers. Each preservice teacher worked with two Vision Center students to create a page which would eventually connect to the school’s web page. Students selected an aspect of the elementary school to research, storyboard and present as a web page.

### The Web Page and WebWhacker Project

During the fall of 1997 semester a new collaborative project with the elementary school was implemented. Again, volunteers were recruited from two sections of University preservice teachers enrolled in *Teaching Strategies I* (the very first course taken by all education majors) to complete their required field experience with the Vision Center students. Their task was to finalize the Web pages begun by students during the previous school year and harvest sites from the Internet using WebWhacker. Eight teams of two preservice teachers were paired with three or four elementary students. During the first half of the semester the university students reviewed web page creation with the elementary students who participated in the Vision Center projects last year or introduced the concept to new students.

A schedule was implemented to allow the elementary students to participate in the project two times during the semester by being excused from math or science classes. The teams worked at computers in the Vision Center classrooms, or out in the media center, depending on availability. After all of the students were comfortable with Web page creation, the teams began learning WebWhacker.

The goal for the experience was two fold. First, it was hoped that the Vision Center students would become the Web masters who maintain the school’s Web page once it is placed on the Internet. Secondly, the Vision Center students would serve as resources for any teacher in the school who would like a site harvested using WebWhacker.

All *Teaching Strategies I* students received training in Web page development using Netscape Composer and training in Web page harvesting using WebWhacker. In addition, a graduate assistant was available for one-on-one training and guidance in both Web page development and the use of WebWhacker. Preservice teachers working with the Vision Center students also received a second workshop with WebWhacker prior to their collaboration with the elementary students.

At the end of the semester, all *Teaching Strategies I* students were asked to complete a survey designed to provide a self-assessment of their technology competencies and computer use. A section of this survey was intended to measure the attitudes of the preservice teachers towards technology and the integration of technology and teaching. In addition, group interviews were held with the preservice teachers who participated in the Vision Center collaboration, and these students also completed a separate survey that evaluated specifically their Vision Center experience.

### Preservice Teachers’ Responses

The overall response of the preservice teachers towards this collaborative project was mixed. The preservice teachers’ feelings towards the collaboration with their classmates and the collaboration with the elementary students were quite positive. Preservice teachers also
expressed many positive aspects regarding technology and technology integration. However, the group interviews and the survey analysis revealed that several areas were problematic for the preservice teachers. These concerned organization, access to computers, the need for well defined activities for each session, and the need for more time with the students. The preservice teachers offered many helpful suggestions for revisions which will be implemented during the spring 1998 semester.

Collaboration with Classmates and Elementary Students

Most preservice teachers expressed very positive feelings regarding collaboration with their classmates. They found that working in teams provided moral support and technological support. Many of the preservice teachers began this semester with little or no computer training. They felt that having a classmate with them in the Vision Center allowed them to compare notes and ideas which greatly improved their effectiveness during the collaborative sessions with the elementary students. Some suggested that this collaboration not only helped to improve their computer skills but also allowed them to observe their classmates' teaching styles and strategies. Overall, collaboration with a fellow preservice teacher contributed positively to their Vision Center experience.

Preservice teachers also felt they gained much from the collaboration with the elementary students. Many of the elementary students entered this project with more technology skills than the preservice teachers. Some of the preservice teachers had never used a Macintosh computer. The preservice teachers reported that the elementary students were very excited about being able to teach a teacher something about computers. Not only did this help the preservice teacher when computer glitches occurred, it bolstered the confidence of the elementary students as well. Although the technology skill level of the elementary students was varied, overall the preservice teachers were surprised and pleased to find so many students quite proficient with the technology. This also reinforced the preservice teachers' desire to learn more about the technology so that they may feel more competent when they interact with their students.

Attitudes towards Technology and Technology Integration

As was expected, this technology-based experience broadened each preservice teachers' technology skills. Each learned how to develop a Web page and to harvest Web sites from the Internet. These tasks required that the students find information on the Web, copy clipart, create multiple pages that are then linked, and create links on their pages to other Web sites. The preservice teachers learned how to download sites from the Internet using WebWhacker so that these sites may be visited in classrooms where an Internet hookup is not available. More importantly, having an opportunity to apply what they learned in a real-world setting greatly enhanced their technology knowledge and skills.

The preservice teachers also expressed that their newly gained knowledge gave them additional ideas about how they might integrate technology and their future teaching. All expressed that integrating technology was the most important aspect of their future teaching. Seeing how technology can be infused in teaching and classroom activities provided them with a model to work from - what to do and what not to do. One preservice teacher stated that previously she had “never thought much about computers in a classroom until this semester” (personal communication).

On the end of the semester survey, all of the preservice teachers who volunteered in the Vision Center were able to list at least three applications of technology in their curriculum/content areas. Several mentioned that Web page development could be taught as a tool for students to do subject specific projects and reports, rather than relying on paper-based reports. Others suggested that they became more aware of how using the Internet can enhance learning and the learning process through exploration and discovery. One preservice teacher said she would like to have a Web site for her class where other schools or classes could see what her class was doing and perhaps exchange ideas. She could post homework and assignments that could be accessed by absent students, and she could list valuable web sites for content areas and even parenting skills. She also suggests that teachers, parents and students could communicate by e-mail. As you can see, this technology-based experience enlightened and inspired these preservice teachers.

Problematic Areas

Technology integration and collaboration does not occur without some pitfalls and obstacles. This became quite evident to our preservice teachers - a good lesson to learn in and of itself. First, a general consensus indicated a need for more organization and coordination between the University preservice teachers and the Altamonte faculty. Unlike previous semesters, the University faculty member was not on site at Altamonte Elementary for many of the collaborative sessions. The preservice teachers frequently arrived at Altamonte Elementary with a preconceived idea of what was to occur within the session; however, the classroom teachers' perception of the tasks would not be the same. The preservice teachers felt that this was very evident to the elementary students and that it affected their role as an authority figure. Also, they felt much time was spent getting organized and coordinated rather than on the task to be accomplished. Most expressed that they felt this could be remedied by better organization and communication.

Second, the preservice teachers found it very difficult to work in teams of two with four elementary students at one
computer, especially when they worked in the Vision Center classroom. They observed that the elementary students who were not sitting at the computer often lost interest in the task and were more distracted by the other activities in the classroom, prompting some elementary students to say they felt the session was a waste of time. This was not very reinforcing for the preservice teachers, although they recognized these were circumstances beyond their control. Most suggested that only one preservice teacher work with two elementary students at a time, and that they be allowed to work in the media center away from the classroom activities.

Third, the preservice teachers felt there should be a clear goal for the collaborative project with well planned activities for each session. Although the preservice teachers were successful in teaching the basic skills of Web page development and Web harvesting, they were unable to complete a project that the elementary students could see and show at the end of the term. Thus, the functional tasks had little meaning to the elementary students which the preservice teachers felt contributed to some elementary students' feelings about the usefulness of the project. Some questioned why they were going through the process if they weren't going to do anything with it. One suggestion from the preservice teachers was to create Web pages that were related to a topic the students were currently studying. The elementary students could then search the Internet for related sites to harvest with WebWhacker, and use the Web page as an index to the sites that they found. This would give the elementary students a completed project to strive for and a product that could be used in their classroom activities.

Finally, most of the preservice teachers felt that many problems could be alleviated if more time could be allowed for each collaborative session and if there could be more sessions with each group. (Don't we all wish for such time!) They felt that they could then better overcome the computer glitches and problems with organization, and provide a more coherent project for the elementary students. Many of the preservice teacher teams expressed frustration with computer freezes and problems accessing the Internet. Also, when harvesting sites with WebWhacker, the preservice teachers said that much time was spent waiting for the site to download because of the speed of the connection. This left the team with four idle elementary students, a situation they felt contributed to the elementary students' lack of interest and enthusiasm. Also, the preservice teachers felt additional time would allow for all of the students to have the hands-on experience rather than merely watching the activity, which they viewed as crucial to the project's success.

Summary and Conclusion

It is clear that this collaborative technology-based project brought many rewards for these preservice teachers. Their technology skills were broadened and enhanced, and they gained a new perspective on collaboration with fellow classmates as well as with the elementary students. They all learned much from each other and the collaborative experience. These teachers also learned valuable lessons regarding collaboration and technology integration. Both require considerable planning and clear communication for effective integration to occur. In addition, the value of access to good computer technology became very evident, especially in an elementary school environment. Elementary students' tolerance for idle time is very limited. The preservice teachers found how quickly they could lose their students' attention because of a lack of clear goals and objectives and computer glitches and downtime.

Many educators recognize the potential of computers to change learning and teaching. In so doing, they draw attention to the computer and ignore other factors that would impact the computer's potential in education. The key to influencing the use of the computer is the teacher (Papert, 1993; Byrum & Cashman, 1993); more specifically, the teacher's beliefs (Dupagne & Krendl, 1992; Hannafin & Freeman, 1995; Moar & Taylor, 1995), attitudes toward computers (Byrum & Cashman, 1993; Koohang, 1987), and experiences with computers determine how the computer will be used with students (Byrum & Cashman, 1993; Chiou, 1995; Clement, 1981; Davidson & Ritchie, 1994; Koohang, 1987).

Pedagogical Theories

Computers in education are part of the larger context in which they exist. It is important to consider the instructional theories that dominate because they influence how computers are incorporated into the larger instructional context. Pedagogy refers to the art or science of teaching (Ferguson, 1995). Growing disagreements among learning theorists have centered around which teaching strategies are most effective in the technological classroom. This controversy has inspired the growth of two very different views about teaching and learning (Jonassen & Duffy, 1992). One view, behaviorism, is grounded in systematic, teacher-directed, instruction (Evans & Nation, 1996; Wallace, 1996; Gagne, 1985). The other, constructivism, is based on student-centered knowledge construction (Perkins, 1992; Bransford, Franks, Vye & Sherwood, 1989; Bruner, 1973).

When teaching within a behaviorist framework, instruction is teacher-directed, student objectives are clearly stated and tested, and traditional teaching and assessment methods are emphasized (i.e., lectures, worksheets, tests). Behaviorists believe that students learn through stimulus and response actions. The teacher creates an environment where the students are shown how to complete a task, then students are asked to complete the task using the manner in which they were shown (Burden & Byrd, 1994; Jonassen & Duffy, 1992).

In the constructivist classroom, learning occurs when the student creates his/her own knowledge. The teacher creates an environment in which students develop their own understanding and meaning through experimentation and active engagement. Students are self-motivated and learn through real-life experiences, which help them to construct their own knowledge (Burden & Byrd, 1994; Jonassen & Duffy, 1992).

Research

Teachers' use of pedagogical theories are based upon their beliefs and attitudes about knowledge acquisition (Dupagne & Krendl, 1992; Pope & Gilbert, 1983; Tobin, 1990).

Teacher Attitudes and Beliefs About Knowledge Acquisition

Teachers' beliefs about knowledge acquisition influence their instructional practices and their conceptions of the role of the computer in learning and teaching (Hannafin and Freeman, 1995). Dupagne and Krendl (1992) noted that many educators tend to teach in a behaviorist manner in which knowledge is acquired as a result of information being given to the learner. Moreover, teachers who believe knowledge is acquired in a behavioristic manner tend to use the computer for reinforcement or reward (Hannafin and Freeman, 1995). Teachers who believe that knowledge is the product of each students' experiences and construction, find that the interactive nature of the computer enables them to design environments which create knowledge. A teacher's tendency to see students as passive beneficiaries (or active builders) of knowledge may undermine (or enable) their willingness to use the computer for anything other than reinforcement or information recall (Hannafin & Freeman, 1995).

Unger, Draper and Pendergrass (1986) investigated students' beliefs about knowledge acquisition from a world view and categorized their results into two positions: students who held beliefs in the social constructionist position (SC) and students who held beliefs in the logical positivist position (LP). Unger et al. (1986) found that many epistemological beliefs are rooted in life experience, and that many students, due to their epistemological beliefs, would not enroll in courses that were inconsistent with their...
beliefs (Unger, 1989). The results of Unger et al. suggest that, an adherence to one epistemological belief over another may effect a preservice teachers’ preconceptions about and cognitive development in the area of computer use for learning and teaching.

**Computer Use In The Classroom**

The early focus of the educational computing community on the features of software applications caused Thomas and Boysen (1984) to theorize about a classification system in which they contended that the categorization of software was insufficient. Thomas and Boysen (1984) argued that “since student learning is the ultimate purpose in utilizing computers for instruction, a taxonomy should focus on the needs of the learner. It should provide guidance for the development of lessons and their instructional use” (1984, p. 15). Thomas and Boysen proposed a taxonomy for computer use in the classroom where the classifying variable was the state of the student with respect to the knowledge being acquired. That is, the role of the computer in instruction was contingent on the students’ level of knowledge of the topic being taught. The Thomas and Boysen Taxonomy consisted of five categories: experiencing, informing, reinforcing, integrating and utilizing.

When a new topic is introduced, the student generally has little knowledge of the concepts. The role of the computer at this level is experiencing. The computer helps set the stage for the concepts to be taught and serves as a catalyst for future learning. When using the computer in an informing manner, the student is prepared to receive formal instruction about the topic of study. As such the computer helps to supplement or replace the textbook and support the initial introduction to a topic. The computer also can be used by the learner to acquire information. When using the computer for reinforcing, the computer helps the learner to strengthen knowledge that has already been acquired. This level is similar to Taylor’s (1980) tutor example in that, the student works with the computer to practice and build on concepts that have already been taught to the student by the instructor. At the integrating level, the learner is linking previously unrelated ideas to form new knowledge. In so doing, the computer is used to help make the connections. Also, at the integrating level, students may connect classroom knowledge with real world situations to solve problems. For example the student can work with a program in which the user is asked to sell pizza. Through the use of this program, the student needs to consider sale prices (i.e., percentages) and slices or portions of pizza (i.e., fractions). At the utilizing level the computer functions as a tool to build, organize, and make students’ previously learned knowledge concrete. That is, tool software such as databases and word processors can be used to eliminate menial tasks and allow the student to concentrate on the context and the quality of the finished product (e.g., the arguments presented in the term paper), not the process in which they arrived there (e.g., spelling, punctuation, etc.) (Thomas & Boysen, 1984).

In the Thomas and Boysen Taxonomy, a single computer program can be used at many levels and in many different ways contingent upon the state of the student. If a program is used prior to formal instruction (experiencing), the student is introduced to the topic of study in preparation for formal instruction. If the same program is used after formal instruction, the student will reinforce concepts learned during formal instruction. It is important to recognize that informing and reinforcing programs are based on behavioristic theories, whereas, experiencing, integrating and utilizing programs are constructivist-based. It is these student-directed uses of the computer that force the student to hypothesize about the nature of the content being studied. It is through learner-directed computer use that the highest levels of learning are achieved (Thomas & Boysen, 1984).

The existence of instructional models for computer use will not cause teachers to use computers. There are many factors effecting teachers’ use of computers. The instructor’s epistemological beliefs effect pedagogical beliefs, which determine how teachers teach.

**Inservice and Preservice Teachers’ Beliefs and Attitudes Toward Computers in the Classroom**

Although many teachers advocate the use of computers in education, this endorsement is given only after they have had experience with computers (Dupagne & Krendl, 1992). Computer experience often fosters positive attitudes toward computers. Lack of training accounts for teachers’ low confidence level when they initiate computer activities (Dupagne & Krendl, 1992; Koohang, 1987). This lack of training often results in high anxiety about computer use in the classroom. High levels of anxiety can lead to negative attitudes about computers, and, eventually, negatively influence the use of computers in the learning process (Koohang, 1987).

Dupagne and Krendl (1992) reported that many teachers were skeptical about the value of computers in education. This skepticism related to hostility, fear and uncertainty about how to use computers (Chin & Horton, 1995). Davidson and Ritchie (1994) found that teachers were concerned about the impact computers would have on their role in the classroom. Many teachers feared they might have to compete with computers in the classroom. In addition, Davidson and Ritchie (1994) reported that educators believed teaching with computers would be more complex.

While some teachers viewed the computer as a valuable tool for enhancing student learning, Bosch (1993) found that others saw the computer as a subject to be taught in a separate class. If the computer was taught in a computer class, many teachers believed it did not need to be used in
their class. In addition, teachers thought that there was not enough time for students to carry out computer activities in the content classrooms (Bosch, 1993; Dupagne & Krendl, 1992). Kerr (1991) stated that educators tend to see themselves as teachers first, and as users of technology second. Many teachers stated they had to learn how to use the computer before they could try to integrate it (Kerr, 1991).

Statement of the Problem
Interest in educational computing centers around why some teachers do and others do not use computers (Hannafin & Freeman, 1995). It is important to understand preservice teachers' preconceptions about how computer technologies impact student learning (Darling-Hammond, 1996). Understanding preservice teachers' preconceptions about the role of the computer in the classroom may enable teacher educators to design and implement instruction that will assist in the development of more complete and comprehensive conceptions about computers.

Limitations of the Study
The subjects for this study were undergraduate students at a midwestern university, where the majority of students are midwestern natives. Undergraduate students' experience and knowledge of educational disciplines and the field of education may be a limitation.

The Thomas and Boysen Taxonomy contains five categories. The items in the data collection instrument were configured around these categories, thus limiting the range of responses from which the subjects had to choose. The Thomas and Boysen Taxonomy implies two general levels of computer use in the classroom: simplistic and advanced. Reinforcing and informing are simplistic levels and experiencing, integrating, and utilizing as advanced levels of computer use in the classroom.

Research Procedure
During the first week of the 1997 fall semester, 289 preservice teachers enrolled in an introductory technology course were asked to participate in the study. Students enrolled in the course were informed verbally and in writing that participation in the study was voluntary and that their participation would not affect their final grade.

During the first week, each student was given the Preservice Teacher Perceptions of the Impact of Computer Use on Learning Scale (PTPICL) and asked to complete it. During the second week, students completed the Attitudes About Reality survey (AAR) and the Beliefs About Effective Computer use for Learning assignment (BACL) in their laboratory sections.

The instruments contained items believed to effect teacher use of the computer. Two hundred and seventy nine (279) of the two hundred and eighty nine (289) surveys distributed were completed. The final survey response rate was 96.5%. The instruments had a Cronbach alpha reliability coefficient of $r = .8252$ for the PTPICL and $r = .6372$ for the AAR scale.

Research Question Results
The purpose of the study was to investigate preservice teachers' preconceptions about the role of the computer in learning and teaching, and to identify and examine factors that effect preservice teachers' preconceptions about computer use. Below are the results of the four research questions created for use in this study.

Research Question 1
What category of the Thomas and Boysen Taxonomy is most representative of the preservice teacher population?

The data generated by the Impact of Computer Use on Learning (ICL) section of the PTPICL were used to address this research question. This section of the survey consisted of five items for each level of the Thomas and Boysen Taxonomy for a total of twenty five items. Subjects' responses to each item were weighted on a contingency scale using the following system: strongly disagree=1, moderately disagree=3, slightly disagree=5, slightly agree=7, moderately agree=9, strongly agree=11. A mean score for each Thomas and Boysen category was generated for each participant and the sample as a whole. The data revealed that the categories with the highest means were integrating (8.6) and reinforcing (8.5).

A paired t-test was computed to determine if there was a significant difference between the two category means. Results of the paired t-test showed no significance ($p=.066$) between the reinforcing and integrating categories.

Research Question 2
Will preservice teachers with high computer proficiency scores conceptualize more advanced ways of using the computer in the classroom?

The subjects were asked to rate their proficiency with computers in four categories: computer based instruction, software, telecommunications, and other. Subjects rated their proficiency using the following five point Likert scale: unfamiliar (0), no proficiency (1), low proficiency (2), medium proficiency (3), high proficiency (4). Overall, the subjects rated themselves moderately proficient with computers (1.930). Specifically, they were moderately proficient with computer based instructional applications (2.053), telecommunication software (2.050), and tool software (2.120). The respondents had low proficiency in the area of other computer-related technologies (1.459). The subjects were most proficient with word processing (3.344) and email (3.208) applications. The respondents least proficient in using Hyper Text Mark-up Language (HTML) (3.928) and File Transfer Protocol (FTP) (.888) application.

To compare subjects with high computer proficiency and subjects with low proficiency the following scale was
used: 0-2 = low computer proficiency (n = 123), 2-4 high computer proficiency (n = 140). Because the respondents as a whole, rated their proficiency with other computer-related technologies low, this section was not included in the subsequent analysis. The proficiency scores were computed based on the items in the computer based instruction, tools and telecommunication sections. The mean for this section was 2.068. T-tests were computed to determine if there was any difference in ability to conceptualize advanced ways of using the computer between subjects with high computer proficiency and those with low computer proficiency. Results showed that subjects with higher computer proficiency scores conceptualized more advanced ways of using the computer than those who had low computer proficiency scores. Specifically, those with high computer proficiency, conceptualized using the computer in a utilizing manner (p=.003) and in an experiencing manner (p=.050).

Research Question 3
Will preservice teachers with high epistemology scores (social constructionist or constructivist perspectives) conceptualize more advanced ways of using the computer in the classroom?

Data from the 40 item Attitudes About Reality (AAR) scale were examined. This instrument was based on a seven point Likert scale ranging from strongly disagree (1) to strongly agree (7). A mean AAR score was calculated for each subject. The respondents scores ranged from 2.78 to 5.00 with a mean score of 3.88 (four (4) was the mid-point on the AAR scale). Because the majority of the scores fell in the middle of the scale (i.e., eclectic), for comparison purposes, the sample was separated into three epistemological groups: eclectic behaviorist, eclectic, and eclectic constructivist (Hannafin & Freeman, 1995). The eclectic behaviorist group consisted of subjects whose scores ranged from 2.78 to 3.5 (n = 33); the eclectic group consisted of subjects whose scores ranging from 3.53 to 4.00 (n = 130), and the eclectic constructivist group consisted of subject whose scores ranging from 4.03 to 5.00 (n = 59).

An analysis of variance (ANOVA) test was computed to determine if there were significant differences between the three groups on the five categories of the Thomas and Boysen Taxonomy. The data indicated that significant differences existed between eclectic constructivist individuals and both eclectic behaviorist and eclectic individuals for conceptualizing the use of the computer in a utilizing manner. The data indicated that significant differences existed between eclectic constructivist individuals and eclectic behaviorist individuals on the experiencing level.

Research Question 4
Will subjects with low computer attitude scores be able to conceptualize more advanced ways of using the computer in the classroom?

The attitudes towards computers were used to collect data about the respondents’ attitudes. Responses in these sections were based on a five point Likert scale ranging from I don’t know (0) to strongly agree (4). Overall, the participants held moderately negative attitudes toward computers in general with a mean score of 2.2 and computers in education with a mean score of 1.9.

To determine if subscales existed within the attitudes about computers in general, a rotated varimax factor analysis was computed n the fourteen items from the section. The factor analysis of the attitudes about computers in general resulted in two factors reflecting subjects' attitudes towards computers: comfortable with computers and confused by computers. The comfortable with computers factor resulted in a mean score of 2.93 and consisted of four items. The confused by computers factor resulted in a mean score of 1.97 and consisted of six items.

The frequency distribution on the confused about computers factor indicated that 117 respondents were not confused about computers and 161 were confused about computers. The frequency distribution on the comfortable with computers factor indicated that 243 respondents were comfortable with computers and 33 respondents were not. These data suggest that many of the respondents were confused by computers and were comfortable with them.

To determine if there were significant differences between subjects who were and were not confused with computers, a t-test was computed. The t-test showed that subjects who were confused about computers had significant differences in their beliefs about how the computer should be used in the classroom for the informing, reinforcing and utilizing categories of the Thomas and Boysen Taxonomy. To determine if there were significant differences between subjects who were comfortable with computers and subjects who were not, a t-test was computed. The results of the t-test showed that there was no significance between students who were comfortable with computers and subjects who were not.

To determine if subscales existed within the attitudes about computers in education section, a rotated varimax factor analysis was computed on the twenty one items from the section. The factor analysis resulted in four factor reflecting subjects’ attitudes about computers in education: computers should be used in the classroom, computers are an unnecessary luxury in the classroom, computers are better than teachers, and computers should be used for rewards.

The computers should be used factor consisted of four items and resulted in a mean score of 3.12. The computers are an unnecessary luxury in the classroom factor consisted
of three items and resulted in a mean score of 1.50. The computers are better than teachers factor consisted of four items and resulted in a mean score of 1.43. The computers should be used for rewards factor consisted of two items and resulted in a mean score of 1.53. Because the latter two factors (computers are better than the teacher and computers should be used for rewards) did not clearly denote positive or negative attitudes about computer use in education, they were not used to address the research question.

To determine if there were significant differences between subjects who thought computers should be used in the classroom and those who did not, the mean scores computed for each subject on the computers should be used in the classroom factor were used. Respondents with a mean 0-2 comprised those who did not think computers should be used in education (n = 14). Respondents with means of 2.1-4 comprised those who thought computers should be used in the classroom (n = 263). A t-test was then computed to compare these groups on each level of the Thomas and Boysen Taxonomy. Subjects who reported that computers should be used in the classroom significantly conceptualized the use of the computer in an informing (p=.001), an integrating (p=.002), and in a reinforcing manner (p=.026) higher than subjects who thought computers should not be used in the classroom.

To determine if there were significant differences between subjects who thought computers were an unnecessary luxury in the classroom and those who did not, the mean scores computed for each subject on this factor were used. Respondents with a mean score of 0-2 comprised those who thought computers were not an unnecessary luxury in the classroom (n = 264). Respondents with mean scores of 2.1-4 comprised those who thought computers were an unnecessary luxury in the classroom (n = 13). A t-test was computed to compare these groups on each level of the Thomas and Boysen Taxonomy. The results of the t-test showed that subjects who did not consider a computer to be an unnecessary luxury in the classroom were able to conceptualize the use of the computer in an integrating manner (p=.020) more significantly than students who thought the computer was an unnecessary luxury in the classroom.

Discussion of the Results

Hewson and Hewson (1984) suggest that students develop their ideas through observations and experiences. Those activities designed to strengthen students' understanding of concepts taught in formal instruction are not new to education (Becker, 1991). The results of this study support the conclusion that preservice teachers', prior to formal instruction, conceptualize the use of the computer as a reinforcement. It is interesting to note that the students also conceptualized integrating as an appropriate use of the computer. However, there was no significant difference in their rating of reinforcing and integrating activities (p = .066). Thus, they may not have distinguished any difference between the reinforcing and integrating categories of the Thomas and Boysen taxonomy. The clarity of these categories may have been a limitation of the study.

Although examined as independent constructs, many suggest that attitudes toward computers and computer proficiency are related. Overall, the subjects' attitudes toward computer use in the classroom were moderately negative. Previous research studies have found that preservice teachers and inservice teachers expressed attitudes toward computer use in the classroom such as: high anxiety (Koohang, 1987), low confidence (Dupagne & Krendl, 1992; Koohang, 1987), uncertainty, fear and hostility (Chin and Horton, 1993). Subjects in this study trusted computers, did not feel nervous, were not threatened, and did not lack confidence with computers. Overall, they felt comfortable with using computers. Although the subjects did not feel uncomfortable working with computers, they held poor attitudes toward computers. Only one third (35%) of the subjects felt lost, confused and frustrated when using the computer.

Attitudes towards computers change alter receiving formal instruction and after having had experience with computers (Dupagne & Krendl, 1992; Koohang, 1987; Byrum and Cashman, 1993). Results of this study showed that sixty four percent (64%) of the subjects had received formal computer instruction, primarily in high school (75.3%). In contrast to Koohang and others, results of a t-test comparing subjects with formal instruction and subjects without formal instruction showed no significant difference in computer attitudes at the .05 level.

Stevens (1980) attributed poor attitudes towards computer use in the classroom to low computer proficiency. Participants in this study were asked to rate their computer proficiency using a five point Likert scale ranging from unfamiliar (0) to high proficiency (4). Overall the subjects rated themselves with medium proficiency (1.930). Similar to Stevens (1980), results of a t-test comparing subjects who were comfortable with computers and subjects who were uncomfortable with using computers showed significant differences

(p = .000). Subjects who were confused about using computers had significantly lower computer proficiency than subjects who were not confused when using computers (p = .000). The results of t-tests also showed that subjects with high computer proficiency rated using the computer in an experiencing (p=.05) and utilizing (p=.003) manner significantly higher than subjects with low computer proficiency.

Research has shown that beliefs about knowledge acquisition affect the manner in which teachers teach. Moar and Taylor (1995) reported that most teachers teach in a didactic, behavioristic manner. Hannafin and Freeman (1995) and Moar and Taylor (1995) examined the effects of
epistemological beliefs on teachers' use of computers in the classroom. Moar and Taylor's research showed that epistemological beliefs tend to effect how teachers use computers in the classroom. Since many instructors teach in a behavioristic manner, the computer tends to be used most often for reinforcement activities. This research has found that most preservice teachers have eclectic views toward knowledge acquisition. Moreover, subjects who had more constructivist views toward knowledge acquisition were able to conceptualize more advanced ways of using the computer in the classroom than subjects with behaviorist views toward knowledge acquisition. These results are consistent with other researchers (Dupagne & Krendl, 1992, Moar & Taylor, 1995, Hannafin & Freeman, 1995) who have noted that the computer is well suited for instructors who teach using a constructivist framework.

This assessment of preservice teachers' preconceptions about computer use in this classroom serves as a basis for designing instruction that will help preservice teachers to develop more comprehensive conceptions of the role of the computer in learning and teaching. With a national push to restructure education and increase the use of computer-related technology in the classroom, it is imperative to prepare preservice teachers with the knowledge and skills needed to use computer-related technologies effectively to enhance student learning.

Are Your Students Like Mine? Pre-service Students' Entering Technology Skills: An Update

Caryl J. Sheffield
California University of Pennsylvania

The number of microcomputers in K-12 schools has increased dramatically over the past 10 years. The ratio of students per computer in 1988 was reported to be an average of one computer for every thirty children (OTA, 1988). It was projected that by the spring of 1995 the ratio will have decreased to one computer for every 9 students (OTA, 1995).

With more and more students in K-12 schools having access to computers, it might be expected that high school graduates, particularly those who matriculate at a college or university, have some degree of computer literacy skills. Recent research suggests, however, that most college students have not had much experience with a personal computer prior to entering the university (Sheffield, 1996; Sheffield, 1994; McAulay, 1993; Cardinale, 1992; Beaver, 1990).

This paper presents the results of a study of the computer literacy skills of preservice teachers. A prior study conducted by the researcher (Sheffield, 1994) yielded a description of pre-service students self-reported skills in word processing, spreadsheet and database applications. The intent of this study was to expand the original analysis using additional data and more sophisticated statistical analysis. Specifically, the objectives of the study were to (1) identify the level of experience of pre-service teachers in word processing, database, and spreadsheet applications, (2) analyze the change in reported experience over 7 academic years, and (3) determine the effect that such factors as gender, academic classification, comfort with computers, and access to a PC at home have on pre-service teachers' self-reported experience in word processing, database, and spreadsheet applications.

Data Collection and Analysis

The university where the study was conducted is a small public multipurpose institution serving a regional population. There are approximately 6,000 students enrolled in undergraduate and graduate programs in the fall semester of 1993. The College of Education is the second largest in the university in terms of student enrollment (the largest college is science and technology), with approximately 1,900 students.

The participants in the study were preservice teachers enrolled in an introductory educational computing course. Data for the study were collected over 7 academic years, from 1991-92 through 1997-98. At the beginning of each semester, students were administered a questionnaire requiring them to evaluate themselves, using a Likert-type scale, in word processing, data base, and spreadsheet software. The scale ranged from 1 = no experience, to 3 = basic familiarity, to 5 = expert.

Data from each of the fall semesters (739 respondents) were used as cohort groups to analyze the self-reported level of word processing, database, and spreadsheet experience. One-way analysis of variance (ANOVA) was applied to determine whether or not the differences in the means between the cohort groups were statistically significant and yielded a significant linear trend. After a determination that the means were different, the post hoc Scheffe test identified the specific pairs of cohorts between which statistically significant mean differences existed. The .05 level of probability was used as the criterion for statistical significance.

There were 4 other variables for which data were collected. In addition to gender and academic classification (freshman, sophomore, junior, senior, or post-baccalaureate/graduate), students noted if they were computer-phobic and had access to a computer at home. Using Chi-square statistical tests, this analysis focused on whether or not the self-reported skills in word processing, database, and spreadsheet software varied across these variables.

Results

Responses from a total of 1315 respondents over 7 academic years were included for analysis in this study. The gender composition was 29% male and 71% female. The sample consisted primarily of juniors (41%), followed by sophomores (28%) and seniors (18%). Approximately 5% were freshmen and 3% were post-baccalaureate students. Almost one-third of the students indicated that they were computer-phobic; females were more likely than males to indicate that they were not comfortable with computers (Chi-square value = 11.7, p = .00.) Those students who no
access to a PC at home were more likely to report that they were not comfortable with computers (Chi-square value = 25.5, p = .00).

Table 1 shows the overall mean experience level for each software application, from highest to lowest. As shown, students report more knowledge of word processing than either database or spreadsheet.

Table 1.
Overall Level of Experience

Generally speaking, the results of the one-way ANOVA for each of the 3 applications indicate that there is (1) a significant difference among the means of each cohort group, and (2) a significant linear trend component.

**Word Processing**

Figure 1 presents the level of experience for word processing over 7 survey cohort years. With an overall mean of 2.61, students report less than basic familiarity with word processing; this represents the highest rating of all three productivity programs. The trend for word processing experience shows a significant linear pattern of increasing means over time (F = 42.9, P = .000).

![Figure 1. Experience level for Word Processing.](image)

The mean experience level for word processing for 1991-92 (G = 2.13), the first cohort group, is significantly different from the mean experience level for the 1994-95 (G = 2.69), 1995-96 (G = 2.76), 1996-97 (G = 2.89), and 1997-98 (G = 2.90) academic years, the last 4 cohort groups. Similarly, the mean experience level for the 1993-94 (G = 2.21) academic year, the third cohort group, is significantly different from the mean experience level for both the 1995-96 (G = 2.76), 1996-97 (G = 2.89), and 1997-98 (G = 2.90) academic years, the last three cohort groups.

Results of the chi-square analysis of gender, academic classification, comfort with computers, and PC at home are depicted in Table 2. There were no significant differences across gender. However, the results do indicate that there were significant differences across comfort with computers, classification, and PC at home. Students who did not consider themselves computer-phobic rated themselves higher in word processing experience than students who considered themselves computer-phobic. A higher percentage of post-baccalaureate/graduate students rated themselves above the basic experience level. Finally, students who reported having access to a PC at home rated themselves higher than students who had no access to a personal computer at home.

<td>85.8</td>
<td>.00</td>
</tr>
</tbody>
</table>

**Database**

Figure 2 presents the level of experience for database over 7 survey cohort years. Students report even less experience with database software than word processing; the overall mean is 1.78. The trend for database experience shows a significant linear pattern of increasing means (F=13.3, P=.00).

![Figure 2. Experience Level for Database.](image)

The mean experience level for database for both the second and third cohort groups, 1992-93 (G = 1.66) and 1993-94 (G = 1.52), were significantly different from the mean experience level for only the 1997-98 (G = 2.11) academic year, the last cohort group. These differences reflect the most recent year of the study.

Results of the chi-square analysis of gender, academic classification, comfort with computers, and PC at home are depicted in Table 3. There were significant differences in experience with database software across all of the variables tested. Males rated themselves higher in database skill than females. A higher percentage of post-baccalaureate students rated themselves at the level of basic familiarity and above.
Students who considered themselves to be computer phobic report less experience with database software than students who are comfortable with computers. Lastly, students with access to a PC at home rated themselves higher than students without a PC at home.

Spreadsheet

Figure 3 presents the level of experience for spreadsheet. This productivity program showed the lowest overall mean experience level of 1.69, indicating that students have even less experience with spreadsheets than word processing and database. The trend for self-reported spreadsheet experience shows a significant linear pattern of increasing means (F = 21.9, P = .00).

Discussion Related to Teacher Education

In general, the results of this study indicate that preservice teachers, upon enrollment in their first educational computing course, have little experience with the three most commonly used productivity programs. This may be surprising to those who believe that the increasing presence of computer technology in K-12 schools means that students are entering the university computer literate. It is clear, however, that over the 7 year period from 1991-92 through 1997-98, students' self-reported experience increased in word processing, database, and spreadsheet software. In all 3 of these categories, there was a significant linear pattern of increasing means, indicating that the level of self-reported experience has increased over the years. The pattern was especially profound with respect to word processing. This suggests that students may have some opportunity to use a word processor, perhaps as they fulfill writing assignments in other university courses. This finding may also be the result of increasing access to computers in high school.

The potential impact on teacher education programs is that in the near future, word processing may be able to be eliminated as a topic in the educational computing course in exchange for other advanced instructional technology issues, such as multimedia, presentation programs, desktop publishing, and curriculum integration of technology. The results of this research can help inform such curricular decisions.

While neither male nor female students appear to have much experience with application software in general, some gender differences have emerged from the study. Males and females report similar levels of experience in word processing, but males rate themselves higher in both database and spreadsheet applications. Males seem to be more comfortable with quantitatively-oriented applications than females. Given this gender variance, professors of introductory educational computing courses may need to consider software than students who are comfortable with computers. Students with access to a PC at home rated themselves higher than students without such access.
specific instructional strategies, e.g. demonstration, practical examples, and problem-solving, that appeal to females and males alike.

Given the distribution of upperclassmen in the sample, a stronger connection between academic classification and computer literacy might have been anticipated. By the time preservice teachers reached their junior year, one would expect that they had some exposure to computer technology. It does appear that post baccalaureate/graduate students report a higher experience level with word processing than any of the other academic classifications. However, limits in the data precluded a conclusive assessment of the relationship of academic classification to word processing, database, and spreadsheet experience.

The preservice teachers in this study who were computer-phobic or who had no access to a PC at home tended to report low levels of experience in all three applications. Opportunities for early experiences with technology through other courses in the teacher education program may alleviate student’s concerns with discomfort with computers. For example, faculty could require students to use a word processor for projects, or provide hands-on learning activities that integrate the use of technology into the course requirements.

**Future Research**

Future research that explores computer literacy in both high school and university students would be informative. By examining student access to and use of technology in high schools, a clearer picture of the development of computer literacy in high school students will emerge. In addition, university students could be studied at the completion of the first educational computing course to measure the acquisition of specific computer literacy skills.

If the role of teacher education programs is to produce teachers who are able to use the new computer technologies, we must take our preservice students from where they are when we get them and advance them to where the technological society needs them to be.

808 — Technology and Teacher Education Annual — 1998
Many dynamically interacting variables influence the role of computer technology and the effects of computer-supported activities within an educational setting. Researchers have recognized teachers’ and students’ experiences with and understanding of computer technologies (Collis & Lai, 1996; Pea & Sheingold, 1987) to be among these factors. Teaching builds on the common knowledge shared by teachers and students in the learning environment (Edwards & Mercer, 1987). The experiences and perceptions brought by the teacher and the students to the learning environment are two factors that influence the degree of common knowledge shared by the participants in that environment.

We live in a world of rapid change driven in large part by the evolution of computer technology. The pervasiveness of the computer in society has resulted in a generation whose members have grown up knowing only a world with computer technology and whose responses to technologies differ considerably from those of adults who have experienced more of the history and many of whose formative experiences occurred at a time when technology was less sophisticated. These differences have led to claims that computer technology is responsible for widening the generation gap (Negroponte, 1995; Turkle, 1984, 1995; Wright, 1988). According to Collis and Lai (1996), “There is little doubt that far-reaching changes have occurred throughout the world within our lifetimes that make the society within which children in the 1990s are growing up different from that for which their parents, grandparents, and teachers prepared” (p. 1). Such differences have created new challenges for teachers who must recognize that they and their students do not necessarily share the same perception of a situation (Perret-Clermont, Perret, & Bell, 1991) or the technology involved (Papert, 1996).

In this paper, I will describe questions and issues raised in a study exploring the effects of differences in teachers’ and students’ perceptions of computers in a fourth grade classroom. Insights gained from that case study will then be examined in a setting involving the technology-related education of pre-service teachers in an attempt to see what lessons learned in the first setting can be applied in the second setting. Specifically, the paper will raise questions and issues related to the use of technology by teacher educators.

Description of a study concerned with perceptions of computers

In a recent study, I explored the question of what effects differences among teachers’ and students’ perceptions of computers have in a computer-supported classroom (Stephen, 1997). The study employed qualitative research techniques for an in-depth study of one class of fourth grade students, the classroom teacher and the computer lab teacher in an urban, technology-rich school. Sources of data included: persistent observation; informal and semi-structured interviews with the two teachers and 25 students; and examination of lesson materials, software and students’ computer journals. Data collection and analysis extended over a period of eight months. In this study, perception of computers was defined as a combination of an individual’s understanding of what computers are, what computers are used for, and what computers are capable of doing; the personal relevance of computers; personal belief about ability to use computers; and level of personal enjoyment using computers. The theoretical foundation for the study was influenced by the belief that social and cultural factors play important roles in learning, and that learning is an active process that involves social interaction, communication and negotiation or sharing of meaning within a cultural setting.

While the teachers in this study had very different experiences with and perceptions of computers than their students, the teachers’ experiences and perceptions of computers were surprisingly similar. Both teachers were confident, competent, long-time users of technology who perceived the computer as a tool. This perception of computers influenced the intended use of computers in the activities the teachers designed. Analysis of data revealed
that while the teachers' perception of computers influenced their design of computer-supported activities, other factors, such as teaching style and view of students' competence with computers also played roles in their design of such activities.

Students in this study did not share their teachers' perception of the computer as a tool except in terms of helping them learn to type. Each of the 25 students in the classroom described a computer as either a machine that played games or a machine used to learn or type. While students reported diverse experiences with computers, the descriptions of what they used computers to do did not vary. All students mentioned playing educational games and typing. A survey conducted as part of this study showed the high value students of both genders placed on knowing how to use computers, their perceived ease of using computers, and their universal enjoyment of computer games. Unlike their teachers who had experienced rapid changes in computer technology and predicted significant future changes, students were unaware of changes in technology and described future changes in computer technology in terms of the technology with which they were currently familiar.

In the setting for this study, students' perceptions of computers influenced both their confidence using computers and their understanding of computer-related activities. Students defined expertise with computers as being able to play games and type. When asked how well they could use computers, students interpreted the question in terms of their perception of computers. Smagorinsky (1995) noted that individuals determine how a tool is to be used based on the individual's cultural bias and judge if the tool is successful from that same context. Activities in the computer lab and exploration of software in the classroom reinforced the majority's perceptions of computers, and this in turn, contributed to the students' confidence with computers.

Students' perceptions of computers also influenced their understanding of computer-supported classroom activities. When students were left on their own with computer-supported activities their understanding of the activity and what they actually accomplished in the activity did not necessarily match the teacher's understanding and intended outcome of the activity. The teachers in this study viewed the computer as a tool. They believed it was important for the children to use the computer as a tool, and they designed classroom activities which they believed emphasized the use of the computer as a tool. However, without mediation from the teacher, the way the students approached and understood these activities reflected the children's perceptions of computers, as machines to play games. Guidance provided by the teacher during an activity is a critical element in determining how closely the teacher's and students' understanding of an activity agree.

Previous studies support this finding (Collis, Knezek, et al., 1996; Downes & Reddacliff, 1997; Edwards & Mercer, 1987; Salomon, Globerson, & Guterman, 1989).

The study just described points to the importance of recognizing the effects that teachers' and students' experiences and perceptions of computers can have on computer-supported classroom activities. The findings of this study reflect my understanding and interpretation of this one site. Ely (1992) has noted that the importance of results emerging from a single case study lies in the possibility that analysis of the findings might lead to general principles that others in similar situations could follow. Such a study also serves the purpose of raising questions and issues to encourage exploration of these questions and issues in other settings. The questions and issues raised in the study of the fourth grade classroom should also be of interest to teacher educators.

**Implications for teacher educators**

The fourth grade students in the previous study had remarkably similar perceptions of computers. The students that teacher educators encounter in education classes have experienced more of the changes in computer technology than the fourth grade students have experienced. The pre-service teachers come to our courses with a wide range of perceptions of computers. At the first class meeting of the semester, I ask the pre-service teachers in my instructional technology classes to respond in writing to several questions designed to give me some insights into their experiences with and perceptions of computers. The majority of my students at the small, urban, state college where I teach are non-traditional, first generation college students who have had minimal, if any, exposure to computers in their own K-12 schooling. Many of the students who report prior experience with computers indicate the exposure came through a word-processing class in high school. In one of the questions on my questionnaire, the students are asked to describe what a computer is. There is usually a wide range of responses. The following list illustrates some typical responses and some of the more extreme responses.

- A computer is a man made machine that requires the user to input data in order for it to work. A computer gives output and is a device that is very useful to Man.
- A computer is a tool or instrument used to do different types of programs. Almost like a typewriter but processes information at a greater speed. Takes away people's jobs.
- A computer is a form of expanding new heights to education.
- A computer is a machine to entertain, facilitate learning, and communicate with people globally.
- A computer is something a person under 30 knows about.
- A computer is a tool to gain and express knowledge.
• A computer is something that needs to be upgraded. I believe a computer is a tool that can be used for almost any work that needs to be done. The computer can store, manipulate, and organize information for the user when used properly and with the appropriate programs. Those who learn to use this tool properly will be better off in the future than those who do not.

• A computer is an advanced system that we now use in our daily life which helps us to do a lot of things that we could not have done in the past.

• A computer is the DEVIL INCARNATE!

Once I have obtained the students’ responses, I mix an anonymous sampling of their responses with responses to the same question obtained from elementary and middle school children. We then discuss what information we might learn about each individual’s perception of computers from these definitions. This exercise is designed to increase their awareness that individuals they will work with, both in this class, and when they are teachers, will not necessarily hold the same view of computers as they do. The exercise includes discussion on what those differences mean in terms of working in cooperative groups on course projects and on their role as a teacher designing and implementing computer-based learning activities.

The way teachers view computers can have an effect on the way their students view computers. Studies with children have established the importance of the teacher’s role in modeling the use of technology for students (King, 1994/95, Moore, 1986; Reinem & Plomp, 1996) and as a crucial factor affecting students’ attitudes towards computers (Todman & Dick, 1993). In the study of the fourth grade students, the classroom teacher and the computer lab teacher both created computer-related activities that increased the students’ confidence in their ability to use computers. A teacher educator also has a responsibility to model the use of technology for pre-service teachers. Decisions the teacher educator makes about how to integrate computer-related experiences that help pre-service teachers holding negative views of computer technology. The teacher educator needs to provide a variety of experiences designed to increase students’ experiences with computers and to expand their understandings of computers and the uses of computers in education.

Decisions made by the teacher on how to integrate the computer into the learning experience can help form the way students view computers, but the students’ experiences and perceptions also play a role in how the students’ interpret these computer-supported activities (Hawkins, 1987; Newman, Griffin & Cole, 1989, Winograd & Flores, 1986). In the study of the fourth grade students, I found that the students’ understanding of the computer as a machine to play games often played a dominant role in how they approached and understood computer-supported activities in the classroom, particularly in situations where there was minimal mediation by the teacher. Teacher educators need to recognize that this same phenomenon can occur in their classes too. A student’s view of computers can influence that student’s understanding of computer-related activities in the class particularly if there is little or no mediation by the teacher while the student works on such activities. I regularly have my students work on computer-related projects in cooperative groups. Interactions between students in a group as they seek to understand and define their project are often influenced by the combination of how the different students understand and view computers. The challenge to us, as teacher educators, is to be aware and help our students become aware that not everyone has the same view of computers and that this has implications not only for the type of computer-supported activities they design, but also for how the students will understand the activities. Teacher educators face the challenge of designing computer-related experiences that help pre-service teachers question the perceptions of computers they hold when they come into our classes. Our students will face the same challenge when they enter the classroom.

Cooperating Teachers' Technology Use: Expectations of Student Teachers' Technology Knowledge

William J. Valmont
The University of Arizona

In the fall of 1997, 102 Tucson, Arizona, teachers who serve as cooperating teachers for the College of Education at the University of Arizona were given a survey designed to determine their familiarity with and use of various technologies. They were also asked to respond to questions about how extensively they are supported by their schools in their use of technology. In addition, they were asked to comment about their student teachers' knowledge of technology and what they would like future student teachers to know before starting their student teaching. This article reports the data obtained from 51 cooperating teachers (50% return). Implications drawn from the data will be offered, and suggestions for those who are engaged in the preparation and placement of student teachers in schools will be made.

General Findings
Cooperating teachers (N=51) from twenty-nine schools located in six school districts in the Tucson, Arizona, area are represented.

Table 1 reveals the number of years they have taught.

Table 1. Number of Years Taught

<table>
<thead>
<tr>
<th>Years Taught</th>

<td>11</td>
<td>22</td>
</tr>
<tr>
<td>K-3</td>
<td>15</td>
<td>29</td>
</tr>
</tbody>
</table>

Respondents were almost evenly divided between elementary and secondary school teachers. A variety of content areas were reported by secondary school teachers.

Table 4 indicates the number of student teachers that the cooperating teachers had worked with in previous semesters/years.

Table 4.

<tr>
<td>No response</td>
<td>6</td>
<td>14</td>
</tr>
</tbody>
</table>

Most of the cooperating teachers have a track record of working with previous student teachers. It is likely that the "no response" group is working with their first student teachers.

Table 5 reveals the cooperating teachers' ownership of personal computers.
By far, the cooperating teachers surveyed own their own computers.

Table 6 shows the number of computers these teachers have in their own classrooms.

Table 6.

<td>1</td>
<td>2</td>
</tr>
<tr>
<td>No response</td>
<td>4</td>
<td>8</td>
</tr>
</tbody>
</table>

A little over 40% of the cooperating teachers have just one computer in their classroom. Most of the others have between two and ten computers for classroom use. Perhaps, eight percent have no computers in their classrooms.

Table 7 reports the number of teachers who take their students to a computer lab.

Table 7.

<table>

</tr>
<tr>
<td>5+</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>No response</td>
<td>15</td>
<td>29</td>
</tr>
</tbody>
</table>

Students in about half of the cooperating teachers classes visit computer labs once a week. Few students visit a computer lab more than twice each week, and approximately 30% do not visit computer labs at all.

Table 9 indicates which computer platforms the teachers had used.

Table 9.

<table>

<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

The survey reveals that most cooperating teachers were familiar with both of the major computer platforms. If they knew just one type of computer, it is most likely to be an Apple computer.

Use of Applications

After asking for background information, the survey becomes more specific, asking cooperating teachers about their usage of various types of technology applications. Teachers were asked to rate twenty-four items, most of which are applications for computers. They were asked to indicate whether they used the items frequently, used them in a limited fashion, or made no use of the items. They further indicated whether or not the items were available for use in their school. Tables 10-16 report the findings from this portion of the survey.

Table 10 shows, in descending order of frequency of teacher use, those applications that the cooperating teachers say they frequently use.

The only computer application that teachers use frequently is word processing. Almost half of the cooperat-
ing teachers use teacher utility programs such as grade books and electronic attendance sheets. VCRs are also used frequently. None of the other applications is used by many of the cooperating teachers.

Table 11 indicates, in descending order of frequency of teacher use, those applications that the cooperating teachers say they use on a limited basis.

While older technology such as VCRs and camcorders are listed as being used in a limited way, databases and spreadsheets are being used by half or more of the cooperating teacher at least some of the time in their teaching. Nearly half of the teachers also use teaching software, multimedia, and desktop publishing in their work.

Table 12 combines the Frequent Use and Limited Use categories in order to reveal the highest ranking applications that do get used by cooperating teachers.

The use of word processing and VCRs is nearly universal, and about three-quarters of the teachers use teaching software and teacher utility programs. While using them less frequently, two-thirds of the cooperating teachers do make some use of spreadsheets, databases, camcorders, and multimedia.

Over half of the teachers indicated that probeware was not available to them. About 40% indicated they had no access to video editing equipment nor a way to FTP files. Image processing as well as electronic bulletin boards, videodiscs, and statistical applications are reported to be unavailable to one-third or more of the cooperating teachers.

Table 15 combines the Not Use and Not Available responses to give a fuller picture of the applications that teachers either do not or cannot use.

Table 15.

One-third or more of the cooperating teachers did not check a response to probeware, image processing, or FTP questions. About twenty percent of the teachers did not respond to questions about electronic bulletin boards and authoring software.
Additional Survey Information

The last part of the survey dealt with miscellaneous information about the teachers’ use of computer applications, their assessment of technology assistance in their schools, and what they would like their student teachers to know about technology. This section reveals these findings.

Table 17 shows the cooperating teachers’ confidence in identifying computer software that is instructionally sound in design and content.

Less than half of the cooperating teachers believed their student teachers were prepared well or very well to use technology.

Comments by Cooperating Teachers

Comments were made by 37 cooperating teachers in response to a question about the use of technology by them or their school. By far, most of the comments dealt with their inability to access computers because the labs are used extensively. Almost no comments indicated that the teachers used computers for direct instruction with students.

Comments were made about specific technology applications and specific knowledge that the cooperating teachers would like student teachers to know more about. Some items are not applications, but teachers believe they are important for student teachers to know. The specific areas mentioned are:

- Word processing (9 people mentioned), basic operations of a computer—Mac and PC (8), spreadsheets (6), Internet (4) gradebooks (3), research skills (on Internet) (3), calculator (2), general computer literacy (2), keyboarding (2), types of software available (2), VCR (2), CD-ROM, desktop publishing, doing lesson plans on a computer, e-mail, experience in a computer lab, laserdiscs, multimedia, music software, probeware, software evaluation, teacher utility programs.

Specific programs mentioned by the teachers were: PrintShop, Finale, Advantage, Pyware, Making the Grade (2), Computer-Based Lab program, ClarisWorks (2), Kid Pix, Writing Center, GroupSystems, Logo, and Word Perfect.

Comments were made about the kinds of technology the cooperating teachers, themselves, want to learn more about. Specific items mentioned were: E-mail (4 people responded), Internet, (3) music technology and software (3), scanner (3), physical education software (2), basic information about computers, calculator-based lab programs, camcorder, databases, Excel, Graphics, GroupSystems, Hypercard, image processing, multimedia, presentation tools, Spanish language software, spreadsheets, telecommunications, and word processing.

Implications and Suggestions

Findings from the survey have implications for teacher preparation institutions as well as for cooperating teachers. The cooperating teachers surveyed have been in the teaching profession for quite some time. This may be a problem, since it ensures that probably none of the cooperating teachers grew up with technology and, if they are computer savvy, they had to learn on their own or through district efforts. In sum, teachers in the profession 15 years may not be the best people to model technology to beginners. It is encouraging, however, that over 80% of the teachers own their own computers. Unless they are connected to the Internet, however, it is likely that the teachers are using them mainly for word processing.

The number of classrooms with one or more computers reported in this study may not accurately reflect national trends. Although most of the teachers take their students to labs, students have access to computers relatively infrequently, and this may be a barrier to promoting the effective use of technology for either teaching or learning.

Findings indicate that cooperating teachers use technology most for word processing and use mainly those teacher utility programs that help them maintain their classes. Few of the computer technologies that are likely to impact teaching/learning best are used with great frequency, partly because they are not available. Even when some applications were available, many did not use them in instruction possibly because they do not use them for their own teaching or because they don't know how to use the applications for teaching/learning. Some of the applications (FTP, probeware, and electronic bulletin) may not be used because teachers are unclear what they are.

Teachers' belief that they can confidently identify "good" software is questionable, since half never evaluated more than three software programs. It is highly questionable, with such little exposure to evaluation of software and their limited faculty development opportunities, that
teachers can competently integrate computers into a student-centered, constructivist, learning environment. Since only half of the teachers believe they are comfortable being independent learners of technology, it appears critical that faculty development activities be provided.

Teachers surveyed were very happy with their technical support people, and they reported almost full access to them. (Note: one of the districts, because of a successful bond approval, was able implement technology swiftly compared with most.) Schools should look at the technical support issue carefully.

Fewer than half of the teachers were satisfied with their student teachers' preparation in using technology, and they made specific recommendations that should inform teacher preparation programs. They also suggested areas that districts could consider when planning faculty development activities. Finally, almost 90% of the teachers do not use even an easy-to-use presentation product in their teaching. Not only does this fact indicate that the lecture format is probably the main method of teaching, but it also indicates that students in the schools are not in a position to share their on-line or off-line presentations effectively.
Positive teacher attitudes toward computers are widely recognized as a necessary condition for effective use of information technology in the classroom (Woodrow, 1992). At least fourteen instruments with acceptable measurement properties have been reported in the literature over the past decade (Chu & Spires, 1991; D'Souza, 1992; Francis, 1993; Gardner et al., 1993; Kay, 1993; Knezek & Miyashita, 1994; Loyd & Gressard, 1984; Pelgrum, Janssen Reinen & Plomp, 1993; Woodrow, 1991). During 1995-96, a compendium of these instruments for assessing teachers' attitudes toward computers was administered to 621 educators in Texas, Florida, New York, and California. Reliabilities for the resulting Teachers' Attitude Toward Computers Questionnaire (TAC), which contained a total of 284 items falling on 32 Likert subscales, were presented at SITE '97 (Christensen & Knezek, 1997).

Construct Validity

Additional data analysis has been performed on the TAC with the goal of refining it to be a more parsimonious instrument. The primary questions were: (a) Does the instrument really measure 32 separate attributes? and (b) Are 284 items really needed to cover the domain measured by the TAC? A factor analysis of the 284 individual items on the questionnaire, using the 621 responses, indicated that between four and twenty-two different attributes were actually being measured by the items collected from the 32 previously published subscales. Examination of the factor structures for all 4-22 feasible solutions resulted in selections of 7-factor, 10-factor, and 16 factor structures for development into derivations of the TAC. For the seven-factor solution, 135 items were found to be sufficient to cover the entire domain. The names assigned to the factors identified, and the reliability for each measurement index produced by summing the responses to items closely related to each factor, are listed in Table 1.

Parallel Forms Development

Within the seven factor structure of the TAC we found sufficient numbers of highly loading items to enable the derivation of parallel forms (Form A and Form B) for three subscales. We envisioned that parallel forms might be especially useful for short-term training sessions where it is possible that respondents remember their previous responses to items administered several hours (or days) before the post test, if both versions are identical. Parallel forms would remove one source of pre-post measurement bias (Campbell and Stanley, 1961).

An iterative procedure was carried out to produce equivalent forms for a subscale. First the items for a given subscale were arbitrarily divided into even items (Form A) and odd items (Form B), with the single strongest loading item retained as item 1 and duplicated on both forms of the subscale. Next, remaining items were shuffled from Form A to B and vice-versa, as necessary, so that highly similar items would fall on opposite forms. Finally, the discrimination ability of each shorter form was checked by carrying out an analysis of variance among 1995-96 sites. Stronger items were exchanged with their weaker counterparts on the other subscale, Form A to B or vice versa, until the F-ratios (discrimination ability) of each form was as close to identical as possible.

Discussion

Fifteen item Likert-type questionnaires require very little time for respondents to complete. The availability of parallel forms instrument for the subscales of enthusiasm, anxiety, and productivity improvement makes it practical for short-term training sessions.
for teacher educators to administer one or more of these to their trainees, in a pre-post fashion, even when the sessions are relatively short and time is of the essence. Items for form A and B for each of the three previously mentioned subscales are listed in the Appendix (items for the remaining four subscales are also listed). It is our hope that practitioners will find them useful.

Alpha = .93 (15 Items)

Factor 3 (Avoidance)
Learning to operate computers is like learning any new skill - the more you practice, the better you become.

Knowing how to use computers is a worthwhile skill.

I do not think that I could handle a computer course.

I would never take a job where I had to work with computers.

You have to be a "brain" to work with computers.

Someday I will have a computer in my home.

Alpha = .90 (13 Items)

Factor 4 (Email)

Var no. Items

282 The use of E-mail makes the student feel more involved.

284 The use of E-mail helps provide a better learning experience.

281 The use of E-mail makes the course more interesting.

283 The use of E-mail helps the student to learn more.

280 The use of E-mail increases motivation for the course.

276 More courses should use E-mail to disseminate class information and assignments.

278 The use of E-mail creates more interaction between students enrolled in the course.

279 The use of E-mail increases motivation for the course.

277 E-mail provides better access to the instructor.

274 Electronic mail (E-mail) is an effective means of disseminating class information and assignments.

I prefer E-mail to traditional class handouts as an information disseminator.

Alpha = .95 (11 Items)

Factor 5 (Negative Impact on Society)

Var no. Items

142 Computers are changing the world too rapidly.

215 I am afraid that if I begin to use computers I will become dependent upon them and lose some of my reasoning skills.

138 Computers dehumanize society by treating everyone as a number.

135 Our country relies too much on computers.

144 Computers isolate people by inhibiting normal social interactions among users.

176 Use of computers in education almost always reduces the personal treatment of students.

134 Computers have the potential to control our lives.

218 I dislike working with machines that are smarter than I am.

257 Using a computer prevents me from being creative.

251 Working with computers means working on your own, without contact with others.

FACTORS INFLUENCING ELEMENTARY TEACHERS’ INSTRUCTIONAL COMPUTER USE

Kara Dawson
University of Virginia

Research suggests that at the elementary level computers are overwhelmingly used for drill and practice or instructional gaming (Evans-Andris, 1995; Office of Technology Assessment (OTA), 1995; Becker, 1994). Research also suggests that current instruction would not be altered if computers were suddenly unavailable for use (Marcinkiewicz, 1994). However, approximately $500 million dollars have been spent on new computers over the last decade. The mismatch between the amount of money spent on computers and the nature of their instructional use suggest that teachers must be better prepared to use computers in instruction.

A large school district in southeastern Virginia commissioned the present study to explore this mismatch. They sought to identify instructional uses of computers by elementary teachers (grades one through five) and factors that may contribute to these uses. The end goal was to develop recommendations for inservice teacher preparation within the district that may result in increased effective instructional computer use. Skill, support and self-efficacy were explored as they related to the instructional computer uses reported by teachers.

Method

The population (N=1298) for the present study was teachers from the 53 elementary schools in the district. Systematic random sampling was used to ensure that all schools were represented in the sample of 300 teachers (Babbie, 1990). The sampling error for the survey was plus or minus ten percent. The sample was well distributed among grade levels with no less than 18% and no more than 23% of the sample being represented by a single grade level.

A pilot study of 23 elementary teachers served as the initial validation for the instrument. The instrument included 98 items and took ten to fifteen minutes to complete.

Stepwise multiple regressions were used to predict Instructional Computer Use from Skill, Self-Efficacy, and Support. Variables were entered into the equation if their significance level was less than .05 and removed if their significance level was greater than .05. Ninety-two percent (92%) of the selected teachers returned the survey.

Results Regarding Types of Instructional Computer Use

Teachers reported using computers most frequently for motivating interest in schoolwork, for mastery of language arts/math skills and for remediating deficiencies in some students and least commonly for learning research and study skills and for communicating with others.

A closer examination of how teachers reported using computers in instruction was accomplished using factor analysis (see Table 1). The first factor contained five items reflecting Traditional Instructional Computer Use. Teachers with high scores on this factor tend to use the computer to motivate faster learners by challenging them with more difficult concepts and skills and to motivate slower learners by reviewing concepts and skills previously covered in class. The second factor contained four items reflecting Instructional Computer Use via Curricular Integration. Teachers with high scores on this factor tend to integrate the computer into the curriculum by communicating with others, by integrating writing activities, and by implementing research activities. The third factor contained one item reflecting Instructional Computer Use as Reward for Completing Work. Teachers with high scores on this factor tend to use the computer as a reward for completing assigned classwork.

Results Relating to Skill

Measurements of Skill included use of computers for non-instructional activities and computer training. For the purposes of the present study non-instructional uses were defined as uses that did not directly relate to classroom instruction. Word processing and graphics were reported to be used most frequently for non-instructional activities while databases and spreadsheets were reported to be used the least frequently. These uses were collapsed into a single-factor, renamed Professional Use (see Table 2). Teachers scoring high on this factor report using all the applications for non-instructional activities.

Teachers reported having the most formal training on word processors and the least formal training on computerized gradebooks. Over half of the teachers reported never learning how to use databases, gradebooks, and spreadsheets while over half of the teachers report learning classroom organizational skills related to technology via personal trial-and-error. A principal component factor analysis yielded three factors relating to computer training (see Table 3). The first factor contained four items reflecting General Tools Training. Teachers with high scores on this factor tend to have had training with general tools such as databases, spreadsheets, word processors, and graphics. The second factor contained two items reflecting Classroom Integration Training. Teachers with high scores on this factor tend to report that they have had training on how to integrate computers into their curriculum. The third factor contained two items reflecting Training with Gradebooks and Telecommunications. Teachers with high scores on this factor tend to have had training with these two applications.

Results Regarding Support

Teachers reported being most satisfied with the access and technical support they receive while they report being least satisfied with the time support they receive. A principal component factor analysis yielded four factors related to support (see Table 4). The first factor contained six items reflecting satisfaction with Access and Technical Support. The second factor contained four items reflecting Curricular Support. The third factor contained three items reflecting Peer Support. The fourth factor contained three items reflecting Time Support. Teachers with high scores on these factors tend to report satisfaction with the type(s) of support represented by the factor.

Results Related to Self-Efficacy

Items relating to self-efficacy were subjected to factor analyses which yielded one factor related to each type of self-efficacy, Personal Computing Efficacy and Instructional Computing Efficacy (see Table 5 and 6).

Predicting Instructional Computer Use from Skill, Support and Self-Efficacy

Three separate stepwise regressions were used to predict the three types of instructional computer use from measures of Skill, Support, and Self-Efficacy. The following statistics are reported in each table: the variable entered at each step, r, R², F, and FD.

Prediction of Traditional Instructional Computer Use.

Classroom Integration Training Time Support, and Peer Support entered the regression equation with Traditional Instructional Computer Use (see Table 7). Teachers who reported having more integration training, more satisfaction with the time they are given to use computers, and more satisfaction with the collaboration they have among their peers related to computers were more likely to use computers for concept reinforcement. The R for this equation was .167 indicating that nearly 17% of the variation in the Traditional Instructional Computer Use was accounted for by these four variables.

Prediction of Instructional Computer Use via Curricular Integration.

Instructional Computing Efficacy, Classroom Integration Training, and Access and Technical Support entered the regression equation with Instructional Computer Use via Curricular Integration (see Table 8). Teachers who reported having more instructional efficacy related to computers, more integration training, and more satisfaction with computer access and technical support were more likely to integrate computers into their curriculum. The R for this equation was .159 indicating that nearly 16% of the variation in the Instructional Computer use via Curricular Integration was accounted for by these three variables.

Prediction of Instructional Computer Use as a Reward for Completing Work.

No variables entered in the equation with Instructional Computer Use as a Reward for Completing Work. The use of computers as a reward for completing work is not related to personal or instructional efficacy nor is it related to satisfaction with support. It is also not related to the use of computers for non-instructional activities or to computer training.

Discussion of Results

The three types of instructional uses dominating the self-reports of teachers participating in the present study have been found in previous studies as well. According to Evans-Andris (1995) teachers exhibiting an Avoidance Orientation attempt to provide students with access to computers but try to avoid contact with both students and computers during this time. Such teachers who fit this description use computers as rewards for completing work. Becker (1991) also referred to this as a common use of computers in K-12 schools; however, it is the least desirable instructional use identified in the present study. Some may argue whether it can even be considered an instructional use. Traditional ways of using computers were frequently reported in the present study in agreement with numerous previous studies (Evans-Andris, 1995; OTA, 1995; Becker, 1994). Likewise, curricular integration was identified in the present study and has been cited elsewhere as the most effective instructional use of computers (Hill, Manzo, Liberman, York, Nichols & Morgan, 1988; Hurst, 1994; Maddux, Johnson & Willis 1997; Dwyer, 1994; Means & Olson, 1994; Singh & Means, 1997; Hawkins & Collins, 1992).

Teachers reporting both traditional uses and curricular integration reported having classroom integration training. While using computers in traditional ways has appropriate uses in the classroom, “these uses in essence use technology to do the same things that schools have traditionally done for students—albeit perhaps more systematically and efficiently” (Means, 1996, on-line).

The main difference between teachers reporting mostly traditional uses and those reporting curricular integration was their perception of their ability to use computers in instruction. This suggests that teachers’ instructional efficacy related to computers is an important factor to consider when trying to help teachers use computers as an integral part of the curriculum. Similar results were obtained by Marcinkiewicz (1994) and Vockell and Sweeney (1994). According to Hadley and Sheingold (1993), self-efficacy related to instructional computer use fosters flexibility, experimentation, and multiple approaches to using computers in instruction.

Support was also a common factor for teachers reporting both traditional uses and curricular integration. Access and technical support was particularly important to those teachers reporting curricular integration while peer support and time support was particularly important to those teachers reporting traditional uses. At first glance this seems illogical since peer and time support intuitively seem more crucial to curricular integration than to traditional uses.

However, research shows that it takes time for teachers to become adept at integrating computers into the curriculum (Hadley & Sheingold, 1993; Becker, 1994). These studies also show that initial implementation involves traditional instructional computer uses. It is probable that teachers reporting traditional uses are in the beginning stages of instructional computer use and will, in time, progress to curricular integration. While this hypothesis cannot be confirmed; it can be supported by the fact that the school district has recently embarked on a plan to foster the curricular integration of computers, thus, many of their teachers will be in the initial implementation stages.

Likewise, literature suggests that teachers who integrate computers in the curriculum, have a strong system of peer support as well as time to plan lessons (Becker, 1994; Hadley & Sheingold, 1993). Since the district has recently adopted a plan to foster curricular integration it is probable that teachers reporting curricular integration are the district-wide leaders in instructional computer use. As early adopters, it is probable that they have attended educational technology conferences and collaborated with teachers from outside their building (Rogers, 1995). It is also probable that as more teachers in the district begin to integrate computers, these teachers’ instructional computer use will also be enhanced via both peer and time support. However, at the present time, these teachers view access to computers and the availability of technical support as important to their instructional use of computers.

Implications for Inservice Teacher Preparation

Curricular integration has been sited as the most effective use of computers in instruction. Results from the present study, in combination with, related literature can be used to make recommendations that may help to foster effective instructional computer use via inservice teacher preparation programs.

Teacher Perception of Self-Efficacy Related to Instructional Computer Use

Self-efficacy is likely influenced by training (Abdel-Gaied et al., 1986; Ashton & Webb, 1986; Delcourt & Kinzie, 1993; Jorde-Bloom, 1988; Olivier & Shapiro, 1993). Consequently, training should be designed with a goal of developing instructional computer efficacy. Data from the present study suggest that a main difference between teachers who integrate computers into instruction and those who do not is self-perception of their ability to use computers in instruction.

Current technology advocates recommend that skills relating to applications that are content and grade level
specific should be emphasized during inservice teacher preparation. (Education Week, November 10, 1997; Center for Technology and Teacher Education, 1997; President's Panel on Educational Technology, 1997; Cooper & Bull, 1997; Bull, Gansneder, Short, Dawson, Nonis & Berg, 1996; O'Donnell, 1996; Hurst, 1994). Likewise, inclusion of exemplary computer-using teachers as instructors for classroom integration training may foster the development of instructional computing efficacy via modeling. Because successful teachers are similar to inservice participants, participants' beliefs that they can successfully implement successful teachers are similar to inservice participants, their beliefs that they can successfully implement the strategies presented will tend to increase (Bandura, 1977).

Becker (1994) reported that the presence of other computer using teachers was the factor that most heavily influenced exemplary computer use. Participants in inservice computer training should be selected so that cadres of computer using teachers are formed within schools. Such cadres encourage collaboration and more effective problem solving (Moursund, 1989).

A Systemic Approach to Inservice Teacher Preparation

In the present study satisfaction with access and technical support is related to integrating computers into the curriculum. Teachers should be provided with technical support during and after inservice computer training. Teachers should also be provided with easy access to computers that can be used both for instructional and preparatory uses. Fostering such conditions implies that a systemic approach to inservice preparation may be most effective. A systemic approach to inservice technology preparation should provide collaboration between those conducting the inservice preparation and building level administrators and include both short range and long term goals.

Future Directions

Similar studies are being conducted in this district with middle school and high school teachers. Related studies involving direct classroom observation and teacher interviews are also being conducted to determine factors that may influence effective instructional computer use.

Acknowledgments

I wish to thank Bruce Gansneder and Glen Bull from the University of Virginia (Charlottesville, VA) and Paula Cochran from Truman State University (Kirksville, MO) for assistance with this submission.

INTERNAL CONSISTENCY RELIABILITY FOR THE TEACHERS ATTITUDES TOWARD INFORMATION TECHNOLOGY (TAT) QUESTIONNAIRE

Gerald Knezek
University of North Texas

Rhonda Christensen
Texas Center for Educational Technology

The Teachers' Attitudes Toward Information Technology Questionnaire (TAT) was developed during the second phase of the 1995-97 Matthews Chair for Research in Education Project at the University of North Texas. During Phase I (1995-96) activities focused on developing a more parsimonious instrument to assess the areas covered by 14 previously validated computer attitude scales. The result of that effort was the Teachers' Attitudes Toward Computers questionnaire (TAC) (Christensen & Knezek, 1996; 1997).

During 1996-97 construction of the TAT was begun to address areas not covered by the TAC. These were primarily areas that have come to be known in Europe as the New Information Technologies (NIT) — multimedia, electronic mail, and the World-Wide Web (WWW). In addition to the NITs, other areas, such as the use of information technology to improve teacher productivity, were also included because previous analyses indicated they might be important. Two well-validated subscales from the TAC were also included instrument for comparison purposes: a) Kay's semantic perception of computers (Kay, 1993) and b) D'Souza's (1992) classroom learning via Email.

Refinement of the TAT is ongoing. In this document internal consistency reliabilities are reported for the first large-scale pilot test of the instrument.

Subjects

The subjects in this study were 147 teachers from six schools in a large, urban public school district in northern Texas. TATs were completed during May of 1997. This was the last month of the 1996-97 school year in Texas.

Data Acquisition, Preparation, and Analysis

Data were gathered for 10 separate indices from the respondents. Eight of these ten subscales were newly constructed using semantic differential items taken from Zaichkowsky's (1985) Modified Personal Involvement Inventory, a context free 16-item semantic differential scale that focuses on "a person's perceived relevance of the object based on inherent needs, values, and interests" (p. 342) (see Figure 1). Semantic items were hand coded with a number from 1-7, representing the particular space the respondent marked between the adjective pairs, then keypunched by the University of North Texas Computation Center data entry staff. Cronbach's Alpha was produced for each subscale using SPSS on a Macintosh computer.

To me, Electronic Mail is:

| important | unimportant |
| boring    | interesting |
| relevant  | irrelevant  |
| exciting  | unexciting  |
| means nothing | means a lot |
| appealing | unappealing |
| fascinating | mundane |
| worthless | valuable |
| involving | uninvolving |
| not needed | needed |

Figure 1. Sample Semantic Differential subscale from the TAT Questionnaire

Internal Consistency Reliabilities

As shown in Table 1, internal consistency reliabilities for the ten TAT subscales ranged from a low of .91 to a high of .98 (These reliabilities are based on responses from 74 subjects who furnished complete data). According to the guidelines provided by DeVellis (1991), this is excellent reliability for a research instrument. Additional strength is added to this conclusion because the two subscales carried over from the TAC exhibited internal consistency reliabilities quite comparable to the .93 (Kay's Semantic) and .95 (D'Souza's Classroom Email) found for these indices in the previous study of TAC reliability (Christensen & Knezek, 1997). The earlier study involved a much larger and diverse sample.

Future Work on Validity
Content validity for the TAT is believed to be quite high due to the way the instrument was constructed. Subscales were selected precisely because various scholars and practitioners in the field had identified these areas as important but not measured by previously-existing questionnaires. Construct (factor) validity needs to be checked through confirmatory factor analysis to see if some of the ten current subscales are not in fact duplicates of another. Criterion-related validity, such as the ability of the instrument to separate (discriminate between) groups thought to be different on one or more attributes, or the ability to measure pre-post change in a single group, needs to be established as well. Future research is planned in these areas.

Teachers' Attitudes Towards Technology

Sadegul Akbaba
University of Cincinnati

Gulsun Kurubacak
University of Cincinnati

Today's schools have heavily invested in computers and related technologies over the past decade. These technologies are playing important roles in education and training at many levels, such as multimedia, internet, world wide web, intranet, etc., are used to a greater extent. Future plans include networking computer technologies for whole-class viewing of computer information technologies. Resulting in most of the expenditure going to purchasing computers.

Between 1989 and 1992, schools' computer technologies have increased by nearly 50%, jumping from 2.9 million units to 3.5 million units (http://www.access.gpo.gov/). Today, there are an estimated 5.8 million computers for instructional use. Although schools spent merely $ 3.3 billion on technology in the 1994-1995 school year alone, in many schools integration of the computers and related technologies into the classroom has been minimal, characterized by limited use of the technology as an add-on rather than as integrating to teaching and learning (Zappone, 1991).

One problem is that the growth of technology as an instructional tool is influenced by teachers' attitudes towards these technologies and their ability to use them successfully. While bombarded with promises of tomorrow's technology, many teachers are struggling to make efficient and effective use of today's technologies (Planow, Bauder, Carr, and Sarner, 1993).

Although the integration of all types of technology into the classroom is viewed as an effective instructional strategy for improving the students, many teachers often do not have favorable attitudes towards the effectiveness of technology (Huan, Compley, Williams, and Waxman, 1992; Padron, 1992).

Teachers' attitudes toward computers and related technologies can also influence students' attitudes toward technology. A number of studies have investigated teachers' attitude toward use of technology and anxiety about technology (Kay, 1989; Koohang, 1987; Marshall and Bannon, 1986).

It was found that teachers' attitudes towards technology has influence on the utilization of technology (OTA, 1988). Thus, teachers can not be assisted for providing relevant using and supported to integrate into curriculum, unless we do not know teachers' attitudes towards computers and related technologies as educational tools.

Speaking of the integration of technology into classroom, we can think how teachers are reoriented the terms of skills on technology. This is important since teachers are able to use all types of technology as an instructional instrument, and to feel comfortable with them before integrating into their daily teaching-learning activities.

Teachers' attitudes about technological innovation can significantly change the curriculum, teaching methodologies, and the roles between teachers and students. So, their attitudes should be improved positively toward the use of technology. If teachers are indeed to embrace technology and make it a part of their teaching culture, such as feelings, beliefs, values, etc., of their classrooms. In sum, if we know teachers' vision about technology we can learn their feelings about technology.

The purpose of the present study was to find out teachers' negative attitudes towards technology and to determine what kind of techniques that change their negative attitudes towards positive ones. It is expected that if elementary school teachers have positive attitudes toward technology, they may use novel technology more than before into their classrooms and integrate the use of the technology into classroom.

Participants
Twenty elementary school teachers (13 women and 7 men) who attend their graduation program in the University of Cincinnati, Teachers College volunteered to participate. However, researchers received only seven questionnaires from among these teachers.

Material
The questionnaire was designed gather data about teachers' attitudes toward technology based on theory of Planned Behavior by the researchers. The questionnaire had three sections that each has three questions.

The first section of the questionnaire was designed to find out and determine teachers' behavioral beliefs towards technology. In this section, the first question tried to find out the advantage of using the technology in the classroom, the second question tried to find out disadvantages of using technology in the classroom, and the final question attempted to find out what other factors influenced teachers attitudes towards using technology.
The second section of the questionnaire was designed to find out and determine teachers' normative beliefs towards technology. In this section, the first question tried to find out which people are the most important in influencing the teachers' attitudes towards technology, the second question tried to find out which people are the least important in influencing the teachers' attitudes towards technology, and the last question was used to find out whether another group influences or does not influence the teachers' attitudes towards technology.

The last section of the questionnaire was designed to find out and determine teachers' control beliefs towards technology. In this section, the first question tried to find out what the most influential factors are about technology for teachers, the second question tried to find out what the least influential factors are about technology for teachers, and the last question tried to find out whether there are other things that would influence the teachers' beliefs towards technology.

**Design and Procedure**

The study had these steps: researching the literature; determining the positive indicators of teachers' attitudes towards technology; determining the negative behaviors/actions of teachers towards technology and the salient beliefs of teachers towards technology; designing the questionnaire; distributing and having them back; establishing the dimensions of behavior, normative and control items; tabling the model salient beliefs for behavior, normative and control beliefs; attempting to change teachers' negative attitudes towards technology by using operant conditioning theory and persuasive communication theory.

**The Positive Indicators of Teachers' Attitudes Towards Technology**

Researchers defined the positive indicators based on literature review and their personal experiences. They could find fifteen positive indicators to show teachers' positive attitudes toward technology. These are: Teachers would like reading magazines or books about technology; buying books about technology; watching technological TV series; using computerize materials; using computers; being in a situations where people talk about technology; using new technology versus old instructional materials; hearing information from my students about technological improvements; talking about technology with my colleagues; having new technology in my school; informing people about new technological development; encouraging people to use new technology; being member of technological associations or clubs; attending technological fairs; searching the Internet.

**The Negative Behaviors/Actions of Teachers Towards Technology**

Researchers defined the negative behaviors/actions of teachers toward technology based on literature review, their personal experiences and defined teachers' positive attitudes towards technology. These are: Teachers do not use technology in their classrooms; encourage their students using technology; support technology buying schools; research on the Internet; use email in their daily lives; have a homepage on the World Wide Web; encourage their students surfing on the Internet; read any published things about technology; watch the science-fiction programs or movies on TV; prefer using traditional teaching methods into their classrooms; want to gain any information about technology; want to attend any in-service education program about technology; being the member of any technological associations or clubs; enjoy talking about technology with their colleagues; attend any technological fairs.

**The Salient Beliefs of Teachers Towards Technology**

The following items are determined as the salient beliefs of teachers towards technology based on the literature review and experts' opinions. They think that they will lose their authority in the classroom; are too old to learn new technology; see learning of technology extra load for them; afraid of being unsuccessful using technology; afraid of changing their roles into classrooms; will lose their jobs; do not want to attend training programs; as if they are students; are afraid of addiction to the Internet; will lose their status to be the first and unique sources of information; and they think that technology will replace them; brings alienation; creates uncertainty due to unknown results; reduces of the interaction among people; and learning new technology is the waste of time.

**Responses to the Questionnaire**

Researchers gathered information about the dimensions of behavioral, normative and control beliefs from the elementary teachers' answers.

Each given answer was read, and then, the short sentences about teachers beliefs towards technology for three sections of the questionnaire were written by the researchers in order to find out the frequency distribution and percentage of each answer given by teachers.

**Findings**

The following items were gathered according to seven teachers' answers to the questions of the dimensions of behavioral, normative and control beliefs.

Behavioral beliefs are: save time; doing task efficiently; take more time; need to know how to use it; technology may not be as effective as teachers in instruction; bring the more current issue to the classroom; no enough computer to
use; to prepare students for future by using technology; to take over being the teacher; using technology need more money; rethinking and restructuring of teaching methods, class size, individualized instruction; to supply feedback easily to students; not all students respond well to computers; instructional technology is not prepared but also by others; increase self-esteem and competency; students feel good about what they can do; send journals via email; organize files; inventory class items (keep many things); relaying on computerized task taking programs to “do the job”; need to have reliable students and trust that they don’t destroy program on cause damage to equipment.

According to “Model Salient Beliefs Table 1” for behavioral beliefs, the most important belief about using technology is to take more time. Doing task efficiently using technology is the second important belief in this section for teachers. “Need to know how to use it”, “Rethinking and restructuring of teaching methods”, and “Inventory (keeping) class items” are the least important behavioral beliefs for teachers attitudes towards technology.

Normative beliefs are: those who are using it; people who are not using it; media; politicians; principals; other teachers; parents; experts; school boards; students; community members; benefits of technology; environment, and professors.

According to “Model Salient Beliefs Table 2” for normative beliefs, experts and students point of views about technology are two most important beliefs about using technology for teachers into their classrooms. “People who are not using it”, “Principals”, “School boards”, and “Benefits of technology” are the least important people or group for teachers.

Control beliefs are: media; students’ interests; other teachers; in service training and seminars; the skilled students; availability of equipment; addition of objectives in the curriculum; to prepare students for future; to search for information; ease of teaching instruction; to be competent in using technology; to live comfortably with technology; coordination of curriculum; to believe that we can’t live without it, and information and success in Ed/Tech journals.

According to “Model Salient Beliefs Table 3” for control beliefs, students’ interests about technology are the most important belief about using technology for teachers into their classrooms. “In service training and seminars”, “Availability of equipment” and “Search of information” are less important than students interest for teachers. However, they believe that these are important things to use for technology in the classroom.

The findings of this study can be listed as: technology takes more time; doing task efficiently; experts’ opinions and students’ interests are important for teachers to use into classroom or integrate into curriculum; teachers need in-service training and seminars about technology as an instructional tool; teachers need the support in terms of availability of equipment and searching of information about technology.

In summary, teachers seem to have positive attitudes towards technology. Especially, students’ interests and experts’ opinions, encourage them to use technology. However, they need to support the use and integrating of technology in their classrooms. The seminars or in-service program can be designed for teachers to improve their attitudes or to change their negative attitudes towards positive attitudes.

Discussion and Conclusion

A number of studies have investigated teachers’ attitudes toward the use of technology. In this study it was found that teachers seem to have positive attitudes towards technology. Students’ interest and experts’ opinions encourage them to use technology in educational settings. However, they need to encourage and support the integration of technology into the curriculum. The seminars or in-service training programs can be designed for teachers to improve their attitudes or to change their negative attitudes towards positive attitudes.

These findings are supported by related literature. The findings from the literature have also shown that: there is a significant difference between the attitudes of teachers and students who are from different countries towards technology; more computer experiences make people feel comfortable and have positive attitudes towards technology, on the other hand, having computer anxiety prevents people’s positive attitudes towards technology.

It is important for us as educators to understand teachers’ attitudes towards technology as an educational instrument for providing relevant technologies and integrating them in curriculum.

To overstate the obvious...technology is upon us and there would appear to be no end in sight. Educators must increase the use of technology in the classroom. To do this, educators from classroom teachers to media/technology specialists, to administrators, to college and university faculty must become aware of new technologies and be trained in their uses (Brownell, 1997; Dede, 1997; Paccione, McWhorter & Richburg, 1997; Parker, 1997). For the training needs of educators to be met, technology trainers must identify the competencies and skills for which educators have the greatest needs and then design programs which will meet those needs (Ferris, Roberts, & Skolnikoff, 1997).

The two previous studies, involving the surveying and interviewing of technology and media specialists in two school systems on the technology training needs of school personnel, were successful in identifying the current and future training needs of those systems (McKenzie, Kirby, Clay & Davidson, 1997). This third study seeks to extend and refine (that is, validate) our ability to obtain training information on the technology uses of teachers and students as well as the training needs of teachers, especially those that are new practitioners.

**Methodology**

To extend and refine our ability to find out what the technology training needs of educators are, the instruments used in previous studies were revised for improved clarity; altered to include the use of a 5-point Likert scale response system; and expanded to incorporate open-ended, sentence completion items.

To validate the findings of the two previous studies, the redesigned instrument was distributed to additional school systems including the two previously involved systems through media specialists and technology trainers. Those participants that were part of the first two studies were either called on the phone for their responses to the validation survey or had face to face meetings with the investigators. New participants, consisting of media and instructional technology graduate students at the State University of West Georgia, were asked to complete the survey at the end of their class in a written format or respond electronically on their class listserv.

**Analysis**

Forty-one surveys were collected and analyzed by the research team. It was discovered that the majority of the respondents were from the high school level, had 1-5 years of experience in their position, served as lead teachers in technology in their schools, had a master’s degree plus additional graduate work, and were female. Table 1 below summarizes the study’s demographic data.

Research — 837
Mean scores were computed for the closed-ended questions utilizing the 5-point Likert scale. The responses to each technology question within the study’s three areas of interest, teacher use of technology, student use of technology, and technology training needs; were then ranked from the high to the low mean scores so that frequency could be identified. A five indicated that the item was used “very frequently” while a one stood for “not at all.”

In examining how often teachers used specific technology equipment, mean scores ranged from a 4.61 to a 2.0. The most frequently reported type of technology was the overhead projector. This was followed by the use of computers for word-processing, videocameras, computers with multimedia development capabilities, and computers with Internet access. It was not surprising to find that three of the top five types of hardwar e dealt with the teacher utilizing the computer for classroom instruction.

On the software dimension mean scores ranged from a 4.46 to a 1.98. Respondents reported that the software they used the most frequently involved videotapes and word-processing computer programs. The next most frequently cited types of software were on-line encyclopedias such as Grolier and World Book, CD-ROMS, and on-line periodical databases. Running parallel to the hardware findings, four of the top five types of software used the most frequently by teachers were computer related.

The rank order findings of the types of technology hardware and software used by teachers are listed in Table 2 below. Only those items that had a mean score of 2.5 and above on the 5-point Likert scale are reported.

Mean scores computed for student use of technology hardware and software ranged from a 4.19 to a 1.34 on the 5-point scale. Respondents reported that students predominantly used the computer for word-processing, multimedia, and Internet access. The software that was identified as being used the most often included word-processing computer programs, on-line encyclopedias, CD-ROMs, videotapes, and on-line periodical database. Table 3 highlights the rank order findings. Only the items that scored a 2.5 and above are listed.

| Table 3. Student Use of Technology in Rank Order |

| **Hardware Use**                              | Mean | S.D. |
| 1. Computers for word-processing              | 4.19 | 1.05 |
| 2. Computers with multimedia capabilities     | 3.11 | 1.24 |
| 3. Computers with Internet access             | 2.93 | 1.25 |
| 4. Video cameras                              | 2.78 | 1.01 |
| 5. Overhead projector                         | 2.76 | 1.01 |

**Conclusion**

The results of this study should be used by teacher training institutions to examine their present technology training curriculum. Restructuring should take place where needed to ensure that current needs are mirrored in curriculum and that graduating pre-service and inservice students will take the lead in schools systems to better integrate technology into the curriculum.

ERIC
Better Staff Development Planning Using the Teaching with Technology Instrument

Nancy E. Atkins          Ellen S. Vasu
Wake County Public Schools /TechnologyNorth Carolina State University

The purpose of this study was to examine teachers' concerns, knowledge, and actual use of technology, and how these related to the level of technology at their school. The measurement instruments used in the study were the Computing Concerns Questionnaire (Martin, 1989) and the Teaching with Technology Instrument (TTI) (Atkins, Frink, and Viersen, 1995). The TTI has forty-six questions and can be analyzed through a bubble scanner, so that administration and analysis of the TTI can be conducted at the school or district level.

Literature Review

According to teachers, the school principal is a major stimulus for computer integration in the school (McGee, 1985; Hall & Hord, 1987; Knupfer, 1989). Staff development training helps to increase teachers' use of computers and helps to develop more positive attitudes toward computers (Hagey, 1985; Martin et al., 1988). Hands-on training with peers is the preferred type of training (Johnson, 1988). Teachers give high ratings to software applications that allow them to manipulate information, such as word processing programs (Woodrow, 1991).

Teachers have many concerns about the use of computers in instruction. Some of these are: software, hardware; lack of time, training, and support; possible negative effects of computers on children or on the teacher's role in the classroom; and problems of curriculum integration (Aust, Allen, & Bichelmeier, 1989; Callister, 1986; Cosden, 1988; Cumming, 1988; Knupfer, 1989; MacArthur & Malouf, 1991; Taylor, 1987; Vermette, Orr, & Hall, 1986; Woodrow, 1987).

Many staff developers in planning for change use the Concerns Based Adoption Model (CBAM) (Puller, 1969; Hall & Hord, 1987). Martin (1989) used the CBAM mode to develop the Computing Concerns Questionnaire. Martin categorized teachers' concerns into eight Stages of Concern about Computing (SoCC): contextual; information; personal; management; consequence on self; consequence on others; collaboration; and refocusing. Using Martin's questionnaire, Bly (1993) found differences among teachers on SoCC and what they perceived to be good staff development. Teachers at low stages of concern rated structured introductory hands-on workshops, as being more effective than teachers at higher stages of concern. There were also differences in many demographic variables in relation to stages of concern.

Methods

Demographic questions, the Computing Concerns Questionnaire (Martin, 1989), and the Teaching with Technology Instrument (TTI) (Atkins, Frink, and Viersen, 1995) were administered to a sample of teachers at three middle schools in a large school district (N = 155). School One, with the lowest amount of technology integration of the three schools, was a rural school with no technology related goals in the school improvement plan, and no support personnel for technology. School Two was an urban school that had a technology grant and technology specialist in the past, but not longer had either. They had somewhat integrated technology into the curriculum. School Three, with the highest level of technology integration, was an urban inner city magnet school that had technology-related goals in the school's improvement plan, up-to-date computer equipment, and a technology specialist. Qualitative analyses also conducted will be discussed briefly.

Assessment Instruments

In addition to the two instruments discussed below, teachers were also asked to respond to ten demographic questions.

Through their responses to the Computing Concerns Questionnaire (Martin, 1989), individuals are measured with respect to their Stages of Concern about Computing (SoCC). Coefficients of internal reliability for different stages of the Computing Concerns Questionnaire ranged from .65 to .83.

The Teaching with Technology Instrument (TTI) was developed to assess training needs for teachers in three areas: writing and communication, information awareness and management, and construction and multimedia (Atkins, Frink, & Viersen, 1995). The forty-six dichotomous choice (yes/no) questions relate to the basic computer competen-
cies recommended by ISTE and others (ISTE, 1992; Sheingold et al., 1990; State Board of Education, 1995). By tabulating a percentage score from this instrument, one can assess the three areas of technology use. The TTI can be answered on a bubble sheet and scanned for easy interpretation (Bubble Publishing Program, 1992). The scanned output displays a histogram of the responses (yes/no) for each item grouped by topic area and increasing level of difficulty. As Figure 1 illustrates, these histograms can be visually interpreted, and even color coded, to determine staff development needs within a given area. Cronbach’s alpha (.9462) was used to establish reliability of the TTI.

<td>1. There will be a significant positive relationship between the Stages of Concern about Computing (SoCC) and the total score on the Teaching with Technology Instrument (TTI).</td>
</tr>
<tr>
<td>2. There will be a statistically significant positive relationship between the Stages of Concern about Computing (SoCC) and each of the independent variables: age, computer confidence level, gender, home access to computers, level of college education, number of hours of technology training during past two years, school access to technology, and teaching experience.</td>
</tr>
<tr>
<td>3. There will be a statistically significant positive relationship between the Teaching with Technology Instrument (TTI) and each of the independent variables (see Hypothesis 2).</td>
</tr>
<tr>
<td>4. Teachers at schools with higher levels of technology integration (Schools Two and Three) will have overall higher mean scores on the TTI than teachers at School One. In addition teachers at Schools Two and Three will report more usage of technology, and demonstrate that behavior in their classroom.</td>
</tr>
</tbody>
</table>

**Statistical Analyses**

In order to address the first research question a Spearman correlation coefficient was calculated between the Stages of Concern about Computing (SoCC) score and the Teaching with Technology Instrument (TTI) score. To answer the second research question, the appropriate measure of association was calculated between SoCC score and each of the independent variables: age, computer confidence level, gender, home access to computers, level of college education, number of hours of technology training during past two years, school access to technology, subject taught, and teaching experience. The measures of association used were: interval with ordinal, Spearman r; interval with dichotomous, point biserial r. Since TTI was interval, a single factor anova was calculated on the TTI score for each independent variable for which a significant relationship was found. An alpha level of .05 was used for all statistical tests.
Results

SoCC and TTI

A statistically significant positive relationship was found between the SoCC and TTI scores ($r = .322, p \leq .0001$).

Demographic Variables

SoCC score was significantly related to computer confidence level ($r = .332, p = .000$), and number of hours of technology training ($r = .224, p = .005$). No other significant relationships were found.

A significant positive relationship was found between TTI score and each of the following variables: age ($r = .224, p = .005$), computer confidence level ($r = .651, p = .000$), home access to computers ($r = .267, p = .001$), number of hours of technology training ($r = .199, p = .013$), and school access to computers ($r = .291, p = .000$). One-way ANOVA conducted on TTI for each of the following variables were significant: levels of computer confidence ($F(3,150)=44.00, p = .0001$); home access to computers ($F(1,152)=11.69, p = .0008$); and school access to computers ($F(1,152)=14.07, p = .0003$). The mean TTI scores for these variables are shown in Table 1. No other significant relationships were found.

Pairs of means with the same superscript, for example a, are significantly different, Scheffe, $p < .05$. Only independent variables for which a significant association was found are reported.

School's Level of Technology Integration

A one-way ANOVA revealed significant differences between the mean TTI total scores of School One ($M = 12.00, SD = 10.95, n = 57$), School Two ($M = 18.42, SD = 13.08, n = 39$), and School Three ($M = 26.31, SD = 12.23, n = 59$) ($F(2,151)=16.45, p = .0001$). All means were significantly different from each other (Scheffe, $r = .05$) (see Figure 2). As predicted the schools with more technology integration had teachers with significantly higher mean TTI.

Follow-up interviews and observations were conducted on twelve teachers. At School One, teachers were at lower levels of concern, and little technology was being used in instruction. School Two previously had a technology grant, but now had no extra funding or personnel. Two of the teachers were at higher stages of concern. The computer lab was closed for remodeling, so no classroom observation took place. These teachers wanted to use more technology, but expressed frustration about the lack of coordination. School Three was the most technologically advanced with a full time technology specialist. Classes incorporating technology occurred everyday. The school offered technology training to all their staff, and had more technology resources available for use than at the other schools. The principal made the use of technology a priority for the school, and every teacher had a computer in the classroom.

Discussion

Teachers at higher stages of concern about computing (SoCC) tended somewhat to have higher mean scores on the Teaching with Technology Instrument (TTI). The Spearman coefficient, although significant, was not strong ($r = .322, p = .0001$). This relationship probably cannot be perfect, since the SoCC score is subject to change as new technologies are introduced to teachers. As teachers become more knowledgeable about technology, their concerns tend to move to higher levels (consequences on self and others).

Computer Confidence Level

A teacher's computer confidence level is strongly related to knowledge and use of technology in teaching ($r = .651, p = .0001$). The relationship between confidence level and stage of concern about computing is somewhat weaker ($r = .332, p = .0001$). Even though a teacher might be competent in basic word processing, the introduction of a new technology might return them to more lower level...
informational concerns until they acquire the new competencies.

**Number of Hours of Technology Training**

The number of hours of technology staff development a teacher had was significantly related to SoCC score ($r = .224, p = .005$). Generally, teachers with more technology training are at higher stages of concern.

A weaker, but statistically significant relationship exists between number of hours of technology staff development and TTI scores ($r = .199, p = .013$). This correlation indicates that attending many hours of technology training does not completely ensure acquisition of computer knowledge. Other factors must be in place in order for teachers to integrate computers into the curriculum.

**Age**

There was no relationship between a teacher's age and the Stages of Concern about Computing. However, age was related negatively to TTI score ($r = - .224, p = .005$). Younger teachers tended to score higher. This may be a reflection of the changes in preservice teacher education. (Nicklin, 1992).

**Access to Computers**

No relationship existed between Stages of Concern about Computing and home access to computers. Even though teachers may have a home computer, they may not use it for school instructional planning. However, home access was significantly related to TTI score. Teachers with a home computer scored almost eight points higher on the TTI ($M = 22.10$) than those without ($M = 14.28$).

Teachers who have computers and technology equipment at school did not have higher SoCC scores than teachers with no access. Even if teachers have technology at school, they may not use it. However, school access was related to TTI score. Teachers who have technology equipment readily available in their schools had higher mean TTI scores ($M = 21.76$), than teachers who did not ($M = 12.156$). Having school access to technology helps teachers to learn to use it and integrate it into instruction.

**School's Level of Technology Integration**

Schools with more technology integration had teachers who had significantly higher mean TTI scores (see Figure 2). This suggests that schools that have technology support can progress further in its use in instruction. For these three schools, those that received more technology support had more technology integration. This suggests that if we are to use technology in schools effectively, a school level technology specialist should be present for technical support and staff training.

The Stages of Concern about Computing distributions for the three schools are displayed in Figure 3. Schools with higher levels of technology integration tended somewhat to have teachers with more advanced levels of concern.

**Conclusions**

Looking at the three schools in this research study, School Three had funding, supplies, technology support personnel, and a principal who strongly advocated technology integration. Schools Two and One did not have current equipment, or a school technology specialist to implement ongoing technology staff development and support for teachers. If a technology program is to succeed, there should be a clear vision of technology-mediated education, strong administrative backing, an adequate budget, good supplies and equipment, consistent expectations, and a clear evaluation system. The findings of this study seem to indicate that schools that have technology specialists have a better chance of achieving the integration of technology into the curriculum.

Change carries major ramifications for schools as the use of the technology becomes more prevalent. Knowledge of teachers’ stages of concern, and their knowledge and use of technology in instruction may help planners provide effective staff development activities. This knowledge, in turn, can increase the likelihood that resources committed to instructional computing will lead to successful integration. The Computing Concerns Questionnaire requires sophisticated analyses. Since the SoCC score and TTI score were significantly correlated in this research, the TTI may be useful to schools in order to better plan technology related staff development activities.

The TTI assesses self-reported knowledge and use of technology in the classroom. A typical bubble scan program can be used to produce histograms for the different areas on the TTI. A principal could use the TTI to get a school profile identifying areas where technology training is needed, and individual teachers could receive a profile of their technology competencies in relationship to the whole school. The TTI needs further testing to assess its capability as a tool to assist administrators in planning for staff development. The result could be more appropriate staff
development activities for teachers, and hopefully a corresponding increase in the effective integration of technology into schools.

THE MEANING OF TECHNOLOGY: A MODEL FOR UNDERSTANDING TECHNOLOGY ADOPTION

Yong Zhao
Michigan State University

Sheri K. Rop
Michigan State University

This paper reports on a study that investigated the issue of technology integration from an angle that has been traditionally ignored in mainstream research on educational applications of technology. The fundamental question here is why teachers use or do not use technology. Most researchers have been seeking the answer by looking for external factors and individual differences that lead to the use or non-use of technology. The result is a long list of both internal and external factors, ranging from technical skills to the availability of educational software (Cuban, 1986; Miller & Olson, 1994; US Congress Office of Technology Assessment, 1995). Drawing on a psychological theory known as Perceptual Control Theory (PCT) (Cziko, 1995; Powers, 1973), the present study took a different approach. It sought to understand why teachers use or do not use technology in their teaching by looking into their perceptual world instead of the environment. Rather than trying to identify factors that may be responsible for a teacher's use of technology, this study attempted to depict the mechanism that teachers use to construct and change the meaning of technology for their lives, which then determines whether and how they use technology.

Research Context
Historically, teachers have not responded to technology innovations as enthusiastically as expected by technology advocates (Cuban, 1986), resulting in only spotty instead of widespread uses. As the Office Technology Assessment (OTA) (1995) reports, “despite over a decade of investment in educational hardware and software, relatively few of America’s 2.8 million teachers use technology regularly in their teaching.” Thus in order to achieve universal adoption, substantial efforts are being made to ensure that teachers use technology in their teaching. Essentially, the efforts come in two forms: pressure and training. First, tremendous amounts of social, psychological, and even economical pressure are being applied to both preservice and inservice teachers in the forms of technology competency requirement in certification, technology use as part of performance evaluation for tenure and promotion, and the promotion of the idea that teachers who do not use technology will soon become unemployable (OTA, 1995). Second, teacher preparation institutions, school districts, and businesses have begun to provide a variety of training programs to increase teachers’ technological knowledge and skills (OTA, 1995).

Underlying these efforts is the assumption that if teachers are required and prepared to use technology they will do so. The assumption, however, is not supported by research findings. Cuban (1986), for instance, found that “token compliance is a common response” to mandates that are incompatible with teachers’ goals and beliefs (p. 55). While it is true that training may increase teachers technical skills and understanding of technology, there is little evidence suggesting that increased knowledge and skills result in increased and more effective use of technology. Available evidence suggests the opposite. Technology users are not necessarily more technologically advanced than non-users to begin with (Miller & Olson, 1994). Rather, their knowledge and skills increase as a result of using technology.

The flawed assumption is the result of insufficient understanding of the process whereby teachers interact with technologies. In spite of the widespread recognition of the central role of teachers in the effective use of technology (Cuban, 1986; OTA, 1995), “there has been relatively little research on how and why American teachers use technology” (OTA, 1995, p. 51).

Those few studies which have examined technology and teachers have all invariably taken a “net-casting” approach (Runkel, 1990) in that they attempted to identify and establish an exhaustive list of factors that may affect technology use. The focus is generally on the environment. Cuban (1986), for example, explains “teacher use of machines in classrooms” by examining environmental factors such as school and classroom structures. Researchers for the OTA report suggest that environmental factors such as time, technical support, and system incentives influence teacher use of technology (OTA, 1995, chap. 4). This
approach is problematic in a number of ways. Most serious is its failure to recognize teachers as purposeful human beings who act on their environment to achieve their own goals (Zhao & Cziko, 1996). Drawing upon previous research findings and based on a much under-utilized psychological theory known as Perceptual Control Theory, the present study examined teacher use of technology by looking into the teachers’ perceptual instead of environmental world.

A Perceptual-Control-Theory Perspective on Technology Adoption

Perceptual Control Theory is a model of behavior based on control theory (for details of the theory see Powers, 1973). Essentially, PCT maintains that human beings have internal goals which they strive to reach. As control systems, human beings act to keep their perceptions in synchronization with these reference conditions. We do this by acting on our environment, producing effects which, when combined with prevailing circumstances of the environment, produce the desired perceptions. Human goals are hierarchical. In order to maintain a higher-level goal, it is necessary to vary lower-level goals. In other words, lower-level goals serve as means to achieve higher-level goals (Cziko, 1995; Powers, 1973).

The most important implication PCT has for research on technology adoption is the assumption that the decision to use or not to use technology is completely made by individuals based on the two interwoven concepts which distinguish this model from others: perception and hierarchy of goals. First, focusing on perception, this new model suggests that the decision is the result of subjective rather than objective decision-making processes. An individual will use technology only when it is perceived as a way to achieve a certain goal or a number of goals at a high level. In other words, the use of technology must have clear “benefits.” But while this is a necessary condition, it is not sufficient, because a person may have multiple but conflicting goals at the same hierarchical level. While the use of technology may meet some goals, it can also have “costs”—it can impede or disturb other goals. The individual will then need to make choices based on the importance of the conflicting goals, often factoring in the role of the various goals in achieving even higher level goals (Zhao & Cziko, 1996).

This leads to a disarmingly simple model of technology use: the degree to which a teacher uses technology (or any innovation for that matter) depends upon his/her perception of its relationship to the goals s/he tries to achieve. In other words, teachers judge any change on two dimensions: costs and benefits. For a teacher to use technology, the perceived benefits (potential to meet higher-level goals) must exceed the perceived costs (potential to disturb higher-level goals). For example, although one can learn to access the World Wide Web in about 5 minutes, many teachers believe it would take much more time. That perception can prevent them from using it because taking that time could mean giving up other goals, such as preparing for instruction, meeting with students, or spending time with their families.

“Perceived benefits” imply that whether or to what extent one uses technology depends on personal understandings about whether or to what extent the use of the technology helps meet important individual goals. For example, one of the perceptions that fuels the current push for educational uses of the Internet is that it can engage students in authentic tasks. Unless a teacher believes that the Internet offers a way to more effectively accomplish goals that were already part of her current practice it is unlikely that she will use it. Of course, the use of Internet might be perceived to meet other goals: to maintain the image of being professionally progressive and a life-long learner, for instance. Similarly, “perceived costs” refers to each individual’s perception of the amount of disturbance the use of a technology may cause to other goals.

At this point, we must emphasize that both the construction and pursuit of hierarchy of goals and the process of determining benefits and costs is not necessarily rational and logically carried out. In fact, it is very often intuitive and even irrational. Moreover, costs and benefits are not always physical. They are often psychological and emotional. For example, a teacher may decide to use a certain technology because it enhances a self-conception of being a professional who is on the cutting edge. On the other hand, a teacher may not use technology simply because the possibility of being embarrassed in front of his students by having trouble operating the computer may threaten his self-perception as a competent professional in control of the teaching environment (OTA, 1995).

Research Questions

The issue of central interest in this study, then, is teachers’ perceptions of technology. Specifically, the study was intended to answer the following questions:

1. What are teachers’ perceptions of the educational uses of technology in terms of costs and benefits? Are teachers’ perceptions different from those of school administrators, technology supporting staff, and parents?
2. How do teachers construct their perceptions? What are the sources of these perceptions?
3. In what way do teachers reconstruct and change their perceptions?

Project Description

At the beginning of 1997, the researcher initiated discussions with two local administrators who were interested in helping their schools move forward with technology integration. A project was designed in which a
volunteer group from each school composed of personnel who had expressed interest in learning more about technology would come together four times over a period of four months to interact around the ideas and issues of incorporating technology into their schools and classrooms. The intention of the researcher was that the project would begin with a series of interviews which he and an assistant would conduct with each of the participants. This would be followed by four sessions which would consist of a hands-on activity in which all participants would have an opportunity to experience some interaction with technology assisted by graduate students, followed by a discussion among the participants which would center around the educational possibilities and issues relative to classroom use of that technology. After the completion of the four sessions, the researcher and assistant would conduct exit interviews with all the participants.

The two schools represented widely different educational contexts. Fairview is a middle to upper middle class suburban town approximately five miles from a major midwestern city. The affluence is reflected in the quality of the school system. The test scores, always an important indicator of success for government officials, bureaucrats, and as well as parents and prospective homeowners, are consistently among the top in the state. The middle school itself is a new, clean and attractive building with wide hallways, spacious and seemingly well-equipped science labs, and a library/media center featuring a large glass-roofed reading bay overlooking the lawns. With regard to technology integration, however, the picture becomes complicated. The community has registered its support for technology in the schools by passing a bond issue for approximately 5 million dollars. In spite of the obvious community support, in spite of rhetoric supporting the vital role of technology in education teachers report that the first dollar of the bond money has yet to be spent and the district technology committee has been disbanded. No computers have gone into classrooms; no connections have been wired in. The lack of action by the district administration has caused the teachers to lose hope that the administration is committed to supporting technology advancement.

It is hard to imagine a school more different from Fairview Middle School than the Cultural Resource Center. This elementary school is a magnet school in an urban school district. It enrolls approximately 400 students in K-5. Plans call for adding 6th grade next year and 7th and 8th grade in the two subsequent years. The building is an older square brick structure in a section of mostly neat but very modest homes is being used beyond its capacity and the planned expansion will require either a move or an addition to the present facility. It is not a neighborhood school; students apply to come and are bussed from other areas of the city. Nearly all the students qualify for the government free lunch program. A high percentage of the students are from bilingual homes; many of the families are immigrant families in which the parents speak little or no English. The school prides itself on serving the interests of a multi-ethnic, multi-lingual population in a variety of ways. The name, the Cultural Resource Center is a clear signal that it chooses to present itself as more than just a typical 9-2:30 elementary school. Examples of the broader service mission is the field trip program for parents who are new to the community and perhaps the country and the parent-teacher association whose meetings are conducted with simultaneous translation into 7 different languages. The school includes a computer lab to which all students go at least twice a week. In addition, each classroom has one or two computers. The staff includes a full-time computer person who teaches the classes in the lab and trouble shoots for the teachers' classroom computers.

Participants

The groups

The Fairview group was made up of six teachers, all but one of whom had extensive experience, the library/media person, the school secretary, an assistant principal, two mothers of students, and the principal, Kathy. The teachers in the group were middle class, white, and very confident, exhibiting the independent spirit so often typical of teachers. They generally lived in the community and took pride in the good reputation of the school. They were lively and opinionated. They valued their time and were not hesitant to express whether they felt it was being well used by participating in the project. It was at all times clear that they would not participate unless they felt it were beneficial to them.

The CRC group, in contrast, was composed of two teachers, four paraprofessionals, and the administrator, Gina. The teachers were quite young, having less than five years of experience each. The groups was much more clearly willing to be led by the administrator's goals than the Fairview group. Three of the four instructional assistants were also parents of students in the school and so brought a dual perspective. They all expressed a strong enthusiasm for the school program and an equally strong desire for the school to help their children do more with computers. One said, "I don't want [my daughter] to be held back. I want her to know more than we do in school."

Results

Semi-structured interviews were conducted among 18 teachers, teaching assistants, school administrators, and parents. Each interview lasted from 30 to 40 minutes. While specific questions were not exactly the same for each interviewee, the interviews centered around the following questions, which were designed to support the primary research questions:
1. What do you think about the role of technology in education?
2. In what ways and for what reasons do you currently use technology?
3. What kinds of experiences have you had learning about technology?

Although the groups were considerably different both in makeup and in the school/community contexts from which they came, the attitudes and perceptions revealed by the interviews showed some remarkable consistencies. In examining the data from the perspective of the three questions identified above, issues of costs and benefits surfaced.

These interviews revealed that:

- Teachers, administrators, and parents share a common perception of the use of technology in education at a generic level: technology is useful and compelling. However, perception of the costs and benefits associated with this infusion differed quite widely.

Without exception, all participants were emphatically certain that education needs to bring technology to students. All the teachers felt strong pressure to learn more about technology in order to serve students. This pressure did not come from the school district but from their certainty that technology is an inevitable part of life, will continue to become more important, and “the kids need to learn to use it.” Which technologies, what exactly kids need to know about technology, and what purpose technology expertise will serve in education and life was not clear and did not seem to draw much of their attention. Perceptions of costs and benefits varied quite widely across the participating groups of parents, teachers, and administrators. Perceptions of costs expressed by the administrators tended toward actual financial costs for equipment and training time, and their perceptions of benefits tended to be focused on school or district benefits. For example, the CRC administrator had a goal of having the school develop expertise with video broadcasting:

- A video kind of thing—more collectable kind of thing. It makes it more meaningful if you have something to keep and show. I’d like to see more—a-channel. When we have fiber optics we could broadcast to the district. We could be a resource for the whole district.

Teachers’ perceptions of costs and benefits were primarily focused on the contexts of their own lives, classrooms, and students. All teacher participants who referred to disadvantages associated with technology identified time they would have to take from their already hectic schedules to learn new technologies as the primary and significant cost.

Another difference in perceptions among the groups was revealed by opinions of the “benefits” and “costs” of educational uses of e-mail. Parents viewed it as a valuable tool to have access to teachers. However, several teachers perceived it as potential invasion of privacy and “taking school work home” because they would be expected to respond to any and all parents’ emails.

Each individual in the project had found some small niche of technology use which felt comfortable to him or her and which seemed to provide clear benefits which had meaning for his or her professional life.

This niche functioned as a safe base from which to gradually expand their skills. One teacher at Fairview had found her niche in setting up a computer grading system to which she was very committed as an important tool for developing student responsibility. That such a decision is an interplay of costs and benefits is indicated by the following exchange (R=Researcher, T=Teacher):

R: Grade manager changed your way of grading, expanded your way of thinking about grading?

T: Keeps me on top of it. I look everything over every week. There was some games playing with the students, saying: I didn’t know what my grade was—this makes the kids more responsible. I want to find a program that works better for me, for the extra credit. I’m very quick on keyboarding so its quick to do.

R: Are there any downsides?

T: Duplication. I keep it in a book so it’s double work. The office wants a book. I like to show every piece of work. But the computer does all the calculation. So if the kid says why did I get a zero, the book shows the title of the worksheet.

R: Do many people feel like this is a good idea?

T: I survey the students at the end of each semester... they say they like having access to the grades. I have had some colleagues say they couldn’t get it to work.

A teacher at CRC had encountered an elementary math program and found it fit her goals and teaching style. A teacher at Fairview had found that Adobe Pagemaker transformed her task of developing the student yearbook. Each of these individuals was interested in learning more technology, in expanding on the knowledge and experience he or she had, but in ways related to a self-defined comfort zone. Although the specific benefits perceived by these teachers varied widely, from pedagogical to practical, this method seemed to provide a way to provide a general benefit—increased technology use—while minimizing costs associated with such change.

Teachers were only interested in learning about technology applications which they perceived to have
direct professional or personal application. This finding was clearly connected to the primary cost teachers expressed about technology adoption—the time it takes from their limited resources.

This finding was based on the teachers' comments about the choices they made for the hands-on sessions of the research project, on reports of frustrations with workshops and classes they had attended, and on the difficulty of getting them to engage in theoretical discussions about implications of technology for teaching and learning. One CRC teacher, in response to the focus on developing a technology plan in the research project discussion sessions said:

I understand that we have to create the technology plan for the school. That would be . well I guess that would be a fine outcome, but to be honest, more knowledge about what I could do with my kids now, or how the tech plan will help me figure out what to do in my classroom.

Similarly, although the Fairview teachers were very interested in the hands-on exploration sessions for the purposes of finding out "what's out there" as a research process for discovering classroom resources, they were unwilling to spend time in sessions which they did not believe fit their specific needs.

Teachers valued learning about new technology uses from each other—by observation and through casual conversation and were willing to teach other staff about a technology use which they found personally satisfying.

This attitude seemed to be true of both groups in the project. However, it was much more strongly voiced by the Fairview group. It is interesting that one of the contexts which they reported to be valuable was the ride to and from the university for meetings. This provided a time for informal professional interaction which they had not previously experienced. The CRC group, in contrast, participated in a structured discussion and then went their own ways. It is possible that peer support in technology learning is vital and can occur when time is spent together around technology in non-structured settings. The value of this informal interaction to these teachers is an important finding.

All the teacher participants were willing, even eager, to help someone else learn what they already knew and considered valuable. Nearly all of the participants considered themselves beginners at technology use, but felt that if they new how to do a certain thing it must certainly be easy enough for others to learn and they were willing to share.

Summary

These findings suggest an entirely new model for enabling teacher learning of technology, a model which is teacher-driven rather than district-designed, which is based on making time and resources available for teachers to experiment with technology on their own terms, and which includes finding ways to enable teachers to interact with each other informally about personally satisfying and effective technology uses. Essentially, such an environment should enable teachers to change their perceptions of the benefits and costs of using technology in their teaching.

DIFFERENT COMPUTER ATTITUDES BETWEEN AMERICAN AND CHINESE STUDENTS

Leping Liu  D. LaMont Johnson  Beth Chandler
University of Nevada, Reno University of Nevada, Reno University of Nevada, Reno

Research findings have suggested that students' computer attitudes tend to influence both their learning and achievement (Freedman & Liu, 1996; Liu, 1997) with regard to computer mastery. It has also been shown that students with different ethnic backgrounds have different attitudes toward computers (DeVillar & Faltis, 1991; Freedman & Liu, 1996). As computer education has become an issue in many countries around the globe, the examination of student attitudes relating to computers and their use has become a topic for research. Of particular interest is the examination of possible differences in attitude among students from various countries and cultures. A number of studies have been conducted where American students have been compared to students of other countries (Martin, Heller, & Mahmoud, 1992). There is, however, a paucity of information on this topic relating to Chinese students. It is well documented (Stevenson, 1992; Johnson & Liu, 1996), that the Chinese educational system is extremely unique, particularly in its attainment of high student motivation and exceptional work ethic.

A review of the literature suggests that studies comparing cross-cultural differences in computer attitudes have used a variety of variables to make comparisons. Such variables include: (a) the degree to which students enjoyed using a computer (Cooper & Stone, 1996; Temple & Lips, 1989; King & Bond, 1996), (b) the degree of motivation students have to learn and use the computer (Kellenberger, 1996; Clarian, 1993), (c) the extent to which students see learning and using the computer as important (Pelton & Pelton, 1996; & Corston & Colman, 1996), and (d), the degree to which students experience anxiety while using a computer (Liu, 1997; King & Bond, 1996; Ayersman, 1996). The literature suggests that all of these variables are related to student learning with and about computers.

For purposes of this study, four variables have been identified from the literature. The four variables are: (a) enjoyment, (b) motivation, (c) importance, and (d) freedom from anxiety.

In this study, American and Chinese students were compared on these four variables. These four variables were also employed as the predictor variables in detecting the relationships between attitudes toward computers and computer achievement for both American and Chinese students.

The following research questions were posited in this study:

1. Is there any difference between American and Chinese students' attitudes toward computers?
2. Is there any difference between American and Chinese students' attitudes toward using computers when attitude is broken down into the four aspects we are defining as variables: enjoyment, motivation, importance, and freedom from anxiety?
3. What relationship exists among the four aspects of computer attitudes with respect to American and Chinese students' computer achievement?
4. Which of the four aspects of attitude most influence the computer achievement of American and Chinese students?

Based on the findings of previous research, it was hypothesized that questions one and two would be answered in the affirmative—differences would be found. It was further hypothesized that a linear relationship would be found among the four aspects of attitude when question three was investigated. Finally, it was hypothesized that a definitive answer to question four would be provided (i.e., at least one of the four aspects of attitude would have a significant influence on computer achievement).

Method

Subjects

The American subjects in this study were 208 teacher education students enrolled in the College of Education at the University of Nevada, Reno. These students ranged in age from 18 to 53 (the average age was 24.29). Of these students, 138 were female and 70 were male. The Chinese
subjects included in this study were 210 teacher education students in a middle China teacher education college. They ranged in age from 20 to 33 (the average age was 23.58). Of these students 112 were female and 98 were male. Most of the American students and all of the Chinese students had no computer experiences.

Instrument
The instrument used in this study was derived from Aiken’s (1979) Likert-type questionnaire consisting of 24 statements designed to measure the four attitude variables described above. The instrument has been shown to be a valid way to measure each of the four variables independently (Aiken, 1979).

Final scores in a basic computer technology course comprised the measure of computer achievement for both American and Chinese students. The American and Chinese courses covered the same basic topics. The topics covered in the two courses included: Windows95, word processing, telecommunications, multimedia, hypermedia, World Wide Web, spreadsheets, and databases.

Data Analyses
A repeated measurement procedure was employed to examine the difference between American and Chinese students' attitudes toward computers as reflected by four variables: enjoyment, motivation, importance, and freedom from anxiety. These four variables represented levels in the data analyses. Multiple regression analyses were conducted to test the relationships between computer attitude and computer achievement for both American and Chinese students. For both the repeated measurement and multiple regression analyses, the assumptions were checked and no significant violation of the assumptions was found.

Results

Repeated Measurement

The repeated measurement compared the attitude scores of the two groups of students—American and Chinese (referred to as TYPE in Table 1)—on the four variables considered levels in this analysis (referred to as ATTI in Table 1). Based on Aiken's information criterion, the CS (compound symmetry) was the appropriate type for this analysis. So, the Fixed Effects table was used (Table 1).

The interaction effect is significant ($F = 15.58, P > 0.0001$). Results show that the mean score of American students and the mean score of Chinese students at the enjoyment level is different from that at the importance level. The mean score of American students and the mean score of Chinese students at the freedom from anxiety level is different from that at the importance level. The mean score of American students and the mean score of Chinese students at the motivation level is different from that at the importance level.

These results also show that significant differences were found between American students and Chinese students at the levels of enjoyment ($T = 2.84, p > 0.0046$), freedom from anxiety ($T = -2.26, p > 0.0237$), and motivation ($T = -3.06, p > 0.0023$); and no significant differences were found between American and Chinese students at the importance level ($T = 0.48, p > 0.6298$). The positive $T$ value (2.84) indicates that American students had higher mean response scores at the enjoyment level than Chinese students. And the two negative $T$ values (-2.26 and -3.06) indicate that Chinese students had higher mean response scores at the freedom from anxiety level and motivation level than American students.

Multiple Regression Analysis I: American Students

In this multiple regression analysis, enjoyment (X1), motivation (X2), importance (X3), and freedom from anxiety (X4) served as the predictor variables, and the response variable was computer achievement. The data collected from American students were analysed to detect the relationships between the four computer attitude variables and computer achievement, and to examine whether the attitude variables can be used to predict computer achievement. The multiple regression analysis shows:

1. The overall model is significant $F = 162.446, p < 0.0001$, indicating that at least one of the four predictor variables has a linear relationship with, or has an effect on, the response variable. The $R$-square value is 0.7756, indicating that approximately 77% of the variation in computer achievement can be accounted for by the variation in the four attitude variables.

2. The $F$ ratio for the linear trend is significant ($F = 159.2, p < 0.0001$), indicating that all the linear terms (X1, X2, X3, X4) should be included in this model. The quadratic trend and crossproduct are not significant; therefore, there was no need to test other quadratic and crossproduct terms.

3. The $t$ statistics for the four variables are: $X1\, t(= 5.548, p < 0.0001)$, $X2\, t(= 4.110, p < 0.0001)$, $X3\, t(= 2.033, p < 0.0434)$, $X4\, t(= 1.601, p < 0.0001)$. All four of the $t$ statistics are significant, indicating that all four variables have linear relationships with, or have effects on, the response variable. In other words, each predictor variable has an effect on computer achievement in the presence of the other three variables.
4. The $F$ ratios testing the contribution of each variable are: $X_1 (F = 6.116, p < 0.0001)$, $X_2 (F = 3.846, p < 0.0025)$, $X_3 (F = 1.453, p < 0.2074)$, and $X_4 (F = 27.026, p < 0.00001)$. The $X_1$, $X_2$, and $X_4$ contribute significantly to the variation of computer achievement.

The order of the contribution of the four variables is—
from the most important to the least important—$X_4$ (freedom from anxiety), $X_1$ (enjoyment), $X_2$ (motivation), and $X_3$ (importance).

5. The resulting regression equation is:

$$Y = 27.9589 + 0.7879(X_1) + 0.5557(X_2) + 0.2334(X_3) + 0.9843(X_4)$$

**Multiple Regression Analysis II: Chinese Students**

This multiple regression analysis examined the relationships between Chinese students’ computer attitudes and their computer achievement. Enjoyment ($X_1$), motivation ($X_2$), importance ($X_3$), and freedom from anxiety ($X_4$) again served as the predictor variables, and the response variable was computer achievement. The analysis shows:

1. The overall model is significant $F = 198.961, p < 0.0001$, indicating that at least one of the four predictor variables has a linear relationship with the response variable. The R-square value is 0.7981.

2. The $F$ ratios for the quadratic trend and crossproduct are significant ($F = 19.279$, and $5.356$ respectively, $p < 0.0001$). The quadratic term $X_2$ and the crossproduct termed $X_1X_2$, $X_2X_3$, and $X_3X_4$ were shown to be significant at the 0.05 level. And, these four terms will be included in the model with the four linear terms $X_1$, $X_2$, $X_3$, $X_4$.

3. The $F$ ratios testing the contribution of each variable are: $X_1 (F = 14.440, p < 0.0001)$, $X_2 (F = 12.634, p < 0.0001)$, $X_3 (F = 6.876, p < 0.0001)$, $X_4 (F = 13.677, p < 0.00001)$. The $X_1$, $X_2$, $X_3$, and $X_4$ variables all contribute significantly to the variation of computer achievement. The order of the contribution of the four variables is—
from the most important to the least important—$X_1$ (enjoyment), $X_4$ (freedom from anxiety), $X_2$ (motivation), and $X_3$ (importance).

4. The resulting regression equation is:

$$Y = 25.6937 + 6.6949(X_1) + 7.2177(X_2) + 3.3038(X_3) + 2.2062(X_4) - 0.2435(X_1X_2) - 0.2600(X_2X_3) + 0.1426(X_3X_4) + 0.1113(X_2^2)$$

**Conclusions**

The research hypotheses set forth in this study were validated. American students and Chinese students differ in their attitudes toward using computers in terms of the degree to which they enjoy using computers, feel free from computer anxiety, and feel motivated to learn about and use computers. American students had a more positive attitude toward computers than Chinese students when the degree to which they enjoyed using them was assessed. However, Chinese students were more positive than American students about the degree to which they felt motivated and the degree to which they felt free from computer anxiety. There was no difference between American and Chinese students in terms of the degree to which they felt learning to use computers was important.

For both American and Chinese students, the four attitude variables—enjoyment, motivation, importance, and freedom from anxiety—can be considered variables in predicting computer achievement. Consistent with previous research findings, motivation and freedom from anxiety were found to have at least a linear relationship with computer achievement, and a positive effect on computer achievement. This study demonstrates enjoyment and importance also have linear relationships with computer achievement. Among the attitude variables explored in this study, freedom from anxiety and enjoyment were found more important than the other three. When a person is highly motivated to learn to use a computer, does not feel anxious about using the computer, or is aware of the importance of learning to use the computer, it is evident from this study that the chances are increased that that person will benefit from computer instruction and learn to use the computer well. The connection between enjoyment and achievement, as shown in this study, is of high interest since it suggests the enjoyment of using a computer will affect achievement even more than motivation and sense of importance. Previous studies on computer attitude rarely treated enjoyment as a variable, or quantified its influence on computer achievement. This finding has important ramifications for those who design and implement computer training programs. It is perhaps not an oversimplification to say that, when it comes to learning to use computers, students will learn best when they enjoy their learning experience.

When the Kentucky educational system was declared unconstitutional in 1989, the state Supreme Court mandated revisions to the entire system of public instruction. The resultant reforms included major changes in curriculum (including assessment and accountability), governance, and finance. To address the technology initiatives, the position of District Technology Coordinator (DTC) was created in each of the 176 school districts. Because of the rapid development of the position and the varying needs of individual districts, there are no certification requirements or specific guidelines for the selection or retention of coordinators. Similarly, districts were not provided specific guidelines regarding job responsibilities, performance criteria or assessment measures.

As educational technology becomes more complex, the qualifications to be a successful technology coordinator are beginning to generate discussion. Moursund (1992) asserts that the technology coordinator holds a leadership position and as such deals with three major components for instructional use of computers: learning and teaching about computers; integrating computers as a tool; and using the computer as an instructional medium. Additionally, a major role of the technology coordinator is to facilitate appropriate uses of technology through the design and implementation of staff development (Moursund, 1992).

Methods

This exploratory study used a mixed-methodology design to examine the various roles and responsibilities of Kentucky district technology coordinators. A researcher-developed survey and personal interviews provided data on various responsibilities and DTC perceptions.

All district technology coordinators (DTCs) from Kentucky (n=192) were targeted for the first two parts of this three-fold study and were mailed a research packet. While there are only 176 school districts in the state, the list generated by the state Department of Education named two persons as DTC in thirteen instances and included two state schools. Thus 192 names were listed for 176 districts.

Volunteers for the interviewing phase were selected based on schedule availability. A total of sixteen DTCs completed the entire interviewing phase of the study.

Data Collection Procedures

Each survey packet included a standard cover letter explaining the purpose of the study and the importance of his/her participation; the researcher-developed questionnaire; a self-addressed, stamped return envelope for the completed questionnaire; a self-addressed, stamped postcard for participants to indicate interest in volunteering for the interview phase; and a page of common symbols as a thank you for completing the survey. An initial and one follow up mailing resulted in 112 representing 58.3% return rate. District participation was at 68% (111 of 176 school districts responded).

Interviewees participated in individual, one-hour sessions either face-to-face, by telephone or through electronic mail. Five face-to-face interviews were held with DTCs in March 1997. All telephone interviews were held in late March or early April 1997. E-mail communications were on-going throughout the months of March and April 1997, as participants would respond to 1 or 2 questions at a time. The interviewer clarified points before sending the next question. Seven DTCs began the e-mail interviews and five completed all questions. Reasons for not finishing related to other job duties. For instance, during the interview phase, one DTC had to divert attention to the state assessment process.

Data Analysis

Quantitative and qualitative data were gathered simultaneously and analyzed both inductively and deductively. For instance, frequencies, percentages and correlation attributes were obtained from quantifiable survey and interview responses. Qualitative data were analyzed for themes and patterns that were used to clarify descriptive information from the survey and provide a richer explanation of the DTCs' perceptions regarding their position.

Quantitative data were subjected to descriptive statistics and the Pearson Product-Moment correlation
techniques. Frequencies and percentages were generated to describe related demographic data obtained through closed-ended items. A measure of the relationship between the demographic information and answers to survey items related to change were also analyzed to determine if any statistical relationships exist. Open-ended responses were grouped according to consistency of responses and used to support emerging themes.

**Findings**

Of responding DTCs, 66% were male and 30% were female. Most respondents, 73%, reported working in a rural school setting, as compared to 23% in urban settings. The average number of students in the school districts was 3398, with a median of 2100 and a mode of 2500 students.

Approximately one third of respondents hold a masters degree (31%) and another third have completed at least 30 hours beyond the masters. Of the respondents, 22% have taught one of more college classes, and approximately 56% have experience teaching in middle school, high school, or both.

The average number of years of teaching was almost 16. Nearly 13% have no teaching experience, or even teacher certification. Nearly half of all respondents had previous administrative experience. The average term of service as DTC was 4 years, and most have worked with instructional technology for an average of 8 years. Still, only 7% of respondents hold Novell certification.

Two of the most frequently identified professional development needs relate to the use of technology in the schools (64%) and a need to learn more techniques for training school personnel (61%). Likewise, 57% of respondents expressed a need for training in the selection of appropriate academic software, and nearly one-half indicated a need to receive more training in the maintenance of hardware. The uses of assistive technology, learning more techniques for evaluation and assessment and learning how to plan collaboratively were also frequently requested professional development needs.

Most DTCs are solely responsibility for completing the district technology plan, overseeing the budget, and make purchases. Most DTCs report being solely responsible for the technology spending, purchase orders, tracking, inventory control and planning for future expenses. When asked to specify the most important or critical decisions they were responsible for making, responses clustered in the planning stages. Purchasing equipment and spending money wisely for future needs were the most commonly mentioned critical decisions. Interestingly, there was a positive correlation among respondents holding Novell certification and high ratings given in the areas of purchasing equipment (significant level .0117) and planning for future expenditures (significant level .0253).

Consultation and problem-solving with teachers and administrators was typically rated as very important. Troubleshooting hardware and software problems also received particularly high ratings, with a mean of 3.5, a median and mode of 4, on a 1-4 scale. Gathering and assessing information was viewed as very important, but communicating information to administrators, conferences with teachers, completing state reports and systematic assessment were viewed as only somewhat important.

According to DTCs, there appears to be no standard means for measuring and evaluating computer progress within school districts.

DTCs are eliciting change through training activities, which occupies an average of 17 hours per month. Among the activities rated as very important or absolutely essential include communications with staff and workshop offerings. Observing the use of technology in the classrooms, clarifying misconceptions and training cadre groups were viewed as somewhat important or very important. All interview participants devoted at least two days per year providing technology in-service workshops. Several DTCs referred to previous years in which up to 21 days of training was provided in an effort to prepare the staff for the new technologies. Many DTCs indicated shift in their training methods to more one-on-one and small group sessions, often conducted in the classroom setting. There was an inverse relationship between Novell certified individuals and significance attributed to conducting workshops with school staff (significance level .0281) and modeling uses of technology to school staff (significance level .0128).

Several DTCs stressed the importance of keeping their Boards of Education informed of the technology needs and progress, since many districts are exceeding state financial allotments to provide more technology to the schools. However, communication with parent groups and presenting at conferences were viewed as only somewhat important.

Insufficient time was the greatest obstacle encountered by 70% of the respondents. The most time consuming activities were technical responsibilities, financial planning and administrative tasks. Additional job responsibilities tended to interfere with completing maintenance activities in a timely fashion.

Several districts have additional, designated staff to provide technical support. However, 34% of respondents indicated that additional technical support was needed. There were no identifiable patterns found based on size of district, gender, classified or certified position among districts that currently have additional support personnel.

Most DTCs were involved in some type of professional group such as the Kentucky Association of Technology Coordinators (KATC). Overwhelmingly DTCs attribute their success to the services of the KETS (Kentucky Education Technology System) engineers (60%) and KETS regional coordinators (37%).
When asked to specify the most important qualifications of a DTC respondents identified three: educational background, technical background, and good people skills. There was nearly a total consensus for higher education to provide additional technical training. The exceptions to listing technical training came from classified personnel, who listed "hands on" experiences as necessary for higher education to consider in their programming. Additionally, DTCs express the need for higher education to improve the training of teachers and administrators in the use and integration of technology into the curriculum.

**Summary and Implications**

As educational technology becomes more complex, schools are creating leadership positions to assist in its implementation. However, the position of technology coordinator evolved at such a rapid pace, the selection of appropriate individuals and support needed to ensure success, has been difficult and resulted in inconsistencies in services.

The persons presently serving as DTCs in Kentucky expressed frustration with the lack of time to perform duties, as well as the need for higher education agencies to provide more for teachers and principals in the use of technology. Similarly, the most frequently identified professional development activities relate to school-based concerns. Specifically DTCs expressed a need for greater education regarding the use of technology in schools, a desire to learn more techniques for training school personnel, and a training in the selection of appropriate academic software. Similarly, the inconsistencies in responses related to consultation activities indicated a need for greater clarity in expectations for the integration of technology into the curriculum.

Kentucky has made an attempt to create equity through the use of systemic reform. The success of the reform is dependent on implementation in every Kentucky school district. While it is not clear how this will best be achieved, Kentucky has made an attempt to provide supports to schools. Leading the way in the implementation of technology upon school districts are district technology coordinators. This study offers baseline demographic and descriptive data which may assist those responsible for developing evaluation procedures, certification requirements and developing professional development activities. Furthermore, clarity in job duties, responsibilities and expectations offer a greater chance of success to schools.

A Statewide Evaluation of the Impact of Technology Integration

Debra Dirksen
Idaho Dept of Education

David Coffland
Idaho State University

Christine Bauer
Boise State University

Sarah Naylor
University of Idaho

Over the past four years schools and districts in Idaho have received $41.2 million in state funds from the Idaho Legislature for the integration of technology into the curriculum. This is an average expenditure of $168 per student over the past four years. During the fall of 1997, research was gathered from a cross section of Idaho’s school district and teachers. From this research, it is graphically apparent that Idaho has reached the point of “critical mass” for full-scale integration of technology into the curriculum. Teachers have taken the initiative of expanding one or two ideas into a plethora of ways to use technology in their classrooms and curriculum to challenge their students. Because of this increased interest, many teachers are using personal funds to purchase software for their classes. They are “scrambling” for access to any technology including “old” equipment. Three or four computer generations are found in classrooms – teachers are repurposing outdated technology to fit a particular need. Schools with computer labs are finding that they are completely booked throughout the school day and many classes wishing to use it find access impossible. Based on the data gathered as part of this report, teachers and administrators are reporting the following as the greatest benefits derived from this funding:

- School libraries are enhancing and greatly expanding their collections by providing increased access to current research via the Internet.
- Teachers are involving students in research which benefits not only the student but also the community. Students are conducting active research and presenting that research to local school boards, corporations, international and national conferences, and other community groups who are listening to them as they would to experts.
- Teachers are using “drill and practice” software to strengthen basic skills, enabling students to better understand the transition to more complex concepts.
- Teachers are using programs such as Accelerated Reader to build student’s reading skills, to provide students with optimal challenges in their reading choices, and to assess reading ability.
- Districts are building a larger educational community by giving students and teachers access to the Internet and e-mail.

This article details and syntheses the data used to derive these benefits and other impacts that the integration of technology is having on Idaho’s teachers and students.

The methodologies used for data collection are described, and results detailed, in the following sections.

Methodology

Eight questions formed the focus of this study:

- How have districts used the technology funds allocated to them by the state?
- What technology hardware and software have the districts purchased?
- What training have teachers received relevant to the integration of technology into the curriculum?
- What technology related skills have teachers acquired?
- How are teachers using technology within the classroom?
- What technology related skills have students acquired?
- How have students used the technology skills acquired to problem solve, do school work, and address real-life situations?
- What impact has the integration of technology had on student performance?

Data have been collected to answer these questions from a variety of sources including, but not limited to: the annual application for state technology funds submitted by districts, district budget reports to the Idaho Financial...
views with K-12 educators, classroom observation, and Accounting Report Management Systems (IFARMS), university reports to the State Board of Education, interviews with K-12 educators, classroom observation, and surveys. The state and university reports were used to answer the first three questions listed above. To investigate the remaining five questions, a sample of just over half of the districts in the state were selected, from those districts one or more schools were also randomly selected to participate. Five to ten teachers were randomly selected from each school and asked to participate in a Level of Use Interview, as well as to complete a survey regarding the impacts of technology integration; only five of the teachers selected at each site were interviewed and surveyed. In total, 80 schools from 67 districts participated in the evaluation and 378 teachers were interviewed, 98% (372) of those teachers completed an Impact of Technology Integration Survey (hereafter referred to as the impact survey.) The results of that study as well as the results gleaned from the districts Technology Grant Application and Progress Reports for 1996-1997 are presented in this report.

The Level of Use Interview is one element of the Concerns-Based Adoption Model (CBAM), a model that was developed, in the 1970s to assess, facilitate, and evaluate change. The Level of Use interview has a 98% correlation with observation (Hall & Hord, 1987). The CBAM model provides a strong tool for evaluating implementation efficiently and effectively. Department of Defense schools, industry, and other state agencies are actively using CBAM to evaluate and facilitate the change process. From university reports we can determine the number of teachers who have been trained; CBAM allows us to assess the degree to which teachers have implemented this training. The impact survey which was administered contained questions regarding the impact of technology integration into the curriculum. The statements to which teachers were asked to respond addressed the quality of student work, learning behaviors, teaching with technology, communication with parents and students, interactive classroom organization, student technology skills, and student-interaction. The purpose of the survey was to assess teacher perception of the impact technology is having on student learning, development of technology skills, achievement, and on the teacher’s teaching pedagogy. The procedures followed in this study allows us to create a profile which reveals the degree to which technology is being used to instruct the students of Idaho and what impact that it is having on their learning.

Population

This report relies upon multiple points for the collection of data: the Technology Grant Application and Progress Report for state technology funds, university reports to the State Board of Education, Level of Use Interviews, and an impact survey completed by a stratified random sample of teachers. Most of the schools (572/672) and 111 out of 112 districts within the state provided information included in this report when completing their Technology Grant Application and Progress Report for 1996-1997. Included in this application were a written inventory survey, a standards checklist, responses to goal congruence, and a budget report. A stratified random sampling procedure was used to select participants in a more detailed study, described above, which focused more directly on the impact that technology integration is having on teachers and students.

As stated previously, participants in the impact study were selected from more than half of the districts in the state; at least half of the districts in each region were included in the study. The participants selected from the districts ranged in age from 23 years to 63 years with the greater part of the sample, 38% (142), being between the ages of 46 and 55; 66% (246) of the sample were female and 34% (125) male, and were largely Caucasian in ethnicity (99% or 368). The number of years teaching ranged from first year teachers to those with 38 years experience. The sample was split more or less evenly between secondary (47% or 175) and elementary (53% or 197) teachers. Secondary teachers were drawn primarily from the core content areas: math (21% or 36), science (27% or 47), English (30% or 52), and social studies (21% or 36). Sixty-eight percent (254) of the teachers held a bachelor’s degree, 26% (96) master’s degrees, and just over one percent (3) have acquired a doctorate or specialist degree.

Results

During the 96-97 school year, districts again expended the majority of their state technology funds for capital objects, including computer hardware, software, networking equipment, telecommunications equipment and other audio-visual related items. Primary among these expenditures was computer hardware. Their expenditure of “in-kind” funds totals $17.2 million. The expenditure of these funds mirrors those made with state-technology dollars. Again, the majority of funds have been used to support the purchase of capital objects in the form of computer hardware. Districts are gaining better access to technology for their students and teachers.

The ratio of students to computers has gradually improved over the last three years. Within the past year, Idaho has finally achieved a 5:1 student to computer ratio, however only 58% of these computers are multimedia ready. When comparing the ratio of students to multimedia ready computers, the ratio is 9:1.

Connectivity has also improved; districts are becoming increasingly connected, both within the districts as well as the outside world through the Internet. Over 76% (435) of
the schools report having a Local Area Network (LAN), averaging two LANs per district. An increasing number of schools, 59% (340), report that their district has developed a Wide Area Network (WAN) to connect buildings to the district office. The majority of the schools reported that they have access to the Internet (84% or 479). To obtain access to the Internet, 51% (292) of the schools reported having a direct link, while 31% (128) reported relying on dial-up services.

An increasing number of teachers are becoming technologically literate through training offered by the universities, district inservice and professional development programs, and informal training opportunities available in their schools. In the district technology applications, 72% (408) of the schools reported that their districts included professional development days as part of their school calendar. Schools reported a varying amount of in-house training ranging from 0 hours to over 500 hours of instruction per school year.

The configuration used by the teacher to integrate technology within the curriculum as well as the teacher’s level of use determined, to a great extent, the teacher’s perceptions as to the types and degree of impact that technology was having on their students and on their teaching. The degree of access that teachers have to technology also influenced the teacher’s view of the impact that technology is having on their students and their teaching. Access also influenced the teacher’s level of use and the primary configuration they used for integrating technology into the curriculum. Those who had a lab available to them were more likely to report that technology was having a positive impact on their students and on their teaching. They were less likely, however, to report that students were developing technology skills such as those associated with word processing, spreadsheets, databases, presentation packages, or authoring systems.

In the following paragraphs, each area of impact will be directly discussed: learning behaviors, quality of student work, interactive learning, teaching with technology, student technology skills, student-interaction, and communication with parents and students. The influence of the teacher’s level of use and the configuration that they were using to integrate technology into the curriculum will also be addressed.

Learning Behaviors

The statements posed in the survey, regarding the learning behaviors exhibited by students, focused on the skills related to self-regulated learning and other behaviors associated with being a “self-starter.” In most cases, 50% or more of the teachers “agreed” or “strongly agreed” that technology was a positive influence. Teachers who were identified as refining their use of technology in order to have a greater impact on their student’s learning were more likely to respond positively to these questions, as were those using a generative or drill and practice model for integrating technology within the curriculum. Those using the computer primarily as a resource tool tended to respond negatively to these questions, expressing the belief that technology was not impacting their student’s learning behaviors.

Quality of Student Work

Statements regarding the quality of student work focused on the actual quality of assignments being completed for the class. The object in asking these questions was to determine whether or not technology was having a positive effect on the attention students paid to their written work. Again, responses were largely positive, with more than 40% of the respondents agreeing or strongly agreeing with the statements posed. Those teachers using a generative model for integrating technology within the curriculum were more likely to agree or strongly agree with the statements.

Interactive Learning

The statements regarding concepts related to interactive learning focus on those instructional processes that directly involve the student with the learning process. The focus of instruction is placed on the student and increasing the student’s role in the learning process. In most cases, more than 50% of the respondents agreed or strongly agreed with the statement. An interaction between level of use and configuration seemed to have some effect on the responses given to these statements, however no particular group was more likely to respond positively or negatively to the statements.

Teaching with Technology

A clear majority, 63%, or 235 of the respondents, declared positively that the computer has become a learning tool in their classroom. In response to these statements relative to teaching with technology, teachers created a picture about their use and comfort in using technology. Statements centered around using technology to design improved opportunities for learning and authentic assessment, increased enthusiasm for teaching, sharing ideas for integrating technology with colleagues, using a greater variety of teaching strategies, making content more relevant to students, and greater access to outside resources. Again responses were largely positive. In most cases, more than 75% of the respondents agreed or strongly agreed with the statement.

Those refining their use of technology or collaborating with other teachers to increase the impact of technology on their students were more likely to respond positively to questions regarding the use of technology to facilitate teaching and learning. Interestingly, those who had achieved a “routine” level of use and were no longer expanding their use of technology did not respond as...
positively to these statements. They seem to have achieved a plateau in their use of technology and did not perceive the need to increase their ability and knowledge to use technology effectively with their students.

**Student Technology Skills**

Students are gaining skills with the word processor, database, spreadsheet, authoring systems, and presentation programs. Configuration and level of use had a strong effect on the teacher's perception of the development of student technology skills. Those teachers using a generative model for integrating technology within the curriculum and teachers refining their use of technology were more likely to respond positively to these statements. Teachers at a mechanical level of use or using a drill and practice or resource model for integrating technology were more likely to respond negatively. The development of technology skills seems to be strongly tied to being given the opportunity to work with these application programs. A generative model typically emphasizes the use of application software.

**Student Interaction**

The statements included in this category focused more on using the student as a resource in the classroom. By giving students opportunities to teach other students and to work collaboratively with other students, teachers are giving students an opportunity to assume the role of the teacher. It is understood that when a student has to explain a concept or procedure to their peers, they tend to gain a greater understanding of that concept or procedure. Statements referenced peer tutoring, facilitating student to student interaction, and using students as a resource for working with the computer. More than 50% of the responses to these statements were positive. Teachers using technology primarily as a resource were more likely to respond negatively to these questions. Those using a generative or drill and practice model for integration into the curriculum were more likely to respond positively.

**Communication with Parents and Students**

Those statements that refer to communication issues include references to using electronic media to communicate with students and parents, keeping grades electronically, and communicating with parents more frequently. The purpose for including these statements was to determine if technology allowed teachers to communicate more frequently with parents and students. A smaller percentage of the responses were positive for this factor, however, more than 30% indicated positive response. This could be an indication that our communication tools (e.g., e-mail) are less extensive than other technologies.

Those teachers refining their technology skills were more likely to respond positively to these statements. Those using a drill and practice model for integrating technology within the curriculum and those using technology as a resource, however, were more likely to respond negatively. Teachers who are expanding their use of technology and using a generative model for integrating technology seemed to be more open to the possibility of using it as a tool for communication.

The teacher’s level of use and configuration had strong effects on their perceived impacts of technology and, therefore, probably an effect on the actual impact technology is having on student performance and the teacher's teaching style. Those achieving greater levels of impact were those teachers still striving to refine their use of technology. Their focus in refining their knowledge and skills is having a greater impact on student learning and achievement. Those with this focus, whether working individually or collaboratively, are achieving greater success with their students and on their teaching. Their students are submitting higher quality work, exhibiting self-regulated learning strategies, and developing technology-related skills. These teachers also see themselves as using technology as a teaching tool, increasing student interaction and interactive learning, and facilitating communication with parents and students. These impacts are increased when the teacher is also following a generative model for integrating technology with the curriculum.

The study shows that students using technology as a tool for learning are receiving greater benefits.

**Summary**

The Idaho legislature has created conditions in Idaho schools that verge on a burst of expansion. From what this researcher has seen the last few months, Idaho has reached critical mass for full-scale integration of technology within the curriculum. Teachers have been provided just enough technology and information to start; they have replicated this knowledge into more ideas for effectively using and integrating technology into their curriculum.

The computer is an adaptable and versatile tool, in essence, an educational Swiss Army knife. While it is an important tool, it is but one of many tools. When used appropriately technology can be a very effective tool. Some of the effects that the integration of technology is having on Idaho's students and teachers have been described in this report. Of primary importance are the following impacts, which were reported by the teachers interviewed:

- Technology is helping to foster positive learning behaviors and self-regulated learning strategies in students
- The quality of student work is improving through the integration of technology by teachers.
- Interactive learning is being fostered in classrooms where technology is being integrated.
- Teachers reported using technology as a teaching and planning tool.
Students are developing technology skills associated with application software such as word processing, spreadsheet, database, or presentation programs.

Interaction between students and collaborative learning is being fostered in classrooms where technology is being integrated.

For many schools, technology has expanded the amount and range of resources available to them. Technology has enhanced many school libraries to a great extent.

E-mail is being used to facilitate communication between educators, parents, and students. Expanded electronic communities are beginning to grow.

AUTHENTIC ASSESSMENT OF COMPUTER COMPETENCIES: THE TECHNOLOGY COMPETENCY PROFILER (TCP)

Henry D. Dobson
Bloomsburg University

The report, "Technology and the New Professional: Preparing for the 21st Century Classroom", recommends the integration of technology into teacher education programs. These recommendations should also apply to in-service teacher staff development programs. This report describes the technology skills and knowledge that must be acquired by the new breed of professional teachers to be competent and effective users of educational technology.

Today, teachers need to understand the impact that technology is having on the world of work, communication, and the acquisition of new knowledge. Teachers must realize and recognize that information can be accessed through a variety of media resources. Technology can help find, organize, and evaluate this information. Information can be compared and reviewed critically using a number of technology-based resources. A new breed of technology competent professionals have the power to change the world of teaching and learning. Technology, like the printing press, has the power to change the way students see and understand our world - our universe. Its users must be competent to harness that power and create effective learning environments.

Technology Competencies

A growing number of states and institutions have adopted standards or competencies relating to professional educators and their ability to know and utilize technology in the teaching and learning processes. In order to meet these standards, teachers must provide evidence that they can use computer technology for solving problems, collecting data, managing information, communicating with the outside world, creating effective presentations, and making informed decisions. They should be competent in creating, preparing, and producing visual instructional materials that support the current curriculum at their grade level or within their subject area. Some organizations require a real-time demonstration of these skills, however, this would be very time consuming for administrators or instructional technology specialists to enforce. To meet this need for evaluating the technological competency of educators, the Technology Competency Profiler (TCP) was developed. This self assessment tool provides the individual with a quantitative evaluation of their knowledge of technology and the necessary skills to apply them in their classroom environments. The Technology Competency Profiler (TCP) is updated every three years to incorporate new concepts and skills.

The Technology Competency Profiler (TCP) is an authentic assessment of technology competencies that must be either documented or demonstrated by preservice or in-service teachers. These competencies are embedded in a 100 statement questionnaire ranging from basic skills and knowledge to a sophisticated use of multimedia in a classroom presentation. Each statement must be true for all criteria to be considered acquired. The following statements are examples taken from the TCP.

Technology Competency Profiler (TCP)

- In a computer Operating System, (i.e. MS-DOS, Windows, Mac OS), I can change the system prompt or desktop configuration. (E)
- In a spreadsheet application, I can paste, edit, and move spreadsheet files into a word processing document. (E)
- Using an appropriate software application, i.e. Powerpoint, MacPaint, Super paint, I can design templates, color schemes, and graphs to produce a professional presentation. (I)
- Using the Internet, I can create, maintain, and delete bookmark entries, perform searches, receive files from remote locations, enter new URL’s. (I)
- Using an appropriate software application, I can create, save and edit a Home Page on the Internet. (I)
- Using current software, I can produce a plan to integrate tutorials, simulations, and problem-solving programs into a course of study. (I)
- From available resources, I can prepare a report that describes at least two successful projects associated with staff development and teacher education to ensure continual teacher computer competency in the classroom. (A)
- I can plan and produce a multimedia presentation. (I)
• I can use and evaluate a distance learning system that includes computer, audio and video conferencing. (A)
• I can list at least three strategies using educational technology in a variety of authentic educational settings. (A)

(E) ENTRY —— (I) INTERMEDIATE —— (A) ADVANCED

Assessing Competency Levels

A scoring sheet for all of the statements allows preservice and in service teachers to evaluate their level of technology skills and knowledge. In addition, recommendations are provided for those individuals scoring below the satisfactory level in the three performance groups.

On the questionnaire’s scoring sheet a one (1) is placed next to each Yes response to the statements containing the technology competencies. There are three columns of statement numbers associated with each level: Entry, Intermediate, and Advanced. Add up the ones (1) in each of the columns and compare the scores at each level with the following evaluation and recommendations.

For each category, 0-15 points is Unsatisfactory; 16-20 points is Below Average; 21-29 points is Average. For the Entry-level category, 30-33 points is Good. For the Intermediate-level category, 30-32 points is Good. For the Advanced-level category, 30-35 points is Good.

Summary

A review of the different levels and degrees of competencies found on the evaluation sheet related to the knowledge and skills in educational technology would provide the guidance for immediate or future staff development projects or course work in this field. A score below 21 points at the Entry-level might suggest some missing basic components, and a self study of reference books or basic undergraduate or graduate course work might help fill in the missing competencies at this level. A score below 21 points at the Intermediate-level indicates that more advanced applications of technology have not been mastered, and if they are to be incorporated into a teaching portfolio, then updating technology course work is strongly suggested. A score below 21 points in the Advanced-level might suggest a need to review current applications of technology in education, and this could be accomplished through graduate course work or professional seminars.

Henry D. Dobson is a Professor of Educational Technology in the Department of Curriculum and Foundations, Bloomsburg University of Pennsylvania, Bloomsburg, PA 17815. Voice, Office: 717.389.4024, Home: 717.784.4685. E-mail: hdobson@planetc.bloomu.edu
Laptops are becoming more and more popular in our everyday life. In some schools, colleges, and universities such as The University of Minnesota, Crookston (alias ThinkPad University), Waldorf College in Forest City, Iowa, Valley City State University in North Dakota, Acadia University in Wolfville, Nova Scotia, Georgia Clayton State College and University and Floyd College in Rome, Georgia, Ursuline Academy of Dallas, ACT Academy in McKinney, Texas, a laptop-for-every-student policy has been in place.

Results of a 1996 pilot study of the 52 schools that participated in a Microsoft and Toshiba laptop initiative called Anytime Anywhere Learning (Microsoft Corporation, 1997) indicate that laptops have a powerful impact on how teachers teach and what students accomplish. In our study of schools, colleges, and universities, we wanted to find out the answers to the following questions about laptops:

- State University of West Georgia: How are students and teachers using laptops?
- State University of West Georgia: How do these schools, colleges, and universities fund their laptops?
- State University of West Georgia: What are some horror stories connected with laptop use?
- What are some success stories connected with laptop use?
- If laptop loan service is available, what are some recommended policies related to laptop checkouts in libraries or lending centers?
- What kind of advice or tips can these laptop users provide the readers?

Data collection

We went through the listserv archives of EDTECH, LM_NET, and AECT found on the net and printed out all the comments and responses related to laptop that were made throughout a period of three years, from 1995-1997. There were 36 of these. We also wrote the listserv members in November 1997 and asked them to tell us how they are using their laptops and to share with us their success and horror stories. We received 15 responses from the listservs. Three respondents referred us to three web sites, namely, those of Anytime Anywhere Learning Microsoft/Toshiba project, University of Minnesota Crookston, and the Waldorf College. Part of our data came from these web sites. A few of the respondents were more interested in our findings rather than providing the answers. We also interviewed ten faculty members from various colleges and universities in the University System of Georgia.

Analysis

Content analysis was performed and the data we received was assigned to categories. Categories used were: educational applications, success stories, horror stories, funding, policies, advice/tips, participant verification (in progress), and laptop management policies (in progress).

Preliminary Results

Educational applications. Professors, librarians, and students are using laptops in many ways. A professor of Criminal Justice is using a laptop to write a textbook. The convenience of being able to work on the book at home as well as at the office was cited. Librarians in Georgia are using laptops to demonstrate the different databases in GALILEO or Georgia Library Learning On-Line, to take notes in off-campus meetings, and to keep in touch with the office.

Many professors are using their laptops to present their Microsoft PowerPoint lectures and other multimedia presentations and to access web resources and CD-ROM based materials. The University of Northern Iowa have two sets of laptops (Macintosh and Compaq) to use in their on and off campus staff development training workshops for K-12 schools. Portability, ease of use, and ease of set up were cited.

Students are using laptops to take notes during class, do the layout for school newspaper, access Internet resources, do multimedia authoring, do science experiments (attaching probes to laptops to collect real data in the field), write their papers, collaborate with peers, contact professors, and send electronic mail to prospective employers. School teachers are using laptops for their lesson plans, grade records, word processing, internet research, and e-mail.
Success stories

The success stories told by users in schools and higher education focused on the following outcomes:
- Students are learning from students and teachers are learning from students about technology
- Teachers are becoming more comfortable with technology
- Teachers are using more small-group, project-based and individualized instruction
- Students are developing communication skills
- Students are spending more time in creative and critical thinking
- Students are more motivated in learning
- Students are taking greater responsibility for their own learning
- Students are doing more collaborative learning
- With the sense of ownership, students are being urged to do extra work simply because it is fun to use a computer
- Students’ way of learning is being expanded
- Students are becoming negotiators and discoverers of information
- Parents are becoming more interested and more involved with the education of their children

Horror stories

There were a few horror stories. One College of Education staff member from Houston, Texas told us that they purchased 20 Macintosh laptops for faculty and students with grant money. One year later, we lost half of them, because it is so easy to walk off with a laptop. The rest were broken because people dropped them or were sloppy with their use. There was not a person to maintain them, charge the batteries, or kill the virus [sic], she stated.

Another public school teacher revealed in the EDTECH listserve that the dirty little secret about laptops is that they are expensive to buy, break easily, and are expensive to fix. An English teacher said that her hard drive crashed just three months after she got it. It took five weeks for it to be shipped back to California and be replaced.

Other schools reported about laptops being destroyed due to one of the following reasons:
- The laptop was dropped on a cement porch
- The laptop was left in a hot car
- The laptop that was left in a car with an open window did not get stolen but got wet from the rain.
- The laptop was dropped from the desk onto the tile floor
- The laptop was dropped in the bus and kids stepped on it

A university professor told us her laptop did not want to cooperate with the DataShow projector but she admitted that it could be an operator’s error

Funding

One respondent said that there was no single way for a school district to finance and acquire computers. Financing options mentioned by various schools were: outright purchase, monthly rentals, three-year leases at a certain finance rate. Adopt-a-kid program for individuals, business and community groups, parental or relatives’ support, community foundation, private and state grant funding were also sources of funds to help support the students’ personal learning tools.

Universities that were involved in a laptop-for-every-student policy required the students to pay for their laptops as part of their tuition.

Advice/tips

The following advice and tips were offered by laptop users:
- Place the emphasis on the curriculum and not on the technology
- Put laptops in the hands of the teachers not just the students
- Provide teacher training
- Provide technical support staff to help with hardware or software problems
- Select laptops you can live with

A NEED FOR TECHNOLOGY-BASED TEACHER RESEARCH

Alex C. Pan
The College of New Jersey

Infusing technology in teaching and learning has become a national norm. Teachers are expected to have good computer skills and know how to integrate technology effectively in the curriculum. At present, most classrooms have some computers, and students are enthusiastic about using them. Computers seem to have provided great potentials to enrich the classroom teaching and to improve teachers’ productivity. However, in real life, after advocating the computer technology for education for over two decades, very few schools have integrated it into their curriculum. In addition, most teachers do not feel comfortable about using it. In order to infuse computers in the curriculum, teachers should know not just how to use computers themselves, but also how to engage their students in active learning with computers. In other words, we need more technology-literate and enthusiastic teachers.

Secretary of Education Dick Riley (1997) predicts that this nation will face a severe shortage of teachers in the next decade if we do not focus our attention on recruiting quality teachers. We are already facing an immediate challenge--most teachers do not feel comfortable using technology or integrating computer technologies into their curriculum. Workers in business and industry have kept up with the new technology whereas educators are falling behind. New efforts are indispensable to engage teachers in using the existing technology and in making it actively functional for better education.

Technology in teacher preparation

One might think that an alternative to infuse technology in school education should come from higher education. The university teacher education programs should assume the leadership and take initiatives to provide public schools with insights. University teacher educators should also provide training and opportunities to help teachers catch up with educational computer technology. However, such a top-down approach where teacher educators provide school teachers with input and guidance, might not work without modifications. Various factors should be considered.

Currently, teachers need more than just training and guidance to integrate technology into education. Researchers such as Zehr (1997) indicate that school teachers do not feel comfortable or ready when teaching with new technology. The majority of teachers, do not possess sufficient technology resources, such as software and hardware to engage their students in meaningful technological activities.

An additional factor that discredited the university teacher educators’ efforts is the gap between the university and public education. It has been widely discussed among teachers that the university professors have become ignorant of the classroom reality. Sengupta (1997) indicated that education professors are “out of sync” with public school teachers and the public on fundamental issues like what and how teachers should teach. In the application of educational technology, oftentimes, teachers criticize the university teacher educators for advocating goals which are difficult to implement or unattainable (Stephenson, 1997). Stephenson (1997) also found that significant differences exist in the expectations about students’ performance in computer education between high school teachers and university instructors.

Most technology-based research is conducted in higher education. In many cases, teachers are included only as subjects, but not as researchers. As a result, regardless of what researchers suggest to improve the classroom teaching with technology, teachers are continuing what they are currently practicing. For example, many studies suggest that a well-planned technology implementation can enhance students’ learning experience and increase their motivation, and teachers should work collaboratively to better such an effort. However, many schools are relying on the technology coordinators to conduct computer lab sessions without the classroom teachers’ direct involvement. The computer coordinators, who may know how the computer operates, might know very little about what is being taught in the classroom. Some teachers even consider students computer time as break time. Such discrepancy should be reduced to the minimum before the research findings can have serious impact on the real practice in the school.

Issues and challenges

Requiring all teachers to possess needed technology literacy and to integrate technology into their curriculum,
though important, is a tough challenge. While many teachers agree to the importance of technology in education and express a desire to pursue the advancement of their skills, we are facing some big challenges: 1) how to make teachers realize the true potential that technology can provide, 2) how to convince them that it is worth their time and effort, and 3) how to lay out a systematic approach to actively involve all relevant personnel such as teachers, students, administrators, professors, and others to infuse technology in education. To meet these challenges, many obstacles as described below need to be overcome.

**Teachers’ computer skills are generally low.**

Teachers’ vision about educational technology is often hindered by the lack of technological skills. Presently most teachers possess very limited technological skills. They would have to spend plenty of time working on various technology projects before they master the skills. Not until they feel comfortable about using technology in their work, will they seriously become involved in implementing technology in curriculum.

**Practical teaching experience is essential to successful implementation of technology in the class.**

From the experience of teaching undergraduate preservice teachers to integrate technology in instruction, the author found that most preservice teachers normally do not perform well due to a lack of clear ideas about classroom scenarios, events, interaction, and procedures. To help them learn to integrate technology effectively, preservice teachers need to be exposed to concrete examples and practical teaching scenarios. Many practicing teachers can catch up with and apply what they have learned to the real classroom setting quickly. It is practical to connect the preservice with the practicing teachers to exchange their technological experience as well as the real teaching experience.

**Many teachers feel outperformed by their students.**

Students often seem more technologically interested and skilled than adults. Many teachers feel threatened by their students’ technology skills. It is important to help teachers to overcome the anxiety and feel ready. Teachers may use skillful students as helpers or role models for the technology-enriched class activities.

**Teachers are concerned about insufficient technological resources.**

Although there are plenty of resources on the software market as well as on the Internet, most teachers find it difficult to locate good resources to meet the instructional needs. In fact, there are many ways to acquire valuable instructional resources, such as finding reviews from educational journals or magazines, consulting with experienced users, checking with the vendors, requesting and testing a sample programs from the vendors.

**Acquiring technological resources does not necessarily guarantee the successful technology integration.**

From the frequent contact with school teachers, the author, on many occasions, witnessed good, expensive commercial software programs being misused in the classroom. However, he also witnessed some teachers developing innovative activities using plain shareware programs to motivate students to learn. It is fair to say that effective use of the resources for instructional purposes is more important than acquiring the resources. Nowadays, with easy access to the Internet, it is possible to locate and retrieve resources directly from the Internet. It takes thinking, organizing, and problem-solving skills to find the needed resources. Once teachers have mastered these skills, they can teach their students to locate information on the web, and even engage their students in higher-level thinking and problem-solving activities.

**Technology-based teacher research: a proposed model**

A model (as shown in Figure 1) derived from the author’s experience of working with practicing teachers to develop technology-based research may have provided a possible solution to the current technology challenge in the school. These practicing teachers participated in a technology-enhanced instruction master degree program. The participant had diverse backgrounds and technology experiences. Some of were novice computer users and others were more experienced. Throughout a few semesters, they mastered basic computer skills, gained new insight about technology in education through exchanging ideas about how computers can be best used to support their teaching. They also conducted research on their own to find solutions to the perceived challenge of improving their teaching performance with new technology. At the end of the degree program, almost all of them became a master of technology in their own school. They continue to implement technology in their own classes and provided leadership to other people in the school.

Several key factors have contributed to the success of this model. They include 1) the reasonable nurturing experiences through which teachers mastered needed skills, 2) the integrative applications and research with which teachers tied what they have learned in the university to their own classrooms, 3) the collaboration between the university and public schools with which teacher educators broke the isolation, touched the school teachers, and helped them become enthusiastic about technology, 4) the self-awareness process through which teachers can identify problems in technology integration and find solutions themselves, and 5) role-shifting with which teachers have...
moved from a passive role of being researched to a role of active researcher.

Engaging teachers in active computer-based research is a means to help teachers to catch up with technology. Cochran-Smith and Lytle (1993) suggest that teachers should not just be passive followers, but function as architects of study and generators of knowledge. Such a radical shift from receivers to researchers transforms the notion of research on teaching and provides a radical challenge to assumptions about how teachers learn and about what constitutes a knowledge base for teaching. If they started conducting computer-based research in their own classroom, they would soon become sensitive to the real needs of technology and be anxious to become masters of the teaching environment and generators of the new knowledge.

Engaging teachers in active classroom technology-based research is a significant practice. Teachers should know not only how to use technology but also how to integrate technology in their teaching practice and to engage their students in active learning and research. Shermis et al. (1991) point out the fact that the computer technology has impacted on the research process cannot be overestimated because microcomputers have touched virtually every aspect of the research process.

Earl and LeMahieu (1997) identified three major factors that may affect teachers’ performance and lead to devastating consequences for educational change and reform include the following: 1) work in isolation, 2) are generally excluded from knowledge production, and 3) are subjugated to external quality control. These factors can apply to the technology application in the school. Just as Earl and LeMahieu suggest, the collegial teacher research may improve the situation. Teachers collaborate and cooperate by sharing experience and information with each other and by working together. If teachers became experienced in using computers for teaching, they are very likely to continue such a practice. If they have realized the power and the ease of use of technology, they will be happy to use it. If teachers have conducted action-research using computers to teach, they will become actively involved and will definitely continue to grow with technology.

How we make teachers understand the significance of the research and hold positive attitudes toward research is the key to inspiring their enthusiasm and confidence in technology. The technology-based research by teachers is the best means to get teachers interested and involved. Teachers will not appreciate the technology-based research unless the research is closely related to their life and work.

Major research areas
Technology can be beneficial to education in the following ways: 1) fostering students’ problem-solving and higher-order thinking, 2) enhancing student-directed learning, 3) providing diversity in instructional methods, and 4) becoming an effective management tool. To maximize the power of technology to serve education, teachers can research the following areas:

- How technology can make a difference in teachers’ work.
- How technology should be integrated into curricula.
- Under what circumstances students can benefit from using technology.
- What key factors may contribute to effective teaching and learning in the content areas.
- How technology can increase collaboration and cooperation among students.

Teachers may also want to expand their research agenda to the relationship between school, parents, and community. Zehr (1997) points out that technology is making it easier for parents, business people, and community members to get involved in education. At the same time, it is forcing some educators to rethink what they mean by “school”. In addition, some broader issues such as communication, effective management, and multicultural awareness may deserve serious attention.

Suggestions
Based on the above discussion, several suggestions are made below to enhance the technology-based teacher research.

- University teacher education programs should provide a realistic setting for teachers so that they can get actively involved in learning about educational technology as well as finding solutions to the technological challenges they are facing. Both university faculty and school teachers should examine the obstacles for technological implementation together.
University should take leadership by providing a vision of what technology should be and which direction schools should go. University should also pay attention to the reality issues. Teacher education professors should provide teachers the learning experience that they can use in their school daily life. Technology will not be successfully integrated and thrive until teachers are convinced that technology is useful and easy to handle.

Encourage teachers to polish their computer skills by taking courses, attending workshops, and conducting action research projects.

Increase connection and communication. Connect the preservice students with the inservice students and bridge the experience gap between them. Help teachers collaborate with each other so that they can break the unnecessary isolation.

Strengthen the ties between university teacher education programs and public schools by establishing collaboration between the university faculty and the public school teachers. We should encourage teachers to take initiatives to conduct action research in their own class while encouraging the university teacher educators to work collaboratively with school teachers so that they will stay in touch with the school reality.

**Conclusion**

Integrating Technology into the curriculum has become a national norm. However the current status of technology in education can be characterized by the scenarios that teachers are desperately in need of help to learn how to use technology and to integrate technology in their curriculum, and the university professors are out of touch with the reality in the public school. Although technology has been around in education for over two decades, it has not made a significant impact on education as it should be. To improve the current situation and to face the challenge of infusing technology in the school, this paper proposes a model to engage teachers in active empirical research in their classroom through which teachers can pick up needed technological skills and learn to tackle the challenges faced by exploring innovative ways to implement technology in their curriculum.

One of the principal challenges to the universities of the future is the changing nature of the student body. The term 'lifelong learner' is now part of the vocabulary of modern day society. It describes the need for people to continue their education and training throughout life. In the modern day society of multiple career changes and extended productive lives, the word 'learner' designates a role rather than an individual. The spreading culture of lifelong learning is even producing changes in the attitudes of the young traditional campus student. These students are demanding flexibility and individualization of the degree process to meet the complexity of their lives.

Higher education is beginning to change in response to these challenges. A new type of university has emerged in the last quarter century. It is the distance teaching university (Daniel, 1996). This distance teaching university may be a totally new university system like the Open University of the United Kingdom which was established in 1969 or the University of Phoenix accredited in 1978. On the other hand, distance teaching may be just receiving a new emphasis at an older traditional campus university like Penn State University, University of Wisconsin, Washington State University, here at Northern Arizona University, and a growing list of others. This is not to say that distance teaching is a new phenomenon. It is the recent developments of technologies within computing and telecommunications combined with the changing nature of the student body that has produced new interests in distance teaching (Daniel, 1996).

One of the most important issues that must be addressed immediately is the issue of quality. What about learning? In terms of distance learning, not teaching, the combination of computing and telecommunications with the cognitive sciences is potentially the most significant issue that must be addressed as many universities move into the distance teaching arena. The uniqueness of these new highly technologically enhanced teaching environments found in modern day distance education are presenting new challenges in terms of providing quality. Some work in the area known as social constructionism, with an "n", may provide some answers into producing quality learning environments in distance teaching.

To understand the possibilities of social constructionist theories in the distance education environment it is important to understand the foundations upon which it is built. The academic usage of the word constructionism expands on the concept known as constructivism (Shaw, 1996). In social and developmental psychology, constructivist models view the subject as a builder of knowledge, not a passive receptor, but an active constructor. Theorists such as Jean Piaget attempt to describe how this building process takes place in order to better understand childhood learning and development (Piaget, 1954). Constructionist thinking concurs with the constructivist viewpoint but highlights the notion that it is through the construction of shared outcomes or artifacts that learners engage in developmental cycles that facilitate conceptual change (Shaw, 1996).

"We understand 'constructionism' as including, but going beyond, what Piaget would call 'constructivism.' The word with the 'v' expresses the theory that knowledge is built by the learner, not supplied by teachers. The word with the 'n' expresses the further idea that this happens especially felicitously when the learner is engaged in the construction of something external or at least shareable...This leads to a model using a cycle of internalization of what is outside, then externalization of what is inside and so on. (Papert, 1990, p.3)

A strong emphasis is placed on created objects being external to their creator, as things "in the world" that can be "shown, discussed, examined, probed, and admired" (Papert, 1980, 1991, 1993). Evard (1996) states, "Sharing a creation can result not only in its refinement, but also in the learner obtaining a deeper understanding of other people's perspective on the object and on the ideas to which it is related."

Constructionism highlights the notion that through the process of constructing shared outcomes and artifacts, doors to understanding are opened. Social constructionism extends the constructionist view by stating that the social
relations and social activities are constructions themselves and have a major impact on the shared outcomes. To social constructionism, the social setting itself is an evolving construction. “When members of a social setting develop external and shared constructs, they engage the setting in a cycle of development that is critical to determining the setting’s ultimate form...” (Shaw, 1996, p 177)

Social settings are not viewed as simply neutral grounds in which developmental activities take place, but they are seen instead as intimately involved with the process and outcome to that development. The impact of the social settings on learning is being recognized from many perspectives. According to Applebee (1996), the paradox of what he calls “knowledge-in-action” is that in order to learn something new, one must do what one doesn’t know how to do. The way out of this paradox is to realize that learning is a social process, we learn to do new things by doing them with others. Applebee (1996, p. 1) argues, “that the power of education is intimately bound up in the social and cultural traditions within which education is set.” When viewing the design of a curriculum in this light, then a curriculum provides for what Applebee (1996) calls “culturally significant domains for conversation.” Applebee believes that the conversations that take place within these domains are the primary means of teaching and learning. He contends that the problem of curriculum planning is the problem of establishing a culturally significant conversational domain and fostering relevant conversations within it.

Social constructionism makes the claim that the individual AND the social setting are intrinsically linked and that learning is a matter of both shared constructions and social relations (Papert, 1980; Wilensky, 1991; Evard, 1996; Shaw, 1996). Constructionism offers an important extension of the constructivist viewpoints by arguing that individual learning is enhanced by shared constructive activity and social constructionism adds further harmony by revealing that learning is impacted by the social setting which is enhanced by the developmental activity of the individual. If the constructionist notion of shared constructions and social relations are key to quality learning, then social settings marked by fractured and limited social activity and less cohesive social relations, as is the case in many distance education settings, may present troubling learning barriers.

A Model

In trying to bridge the gap he observed between theory and practice, the Georgian poet Vladimir Mayakovsky wrote “...I want to insist that I offer no rules to make a poet, by following which he can write poetry. Such rules simply don’t exist. A poet is a person who creates these very rules.” (Mayakovsky, 1974, p. 14)

Like Mayakovsky’s observation that there are no rules that, if followed, will always produce great poetry, there seems to be no rules that a teacher can follow which will always produce great learning. However, just as with poetry, there are parameters that exist that when constructed may create environments which increase the expectations that quality learning will occur. This paper examines a model that may help create those parameters, especially in a learning environment that is characterized by the teacher being separated from the learners and learners being separated from one another.

Connection Between Design and Learning

Recent efforts in the educational community have stressed the importance of self-directed, personally meaningful, and cognitively complex projects for students' learning success. One of the main tenets of constructionism is that learners actively construct and reconstruct knowledge out of their experiences in the world. Constructionist theory suggests a strong connection between design and learning.

“...design involves building a relationship between designer and object. Designers sort out what objects mean to them or others; then they selectively connect features of an object and features of a context into a coherent unity. The relationships that designers build with objects or situations constitute the core focus of design theory; the final artifact is secondary. Design is now viewed as the process though which a designer comes to understand not only objective constraints, but also subjective meanings.” (Kafai and Resnick, 1996, p4) (emphasis added).

Microworlds

The basic idea of social constructionism is that in the construction of shared outcomes or artifacts that facilitate conceptual change, a community is more intelligent than any of its members, including its leaders. The problem is how to mobilize community knowledge so that its members benefit from it. Perhaps an answer can be found in a concept called microworlds. Microworlds is based upon the concept of powerful ideas, or concepts that are useful in many kinds of situations. Papert (1980) developed the concept of microworlds to answer the critics of discovery learning. Two factors that limit discovery learning are inadequate design support and inadequate support for cooperative action (Gargarian, 1996). The solution for design support may come from a concept called “freedom in restrictions”. The solution for cooperative action may come from a concept called “Confidence Building”. If a model can be developed that facilitates the process of developing microworlds and facilitating the interaction of the community of learners, then it must provide a way that learners can identify a number of powerful ideas for engaging other learners and providing the framework by which the
experts of a community of designers is placed at the service of each of its members.

**Freedom in Restrictions**

Designing is in large part redesigning or editing and refining. It is concerned with problems Gardner (1987) describes as open-textured. But therein lies a paradox, in designing there is no way to plan a path toward a solution if what constitutes a solution is, itself, under debate. The solution of designing is emergent rather than planned because the designer is learning what a “problem” is about during the process of design. For this reason if learners are to engage in designs that facilitate developmental cycles and conceptual change through the construction of shared outcomes or artifacts there must be a restricted design process.

“Without restrictions, a designer would be unable to choose from the possible actions he could take; he would be paralyzed. Moreover, an action has little value if there is no way to evaluate the effect of the action. What I call freedom in restrictions is the counter-intuitive notion that restrictions provide the designer freedom rather than enslavement. Within a restricted collection of choices, a designer can explore choices....”(Gargarian, 1996, p. 132)

**Confidence Building**

Designing is a process in which provisional solutions serve as a means of further discovery. The designer needs strategies for identifying factors that restrict the degrees of freedom. These strategies come about through a process of feedback. Through this process certain factors may emerge as particularly important because it is important from many perspectives, not just the perspectives of the creator. The key is that the feedback, no matter what its form, comes from as many perspectives as possible. Gargarian (1996) refers to this as confidence building. It is how restrictions earn their credentials though feedback. Growing confidence makes some restrictions rigid and certain solutions decreasingly provisional. “Proof that certain artifacts become increasingly permanent is that they eventually get made” (Gargarian, 1996, p. 133).

**Explication of the Model**

The model considered in this paper was created by an educator with extensive experience in distance education, primarily IITV. He proposes a six step process in which students are responsible for shaping and reflecting on their own learning, actively engaging in the construction of knowledge. The stages of this model can be applied across the scope of an entire course or to topics within units or sections of a course.

We will begin with a brief summarization of the model as it is designed and move to a discussion of how the notions of microworlds, freedom in restriction, and confidence building as described by Papert (1980) and Gargarian (1996) are central to the examination of the a constructionist model of learning, especially as it applies to telecommunications courses.

The first stage of this model asks students to examine what they, bring to the learning process. Using their prior knowledge as the only avenue for approaching a specified topic, students are asked to generate a one page paper that delineates what they know about that topic. This piece of writing is the first entry into a portfolio of work that can be revisited and revised throughout the semester. Students are told explicitly that the purpose of this first assignment is to help them take control over their own learning by acknowledging what they already know and to shape the initial inquiry into the content of the course.

The second stage directs students to consult with other students in the course to discover areas of common ground, gain new perspectives, and extend knowledge about the topic. Students are urged to collaborate with as many other students as they can, both within and across sites. At the end of this consultation students are then asked to revise and reshape their initial papers to include the thinking constructed through collaboration with peers.

It is in the next stage in which students are allowed to consult texts and other “expert” resources that are readily available. Depth and breadth in the variety and types of sources available is encouraged. Students are not only guided to verify their original thinking but to treat resources as different voices in the conversation about the knowledge held about the topic. Think in terms of many voices, many sources (Bensusan, 1997). The students’ task at the end of this stage is to compare their findings with those of other students and then to write a paper describing the fit between their previous work and what the experts have to say - whether this adds to what is known or not.

In the next several stages, students are asked to examine the topic from a number of different perspectives. Each perspective not only offers a different view of the content, but also requires students to examine sources of information in order to determine what each source brings to the construction of knowledge about the topic. Fields of study, schools of thought, background and expertise of authors, type of resource are considered by students at these stages. Students are encouraged to see how different authors and resources shape the world around or provide different contexts for the same topic that students are examining. This set of stages is capped by writings that refine and recast knowledge of the topic so that the richness of perspectives is voiced.

The culminating steps of the model ask students to resolve the differences in perspectives and reflect on how this process changed or enhanced their thinking about course content. Students are told that these steps are only the end of the course requirements, but that thinking and refining ideas are a lifelong process.

Research — 873
Creating Microworlds Within the Model

In telecommunication courses the participants may not only be separated from the instructor, but also from each other. It is essential that an environment, a microworld, be created that will help participants feel comfortable and confident about working together (Baird & Monson, 1988; Willis, 1994) as well as building support for the exchange of ideas, thoughts, and feeling, between and among people, resulting in new ways of viewing the world or in new ways of acting. (Lauzon, 1992). This model facilitates the creation of such an environment through it’s treatment of each student as a valid contributor to the knowledge construction process. Every source of knowledge, course participants included, is acknowledged, considered, and scrutinized, but treated as one voice in the conversation around a topic. Students are not told what counts as knowledge, but must be actively involved in shaping and delineating the important aspects of content as it is constructed.

Freedom in Restrictions

A second strength of this model is that students are not left to figure out what is to be learned on their own. At each stage the model restricts the scope of the discussion and provides a scaffold for the types of thinking that must be done at that point in time for the learners to collaboratively shape conceptual change. Because the focus of a particular step is narrow in focus, students are allowed to explore boundaries in ways that would not otherwise be possible.

Confidence Building

If students are to be expected to take an active role in constructing knowledge about a topic, they must feel that the efforts that they put forth to learn has substance and worth. Students that are led to feel that they must wait for instructors to validate what they understand will never be able to participate fully in the learning process. This model allows students a variety of modes of feedback as well as the capability to continually reassess and reflect upon their own learning.

Conclusions

The model examined in this paper has the potential to enable students to be active participants in the learning of subject matter content, particularly in telecommunications courses where teacher and students are physically distanced from each other. Through the steps of this model students get first-hand experience in using multiple sources of information to construct their own knowledge. This knowledge construction hinges on the creation of a learning environment in which collaboration and the acknowledgment of different perspectives is not only honored but expected. The model illuminates ways in which the social environment and the individual are united in determining the boundaries for the types and the extent of learning that are possible within a telecommunications course and offers a workable scaffold for future study within this field.

Computer-Mediated Communication (CMC) is an emerging research area in educational technology. The proliferation of research literature indicates various virtues and drawbacks (Ahern, Peck, & Laycock, 1992; Henri, 1992; Kuehn, 1994) in analyzing electronic discourse. Currently, most research studies use quantitative methodology to carry out online content analyses, whereas only a limited number of them employ qualitative tools (Romiszowski & Mason, 1996). This study applied both quantitative and qualitative criteria to analyze the content of computer conferencing and electronic collaboration.

Henri (1992), a pioneer in the development of criteria for content analysis, identifies five dimensions, namely participation, interaction, social, cognitive, and metacognitive, that can be used to classify electronic messages. Although his model provides an initial framework, it lacks detailed criteria for systematic and robust classification of electronic discourse. Howell-Richardson and Mellar (1996) have also pointed out that Henri’s model is sometimes hard to apply as it is not always clear which dimension is the most suitable to use to classify messages. The main focus of our study was to analyze twelve weeks of electronic collaboration for the purpose of constructing better guidelines on how electronic discourse can be analyzed, thus improving Henri’s existing model.

Research Questions

This study carried out a systematic analysis of online discussion in both an undergraduate and a graduate educational psychology course to better understand electronic dialogues. The main research question we investigated was “How is a community of learning built using online discussion?”

Research Site

Our research study took place at a major Midwestern university in the United States. The applied cognitive psychology class was chosen because it made use of the computer conferencing software, FirstClass. The undergraduate educational psychology course used a web-based conferencing tool called COW (i.e., Conferencing on the Web). In the graduate course, students met once a week and were required to participate in online discussions at least once a week. The undergraduate course was entirely Web-based.

In both courses, students were asked to play the role of a “starter,” one who initiated the discussion for each week, or a “wrapper,” one who summarized the conference at the end of the week. Students assumed each role at least once a semester. Research studies (e.g., Ahern, Peck, & Laycock, 1992; Howell-Richardson & Mellar, 1996) show that the teacher’s role is also an important variable in computer-mediated communication, therefore the facilitator’s role was also investigated in our study.

Research Methodology

Initially, Henri’s taxonomy was used for analysis. When the model became too ambiguous and not adequate for capturing the richness of the discussion in a clear manner, more categories were added to it.

For the graduate course (referred to as Applied Cognition and Learning Strategies from here onward), twelve weeks of conferencing using FirstClass were analyzed quantitatively, and four randomly selected weeks were analyzed qualitatively. In addition, interactivity maps were drawn to depict the links between students’ messages. To validate the coding procedures, two of the researchers coded the messages individually and observer agreement was calculated. The Web conference is currently in the process of being analyzed using the same framework.

For the undergraduate course, students in eight sections of an educational psychology class had nearly two months to create two cases of interest and respond to four or five other cases created by their peers. During their online discussions, students assumed a number of different roles such as starter, wrapper, questioner, sage, coach, pessimist, and optimist. In addition, undergraduate students discussed with great interest their field experiences. During these discussions students primarily
reflected on their experiences and compared how their field experiences related to what they learned from textbooks and classroom lectures.

**Findings**

**Applied Cognition and Learning Strategies**

The graduate level applied educational psychology course was analyzed using Henri's five dimensions: (1) participation; (2) social; (3) interaction; (4) cognitive; and (5) metacognitive.

**Participation:** The number of student messages exceeded the number of instructor's messages, a finding which indicated that this conference was student-centered. We considered two reasons to explain this. One was the fact that the roles of starter and wrapper were played by students. Additionally, the instructor was criticized by a student for too much participation, after which, he limited his participation. Most students posted at least one message per week in order to satisfy the minimum course requirements. Although this satisfied the instructor, on the average students did not make extensive use of the conferencing tool. This indicated that students participated in the online discussion primarily to meet a course requirement. Thus, the interaction was not a two-way interaction; instead it was a one-way interaction (see Interaction section below for detail).

**Social.** In the graduate level course, the number of social cues decreased as the semester progressed. Moreover, messages gradually became less formal. This might be attributed to the fact that students felt more comfortable with each other as the semester continued. The correlation between cognitive tasks and social cues was examined. Of the four weeks of cognitive analysis, the eighth week had the lowest number of social cues and the highest cognitive task frequency (88.1%), indicating that during the eighth week students engaged in intense online discussion and focused on the task.

**Interaction.** The concept of interactivity in Henri's model consists of three steps. They include: (1) communication of information; (2) a first response to this information; and (3) a second answer related to the first. This process can be represented schematically in the following manner:

A → B → A → B

The interaction in our conference appeared to be much more complex. First, most participants attended just once. This created a one-way interaction not a two-way one, because the students who initially started a discussion (message A) infrequently participated thereafter. Second, more than two participants were usually involved; therefore the interaction was not always linear as Henri's (1992) model suggested. After analyzing the interactivity graphs week by week, a unique pattern of interaction was found for each week. The following patterns were identified: (1) the second week had "starter-centered" interaction; (2) the fourth week had "scattered" interaction, and this can be explained by the fact that nobody assumed the role of the wrapper in the discussions that took place during the fourth week; (3) the eighth week had "synergistic" interaction; and (4) the tenth week had "explicit" interaction. As Ahern et al. (1992) noted, the starters' questions was one of the main factors in understanding interactivity (see Cognitive section below for detail). The other possible factor that influenced the characteristics of interactivity was the instructor's comments during class. Specifically, he encouraged students to reply to messages posted by their classmates. This might have affected students' behavior while participating in the conference.

**Cognitive.** As stated earlier, starters' questions influenced the quality of the cognitive tasks in the conference. Henri talks about five categories in the cognitive dimension. They include (1) elementary classification; (2) in-depth classification; (3) inferences; (4) judgment; and (5) application. In a highly interactive conference, participants' opinions appeared mostly in the beginning of the discussion rather than at the end of the discussion. This was due to the fact that early presenters discussed their individual positions, whereas later presenters judged the participants' opinions. Therefore, the cognitive engagement of the participants was also an index of how they interacted in the conference.

**Metacognitive.** Henri's taxonomy classifies tasks such as understanding ideas or remembering past learning as metacognitive activities. Even though all metacognitive activities identified by Henri, such as planning, self-awareness, and evaluation, appeared in this conference, we identified others. The processes of self-questioning and reflection (Schon, 1983) were added to the existing model. In addition, more detailed criteria such as the following were added: (1) self-introduction as self-awareness; (2) wrapping the discussion as regulation; (3) starting the discussion as planning; (4) short introduction of the message as planning; and (5) formatting headings in bold and color as regulation.

**The undergraduate educational psychology course**

Harasim (1993) claims that computer conferencing is a potential instructional tool. Content analysis showed that student electronic participation was extremely task-focused - minimal social and off-task behaviors were observed. In addition, students limited their contributions to the requirements of the course and did not engage in extended discourse on a particular topic unless it was required. Student questioning and cognitive processing varied and appeared somewhat dependent on how the instructor structured the task and how he scaffolded learning.
Furthermore, while graduate student dialogue showed critical thinking and rationale, at the undergraduate level, many electronic contributions lacked justification and were simply opinions. Not surprisingly, the level of cognitive engagement depended on the level of cognitive complexity established by the starter’s questions and guidance. In fact, most discussions led directly back to the starter’s comments and ideas. Hence, we conclude that it is important to train students how to start electronic discussions and how to provide various forms of electronic assistance to their peers.

Limitations

One weakness of this study was the lack of student interviews for the purpose of validating the researchers’ interpretation of students' discourse. In addition, as Shapard (1990) also pointed out, only explicit communication was examined, as students’ implicit intentions could not be robustly studied. Therefore, our analysis might have not captured the contributions of students who did not express their discourse explicitly in the conference.

Conclusions

Conferencing tools can help students understand complex terminology and theories in educational psychology classes. They are an emerging aid in applying psychology to education. Students, however, often treat them as means to complete a particular task, rather than engage in rich discussion and debate with their peers. Online analyses of student interactions show that such environments have the potential of becoming rich instructional and learning environments if they are designed appropriately. The recommendations that we have to offer to practitioners are: (1) Structure online discussions; (2) Use pedagogical strategies; (3) Foster student interaction; (4) Test the conferencing software to explore its limitations and possibilities prior to using it; and (5) Realize that different types of conferencing software and features serve different types of instructional purposes.

One teaching approach being trialled in the UK is the use of large scale semi-intelligent teaching packages. These so called Integrated Learning Systems (ILS), are computer-based systems which present individualized teaching at a level appropriate to the child and which is deemed to ensure reasonable success. An ILS incorporates a management system which provides instant feedback to students on the current task and access to progress reports which inform the students and their teachers of their rate of success during that particular ILS session.

The current interest in such systems is stimulated by the need to halt the perceived decline in numeracy and literacy within our schools. So important is this debate within the UK that the Department for Education and Employment has funded three phases of an evaluation project to establish whether or not such systems are efficient and effective tools for teaching and learning.

Such styles of teaching and learning are often deemed impoverished, however. Roy Pea (1993) has argued that the tutorial mode of learning inherent in an ILS is a poor model of learning. He does not argue that there will be an absence of learning but rather that such learning will be in some sense unsatisfactory or of low value. The accretion of facts or skills is deemed less beneficial than the type of learning fostered in an open-ended problem solving curriculum designed to hone the child’s higher order thinking skills.

The argument for a social dimension to learning is well-established (see Howeet al, 1992; Kruger, 1993, Lave and Wenger, Rogoff, 1993; Underwood and Underwood, 1990, 1995). The first argument is that under positive contact conditions working in groups can facilitate interpersonal relationships which may in turn have positive effects on student motivation, self-esteem and academic learning. A more cognitive view would be that co-operative learning emphasizes cognitive interactions such as conflict resolution, hypothesis testing, cognitive scaffolding, reciprocal peer tutoring and overt execution of cognitive and meta-cognitive processes and modeling.

Children working in an ILS environment are not actively encouraged to communicate with, or to support, their peers. Indeed the model of use for much of the ILS work is one of individual or isolated work characterized by limited interaction with the teacher or other pupils. This inhibition of the rich interchange of ideas that are available in more socially oriented classrooms where co-operative or collaborative working is taking place is deemed a major limitation of the teaching and learning environment promoted by these systems.

Is it the case that these environments are zones of social deprivation? Does working with an ILS lead to negative social outcomes. We have written extensively about the strength and quality of the learning taking place in ILS classrooms elsewhere (Underwood & Brown, 1997) here we are focusing on the issue of whether or not these packages which promote individualized instruction have a detrimental impact on the social dynamics of the classroom. In particular we are looking at pupils’ perceptions of their teachers.

This paper presents the preliminary analyses of perceptions held by pupils in the ILS project of their teachers’ behavior in mathematics classrooms. Here we will outline the nature of the changes in the social dynamics of the classroom and discuss possible causal events leading to those change.

Method

The Question

Do pupils, exposed to an ILS working environment, have a different perception of their teachers and the teachers’ role than children who have not participated in the ILS experience? Further does working in an ILS environment lead pupils to hold more negative perceptions of their teachers than non-ILS pupils?

The Sample

The study of pupil perceptions was conducted in all schools involved in the ILS Phase Two evaluation who were using CCC’s SuccessMaker or Sir’s Global Learning Systems software (for fuller descriptions see Underwood & Brown, 1997). Pupils in the ILS study were assigned by their own teachers to either the ILS intervention group or to
a Control group. Six secondary and four primary schools provided data for this part of the project.

**Design and Procedure**

For the present study the evidence was collected using a research instrument based on projective testing. This method consisted of a sentence completion technique with a cartoon drawing as stimulus. Two versions of classroom drawings were available. One set of cartoons asked the children to complete simple sentences as in Example One below. A second set of cartoons provided a context for the children’s responses as in Example Two. Further, the cartoons were set in the context of either a primary (elementary) or a secondary (high school) classroom. Care was taken to alter the order of sentences presented to the pupils.

**Example One:** For primary (elementary school) pupils, the unfinished sentences included:
- One of the girls is saying
- One of the boys is saying
- The teacher is saying

**Example Two:** For secondary (high school) pupils, examples of the sentences included:
1. A boy has been messing about instead of doing his work. The teacher is saying
2. A boy has done his work well. A boy is saying to him
3. A girl has all of her work right. The teacher is saying to her

Both versions of the cartoons were distributed randomly to ILS intervention pupils and to Control pupils. The information given with the sentences stated either that the lesson was an English lesson, or that it was a mathematics lesson. Pupils completed the tests within their normal classroom environment which in all cases was separate from the ILS environment.

Corroborating evidence of pupils’ perceptions was taken from observations of teachers’ self-reports of their classroom practice and through structured interviews with pupils and teachers.

**Results**

Responses were categorized using classifications from Cavendish (1988) with some modifications to allow inspection of the responses in greater detail. The main categories were:
- Routine matters related to task e.g. here’s a rubber
- Non-task matters
- Reference to difficulty or dislike of task
- Reference to ease or liking of task
- Praise for behavior
- Corrective related to behavior
- Praise related to task
- Corrective related to task work
- Asking for help on task
- Offering help on task
- Comradeship and giving emotional support
- Nastiness, scorn, competitiveness
- Comment about stage reached or amount of work done

Responses were compared for the ILS and Control groups. The perceptions of primary (elementary) pupils when commenting on their teacher working in a mathematics lesson are presented in Tables 1.

Twenty percent of the Control group saw the teacher as informing or instructing the pupils about routine matters such as “Get your books out” or “Get some paper for the test”. This compares with less than seven percent of the ILS pupils. ILS pupils, on the other hand, were more likely to express the teacher as offering help with the task “Look this is how to do it” and “I’ll explain how to do it”. Some ILS pupil responses did relate to the teacher commenting on the amount of work done or in making corrective comments related to the task work but the frequencies of these comments were low. About sixty seven percent of Control pupils expressed the teacher as being corrective to behavior compared to a lower fifty-seven percent of the ILS pupils.

These differences in responses are indicative of the relationship that has been established between pupils and teachers. The general observation of ILS rooms is of pupils working silently and continuously at a computer, with the teacher putting high emphasis on performance and gains made during the session and providing help where needed. There appears to be some carry over of behaviors from the ILS environment to the classroom at least as far as the pupils are concerned. Structured classroom observation has shown regular occurrence of corrective comments by the teacher in normal classroom teaching, and while there remains a substantial number of behavior correction comments from ILS pupils, the number is reduced.

While the Control groups see the their teachers’ focus on routine matters or discipline, the ILS pupils comment that their teachers are focused on the academic work: offering help, praising about task work or commenting...
about the stage of work the pupil is at or the amount of work done.

In SuccessMaker secondary (high) schools there were few differences between the ILS and Control groups perceptions of their mathematics teachers although a perceived greater emphasis on the task in hand by the ILS group was apparent (Table 2).

In Global schools, ILS pupils were more likely to comment on teachers’ use of praise in relationship to behavior (Table 3) than control pupils. The latter, however, viewed the teacher as offering help on the task, giving praise related to the task and as a support giver. The view of the teacher by the control pupil, in these Global schools was one of helper and supporter with pupils asking for help as well as being offered it by the teacher. The ILS pupils, however, were more likely to view their peers as helpers and who keep watch on the amount of work done. The ILS pupils certainly saw no lack of opportunities for social contact with their peers.

Corroborating evidence from teacher-self reports (Table 4) show that at both primary and secondary school level ILS-involved teachers reported an overall decrease in disciplinary interactions with pupils in their classrooms in general.

Conclusions

Primary pupils and Global secondary ILS pupils generally view their mathematics teachers as being more focused on work rather than on discipline and organization of the classroom. There were few apparent differences in ILS and Control pupils’ perceptions of their teachers in SuccessMaker secondary schools although a perceived greater teacher emphasis on work related issues in the classroom by the ILS group was noted.

The major change in the social dynamics in such classrooms is the perceived need for the teacher to act in a negative, custodial role. Teachers argue such a role has been reduced because of a positive change in their pupils’ behavior. They have a decreased need to discipline the children in their care. Pupils, on the other hand, increasingly view teachers as helpers, and hence they feel positive towards their work. A plausible conclusion of such pupils’ perceptions is that better behavior will follow. Hence we are in a loop, as is so often the case in education, but in this case the loop is promoting positive impacts on the classroom.

Do pupils, exposed to an ILS working environment, have a different perception of their teachers and the teachers’ role than children who have not participated in the ILS experience? Yes, there are subtle differences between groups. Further does working in an ILS environment lead pupils to hold more negative perceptions of their teachers than non-ILS pupils? No, where differences do occur, the evidence is that ILS groups are more positive rather than less positive about their teachers.

Our preliminary findings provide some evidence that working with an ILS does result in teachers focusing on
more content-oriented activities and on promoting effective learning rather than on the general organization and management of classrooms. Are the teachers over or under optimistic in their self reports of change? Further evidence will now be drawn from actual classroom observations of the teachers in classrooms to establish whether the pupil and teacher reports

Acknowledgments

We are most grateful for the co-operation given by the teachers and children within the ILS project schools. This research was funded by DfEE/NCET and by the ESRC Centre for Research in Development Instruction and Training.

COMPUTER ANXIETY: A TECHNICAL OR AN EXISTENTIAL PROBLEM?

Valerie L. Worthington  
Michigan State University

Andrew Henry  
Michigan State University

There is a proliferation of attempts, such as conferences, teacher professional development activities, and school or district Web sites chronicling "technologized" educational experiences, to address the issue of teaching and learning with technology. It is clear from such measures that technology is becoming part of the fabric of education in this country. Indeed, there is no lack of rhetoric describing the potential for technology to improve the education learners receive by enabling teachers to be more responsive to individual needs; helping learners develop a sense of connectedness to the world outside school; and providing access to the latest information, to name a few examples. On a related note, teachers feel pressure on many fronts, as they are the ones who must address the requests and suggestions of parents, administrators, and researchers for meaningful educational experiences for children that involve the use of technology.

However, "success" in teaching with technology can be difficult to achieve. This is so because institutional and individual resistance to technology is a frequent if unwanted byproduct of many attempts to incorporate technology use into existing school and district practices. Institutionally, physical plants may not be wired to support intense technology use, and bureaucracies designed to funnel information through a central location may prove inefficient in the context of technology use, where quick decisions are often necessary. Individually, student, teacher, or administrator experiences of computer anxiety (fear of working on computers), as well as beliefs that technology will actually decrease the quality of the education a learner receives, can prevent or hinder the smooth integration of technology into a classroom. This is not to say that teachers or school systems actively resist technology incorporation. However, existing school infrastructure and instructional mindsets often have the unwanted effect of hindering successful technology integration.

This paper takes a closer look at one of the phenomena associated with technology resistance computer anxiety. It examines the technology experiences of roughly 50 undergraduate education students, from whom data were collected by means of a computer anxiety survey (Marcoulides, 1989), short answer responses to more open-ended questions, and several in-depth follow-up interviews about students' expectations about using technology, specifically the Internet, in their teaching. Results indicate that the traditional definition of computer anxiety (Cohen & Waugh, 1989; Dukes, Discenza, & Couger, 1989), which links it very closely to actually working on a computer, is limited in its capacity to explain the experiences and beliefs of these students. Rather than fearing that they would not be able to perform specific functions on the computer, the participants reported more general fears that the use of technology, specifically the Internet, would conflict with their capacity to teach in the way they felt was most meaningful for students. In other words, they believed that the use of technology did not coincide with their goals as teachers: that it would restrict interpersonal contact and expose their students to inaccurate and unverifiable information. The phrase "existential computer anxiety" was coined to describe this experience.

These results suggest that it is important to consider the context in which technology is expected to be used. Participants in this study did not perceive themselves to be afraid of using computers. However, in the context of the classroom, many of them expressed reluctance to use the Internet with their students because they perceived that its use conflicted with their beliefs about teaching and learning. The authors of the paper hope to begin to develop a clearer picture of the pitfalls associated with technology adoption, specifically those related to what has narrowly been described as computer anxiety. It is our belief that the concept of existential computer anxiety more accurately describes some of the experiences of teachers and pre-service teachers who are expected to use technology in their teaching. In developing an understanding of the nature of existential computer anxiety, perhaps we can help teachers move beyond it and use technology in the service of meaningful learning.

A Research Framework for Investigating the Effectiveness of Technology on Educational Outcomes

Trevor H. Jones  
Duquesne University

Rocco R. Paolucci  
Cabrini College

Clark stated that, "...media are still advocated for their ability to increase learning when research clearly indicates that such benefits are not forthcoming. Of course such conclusions are disseminated slowly and must compete with advertising budgets of the multi-million dollar industry which has a vested interest in selling these machines." (1983)

Although this statement could be considered cynical in its emphasis, the question of whether the benefits of technology in education are forthcoming are still arguable. This could be taken as a reflection on the lack of valid research into this issue. However, the emphasis on computer-based technology in education has not abated, and, in fact, continues to increase. This is particularly so when considering distance education. In 1994 $2.4 billion was expended on educational technology in kindergarten through 12 grade and $6.0 billion in higher education. Higher education alone has spent some $20 billion over the past 15 years (Katz et al., 1995).

Jones and Paolucci (1996) estimate that less than 5% of published research is sufficiently empirical, quantitative and valid to support conclusions with respect to the effectiveness of technology in educational learning outcomes. They argue that the influence of technology, while substantial, is largely unfounded and serious consequences may result if the sustained acceptance of technology in educational delivery continues without considering the appropriate application. They questioned the untested educational quality resulting from relatively unproven paradigms involving technology and the questionable cost benefit associated with this continuance. Their conclusion was a call for further research concentrating on the application of appropriate technologies to the learning outcomes of the subject matter to which technology is applied.

This paper continues the theme of this argument. While substantial research exists which identifies components of various teaching/learning models, few suggestions have been made to identify a framework which would help to guide a unifies research agenda contributing to the formulation of a technology/content matrix. This matrix, by its nature would allow the identification of relevant technologies to be applied to appropriate content. We identify a matrix of taxonomies, which would provide a framework for researchers to identify and target of specific work and ultimately contribute to a more complete solution.

Evaluation Framework

What is the most appropriate technology to use? In what educational context is a particular technology most effective? How effective is the chosen technology? The answers to these questions are critical in establishing the value added to the student's learning and achievement with the use of educational technology. However, with too many evaluation research studies, these questions are rarely addressed. And, if they are, the results are often unclear, due to the lack of a clear evaluation framework.

In order to address the above questions, we believe that the use of a system-oriented approach to educational technology evaluation is critical. Thus, our evaluation framework is based on the use of widely accepted and researched Instructional Systems Design (ISD) models. Although there are many ISD models: Gagne, Briggs, and Wager (1992); Smith and Ragan (1993); Kemp, Morrison and Ross (1994); R2D2 (1995); Reiser and Dick (1996); Dick and Carey (1996); Seels and Glasgow (1997), they all have life-cycle phases that include: analysis, design, development, implementation, and evaluation (Seels and Glasgow, 1998). Although some of these provide guidelines for selecting media and delivery systems (Kemp, Morrison, and Ross, 1994), they do not adequately address the technology dimensions and how these may relate to learning outcomes.

In response to this shortcoming, this study will focus on the dimensions of the delivery system and technology. It will present a general framework that can hopefully guide researchers in establishing a clearer relationship among instructional objectives, the choice of technology-based delivery system, and learning outcomes.
Instructional Systems Model

As mentioned above, to evaluate the effectiveness of educational technology, it is critical that a systematic approach be used. In its most general form, an instructional system can be viewed to consist of three major components: Instructional Objectives (Input), Delivery System (Process), and Learning Outcomes (Output).

Instructional Objectives

Learning is achieved when a permanent change in thinking, attitude, or behavior is experienced. Therefore, the objective of any instructional system should be to facilitate this process. It should be noted, however, that learning is an internal process which can only be done by the student. For many formal learning situations, an instructional system does not happen by serendipity. It requires significant planning and a sophisticated decision-making process. This process begins by clearly identifying a set of instructional objectives and goals. All instructional objectives can and should be based on one or more of the following factors: learning domain, learner profile, task characteristics, and grouping. These dimensions are described below.

Learning Domain. The instructional objectives should correspond to one or more learning domain(s). There are three basic domains of learning: cognitive, affective, and psychomotor. Taxonomies have been widely used to define learning within each of these domains. The most popular ones by Bloom (1956) for the cognitive domain, Krathwohl (1964) for the affective domain, and Harrow (1972) for the psychomotor domain. In practice it is very difficult to separate these, although it is possible to clearly emphasize one over the others.

Learner Profile. The instructional objectives should be appropriate for the learner’s level of ability. Many learners may need prerequisite skills and knowledge for success with any delivery system. Key information about the learner characteristics can be used to develop a profile. It is recommended that, as a minimum, such a profile should include information on cognitive style, aptitude and ability, relevant experience, educational status, level of achievement with subject domain, attitude, interest level, age, and gender (Seels and Glasgow, 1998).

Task Characteristics. The instructional objectives should be appropriate for the tasks associated with the subject matter that is to be learned. A clear description of the topic to be learned, and the steps necessary to achieve this, can lead to clear instructional objectives. Task analysis is frequently employed to achieve this goal. Its purpose is to define the operational components of a skill or subject matter (Jonassen and Hannum, 1995).

Grouping. The instructional objectives should be appropriate for the grouping arrangement and learning situation. This can be simply determined by deciding whether the instruction will be with a large number of students, small or just one individual. Additionally, it is necessary to identify whether the instructional objectives require independent or group study, and the physical locations of the students.

Many technologies can provide support opportunities for all of the above options. However, research shows that the inherent properties of some technologies have more affinity for supporting some factors over others (Seels and Glasgow, 1998).

Delivery System

The delivery system is the method used by the instructional system to transfer information and knowledge from the subject matter expert (human and/or machine) to the learner or vice versa. The choice of the “optimal” delivery system should be made only after the instructional objectives have been clearly identified and specified. In general, the delivery system can either employ older and more traditional technologies (print, audiovisual, etc.) or newer technologies (computers, telecommunications, etc.), or a combination of both (Seels and Glasgow, 1998). Although both the older and the newer technologies continue to coexist as possible alternatives, the focus of this study is on the newer, electronic technologies. Furthermore, older technologies are increasingly being incorporated in newer technologies (e.g., video and audio information can be delivered by cassettes or by multimedia computer software such as CD-ROMs).

Today, most of the delivery systems are highly integrated information technologies, with the computer playing a pivotal role. They incorporate two major classes of technologies: telecommunications (e.g., teleconferencing, Internet, etc.) and multimedia/hypermedia computing (e.g., CD-ROM, World Wide Web, etc.). These technologies (whether used together or separately) are often used for distance learning and can provide individualized, interactive, and multi-sensory learning experiences. They have the advantage of learner control features, which can allow for interactivity. They can be used to access information and people either linearly and/or randomly, as well as locally and/or remotely. Moreover, they are capable of integrating media of many different types from many different sources, all within the control of the system software and/or learner (Seels and Glasgow, 1998). We believe that these digital delivery systems, when used as components of an instructional system, have major characteristics and dimensions that effect the educational experience. These characteristics include control, presence, media, and connectivity.

Control. The level of interactivity is a measure of the amount of control a learner has in the learning process and over the information source. With many instructional systems, this interaction is complicated by the inclusion of digital technology. That is to say, with the use of technology systems, one needs to determine the relationship to the traditional instructor-learner dyad (Branson, 1997).
The instructor as Lecturer: The instructor has direct control over the learning activities and the technology and content, while the learner does not (e.g., audio-visual technologies, programmed instructional software).

The instructor as Facilitator: The instructor has direct control over the learning activities and indirect control of the technology and content, while the student has direct control of the technology and content (e.g., hypermedia, World Wide Web).

Technology as Mediator: The instructor and learner dyad is mediated by the technology, with the instructor having indirect control over the learning activities, and both the instructor and learner having direct control of the technology and content (e.g., teleconferencing, computer conferencing).

Technology as Tutor: The instructor plays little or no role over the learning activities and has no control of the technology, the learner has complete control of the learning activities and the technology and content (e.g., intelligent tutoring systems, simulations).

Furthermore, in those cases when the learner can directly interact and control the technology and content, one should be able to identify the locus of this control. That is to say, one needs to determine whether the control over the content resides predominantly with the instructional technology (system control), with the learner (learner control), or somewhere in between (both).

Presence. Digital technology systems provide the means for the instructor and learner to come together physically or virtually, synchronously or asynchronously. These modes can be characterized along two dimensions: space or location and time. The possible combinations of these two dimensions yield the following possible spatio-temporal configurations (Hedberg, Brown, and Arrighi, 1997):

Same-place/Same-time: Instructional and learning activities are synchronous and instructor and learner are co-located. Typical technologies available for this configuration may include all computer-assisted and programmed instruction.

Different-place/Same-time: Instructional and learning activities are synchronous and instructor and learner are remotely located. Typical technologies available for this configuration may include MUD’s (Multi-User Dungeons), On-line chat systems, and many types of computer-conferencing systems.

Different-place/Different-time: Instructional and learning activities are asynchronous and instructor and learner are remotely located. Typical technologies available for this configuration may include electronic mail, Internet Usenet (newsgroups), and electronic bulletin boards.

Same-place/Different-time: Instructional and learning activities are asynchronous and instructor and learner are co-located. Typical technologies available for this configuration may include tutoring systems and simulation software.

It is obvious that the choice of any of the above modes of deliveries will require an “appropriate” choice of technology. It is a commonly held view that some are more appropriate than others. However, the level of technology effectiveness in enhancing the instructional and learning processes remains to be seen, especially with distance learning (Recker, 1997).

Media. Digital technology systems allow for the dynamic access and processing of a multitude of media types (multimedia). These multimedia types commonly include text, audio, graphics, and video, and are usually interactive (e.g., CD-ROM, DVD). Furthermore, when these media are dynamically linked or hyperlinked, they allow for significant learner control over the information. Finally, increasingly, these media are becoming immersive, where the information can be presented in three-dimensional space, allowing the learner to interact with a virtual environment (e.g., virtual reality, simulations). In general, the choice of media is highly dependent on the specific learning context (Kozma, 1991). However, much research is still needed, especially with hypermedia and virtual reality technologies.

Connectivity. Digital technology systems allow for the interconnection of people and information resources. More specifically, they can be designed to facilitate and support communication, collaboration, coordination, and cooperation among members of groups. These technologies are often referred to Computer-Mediated Communication (CMC) and GroupWare. Presently, the Internet is the network of choice with educators to connect instructors, learners and information on a global basis. Furthermore, with the popularity of the World Wide Web, this information can be hypermediated, highly unstructured, and readily available. Consequently, we are currently experiencing an explosion of Web-based instructional systems. The Web has suddenly become the de-facto, global technology platform for instruction and learning. Although Web-based instruction is the fastest growing area of educational technology research, we know little about how to effectively design and implement these systems for educational applications (Romiszowski, 1997).

Learning Outcomes
The assessment of learning outcomes provides the major feedback mechanism within the instructional design process. It is critical in evaluating the instructional system and its effectiveness. The information that is collected as evidence of learning achievement will depend on the nature of the competency being measured. Usually, these
consist of cognitive tests (measurements of intellectual skills), performance tests (measurements of capability), and attitudinal test (measurements of disposition and perspective). Additionally, the instrument and technique used to assess these outcomes will also depend on the learning domain and objective — written tests for cognitive objectives, portfolios for performance objectives, and interviews for attitudinal objectives (Seels and Glasgow, 1998).

The use of Bloom’s Taxonomy of Educational Objectives (Bloom, 1956), as an example, provides a widely accepted and researched framework for evaluating cognitive abilities. These include knowledge, comprehension, application, analysis, synthesis, and evaluation. Furthermore, often, these cognitive skills are classified as lower-order (knowledge, comprehension, and application) and higher-order (analysis, synthesis, and evaluation). Assessment tests based on Bloom’s Taxonomy have been effectively employed to measure the effectiveness of educational technology on cognitive learning (Paolucci, 1996).

Finally, too many educational technology evaluation studies minimize the cognitive domain (Jones and Paolucci, 1996). In general, all learning objectives have a cognitive component associated with them, whether these are primarily behavioral or affective in nature. In general, we think that cognitive tests are particularly important in the assessment of learning and technology and, therefore, they should receive much more research attention that they are presently given.

Conclusions

In this paper we have attempted to define a framework which brings together the multiple dimensions of integrating technology with the learning process. Our goal is to establish the relationships amongst the various dimensions of instructional objectives, delivery system, and learning outcomes. This is done with the aim of identifying the need, and laying a foundation to allow controlled studies that contribute meaningful inputs to the open question on the effectiveness of technology on learning outcomes. Only through systematic research and assessment will we identify the appropriate technologies to deliver specific learning objectives and materials. This framework was developed to provide some guidance in the development of this research agenda.

This is a first stage in providing meaningful answers to these questions. Jones and Paolucci (1996) identify that less than 5% of research completed to date may contribute in this respect, which leaves substantial work for the future. In fact, it is this lack of research, addressing the specific mix of the dimensions discussed that warrant this type of academic discourse.

Additionally, while this framework addresses the teaching learning process and the potential for technology to contribute to the system, it ignores what may be a major consideration that at some point must be considered in a full multi-dimensional analysis. That is the issue of cost effectiveness. Given the investment in technology, we must at some level consider the incremental cost of adding technology to the process and the value added to the learning outcomes by the expenditures made. This may indeed be the most difficult of all dimensions to assess.

CONSIDERING STUDENT ATTITUDE ABOUT INFORMATION TECHNOLOGY IN PLANNING EDUCATION COURSES

D. Lamont Johnson
University of Nevada, Reno

Leiping Liu
University of Nevada, Reno

Student’s attitudes toward information technology have been shown to be a major factor affecting their success in learning and using such technologies (Francis & Evans, 1995; Freedman & Liu, 1996; & Liu, 1997a). The most common studies relating to student attitude and technology appear to focus on examining possible differences in attitude across gender and age groups (Lockheed, Nielson, & Stone, 1985; Elkjaer, 1992; & Klein, Knupfer, & Crooks, 1993). Research further suggests that a better understanding of the differences in attitude toward information technology among students of different majors would be helpful for educators in planning information technology courses or designing training programs (Liu & Fernandez, 1997). The purpose of this study is to examine such major-related attitudinal differences among teacher education students. Specifically, we have examined attitudes toward information technology between preservice teacher education students who are seeking elementary certification (elementary-major) and those who are seeking secondary certification (secondary-major).

Attitudes toward information technology can be viewed as a many-faceted variable, for it is difficult to define a single variable called attitude. A review of the literature suggests that researchers have compared student attitude toward information technology using a variety of variables. A common group of variables include: (a) enjoyment—the degree to which students enjoyed learning and working with a computer (Cooper & Stone, 1996; Temple & Lips, 1989; King & Bond, 1996); (b) motivation—the degree of motivation students have when they learn and use the computer (Kellenberger, 1996; Clarian, 1993); (c) importance—the extent to which students see learning and using the computer as important (Corston & Colman, 1996); and (d), freedom from anxiety—the degree to which students feel anxious while learning and using a computer (Liu, 1997b; King & Bond, 1996; Ayersman, 1996). The literature suggests that all of these variables are related to student learning with and about computers.

For the purposes of this study, elementary-major students’ and secondary-major students’ attitudes toward information technology were compared on four variables described above: (a) enjoyment, (b) motivation, (c) importance, and (d) freedom from anxiety.

To obtain information about preservice teacher education students’ attitudes that could be helpful in planning instruction, elementary-major students were compared with their own group on their attitudes toward information technology their attitudes toward the subject disciplines of mathematics, science, language, and social studies. The same comparisons were made for the secondary-major students. Finally a similar comparison was made involving the total group (elementary-major and secondary-major students combined).

The research questions for this study were:
1. Is there an overall difference in attitudes toward information technology between elementary majors and secondary majors?
2. Do elementary and secondary preservice education majors differ on the attitudinal variables of enjoyment, motivation, importance, and freedom from anxiety as they relate to learning and using information technology in education?
3. Do elementary majors differ in their attitudes toward information technology as compared to their attitudes toward the subject disciplines of mathematics, science, language, and social studies?
4. Do secondary majors differ in their attitudes toward information technology as compared to their attitudes toward the subject disciplines of mathematics, science, language, and social studies?
5. Do preservice education majors in general (elementary and secondary) differ in their attitudes toward information technology as compared to their attitudes toward the subject disciplines of mathematics, science, language, and social studies?

Based on the findings of previous studies, it was hypothesized that (a) a difference in attitudes about information technology between elementary majors and
secondary majors would be found, (b) elementary and secondary majors differ in at least one of the four attitudinal variables, (c) elementary-majors' attitudes toward information technology would differ from their attitudes toward at least one of the four subject disciplines, (d) secondary-majors' attitudes toward information technology would differ from their attitudes toward at least one of the four subject disciplines, and (e) the attitude of all the students about information technology would differ from their attitudes toward at least one of the four subject disciplines.

**Method**

**Subjects**

The subjects in this study were 208 teacher education students enrolled in the College of Education at the University of Nevada, Reno. These students ranged in age from 18 to 53 (the average age was 24.29). Of these students, 138 were female and 70 were male, and 112 were elementary preservice education majors and 96 were secondary majors. Most of the students had no computer experiences.

**Instrument**

The instrument used in this study was derived from Aiken's (1979) attitude scale, a Likert-type questionnaire consisting of 24 statements designed to measure the four attitude variables described above. The instrument has been demonstrated by many studies to be a valid measure of each of the four variables independently (Aiken, 1979).

**Data Analyses**

Repeated measures analyses were conducted to examine the research questions described above. The assumptions for repeated measures were checked and no significant violation of the assumptions was found.

**Results**

**Repeated Measurement I**

This repeated measurement analysis compared the attitude scores of the two groups of students (elementary majors and secondary majors) and is referred to as MAJOR in Table 1, on the four attitudinal variables considered the levels in this analysis and referred to as ATTI in Table 1. Based on Aiken's studies, the Fixed Effects table was used to present the results of this analysis (see Table 1).

</tbody>
</table>

The results show that the difference between elementary and secondary majors' attitudes toward information technology is significant $t = 18.24, p < 0.0001$; and $r = -4.27, p < 0.0001$. The negative value of -4.27 indicates that secondary majors have more positive attitudes toward information technology (higher attitude mean scores) than elementary majors.

The Differences of Least Squares Means from the analysis also show that significant differences were found between elementary and secondary majors at the levels of enjoyment ($t = 5.07, p < 0.0001$), and freedom from anxiety ($t = -4.50, p < 0.0001$). No significant differences were found between the two groups of students at the levels of interest ($t = 1.60, p < 0.2610$) and motivation ($t = -1.60, p < 0.1096$). The two significant values are negative (-5.07 and -4.50), indicating that secondary majors have higher mean attitude response scores at the levels of enjoyment and freedom from anxiety than elementary majors.

The interaction between the groups of students and attitude levels was found to be significant $r = 6.22, p < 0.0004$). The difference between the two groups of students' attitude mean scores at the enjoyment level is different from that at the importance level and the motivation level.

**Repeated Measurement II**

This repeated measurement compared the two groups of students (elementary and secondary majors) on their attitude scores for five subject disciplines: information technology, mathematics, science, language, and social studies, which is referred to as COURSE in Table 2.

<table>

<td>0.0036</td>
</tr>
</tbody>
</table>

Table 2 shows that the interaction is significant; that is, the differences between the two groups of students in certain courses are different. Secondary majors had higher attitude scores in information technology (mean 94.14) than elementary majors (mean 86.90), but had lower attitude scores in language (mean 86.43) than elementary majors (mean 93.72).

The results also show that elementary-majors' attitude scores on information technology are higher than their scores on mathematics ($t = 4.16, p < 0.0001$) and science ($t = 2.81, P < 0.0051$), but lower than their scores on language ($t = 2.33, p < 0.001$). There is no difference between their attitude on information technology and social studies ($t = 0.32, p < 0.7489$).

For secondary majors, their attitude scores on information technology are higher than their scores on language ($t = 2.42, p < 0.0156$), mathematics ($t = 5.84, p < 0.0001$), and science ($t = 2.45, p < 0.0144$). There is no difference between their attitude on information technology and social studies ($t = 1.75, p < 0.0796$).
For the total group (elementary and secondary majors combined) the significant differences were found between their attitude toward information technology and their attitude toward mathematics ($t = 7.11, p < 0.0001$) and science ($t = 3.71, p < 0.0002$); and there is no difference between their attitude about information technology and language ($t = 0.20, p < 0.8380$) and social studies $\chi = 1.51, p < 0.1320$).

Conclusions

The results of our analyses answered all the research questions and confirmed the research hypotheses set forth in this study. The findings from the study can be summarized as follows:

1. Secondary preservice teacher education students have more positive attitudes toward information technology than elementary preservice students.
2. While secondary teacher education students do not seem to view learning about and using computers as more important and are no more highly motivated than their elementary counterparts, they do seem to enjoy their learning experiences more and feel less anxious about using computers.
3. Elementary teacher education students seem to have a more positive attitude toward the subject of information technology than toward mathematics and science, but they seem to feel less positive about information technology than they do about language as an academic area of study.
4. Secondary preservice students have more positive attitudes about the study of information technology than they do about the study of language, mathematics, and science.
5. When all of the preservice education students were combined, the data showed that they were more positive about information technology than they were about mathematics and science, while there was no difference between their attitude about information technology and language and social studies.

Taking the position that students’ attitudes toward the study of any subject influence how fast and how well they will learn that subject, the results of this study suggest that teacher education majors will master topics related to information technology quickly and efficiently, while those who intend to teach at the secondary level will tend to be more highly motivated to learn about information technology and less anxious about using computers than those who intend to teach at the elementary level. Therefore, when planning information technology courses in education, teacher education professors may want to plan ways to help elementary majors build a more positive attitude toward technology. Part of the difference in attitude found in this study may be due to the fact that it is easier for secondary majors to envision ways they will be able to use information technology in their future classrooms. If this is the case, the attitudes of elementary majors might be improved by exposure to an array of technology applications in the elementary classroom. Another factor that might make learning to use information technology a better experience for elementary majors would be to present information and plan exercises designed to make them feel less anxious about using computers and related technology.

Two interesting conjectures can be made from this study. The first conjecture is that teacher preparation students feel positive about their learning experiences with information technology partly because most of these experiences have a major hands-on self-paced component. If this is true, incorporating similar learning experiences in other subjects such as math and science might improve students attitudes towards these subjects. A second conjecture is that students see learning to use information technology as a relevant and meaningful experience. If this is true, learning experience in other subjects might be enhanced by incorporating technology into those subjects.

A NEW APPROACH TO SUPPORTING REFLECTIVE, SELF-REGULATED COMPUTER LEARNING

Margaret M Ropp
Michigan State University

Teacher preparation programs in colleges of education around the country are engaged with the challenge of preparing graduates to teach with technology in our nation’s schools. This challenge is, and will become increasingly, an important issue for teacher preparation programs as they respond to demands for technologically prepared teachers in schools. These demands have come from a variety of sources: from recommendations and legislation at the federal level (Goals 2000: Educate America Act (P.L. 103-277), to individual state and local initiatives (Office of Technology Assessment, 1995). For preservice teachers, these expectations for learning to teach with technology will require continuous learning throughout their inservice careers, particularly in light of the rapid pace of technological innovations in education. In fact, the Office of Technology Assessment (1995) found that the majority of inservice teachers who successfully integrate technology into their teaching were not taught how to do this in their teacher preparation programs. These practicing teachers have learned about new technologies, learned how to use them, and then adapted them for use in their classrooms after entering the work force. Often, this process required extensive individual work, even if the teachers were provided with some inservice training, further underscoring the independent nature of developing proficiency.

The need for self-directed learning is additionally impacted by the knowledge that networked computers have particular affordances and constraints. Most current computer interfaces assume interactions with a single individual who controls the mouse, keyboard and menu selections or commands. Learning to work with such individualistic interfaces typically requires hands-on experience and most learners would work alone for the majority of these experiences over the course of a three-year program in teacher preparation and in the years to follow. This kind of environment assumes that a learner who knows how to be self-directed and independent will be more successful than one who is dependent on structured guidance. Independent learning settings do, however, offer the learner more choice and control over the process and pace of learning.

Given the centrality of self-directed lifelong learning to any acceptable model for preparing teachers to use technology, it is essential that the model be grounded in theoretical perspectives that can be used to inform the discourse about continued learning. Research on self-regulated learning in academic settings has provided new directions for theory and practice that show promise for application to settings beyond the K-12 classroom. In defining self-regulated learning, most theorists would agree with Zimmerman’s (1986) portrayal of students as “metacognitively, motivationally, and behaviorally active participants in their own learning process” (p. 308). Much of the research on self-regulated learning has derived from the study of expert learners in a variety of domains and the subsequent distillation of the knowledge and skills that these individuals possess. As these qualities were explored and identified, researchers attempted to develop ways to teach students how to become more self-regulated. Although students in K-12 schools have been the focus of this teaching, the enduring benefits of self-regulated learning are especially well-suited for transfer to teachers who are learning to use computers and technology in their teaching for several reasons.

According to Ertmer and Newby (1996), metacognition and self-regulated learning strategies are essential to the performance of expert learners who are faced with solving problems in new domains. In novel situations, an understanding of “how” to learn by using specific cognitive skills and strategies distinguishes expert learners from novices who may have an equal unfamiliarity with the content of the domain. If learning to use computers, new software, and information technologies in teaching is considered to be a domain that inservice teachers should be comfortable with, it is also an area that is uniquely fraught with novel learning situations and therefore may be particularly responsive to self-regulated learning strategies.
Perhaps one of the most compelling reasons for the encouragement of self-regulated learning is the potential to enhance perceptions of self-efficacy or control over the learning process (Zimmerman, Bonner, & Kovach, 1996). As new technologies such as the World Wide Web emerge quickly, no one, including teachers, will have had experience with them. For some teachers, the gap between their perceived technology competence and learning to use computers in their teaching is often threatening and overwhelming. Given the knowledge that many teachers are also novice computer users, teachers who are reflective and self-regulated in their efforts to learn to use computers in their teaching, regardless of their level of technology proficiency, may be more likely to engage this task rather than avoid it altogether.

At this point, a further exploration of self-regulated learning with a particular emphasis its metacognitive elements is warranted. In Zimmerman's (1986) three-part model of self-regulated learning, metacognition, motivation, and behaviors or actions all play significant and interrelated roles:

Metacognitively, self-regulated learners are persons who "plan, organize, self-instruct, self-monitor, and self-evaluate at various stages of the learning process." Motivationally, self-regulated learners perceive themselves as "competent, self-efficacious, and autonomous. Behaviorally, self-regulated learners select, structure, and create environments that optimize learning" (p. 308).

According to this definition, metacognition is viewed as one of the component processes of self-regulated learning. It also provides the second theoretical perspective that frames this research. In a paper that addressed continuing motivation to learn, McCombs (1984) proposed one way to view the relationships between self-regulated learning, motivation, and metacognition.

In order to maintain learning interest and implement specific self-directed or self-motivated learning skills and strategies, it is necessary for students to know themselves, what's important to them, and their learning competencies and abilities. That is, a metacognitive self-awareness is an integral component of continuing intrinsic motivation to learn. This self-awareness contributes to perceptions of personal competency and control in both a general and a specific sense (p. 200).

As defined by Flavell (1976), who figured prominently in initiating this line of research with work on metamemory, "Metacognition" refers to one's knowledge concerning one's own cognitive processes and products or anything related to them, e.g., the lea..ing-relevant properties of information or data" (p. 232). Furthermore, Flavell (1981) proposed that metacognition can be differentiated into metacognitive knowledge, experience, and strategies (p. 38).

If self-regulated learning is particularly applicable to learning in new domains such as technology, then teacher preparation programs should conceive of ways to support preservice teachers as they develop the relevant knowledge, skills, and strategies for this kind of learning. Essentially, there must be a focus on fostering those characteristics and habits that will endure in domains of continuous change and innovation such as learning to use technology. To that end, the present study details the development of an innovative approach used during a one-semester course that might be replicated and expanded for use in teacher preparation programs spanning several semesters.

Of all the possible metacognitive and self-regulated learning constructs and strategies, metacognitive knowledge and experiences were selected as the primary foci of this research for two reasons: (a) metacognitive knowledge and experiences can precede and initiate metacognitive actions (Flavell, Miller, & Miller, 1993) and self-regulated learning strategies (McCombs, 1984), and (b) metacognitive knowledge and experiences also may require less explicit instruction and time than the more action-oriented elements, a feature that is a good match for the limited amount of time that teacher educators have with students during a one-semester course.

The potential for metacognitive constructs and theories of self-regulated learning to inform practice rests heavily on their application during the preservice teacher preparation years when there are opportunities to teach and support the habits of self-directed learning. To that end, this study sought to investigate ways in which individual characteristics associated with learning to use computers could be used as pedagogical tools for metacognitive reflection once preservice teachers are aware of them. Although many studies over the last two decades have investigated a variety of individual characteristics, five sets of characteristics were selected for their potential to change through experience and instruction. The characteristics that were studied were (a) computer attitudes, (b) computer anxiety, (c) computer self-efficacy, (d) self-report of computer confidence, and (e) computer coping strategies. While many of these characteristics have been studied alone or with other correlates (Bandalos & Benson, 1990; Delcourt & Kinzie, 1993, Hudiburg, 1996; McInerney, McInerney, & Sinclair, 1994, Violato, Marini, & Hunter, 1989), this particular constellation of individual characteristics is unique in the literature and represents a new, pedagogically-based framework of constructs.

Method

The fifty teacher candidates who participated in this research came from two sections of the same teacher preparation course. One section was reserved for elementary education majors and the other for those interested in teaching subject matter at the secondary level. The individual characteristics of preservice teachers associated
with levels of computer competence were measured at the beginning and end of this one-semester class in a pretest-posttest design. The instruments assessed the five sets of "changeable" individual characteristics and included four openly published instruments and three others that were newly developed for this study. About a week after the surveys were returned to the instructors, the data were analyzed and the scored surveys were given back to students and the group data for the class was presented during a class session. Students were asked to compare their individual scores on the surveys and to try and find where they fit in the distribution of class scores that were represented in the graphical displays of data. The instructors led class discussions that emphasized how the surveys could be used as tools for goal setting and reflection. Students generated ideas and talked about ways in which they could help themselves and their colleagues learn to use computers as tools for goal setting and reflection. Students also participated in hands-on technology activities and the surveys were readministered to students at the end of the semester. The results of the data from Time 1 and Time 2 were again shared with students in a brief class discussion.

Three different sources of data were used to investigate candidates' metacognitive awarenesses, experiences, and strategies. At the completion of first survey administration, the class discussion, and the hands-on activities, students were asked to complete a "fast write" which is a one-page set of open-ended questions that can be completed in about five minutes. The majority of the fast write questions assessed metacognitive constructs. In addition, all 50 teacher candidates participated in short, semi-structured interviews and 7 of the students were selected for in-depth interviews as case studies.

**Results**

Results from the fast write data, brief interviews, and in-depth conversations revealed that the technology-based instructional activities provided many of the teacher candidates with metacognitive knowledge about themselves and others as well as initiated metacognitive experiences in a variety of contexts. Metacognitive experiences are described by Garner (1987) as awarenesses, realizations, or "ahas," and these experiences often flow from metacognitive knowledge. The three different methods of data collection provided different facets and layers of depth to the awarenesses and experiences that were the primary metacognitive constructs investigated in this study. Although evidence of metacognitive activity initiated by instructional opportunities is but one of the theorized components of self-regulated learning, it is a promising first step toward supporting the development of self-directed computer learning.

A selection of responses from the fast writes that were given after the survey completion activity, the class discussions, and the hands-on technology sessions indicate that these activities triggered metacognitive experiences and knowledge.

I always knew that I would have to improve my technology skills to be able to integrate it into my teaching, but completing the survey helped me expand my horizons as to how much technology is really used. (Candidate #9, Survey)

I learned that I am actually on the high end of attitudes and aptitudes, which surprised me. I like working with computers, but sometimes I feel overwhelmed. (#26, Discussion)

I have been "surfing" the Internet for teaching ideas for some time. But we did find an idea which integrated "use" of the Internet in class with the students, which I have wanted to learn how to do. (#26, Hands-on)

I plan on using the Internet for my lesson plans in my classes as well as ideas for my collaborating teacher's classroom when I have to teach again! (#39, Hands-on)

The short interviews given to all 50 students provided them with opportunities to describe metacognitive knowledge and experiences that occurred in contexts that included but were not limited to the activities tapped by the fast writes. For example, knowledge gained from the Computer Coping Strategies scale was instrumental in the computing experiences of a student who believed it changed the nature of her subsequent interactions with computers.

I noticed that after taking the first questionnaire, I thought about the fact that I do use the help buttons or balloons more often. Sometimes I'll just pull the balloons out and say "Okay, let's run through the icons and figure out what things are in programs." I'm much more likely to open up new programs that are just on the hard drive and see what they are. Maybe it'll help me. So I've learned that those things are there, why don't I just use them? (#44)

One student expressed an awareness that he was becoming less anxious as he continued to work with computers.

I always feel like I'm always going to somehow break the computer if I type in the wrong command and I feel less and less like that now. I've learned to be more patient. Just realizing that other people are struggling with the same things through this class and my interaction with you. That's comforting and I don't panic as much because I realize that happens to even the experts. (#33)
The final source of data were the case studies of students who were systematically selected to represent diverse computing experiences. One of these students believed that the Technology Proficiency Self-Assessment that was developed for this study was particularly valuable, not only as a benchmark for initial computer competence, but also as an example of how technology could be used in the classroom.

The proficiency survey actually did a number of things for me. It showed me the things that I've been taking for granted that I was able to do with computers. It gave me a sounding board to see where I was situated in terms of the technology requirement. It provided ideas for how I can use technology as a teacher and as a teacher candidate and it showed me how much I still have to do. It definitely helped me pinpoint areas that I need more practice in and things that I would like to learn how to do. ("Jean")

Implications for Education

This research has enriched the field of education in two ways: (a) by developing a pedagogical approach that provides an immediate and adaptive application of research, and (b) by extending research on self-regulated learning to the domain of learning to teach with technology. As an innovative approach to teaching at the preservice level, this study opens the door for a new line of research that combines psychometric measurement and qualitative research methodology with the direct intent of application to educational goals for learning. Although the examples of metacognitive knowledge and experiences triggered by the technology-related activities presented in this paper are but a small selection of a much larger body of evidence, they clearly show that these activities were successful in their application. Ideally, more time would be allotted to class discussions, reflection, and hand-on instruction during the semester than the four total hours provided in this study. It is encouraging, however, to note the compelling evidence that students reported increased metacognitive knowledge, awarenesses, and experiences given these time constraints. Although metacognitive knowledge and experiences are components of the more comprehensive and long-term processes that support self-regulated and self-directed technology learning, this new teaching approach shows promise for successful elaboration and integration in multi-semester teacher preparation programs.

References

This year, Science section for the SITE 98 Annual Meeting offers up twelve selections. These papers embody a changing perspective about the role of technology in science learning as well as teaching. Several authors report the use of Internet or other distance communications technologies. Other authors investigated the use of alternative lecture and learning styles.

Bodzin and Park report the use of an electronic community to help alleviate the feeling of isolation often felt by inservice teachers. Their research centered around the use of an email listserv to encourage discussion between distant teachers for the purpose of exchanging ideas, as well as to share solutions to common problems.

Coverdale describes a classroom environment wherein students are encouraged to integrate several forms of information gathering tools. This integration also may lead to integrated curriculums, activities which engage students in solving a problem by viewing it from various perspectives. Coverdale’s example integrates the MECC Yukon Trail into several different classroom with help from the World Wide Web to investigate topics of student interest.

Eggebrecht and Dosch report on the development and intentions of the Smithsonian Secondary Science Network. This network was initiated in the state of Illinois to engage students in inquiry-based science programs. This emphasis on inquiry-based science learning is advocated by the National Research Council’s National Science Education Standards.

Hemming and MacKinnon describe the effect notebook computers have on student learning. The focus of their research is the Acadia Advantage, a program implemented at Acadia University, Wolfville, Nova Scotia, Canada, which places notebook computers in the hands of all undergraduate students.

Lehman, Rush, Buchanan and Averill report the findings of Project INSITE, instituted in the state of Indiana to help science teachers and preservice teachers augment their science literacy. Activities were hands-on and involved groups consisting of secondary science educators and preservice teachers engaged in a group-devised inquiry.

McGee reported the results of an online master’s degree program at the University of Texas-Brownville. Students enrolled in the program were thus able to register for classes at UT-B and attend classes elsewhere, if necessary. Respondents indicated that the online program gave students more control over their own learning.

Orlik investigated the integration of technology into traditional, lecture-based instruction, as well as suggesting new methods for integrating educational technology into laboratory courses.

Rezaei and Katz investigated the use of educational technology in instructional design and curriculum development. Rezaei and Katz introduce a three phase program to implement educational technology teaching and learning environments.

Van den Berg discussed the development of an online, World Wide Web based science interactive system. The prototype of this system operates within a larger framework called MUST (Multimedia in Science and Technology). Users were able to gain insight into the teaching and learning styles displayed on the WWW pages, as well as view QuickTime movies of actual classroom experiences.

Winslow and Smith reported the use of an online teacher mentoring program in use at Coastal Carolina University. Users are able to communicate their questions or solutions in a World Wide Web-style chat environment.

Yaffe discussed the development of combined learning, training and support environments at the Open University of Israel. The environments are based upon TAMID, which is an Hebrew acronym representing Communications, Science, Knowledge and Teaching.

These papers indicate the state of technology and science education in the United States as well as from other areas around the world. Enjoy reading them.

THE EFFECTS OF PRESERVICE SCIENCE TEACHERS ENGAGING IN AN ELECTRONIC COMMUNITY

Alec M. Bodzin
North Carolina State University

John C. Park
North Carolina State University

Teaching has been characterized as a culture of isolation (Schlagel, Trathen, & Blanton, 1996). A practicing teacher does not usually have access to ongoing development and support in their classroom setting which promotes idea sharing or support from peers. Electronic communities for teachers have the potential to break down these teacher isolation barriers and provide a support network for teachers in the classroom (Bull, Harris, Lloyd & Short, 1989; Casey, 1997). New science reform platforms, such as the National Science Education Standards, recommend including educational technology, especially telecommunications, in K-12 classrooms. Teachers now have opportunities to join on-line discussion groups on the World Wide Web, post questions to electronic bulletin boards, and communicate thoughts and ideas using an e-mail listserv. Many studies describe how teachers learn about telecommunications technology, the kind of support required for teachers to implement such tools effectively, and the obstacles that teachers must overcome in order to successfully incorporate them into their daily practice (Bos, Krajcik, & Patrick, 1995; Caggiano, Audet & Abegg, 1995; Casey, 1994; Casey & Vogt, 1994; Russett, 1994; Russett, 1995; Sunal & Sunal, 1992; Weir, 1992).

Background

Some studies have been conducted on the effects of preservice teachers interacting with an electronic telecommunications network. The Curry School of Education at the University of Virginia created the Teacher-LINK system in 1984 to study the process of establishing a network to support the student teaching process (Bull, Harris, Lloyd & Short, 1989). This study reported that preservice teachers used Teacher-LINK as a communications link to their university instructors during their field experiences using electronic mail (e-mail) and as an electronic conferencing system. Merseth’s (1992) study on first-year teachers participating in the Beginning Teacher Computer Network (BTCN) showed that first year teachers used electronic telecommunications for personal, emotional, and technical support. Casey’s (1994) study on preservice teachers using Teacher Net at California State University reported the following benefits of preservice teachers using a telecommunications network: increased time to reflect on what they were learning; increased feeling of rapport with and support from their university supervisor; decreased feeling of isolation; increased self-esteem due to mastering technology; and increased knowledge and use of information access and retrieval. The preservice teachers in Waugl and Rath’s (1995) study perceived that networks can enhance teacher training and support their work in the schools by using them to access resources and communicate with others. Waugh’s (1996) study on group interactions and students’ questioning patterns in a university course using an electronic network showed that students posted questions predominantly concerned with technical aspects and network strategies more than personal questions. An exploratory investigation of preservice English teachers using telecommunications during their methods instruction and student teaching reported that electronic mail was an asset for meeting course requirements and maintaining contact between students and instructors (Thomas, Clift & Sugimoto, 1996). The results of a study by Schlagel, Trathen and Blanton (1996) at Appalachian State University point to the structure of e-mail use as being an important factor in eliciting spontaneous exchanges of ideas.

The SciTeach Forum

In order to examine the potential benefits of preservice science teachers engaging in an electronic professional community for science teachers on the World Wide Web, we have constructed a “Web Forum” called the SciTeach forum. The SciTeach forum is a place where science teachers can share ideas, reflections and conversations on teaching and implementation of technology in the classroom and other instructional pedagogy, while also providing support for other members of an electronic professional community. The SciTeach forum is designed with NetForum software. Netforum is a Web based group communication and collaboration system provided by the
University of Wisconsin Biomedical Computing Group.
The program is written in Perl and works on any UNIX-based system with Perl 4.0.1.8 or later that supports CGI subdirectories. Forums are organized into discussion topics and messages. A simple, intuitive toolbar allows user access to NetForum features. Forums can be created and managed by "forum owners" with the administrative tools via the World Wide Web. Forum topics and messages can also be edited via the administrative tools. Forum owners can customize many forum features and can add HTML codes into the headers and footers of each of the forum's web pages.

We selected the Netforum software to create the SciTeach forum because it was available to us at no monetary cost; North Carolina State University has a site license to use the software. The software is easy to use. The software empowered us to structure the discussion topics on the forum in any order of our choosing. The software also enables any user to add a new discussion topic to the forum. Within each topic area a user can post a new message, reply to a message, or reply to a reply of a message. When users first enters a topic area, they are presented with a list of message and reply titles. Each message and reply title displays the author of the message and the date the message was posted on to the forum. The most recent message is listed at the top of the screen. Each message and reply title is a hypertext link. The user clicks on a message or reply title to view the posted message. The software also enables the user to read an entire thread of successive replies to the original message.

The SciTeach forum can be accessed by anyone with a connection to the World Wide Web. A special e-mail account is not a requirement to read forum messages or post messages on to the forum. Unlike many other studies involving preservice teachers using telecommunications during their student teaching semester, we did not have additional funding to equip our preservice science teachers with laptop computers and telephone modems. We assumed that at least one computer in the school where a student teacher was placed would have access to the World Wide Web.

We structured the SciTeach forum to contain discussion topics relating to teaching science content, incorporating instructional technology into the curriculum, and topics relating to teaching pedagogy in general. A special topic in the SciTeach forum called "Preservice Science Teachers" was created as a designated discussion area for preservice science teachers. Student teachers are encouraged to use this area to speak freely about their experiences. Initially, the following topic areas were placed on the SciTeach forum:

- IMSE CD-ROM
- CD-ROMs for Science
- Classroom Management Strategies
- Computer Assisted Instruction (CAI) and tutorial software
- Data Collection and Analysis Tools
- Data Sets from the World Wide Web
- Demonstrations
- HyperStudio/HyperCard
- Instructional Laboratories
- Laserdisks and video
- Portfolios - development and evaluation
- Research in Science Education
- Science Fair project ideas
- Science Software Simulations
- Search engines on the World Wide Web
- Sounds of Science
- Telecommunications in the classroom
- Video conferencing/CU SEE-ME in the science classroom
- Web site reviews and evaluations

Pre-Service Science Teachers

Four more discussion topics were later added to the SciTeach forum by our preservice teachers during their student teaching semester. These topics were:

- Science House
- Working with Special Students
- Learning and Teaching Models
- Assessment Strategies

Two other topics were later added by university instructors (one from another institution other than North Carolina State University). These topics were:

- Quick Help
- Staff Development Opportunities

The SciTeach forum is placed in the context of a larger web site on the World Wide Web called IMSEnet (online available at http://www.ncsu.edu/imse). IMSEnet is a "Network of Instructional Materials for Science Educators" which was created originally as a support network for the IMSE (Instructional Materials in Science Education) CD-ROM.

The preservice science teachers were introduced to the SciTeach forum during the second day of their Instructional Materials in Science Education course at North Carolina State University. This course met each day for the first five weeks of the student teaching semester. The students began their student teaching placements during the sixth week of the semester. Each student was instructed to use the forum in class and was required to post a message on to the forum which introduced themselves. As part of the course work for their instructional materials course, all students were required to post three messages per week to the SciTeach forum.
Exploratory questions:
1. How did our preservice teachers use the IMSEnet forum during their student teaching semester?
2. Does the SciTeach forum serve as an effective means of support for a cohort group of preservice science teachers?
3. What are the benefits of having preservice science teachers interact with an electronic professional community?

The remainder of this paper will show an examples of how preservice teachers at North Carolina State University have used the SciTeach forum during their student teaching semester and discuss what types of messages our preservice teachers have been posting on the forum.

An example from the SciTeach forum

The following example comes from an exchange in the "Classroom Management Strategies" discussion topic section. Miranda had discipline problems with a particular class. She posted a message to the forum which described problems with students behaviors she encountered, her attempts at resolving these problems, and a request for assistance.

Kirk had a similar experience with a class during his student teaching semester and used the forum to share some strategies he found useful in solving some of the student behavior problems he encountered.

Wanda also had a similar experience and offered Miranda a suggestion based on her prior experience.

Jack reflected on what was said in the previous thread of messages and concluded that the problem lay with current pedagogical philosophies.

Such exchanges on the SciTeach forum between Miranda and her classmates enabled her to share an experience with her classmates. The content of Miranda’s original message dealt specifically with teaching pedagogy. She used the SciTeach forum as a way to express tension she was experiencing during her student teaching. She used the forum to request assistance for her problem. The replies to Miranda’s original message showed solidarity among the preservice science teachers. They were each experiencing a similar problem and used the forum as a mechanism to support each other. By using the forum, preservice science teachers were able to discuss problems and contribute ideas over extended periods of time. By engaging in this type of dialogue exchange, the SciTeach forum appeared to serve as an effective means of socio-emotional support for a cohort group of preservice science teachers.

Other kinds of messages

The SciTeach forum has been a useful tool to facilitate communication between our preservice science teachers and university instructors. The forum has been used by our preservice science teachers to express their concerns about course requirements. Many messages have been posted regarding specific course-related queries and housekeeping bulletins. The SciTeach forum has also been used by the preservice teachers to critically reflect on the meaning of being a teacher.

Conclusions

There appear to be many benefits of having preservice science teachers engage in an electronic community. The forum provides a means for sharing and discussing common experiences over geographical distances. The forum provides a way for preservice teachers to receive help and support for the problems and tensions they experience during their student teaching experiences. The forum also serves to facilitate communication channels between the student teachers and their university instructors. The open structure of the SciTeach forum appears to be an important factor in the free exchange of ideas, questions, and other types of dialogue among preservice science teachers.

Preservice science teachers used the SciTeach forum to post questions pertaining to pedagogical issues and personal issues. The forum was also used to exchange professional information such as teaching strategies and curricular material.

Science—901
PREPARING PRESERVICE ELEMENTARY TEACHERS TO INTEGRATE INSTRUCTIONAL TECHNOLOGY INTO THE SCIENCE CURRICULUM

Gregory Coverdale
DePauw University

My office bookcase contains hundreds of science education books and technology journals. In preparation for my elementary science methods course, I recently re-read sections of Carl Sagan’s (1996) *Science as a Candle in the Dark: The Demon-Haunted World*. In this book, Sagan describes the evolution of stone age technology and playfully suggests the probability of an apprenticeship system on the East African savanna established to propagate the long-term production of stone tools. After re-reading Sagan, I turned my attention to a selection of current articles on science and technology education that describe how today’s students and teachers utilize instructional technology to meet educational goals. This juxtaposition of views on technology strikingly indicates how far civilization has come in its use of technology as a tool in everyday life.

Even though research on technology’s effectiveness in promoting better learning is still in its infancy (Trotter, 1997; Kay, 1997), technology in the work and school environments is rapidly increasing. In his book *The Road Ahead*, Bill Gates (1996) argues that even though the information technology of most K-12 schools is far from state-of-the-art, America’s continued investment in technology will “empower people of all ages, both inside and outside the classroom, to learn more easily, enjoyable, and successfully than ever before” (p. 208). Gates (1996) metaphorically describes schools’ ever-increasing use of the Internet and other technologies as a “Gold Rush” (p. 260).

Those involved in teacher preparation or work with K-12 schools know that the Gold Rush towards technology use is on, and its effectiveness in the classroom looks promising. Mann and Shafer (1997) report that America’s huge technology investment in schools is paying off in better student achievement. Although in 1996 only 14 percent of America’s K-12 classrooms were wired for Internet use, and even though access to technology remains an issue (Trotter, 1997), technology continues to be seen as central to school reform.

Teacher preparation programs need to integrate the use of instructional technology into methods courses and field experiences (Brownell, 1997). While most K-12 schools in America provide some form of technology instruction to students, many graduates of teacher preparation programs are not adequately prepared to utilize technology once they become teachers (Brownell, 1997). Thus, one of the primary issues related to schools’ use of technology is the preparation of teachers to use it. Most teachers are willing to learn how to integrate technology into their curriculum if given sufficient training and administrative support (Wallinger, 1997; Mann & Shafer, 1997; Zehr, 1997). While inservice staff development in technology integration will be ongoing, the initial preparation of technologically literate preservice teachers is critical in order for K-12 schools to develop and implement successful technology initiatives. In this paper, I describe an elementary science methods course designed to prepare preservice teachers to utilize instructional technology in teaching science, and to develop an initial phase of technological literacy.

Theoretical Framework

The literature on instructional technology is abundant, despite its relatively recent emergence in K-12 schools. Fulton (1993), Viau (1994), David (1990), Cuban (1993) Grejda & Smith (1994) and others offer definitions and rationales for technological literacy and its role in K-12 education. Because of the recent emergence and rapid expansion of various forms of instructional technology, many in academe link the implementation of instructional technology across the disciplines to the process of school reform. In other words, widespread use of instructional technology in K-12 schools is not the traditional paradigm.

In promoting instructional technology as a means of restructuring schools and curricula, David (1990), Collins (1990), and Sheingold (1990) optimistically described technology’s potential for contributing to the systemic reform of schools. In order best to match the technological society students live in with appropriate curriculum experiences in school, instructional technology must become not just available, but indispensable to the process of teaching and learning. Dwyer et al. (1990) and David
(1990) concluded that teaching and learning must fundamentally change from the traditional paradigm to one that embraces the implementation of instructional technology across the curriculum.

The current literature is replete with studies and examples of how preservice teachers are being prepared to utilize technology and how in-service teachers are currently integrating technology into their curricula (Lonergan, 1997; Davis, 1997; Hancock, 1997; Zhang, 1997; Powers, 1997). While these teachers and others are focusing on innovative ways of using technology, as stated previously, technology integration is not the traditional paradigm. Thus, schools and colleges of education are being mandated to do better in preparing preservice teachers vis-a-vis technological literacy.

In its new report, Technology and the New Professional Teacher: Preparing for the 21st Century Classroom, the National Council for Accreditation of Teacher Education (NCATE) argues that teacher education programs are not adequately preparing tomorrow's teachers to enter the workforce technologically literate. The report acknowledges that "re-educating the existing teaching force will not be easy and will require extensive professional development over many years" (p. 5). The report also argues that it is critical for colleges of education to create a vision and develop a curricular plan that will facilitate transforming the culture of teacher education in a way that situates technology centrally in the teaching and learning process (NCATE, 1997). The report provides several case illustrations that epitomize current and future NCATE accreditation requirements.

Course Structure

In piloting a science education methods course for elementary teachers (Educ 426), instruction focused on the integration of technology into the curriculum. In designing the course, course goals were established that were consistent with the National Science Education Standards (NRC, 1996) and the Benchmarks for Science Literacy (AAAS, 1993). Thus, the course was designed to help students develop scientific and technological literacy.

With these literacies in mind, and with the resources available, four technology projects were incorporated into the course. Meeting four hours per week, students worked on the following technology projects:
1. Participation in a nationwide listserv for preservice teachers taking science methods courses;
2. Participation in a "telecommunity," in which students utilized email to communicate with the instructor, each other, and other preservice students about science-related issues;
3. Utilizing the World Wide Web to explore science curricula and Internet-based science projects; and
4. Participation in an Internet-based technology project called MayaQuest.

Description of the Technology Projects

A pre-test given on the first day of class indicated that even though students had fulfilled their liberal arts science requirement, they had little conceptual understanding of scientific or technological literacy as delineated by national reform documents. Answers on the test also indicated that students' use of technology was limited to occasional email use and using word processing to prepare papers. None were using the Internet as a research tool for their coursework. Thus, while developing technological literacy was a course goal, the purpose of the technology projects was to introduce students to using technology as a curriculum design tool.

The Elementary Science Methods Students Listserv

The elementary science methods students listserv and a similar listserv for faculty was established in February, 1997 by Professor Emily H. van Zee at the University of Maryland. Approximately three hundred elementary science methods students actively participated in the listserv. Students enrolled in Educ 426 were required to review the daily messages, and reply to a minimum of one message per week. Students' replies were also forwarded to each of their own class members and myself. Students indicated that the listserv conversations were useful, but participation in the listserv was very time consuming.

EDUC 260 Telecommunity

The primary purpose of the telecommunity was to model the process of accessing and sharing information electronically, an important aspect of technology use in elementary classrooms. A Notes Conference was established so that class members could communicate with each other, the instructor, and global peers on technology issues, particularly issues pertaining to curriculum design and classroom management. Students also completed weekly assignments and submitted reflective journals directly to the instructor via email. Thus, the instructor was able to communicate via email with students collectively, and individually.

Utilizing the World Wide Web

Current rhetoric in education journals seems to assume that the information superhighway is jammed with students and teachers trying to use it. Educ 426 students, however, had only a "general sense" of what the World Wide Web was and did not know how to begin using it. To prepare them, we first read WestEd's book Tales From the Electronic Frontier, which provides several cases of exemplary technology use in K-12 mathematics and science classrooms. Next, the instructor provided the class with a list of science-related web sites and students spent one two-hour session in the computer lab exploring web sites and learning techniques of web site navigation. The instructor
made short assignments that required students to utilize the web in problem-solving exercises. Finally, students developed and taught a two-lesson unit that utilized the World Wide Web in age-appropriate activities (see MayaQuest below).

**MayaQuest '97: Lost Cities of the Rainforest**

Students participated in MayaQuest because it was an interdisciplinary, interactive, Internet-based project lasting approximately one month. Students were able to follow the daily progress of an actual team of scientists as they bicycled through the Yucatan Peninsula, studying the rainforest and Mayan culture. The MayaQuest curriculum guide is thorough, and is cross-referenced to the National Science Education Standards. After participating in MayaQuest, students worked in pairs to develop and teach a two-lesson unit related to Mayan culture.

**Discussion**

Participation in the listserv was time consuming and labor-intensive. The instructor monitored the listserv messages carefully, and downloaded different types of messages daily. On one hand, students were stressed at the management issues related to this project because they received 15-20 email messages per day. Students were not accustomed to such heavy email traffic, and the process of reviewing, sorting, deleting, and saving messages created time pressure on their personal schedules. Also, students had to be careful about message management because they were required to respond to at least one message per week. On the other hand, students felt the listserv participation was valuable for two reasons: a) they learned that students across the country were struggling with similar issues while they were learning to teach elementary science; and b) they were able to obtain many valuable ideas about science resources, and tips on teaching specific topics at specific grade levels.

A pattern of messages was prevalent through the first few weeks of listserv participation. Messages were very short, soliciting assistance in gathering resources on specific topics. While messages seeking curricular assistance initially dominated the listserv, students' replies became more lengthy and sophisticated, often explaining in detail how resources might be used, classroom management strategies, appropriate web sites to explore, and pedagogical suggestions.

**The Telecommunity and the World Wide Web**

To document the outcome of the technology projects, students compiled a "technology notebook" which included samples of work from all four technology projects. Participation in the telecommunity contributed to a large section in the notebook as students included their reflective journals and instructor responses, messages sent and received on the listserv, email messages and information from MayaQuest, class email discussions, and annotations on useful web sites. The instructor used the telecommunity project to make assignments that pushed students' use of the World Wide Web in problem-solving activities. Students enjoyed the inductive process of exploring web sites, and spent a lot of time on education-related sites such as:

- [www.gsn.org](http://www.gsn.org) (The Global SchoolNet);
- [www.learner.org/k12](http://www.learner.org/k12) (The Journey North Project).

Students became very comfortable in using the WWW to research science topics, and shared annotated bibliographies of web sites with class members as part of the telecommunity project. Much class discussion focused on the quality of web sites and their relevance to curriculum design.

**MayaQuest**

The MayaQuest project and web site was very rich in terms of its interdisciplinary content and its built-in interactivity. Students were not familiar with Internet-based projects and enjoyed monitoring the project and communicating with students and teachers throughout the United States. Students indicated that the interactive nature of MayaQuest was the most interesting and useful feature of the project. Students were required to send and respond to a minimum of one MayaQuest email message per week to learn more about the team's scientific research and how others were using the project in their classrooms.

While students enjoyed participating in MayaQuest, they did express frustration due to access problems. They were often unable to access the web site during the day due to the hundreds, perhaps thousands of "hits" on the site during K-12 school hours. This difficulty however, provided a "teachable moment" because this was an authentic issue related to Internet-based projects.

**Conclusion**

The NCATE standards for technology clearly delineate what teacher preparation programs need to do to prepare technologically literate preservice teachers and maintain program accreditation. Fisher (1997) and Brownell (1997) make a strong case for technology competency in today's preservice teachers. What is indicated in the literature is that there are a variety of models beginning to emerge in teacher preparation programs that require preparation in technology integration. In Educ 426, the students entered technologically illiterate in terms of using technology as a curricular design tool. Thus, my goal was to introduce students to a variety of technological tools to enhance thinking about teaching and learning in the elementary science classroom.
In post-course interviews with several class members, several themes emerged vis-a-vis students’ preparedness to utilize technology in their teaching. Prior to the course, students showed a lack of confidence in their ability to utilize technology and were overwhelmed at the thought of participating in the four technology projects. After completing the course, the same students described the motivational aspects of their own use of technology, their own transformations in seeing the power of technology in curriculum design, and the importance of utilizing technology to access and share information in classroom settings. In describing the benefits of using various technologies in teaching elementary science, one student stated:

Going into it, I didn’t know a lot about it. I was kind of scared of it. Going into this class, I was extremely nervous about it and remember the first day you talked about how everything was going to be over email and the listserv and we were going to do technology projects on the web. I had a hard time that day because I knew I didn’t know how to do it.

And now, I enjoy it, I like it. I have found so many neat projects for children on the web that would make a good classroom much more interesting. This has been a tremendous help and I’m hoping that I will have the Internet in my classroom so that I will be able to use it.

Another student responded:
Before taking this class, neither Tracy or [sic] I would’ve been able to sit down and talk about technology the way we have been...

This anecdotal evidence of the utility of technology integration into science methods courses is consistent with research cited in this paper, and with the vision and standards provided in the new NCATE report on technology in teacher preparation programs. The purpose for developing technological literacy in preservice teachers goes beyond developing competency; it speaks to preparing novice teacher who view teaching and learning in new ways. Technologically literate teachers should “help students pursue their own inquiries, making use of technologies to find, organize, and interpret information, and to become reflective and critical about information quality and sources” (NCATE, 1997 p.4).

A professional development network of science teachers, the Smithsonian Secondary Science Network, is working toward the transformation of teaching and learning in secondary schools in Illinois. The goal is to change teachers' beliefs and practices in order to engage all students in an inquiry-based science program aligned with the National Science Education Standards (1996) developed by the National Research Council.

The Network is a coalition of school-based teams composed of teachers with administrative support. The professional development activities of Network participants are aimed at the creation of an integrated science program in each of their schools. Each of these teams develops their own contexts for learning which we call problem platforms. Each of these programs are different, reflecting the interests and talents of the teachers and learners involved and the resources of the school. Some teams begin with the immediate development of full year, or multiple year, courses. Other teams develop their program more slowly with short, two or three week, projects.

The Network is currently composed of twenty schools in urban, suburban, and rural communities and involves approximately sixty teachers. A website documents and supports the work of network. Currently, curriculum materials used at the Illinois Mathematics and Science Academy (IMSA) - which provide the equivalent of three year-long courses in introductory science - are distributed from their webpage and each local implementation of the program is described as well (Dosch, Eggebrecht & Styer, 1997).

Recently, bulletin board and chat room utilities have been added to the website. These are intended to provide convenient and uncluttered communication among participants and with public and private clients whose support is required for success. The expectation is that these resources will extend the conversation beyond the level found at traditional large group meetings and site visits. However, participating teachers, and secondary school teachers in general, are suffering from "task saturation." Although Network activities will encourage use, the real value to teachers will determine whether electronic collaboration will follow an historical trend (Anderson, 1993). Participating teachers have access to the Internet in their schools, most rarely use either e-mail or bulletin boards. Network teachers frequently comment on the benefits of their collaborations which cross discipline and district boundaries. The question to be answered is whether they will regard electronic collaboration as authentic.

**Illinois Science Education Policy Changes**

On July 25, 1997, the Illinois K-12 Learning Standards were approved by the Illinois State Board of Education. The National Science Education Standards provided the model for the science component. Illinois public school students soon will be required to receive instruction in three areas: Content (Biology, Chemistry, Earth and Space Sciences, and Physics); Context (social and personal issues in science and the nature of science); and Process (inquiry and technological design).

While these new standards present a serious challenge at all levels, the challenge is particularly great at the high school level. Illinois School Code requires a minimum of one year of secondary science instruction; most secondary schools in the state require only two years of science instruction. And, like nearly all secondary schools throughout the nation, instruction is dominated by coverage of content with little or no attention to societal context, the history and philosophy of science, inquiry, or synthesis (Tobin & Gallagher, 1987). The new standards will anchor the revised state assessment which has traditionally played a driving role in the design of classroom activities.

Many other states recently have adopted new standards for science. Educational policy envisioned by Science for All Americans is being crafted (American Association for the Advancement of Science, 1989). Will these changes in policy be reflected by changes in the classroom? Prior experience suggests not (Cuban, 1990; Elmore, 1996); not without a reconceptualization of teaching and system-wide support which permits and sustains it (Knapp, 1997).

**Reciprocity: Teachers as Learners**

Michael Fullan wrote that educational change depends on what teachers do and think (Fullan, 1991). NSF-sponsored science curriculum materials projects, and the...
professional development efforts to train teachers to use these, have had limited success in changing teaching practice. We have erred in assuming that good ideas would diffuse into U.S. classrooms and schools. Teachers' beliefs about the value of the behavioral changes intended by these curricula strongly affected their ability to adopt the materials as they were intended; to support the learning of science by engaging students in the process of science. While research indicates that inquiry-based learning experiences in science classrooms have a positive effect on student performance (Shymansky, Kyle & Alport, 1983; Wise & Okey, 1983), they are rarely practiced (Stake & Easley, 1978; Tobin & Gallagher, 1987; Yager, 1992; Yager & Lutz, 1994). The dominant mode of classroom instruction continues to be that of the transmission of information (Elmore, 1996; Goodlad, 1984; Tobin & Gallagher, 1987).

Teachers' personal experiences as students typically did not involve research, and as such, their models are those instructional practices which emphasize conclusions (Schwab, 1966; Talbert & McLaughlin, 1993). Reliance on the lecture places great importance on classroom management; silence implies attention and student-student interactions are distractions (Tobin, Espinet, Byrd & Adams, 1988). When attempts are made to incorporate inquiry-based instruction, conflict with beliefs in the importance of correct-answers, quiet classrooms, and coverage bring a return to the didactic approach (Brooks, 1983).

There is a reciprocal relationship between theories of student learning and theories of teacher learning. Both students and teachers have naïve ideas about the nature of learning borne of years of classroom experience (McRobbie & Tobin, 1995) and enforced by preservice (McDermott, 1990; Schon, 1987). Teachers' and students' learning experiences which involve procedural tasks and are not intellectually demanding and involve little risk may not lead to durable knowledge (Doyle, 1983). This is the compromise about which Sizer (1984) wrote and is reinforced by typical in-service models of professional development (Burke, 1994). Teachers, as well as students, are capable of inquiry and the experiences of both can be designed to produce conceptual change (McCombs, 1992).

The need for constructivist learning experiences in professional development activities is advocated in the National Science Education Standards for Professional Development and in the recommendations made by those who are leading the creation of a new vision of professional development (Darling-Hammond, 1994; Darling-Hammond & McLaughlin, 1995; Lieberman, 1995; Lieberman & Miller, 1990; Szabo, 1996). In particular, the traditional role of teachers as recipients and teacher-educators or consultants as deliverers of professional development experiences is artificial and counter-productive. Instead, teacher-directed inquiry and collaborative reflective practice are advocated.

The traditional conception of professional development as training for the acquisition of new skills or in the delivery of new curriculum should be replaced by an active process of personal, intellectual growth.

The most effective professional development (greatest impact and most sustainable) occurs in the context of the teachers' school, not another setting.

These guidelines have been implemented by the Smithsonian Secondary Science Network. Participants construct programs for their own schools and evaluate these programs using action research. They communicate the results of their work, serving as resources for each other.

**Integrated Science as a Tool for Change Agents**

Only 17% of women and 25% of men are given the opportunity to encounter physics in the high school classroom (Nelson, Weiss & Capper, 1990). One approach, which the Chicago Public School system is considering, is to extend the secondary science requirement to three years. While qualified science teachers are in short supply, particularly in physics, programs intended to recruit qualified, uncertified science teachers are in place. However, to meet the Illinois K-12 Learning Standards through traditional, disciplinary courses could require a fourth year of science. An alternative approach, which we have adopted (Eggebrecht, Dagenais, Dosch, Merczak, Park, Styer & Workman, 1996) is to compress introductory secondary science into an integrated science program by applying the NSES content standards. Unlike content standards recently developed for other disciplines, the NSES can serve science education by deflating bloated curriculums that include superficial encounters into a sufficiently small set of essential concepts and skills that can be more deeply understood. Furthermore, integration eliminates the redundancy of repeated coverage without increased depth encountered in the traditional sequence. It is expected that each participating school system in the Network will implement their own version of this program while at the same time maintaining alignment with the NSES content standards.

According to the National Science Teachers Association (1996) integrated science curriculums are superior to single science discipline curriculums in several ways. These are: science disciplines are more strongly interrelated; topics are taught in a manner compatible with the student's stage of intellectual development; complex ideas are treated repeatedly over the years, each time at a higher level of sophistication; and students have opportunities to influence what topics they study and how they are studied. We also find the following reasons for this approach to be
compelling for their potentially beneficial effects on teaching practice.

Meeting new content standards requires change

Currently, most students terminate science after 10th or 11th grade. It is highly improbable that in the near future all students will complete four years of secondary school science in which they encounter the four disciplines of physics, chemistry, biology, and Earth and space science. Developing one or two year experiences that include all of these without fragmentation will require collaboration between subject-matter departments.

Teachers are isolated

Collaboration between teachers in different departments diminishes teacher isolation (Siskin, 1995) and allows an examination of habits which disciplinary alliances tend to enforce (Little, 1990). Our experiences, (Eggebrecht et al.,1996) and those of the teachers with whom we work, are that deeper understanding of, and appreciation for, a discipline are generated by these collaborations.

Students and teachers integrate their experiences

Useful knowledge is best developed by learning in multiple contexts (Anderson, 1993; Ceci & Ruiz, 1994; Gick & Holyoak, 1987). Students see instances in which learning has relevance beyond preparation for the next topic. A renewed enthusiasm for concepts which have become stale emerges when connections beyond the teacher's discipline boundary are uncovered.

The use of time and individualization are key elements of reform

Though schools are constantly changing in marginal ways in response to frequent policy changes, the core remains through regularities in the rhythm of periods, departmental relationships, and well defined responsibilities (Sizer, 1992). The integration of science instruction can interrupt this pattern in a way which is both sufficiently demanding and achievable (Eggebrecht et al., 1996).

Network Characteristics and the Role of the Internet

The creation of these integrated science programs is the joint work of a professional development network which began as curriculum development project sponsored by the Smithsonian Institution and the Illinois Mathematics and Science Academy. The project began five years ago with three teachers and thirty-five students. It has grown to sixty teachers and sixty students from other schools, and a year-end symposium in which the work of the Network is communicated to a larger audience. Participating teachers confront the usual challenges of conventional high schools: they teach five or six classes each day involving between 100 and 200 students, they have little or no time for preparation for these classes or to give attention to individual students, they are frequently required to implement decisions for which they have no ownership, student absences are high, and motivation to learn is low.

To participate in the large group meetings of the Network teachers must give up class time and devote additional time to preparing materials for a substitute teacher. There is very rarely time during the day for professional growth. The work day is devoted to maintenance and the professional development activities of the Network are relegated to evenings and weekends.

Given these pressures for time, we believe that the Internet may be used to significantly diminish the burden and increase participating teachers' enjoyment. Electronic bulletin board fora can extend this communication beyond the large group meetings and site visits, perhaps even partially replacing them. Curriculum materials which encourage cooperative, inquiry-based learning are distributed on the Internet in a form that can easily be modified in the time available for classroom preparation. When democratic classrooms and non-traditional curricula are attempted, political confrontations eventually occur. Chat room conversations including state and national level policy makers and leaders in science education reform can provide participating teachers and their local clients access to authoritative voices.

Curriculum Resources

Introduction of inquiry-based curriculum materials without teachers' reconceptualization of their roles may not succeed. While some teachers bring a wide variety of curriculum materials to a learning experience, textbooks are used by 90% of secondary science teachers and these traditionally drive the classroom work (Tobin & Gallagher, 1987; Weiss, 1977; Weiss, 1987). In many ways, the design and use of science textbooks mirrors the current structure and function of schools. It is difficult to imagine sustainable change while maintaining a strategy for classroom management rather than improved learning (Tobin, Tippins & Gallard, 1994).

Two important elements of the school culture have contributed to this reliance on textbooks: teachers have little time to prepare and the medium for distributing text materials makes the modification of available curriculum resources time consuming. A significant impact on educational practice has been derived from word processors.
and web browsers (Ehrmann, 1997). These tools are fundamentally changing the nature of curriculum resources. Curriculum resources which are available electronically in a modifiable form make it more feasible for teachers with little or no preparation time to engage in reflective practice. It is likely that textbooks of the future will be of this form.

Science curriculum resources which are the product of ten years of writing by teachers at IMSA, many of whom once were practicing scientists, are distributed from the Smithsonian Secondary Science Network website. These may be downloaded, at no cost, in a form which can be edited with any word processor, independent of platform. We do not intend to produce a textbook. This would serve to reinforce rather than transform current teaching practice. These resources are adaptive; they can be resequenced to respond to alternative contexts and student inquiries. Also, curriculum materials written by teachers at other schools who participate in the Smithsonian Secondary Science Network will be distributed in this form. Over time we will have a set of curriculum resources which can support an integrative approach to high school science and span the broad spectrum of student characteristics and institutional resources.

Extending the Conversation

Electronic network support through bulletin board and chat room has only recently been added to our website, so the usefulness of these to Network participants is yet to be determined. For our implementation of these features we have chosen software which is designed to support courses on the Internet (Goldberg & Salari, 1997). This approach allows the bulletin board and chat room to be accessed by passwords. This should eliminate some of the superficial comments which clog bulletin boards. It also protects the privacy of postings in a pseudo-professional climate where retaliation is common.

Our experiences with bulletin boards suggest that an incubation period is required. Bulletin boards seem to acquire a personality which some find sufficiently engaging to overcome the impersonal nature of a typed comment, however informally it is presented. We are planning to inoculate the culture by requesting summaries of work-in-progress as bulletin board postings and by scheduling chats to discuss this work.

Status Light

Educational reforms through the century have produced isolated pockets of transformed practice but they do not represent larger reforms (Elmore, 1996; National Commission on Teaching and America’s Future, 1996). In the Smithsonian Secondary Science Network our strategy is to transform the culture of the secondary school science classroom by drawing both students and teachers away from the comfort of the passive exchange of a static, fragmented science. Instructors in the IMSA Integrated Science program work with other high schools throughout the State to transform secondary school science education from the teacher-directed, study of science as unambiguous, disconnected and unmysterious facts to student-directed, scientific inquiry aimed at the resolution of meaningful, and realistically complex, problems.

Our goal is the transformation of secondary science education and a fully integrated science program for students which reflects the national standards for content, practice and assessment. Based on the success of our network thus far, the interest it has generated among teachers and administrators throughout the State, policy changes in Illinois, and the Illinois Transformation Initiative there are some reasons to believe that this goal can be achieved.

"THE ACADIA ADVANTAGE": NOTEBOOK COMPUTERS AND TEACHER EDUCATION

Heather Hemming
Acadia University

Greg MacKinnon
Acadia University

A unique teaching and research setting exists at Acadia University for investigating the impact of computer-based technology on teaching and learning. With IBM corporate support, Acadia represents the first university in Canada to venture into a campus-wide laptop project, through an initiative called “The Acadia Advantage”. The intent of this on-going project is to integrate the use of notebook computers into the undergraduate curriculum. All first-year Bachelor Degree students (1997), lease a Pentium laptop computer from the university. A major rewiring of the campus allows for 1400 students and 170 faculty to have computer network access on and off campus. In addition, the university provides on-going faculty professional development in order that faculty might meet the challenge of pedagogically-sound use of computers in the classroom.

In the Bachelor of Education program, all faculty teaching first year students exercise a variety of strategies to integrate the use of computer-based technology into their courses. This paper examines four computer-based teaching and learning strategies used during the first year of The Acadia Advantage project in the curriculum areas of Language Arts Education and Science Education. The instructors in both courses were interested in using teaching strategies that fit within a constructivist, student-centred framework. The strategies examined are: 1) electronic discussion groups, 2) use of MS -Netmeeting software for constructing models, 3) electronic portfolios, and 4) the critical assessment of resources from the internet that might be integrated into Language Arts curriculum. The study is exploratory in the sense that initial attempts at using the technology are reported, in order that they may be critiqued and refined for future use.

Coding Discussion Groups to Promote Substantive Discussion

Students in education courses often benefit from face to face discussions of pedagogical content. To assist in the implementation of The Acadia Advantage, software (ACME - Acadia Courseware Management Environment) was developed at Acadia which allows for student participation in asynchronous (Kuehn, 1994) electronic discussion groups (E.D.G’s). An added feature of this mode of interaction is the availability of the discussion transcript.

The E.D.G. approach was used as an instructional and assessment strategy in the undergraduate Science Education course. A coding strategy was developed in an effort to promote better quality discussion rather than solely to assign a grade for participation. The hardware, software and specifics of the coding system were explained to students using examples and student-led sample coding exercises. The classes were divided into groups of seven students per discussion group. Readings were assigned and a prompt / question(s) was posed to each individual discussion group. Over a period of two weeks students contributed electronic entries to the discussion group in response to the prompt. After the two-week period, each entire discussion was captured and saved as an MS Word 97 document.

Coding systems for use with written work have been developed for a variety of educational settings by (Bales, 1976; Knight, 1990; Butler, 1992; Adrianson and Hjelmquist, 1993; Ruberg & Moore, 1994). In this case, the coding system used was adapted from previous work on coding. Icons for ten categories of discussion contributions were created using macros in MS Word 97. These categories were: acknowledgement of opinions, question, compare, contrast, evaluation, idea to example, example to idea, clarification-elaboration, cause and effect, and off-topic/ faulty reasoning.

The instructor coded the discussion entries of each individual student within their particular group. Using electronic mail attachments, the “captured” discussions bearing only the individual student’s coding, was forwarded to the student. In addition, uncoded discussions were forwarded to the entire class. In order to provide a summary, clarification and closure these discussions were examined in an in-class exchange.

The codes developed were an attempt to highlight specific strategies for contributing to substantive electronic
opportunities to participate create an equitable context for learning. For example, what does shared power and responsibility look like in a computer-based activity such as the project outlined above? And, does equal opportunity to participate create an equitable context for learning?

Electronic Portfolios as a Class Work Organiser

Electronic portfolios have been assessed and implemented by educators at all levels of instruction (Moersch & Fisher, 1995; Doty & Hillman, 1997; Jackson, 1997; Murphy, Foote, McFarland & Erwin, 1997; Milligan & Robinson, 1997). The use of electronic portfolio in this Science Education course represents a depart from a more traditional sense of the portfolio definition to use of the electronic portfolio as a class work organiser.

At the School of Education each student in the first year class has a Pentium 133 MHz Thinkpad computer with a 1.3 GB hard drive and 24MB of RAM. With the implementation of Acadia Advantage one of the strategies for submitting assignments has been for students to design homepages. These pages containing personal information as well as assignments are then accessible via the Internet. The initial reaction to this was mixed because students did not always want their work to be net-published in an open forum. In response to these concerns professors endeavoured in some instances to password protect sites for individual classes. (i.e. only students in the course for which the page was design are allowed access).

In the Science Education course electronic portfolios were used as an alternative to the homepage format outlined above. To implement the strategy students were instructed in the use of Netscape Communicator Composer. Sample exercises were undertaken in which students prepared documents with text and graphics in MS Word 97. These documents were then saved with HTML extensions. In Composer, students prepared a homepage in which they generated links to the aforementioned HTML documents. Taking the time to allow students to become familiar with the hardware, software and technology was regarded as crucial to the success of this approach because as noted by Adrianson and Hjelmquist (1993), students need to feel comfortable with the technology in order to be successful in electronic projects.

Approximately 75 Science Education students were provided with course outlines of the assignment work to be completed over the term. After preliminary exercises (outlined above) students were instructed to assemble a homepage in the form of table of contents of their course work. Individual students saved their pages to a 1.44 MB floppy disk. As assignments were completed they were linked to their homepages and submitted on their floppy disks. Classwork was e-mailed via the course distribution list to the entire class.

This framework for presenting assignment work is clearly not a traditional portfolio in that students do not choose the work they wish to submit. This format is intended purely as a course work organiser. The types of assignments submitted for these Science Education courses included an introductory philosophy of science education, scanned articles, article reviews, constructivist plans, concept maps, electronic discussion group captures, STS curriculum diagrams, samples of plans embedded with process skills, demonstration outlines, role play plans, plans for integration of music and literature into science, internet resources and a course impact summary essay. As mentioned above, use of a distribution list allowed students to accumulate samples of assignment products from fellow students that they then added to their individual course homepage directory. In theory this exchange is quite facile, in practise it requires significant organisation on the part of the teacher and the student.

Although students were given an introduction to the homepage assembly, some students have noted that more practice at the beginning of the course is necessary to reduce the intimidation associated with the technology. At the other end of the spectrum students with previous experience designing pages felt quite limited in presenting sound, extensive graphics etc. due to the size of disks was constraining for these people. In classes of 75 students the lack of available Zip drives was a real limitation to this solution. Students appreciated the fact that they could easily formulate a database of other student’s work (in particular their lesson plans). Students in general have indicated that their work is much better organised and easier to submit.

Integration of Resources from WWW

With the widespread use of the Internet and the fact that Acadia University students have easy access to resources on the World Wide Web. One of the assignments for the Language Arts methods course was to locate a resource on the worldwide web that might be used in the teaching of Language Arts. Knop, Gebrin and Tannerhill (1997) examined the use of a World Wide Web exploration for a final research project in a teacher-education course. Their findings suggest that the “World Wide Web was fun, easy to access, and rewarding for students who worked with it... Students were doing more problems solving and searching for content driven by related, but interest specific questions, instead of instructor guided inquiry generated by lecture/lab (p. 680).”

The aims of the assignment in the Language Arts course were for students to choose a web-site, to critically evaluate the resource in reference to the principles of literacy
within the coding some categories are reflective of higher cognitive processes. To address this issue, an evaluation scheme of one or two points was used. Codes for acknowledgement of opinion, evaluation and question were assigned a single point while the others were assigned two points (with the exception of off-topic/faulty reasoning which drew no score). It was clear from the first session that ambiguity in the scope of the code made it difficult to assign scores in some situations. In other instances it was difficult to categorise a contribution because it reflected more than one code or it was a contribution not accounted for in the coding.

Following each of the discussion sessions, students were encouraged to raise their grades by contributing more high-level response types in subsequent sessions. Students were aware that contributions should be unique, i.e. after an entry idea was posed to the group the identical point being raised later yielded no score. This feature helped to discourage students from simply stating their opinion totally oblivious to other participant’s input.

One might predict that students would not be spontaneous in their participation in the electronic discussion group. However, in this case it was found that students' contributions were excessive at times to an extent that future attempts may include a page limit. This situation may have been due in part to the fact that students would be graded to a maximum score of ten. In a few instances it was clear that students accumulated many single point scores to the maximum and did not improve their discussion patterns. This however was not the norm. Many students improved their scores as well as proportion of higher level contributions in subsequent discussions. This finding raises questions related to the teacher’s role in facilitating electronic discussion groups. Future directions might include examining the effect Kuehn (1994) refers to as “a conversational style of teacher messaging” whereby the teacher participates actively throughout the discussion.

**ICQ and MS-Netmeeting Projects**

In addition to establishing computer-based discussion groups in Science Education courses, in Language Arts one of the goals was to have students experience opportunities to collaborate and co-operate in-class using their computers. Johnson (1997) identified that interactive computer technology has tremendous potential for teaching the Language Arts. Prior to Acadia Advantage, students in this course were required to construct models of their learning. These activities were conducted in groups, to give students opportunities to work together and learn from one another.

When Acadia Advantage was implemented an opportunity was created to use software to enhance the co-operative and collaborative process in completing these projects. Two software programs were used. The first was ICQ, which operates like a communications sub-network, and allows students to speed-dial one another. It informs an individual when another person is on-line and allows the use of other software programs to be initiated. To complete the task of constructing models of learning, MS-Netmeeting, which allows for an on-screen meeting was used in conjunction with ICQ. Establishing the project with laptops and appropriate software allowed all students within a group to concurrently work on the models from their own computers. Prior to the use of computers in this course, only one person at a time could physically work on the model.

All groups engaged in oral discussions prior to beginning the work on computers. The context was such that it was more efficient for them to verbally discuss rather than communicate electronically as a means for orienting themselves to the task assigned. When creating models all students participated in the creation of the “models of learning” with their computers. However, the manner in which groups approached the task varied. In approximately half of the groups students chose to assume responsibility for various roles. In a particular example, one person was responsible for the graphics, another for aesthetics, a third for the language, and the fourth for the artistry. In this context students appeared to draw on their personal strengths and participated in unique ways within the group. All students participated, yet the manner in which they involved themselves in the task varied. This observation raises a concern regarding the nature of student participation in MS-Netmeeting projects when the group approaches the task by having roles assumed by individuals. In terms of this particular task of designing a model of learning, some roles, such as the use of language and the creation of graphics in the model, appeared to play a more significant part in the creation of the product, than did the roles related to aesthetics and artistry.

In contrast to the groups in which students assumed particular roles in the creation of the model, students in the other groups worked on the various components of the models at the same time. In terms of completion of the task these groups did not appear to operate as efficiently. There were several cases in which students would accidentally erase other students’ work. However, in these groups there was more evidence of a dialogical process on the computer screen in the sense that students worked together to revise their thinking and creation of models. The students appeared to view steps in the model creation as more temporary and open to revision than did the groups with assigned roles.

Observational evidence indicated that in general, the use of computers to conceptualize models of learning created a classroom context in which students had the opportunity to share in the process. However, there was evidence to suggest that the manner in which groups approached the task affected the process in terms of efficiency and dynamics of participation of group members. However, this preliminary assessment raises questions...
learning covered in the course and to design strategies for integrating the web site into an elementary school curriculum. It was stressed that for resources to be effectively integrated there needed to be more than an “add and stir” philosophy at the heart of the process.

To assess whether or not students conceptualized the site as a resource within the scope of a Language Arts curriculum, the question was asked whether the site was viewed as a reference or resource that students could use as they participated in meaningful reading, writing, speaking and listening activities in the classroom. In a sample of twenty-six, only two students made no attempt to link the use of the site to other classroom events involving aspects of Language Arts. For these students, the site use was conceptualised as an entity in itself, to be used in isolation of the Language Arts curriculum. The other twenty-four students viewed the use of the site as a resource to enrich Language Arts activities. Generally the site was regarded as a mechanism for bringing into the classroom information and opportunities which could enhance the already existing curriculum. For example, students made reference to the fact that sites can be used to locate resources for students’ interest areas when students engage in inquiry projects. Other assignments focused on web-sites that created an opportunity for students to read stories of children from around the globe and to receive feedback on their own stories. Further, some assignments focussed on sites that created the possibility to compose a piece of writing through the use of the site, which could then be shared and discussed with peers in the classroom.

In addition to examining the site as a resource within the core Language Arts curriculum, the assignments were analyzed to assess whether or not use of the site was conceptualized as a resource to integrate language across the curriculum to areas such as Science and Social Studies. While there was emphasis placed on this quality for designing Language Arts curriculum within the course, fifteen students did not make any attempt to integrate the use of the site across the curriculum. In nine assignments explicit statements were made such as learning about different cultures, learning about scientific content from visuals, video clips, and text.

One of the goals of the assignment was to develop a critical disposition towards the use of resources from the Web. Students were instructed to assess the quality of the site as a resource in reference to the principles of literacy learning examined in the course. Students’ efforts to provide a critical assessment were divided into three categories. Assignments in which there was no evidence of a critical assessment, those with some evidence, and those which reflect a careful assessment based on the principles of literacy learning covered in the course. Four assignments showed no evidence of critical assessment of the web-site. Twelve assignments demonstrated some attempt at critical assessment and ten students were both explicit and comprehensive in their assessment.

In assessing the nature of the student’s projects in reference to aims of the assignment it was clear that students searched out web-sites based on their own interests and what they believed would be useful for developing a Language Arts curriculum. For the most part, the assignment created a mechanism for students to explore teacher resources with relative ease and wide range of availability. The sites selected were generally conceptualised as an opportunity to bring valuable and useful resources into the classroom that could be integrated into the Language Arts curriculum. For the most part students were not overwhelmed by glitter and glitz of some web-site but rather reflected on its relevance to a Language Arts curriculum. However, in many cases evaluation of the web-sites was not conducted in a manner that reflected an explicit consideration of the principles of literacy learning covered in the course. Given that importance for teachers to evaluate resources and justify their recommendations it would appear that modifications may be necessary. It would appear students in this case require more explicit attention to the process of how to evaluate web-sites as a resource for teaching. In the future, the process of critical assessment will be modelled through a think-aloud strategy. The instructor will use a data-projector to display the web-site to the class and then articulate the process of critical assessment with explicit reference to principles of literacy learning and assessment criteria for examining the site.

Concluding Remarks

Acadia University is an ideal environment to investigate the pedagogically-sound use of computers in teaching and learning. The work discussed here encompasses four strategies used in the teaching the core curriculum areas of Language Arts and Science. The instructors aimed to use teaching and learning strategies that fit within a constructivist, student-centred approach to curriculum.

For the most part the experience of teaching in The Acadia Advantage project was exciting and stimulating for instructors and students. As might be expected the strategies discussed above would be modified in the future. Student feedback and instructor reflection should assist in the process of refinement and modification in the future. It is through the close and critical examination of the strategies that sound-pedagogical practices will emerge from attempts to implement computer-based technology into the classroom environment.

Current reform initiatives in science education such as Project 2061: Science for All Americans and Benchmarks for Science Literacy from the American Association for the Advancement of Science, Sequence & Coordination from the National Science Teachers Association, and Science Education Standards from the National Academy of Sciences stress the need for the development of scientific literacy. For the most part, these reform documents also stress the importance of process or inquiry approaches to science, realistic problem-solving for students, and integration rather than segregation of content disciplines (Willis, 1995).

Underlying these calls for reform in science education is the constructivist view of learning. At its core, the constructivist position argues that knowledge is not transmitted directly from one person to another but must be actively built up by learners (Driver, Asoko, Leach, Mortimer, & Scott, 1994). While constructivism is often viewed from either cognitive (within the individual) or socio-cultural (within a community of learners) perspectives (Cobb, 1994), learning science can be seen to entail both personal and social processes (Driver, et al., 1994). As a result, most calls for reform in science teaching emphasize engaging students in inquiry, promoting active development of understanding by individuals, and having students collaborate in small groups, promoting communication and the development of shared meaning.

One way to help students apply what they learn in school to real-world situations is to situate learning in authentic activity (Brown, Collins, & Duguid, 1991). Technology, while perhaps not essential to this view of learning, is seen by many as a unique agent that can anchor students' learning or support/augment construction of meaning (Cognition and Technology Group, 1991; Kozma, 1991). So, technology is often mentioned as an important element of reform efforts (Adams, Krockover, & Lehman, 1996).

A promising approach to school science teaching/learning which incorporates all of these elements of reform is project-based science. While its bases are not new, project-based science in its current form is a relatively recent development (Krajcik, Blumenfeld, Marx, & Soloway, 1994). Project-based science is characterized by: a) a driving question that is meaningful to the learners and that is anchored in a real-world context; b) student-conducted investigations that result in the development of artifacts and products; c) collaboration among students, teachers, and the community; and, d) the use of technology tools to help students represent and share ideas (Krajcik, et al., 1996).

In a "typical" project, a group of middle school science students might tackle a driving question such as, "What is in our water and how did it get there?" The driving question, which is meaningful to the learners because of its direct relevance to their lives, provides a clear but broad framework that affords ample opportunity for student-generated investigations in real-world contexts. Working in teams, students must generate questions, plan investigations, and evaluate their feasibility. Once particular investigations are determined, students do background research as well as collect and analyze data, such as sampling and testing water from a local reservoir or team members' household taps. In this process, students work together, collaborate with their teachers, and often communicate with members of the community who can assist with some aspect of the investigation. Science content is addressed as it arises naturally out of the context of the investigations. The results of the process are artifacts (e.g., water samples, test results, graphs) and products (e.g., reports, multimedia presentations, portfolios) produced by the students. Technology plays an important role throughout the process as a tool for gathering information, analyz-
ing and representing data, and for communicating the results. The project provides a pivot around which science and technology learning, as well as learning in other subjects, can revolve.

**Project INSITE: An Indiana Project-Based Science Initiative**

Project INSITE, Institute for Science and Technology, is a school-based project that embraces science education reform and the approach of project-based science. The goals of the project, which is targeted primarily at grades 5-9, are to: a) provide the pedagogical and philosophical foundations for improving science education; b) develop strategies to increase students’ active learning of science; and c) develop a delivery system that enhances the roles of both students and teachers in order to create an environment that encourages creativity, critical thinking, and communication through the use of information technologies. The project is directed by staff members of the Eagle-Union Schools in Zionsville, Indiana, and it includes a partnership of Indiana school districts, Purdue University, the Indianapolis Children’s Museum, Indianapolis Zoo, Indiana Cooperative Library Services Authority, Eli Lilly Research Laboratories, Dow Elanco, and others (Krockover, Lehman, Buchanan, Rush, & Bloede, 1997).

The project is in the third year of a four year effort to help teachers learn to implement project-based science activities in their classes. Following an orientation session in May, participants attended the 1997 summer institute, which took place in Zionsville, Indiana (an Indianapolis suburb) and surrounding sites during a three week period between June 23 and July 11, 1997. The institute was divided into three phases. Phase 1 involved a project-based science modeling activity, phase 2 provided participants with the opportunity to observe science and technology in action, and phase 3 was devoted to curriculum development and to the development of participants’ technology skills. The summer institute focused on helping in-service and pre-service teachers understand how to develop learner-centered, project-based approaches to science teaching/learning involving appropriate uses of information technologies.

**Summer Institute Approaches**

There were fifty-seven participants including six pre-service teacher from Purdue University and fifty-one in-service teacher from fifteen Indiana school districts involved in the 1997 institute. As noted above, it was divided into three phases. Each of these is described in more detail below.

During the first four days of the first week of the institute, participants were introduced to the institute and the modeling activity; teams of participants were formed, brainstormed investigations related to the driving question “What is in our water, and how did it get there?”, and planned an investigation. On day 2, teams of participants conducted an investigation related to the driving question. Teams went into the field and collected data with respect to their investigation. One team tested tap water samples. Another team tested freshwater samples from area streams and reservoirs. Still another team tested water upstream and downstream of an area landfill. On day 3, the teams analyzed the results of their investigations and prepared presentations about their investigations. Teams used technology to find relevant information (e.g., Internet research), to analyze data (e.g., spreadsheet software), and to prepare the presentations of the investigations (e.g., Powerpoint). On day 4, teams shared their presentations and reflected on the process that had taken place. The modeling activity set the tone for the entire institute by showing the participating teachers what project-based science looks like and how it can occur.

At the end of week one, participants developed their own driving questions related to the theme “models” taken the AAAS Science Benchmarks. The 1997 driving questions were:

- What’s in an ecosystem and how does it change?
- What makes things stop and go?
- What pollutes our environment and how does pollution affect us?
- How does weather affect our environment?
- How do we affect the life cycles of plants or animals in our environment?
- How does genetics affect my everyday world?
- What is in our soil and how does it affect us?
- How do Indiana aquatic ecosystems work?
- How and why do things fly?

Phase 2 of the institute was devoted to establishing links with the scientific community. A series of site visits was arranged to give participants the opportunity to observe and interact with practicing scientists. All of the participants visited Dow Elanco, an agricultural research center in Indianapolis. During this visit, participants were able to tour working research laboratories and hear a panel discussion by staff scientists who stressed the collaborative, problem-solving nature of “real-world” science and the integral part that technology plays in their everyday work. Participants could elect visits to other area sites such as: Eli Lilly Research Laboratories, Indianapolis Children’s Museum, Indianapolis Zoo, National Weather Service, U.S. Geological Survey, and others. At the end of week 2, the
1997 participants also had the opportunity to interact with and see project summaries by the participants from the previous project year. This provided a bridge from one project year to the next and gave the new participants the opportunity to learn what sorts of activities do and do not work well in the classroom.

Phase 3 of the institute was devoted to curriculum development and to the development of participants' own technology skills. In groups related to their chosen driving question, teams of participants worked together to outline planned activities and develop curriculum materials for implementation during the 1997-98 academic year. Technology training was also provided during week 3 in the form of a series of short workshops on topics of interest to the participants (e.g., Internet searching, Web page development, multimedia, etc.). The culmination of the institute was the production by each group of a set of curriculum materials designed to include: a) learner-centered and project-based science, b) appropriate integration of technology, cross-disciplinary and cross-grade elements, and c) a timeline spanning several weeks. Preliminary lesson plans for these projects were posted to the project Web site at: http://www.projectinsite.org.

**Methods and Data Sources**

The evaluation of the Project INSITE summer institute was designed to address the process and product categories of Stufflebeam's (1983) CIPP evaluation model with special focus on Kirkpatrick's (1979) scheme for training evaluation. Guiding questions were developed within this framework. These included: What was the nature of the training participants received?, What were participants' perceptions of the institute?, and Did participants attitudes toward science teaching and/or technology usage change as a result of the experience? During implementation of the teacher-developed project-based activities during the 1997-98 academic year, the evaluation will also examine implementation questions.

To evaluate the summer institute, data were collected from a variety of relevant sources. These included: a) pre- and post-institute administrations of questionnaires assessing participants' attitudes toward science teaching and attitudes towards computers; b) pre- and post-administration of technology usage checklists; c) a Likert-type survey of participants' attitudes toward the institute; d) an open-ended survey of participants and their perceptions of the project; e) on-site observations of the institute; and f) interviews with participants and staff facilitators. Pre-institute questionnaires were administered to participants during the initial project orientation session prior to the institute in May. Post-institute questionnaires were administered during the last two days of the summer institute in July. Quantitative data were compiled, and descriptive statistics were calculated. Means of pre- and post-institute attitudinal data were subjected to paired samples t-tests to determine if, on average, participants' attitudes changed over the course of the institute.

**Outcomes of the Summer Institute**

Participants showed improvement in technical knowledge as a result of the institute. Based on pre-institute and post-institute administration of a technology checklist, overall knowledge gains were noted in several categories related to what was offered or used during the institute, including: integrated software packages (ClarisWorks, Microsoft Works), multimedia (HyperStudio), presentation software (Powerpoint), Web browsing (Netscape), and the development of Web pages (Claris HomePage). Participants' computer attitudes did not show any real change as a result of the institute. However, their computer attitudes were already quite positive and a ceiling effect likely resulted.

Participants' attitudes about science teaching were assessed using pre-institute and post-institute instruments adapted from the work of Bratt (1973). This measure assessed participants' attitudes toward science teaching in twelve categories, half positively and half negatively worded. For each category, represented by a statement, participants could receive a score of up to 6, indicating the most positive attitudes. Positive shifts were observed in 11 of 12 categories; in five categories, this positive shift was statistically significant. See Table 1. These shifts corresponded to a lessening of a teacher-centered view of science teaching and a movement toward a student-centered view. These outcomes were consistent with the aims of the institute and suggest that the institute was successful in helping to change teachers' attitudes.

Participants' reactions toward the summer institute were generally quite positive. Over 90% of the participants rated themselves somewhat to very satisfied with the summer institute and somewhat to very enthusiastic about the project. The technology training and the week 1 modeling activity were the most positively viewed aspects of the institute. Participants also enjoyed collaborating with other teachers and learning to develop project-based science activities.

**Conclusions**

Overall, the 1997 Project INSITE summer institute was the most successful to date. All of the major reform efforts in science education today make similar suggestions. A scientifically and technically literate populous is essential to our future, and, to achieve that goal, science education must take new approaches. These include approaching science from a hands-on and inquiry-oriented perspective, making science more relevant to the real world of the students, and using technology appropriately. In order for these changes to be effected in the classroom, teachers must receive training that will help them move from the teacher-
centered practices of the past to the student-centered approaches that are advocated. Effective models of teacher training are needed. Project INSITE represents one approach to teacher training for project-based science and technology. Others may wish to replicate this approach to bring about the needed changes in science education.

INTEGRATING TECHNOLOGY AND SCIENCE, A MODEL AT NEBRASKA WESLEYAN UNIVERSITY

Michael McDonald  Merryellen Towey Schultz
Nebraska Wesleyan University Nebraska Wesleyan University

The purpose of this project is to demonstrate an effective way to integrate technology instruction into the science methods course of pre-service elementary and middle school teachers at a liberal arts university. Science and technology instruction are seen as being extremely important in preparing today's students for the future (Bybee, Buchwald, Heil, Kuerbis, Matsumoto, and McInerney, 1989). Lack of application is often a problem with science instruction and use of technology is frequently taught in isolation from methods classes. Too many times pre-service teachers do not learn to actually use technology in practica and student teaching but only design technology projects for pre-service requirements and infrequently utilize what they have learned. At Nebraska Wesleyan University the technology skills learned in Education 187, Instructional Technology, are integrated with expectations and assignments in Education 244, Teaching Science in Elementary and Middle School.

Avoidance of science teaching by elementary teachers is a concern in many schools (NSTA, 1997). As teacher educators who supervise pre-service teachers in the field we have observed avoidance of teaching of both science and technology by pre-service teachers. Lack of confidence and training, time constrictions, pressure to focus on the three R's, and management concerns are cited as reasons for the avoidance of teaching science (Victor and Kellugh, 1997). One of the goals of our model for integrating technology and science is to increase the probability that Wesleyan pre-service teachers will more effectively teach science while also integrating technology in their pedagogy.

Background

Nebraska Wesleyan University is a liberal arts institution in Lincoln, Nebraska with approximately 1,700 students. The Education Department has approximately 230 students, all required to take Education 187, Instructional Technology, a 3 credit hour course. All students who are majoring in elementary education complete Education 244, Teaching Science in Elementary and Middle School, a 3 credit hour course in addition to other necessary method classes (Math, English, Social Studies, Music, PE, Art, and Reading). We will concentrate upon Science because this is the first time we have utilized our model and because of practicum logistics at Huntington Elementary School at Lincoln, Nebraska. It should also be noted that one of the main goals of Nebraska Wesleyan and the Education Department is to foster collaboration with surrounding school districts while modeling the effective integration of technology. Consequently, collaboration with Huntington Elementary, a school within the Lincoln Public School District will also assist all involved parties.

Procedure

Education 244 included a two hour per day, two week practicum experience at a local elementary school. The practicum took place late in the term after the pre-service teachers have received instruction in "doing science", the scientific method, science topics, pedagogy of science teaching, inquiry, planning science lessons and units, and assessment techniques. Instruction was given in integrating science with the curriculum and meeting the needs of individual and special needs children. National Science Education Standards were used to guide instructional decisions of the course instructor and the pre-service teachers (National Research Council, 1996).

Education 244 was taught as an active, hands-on course, thereby modeling good science teaching for the involved pre-service teachers. When it is taught as an active, hands-on experience, science is often the most interesting subject taught in elementary school (Howe & Jones, 1998).

Early in the term students in ED 244 were grouped into pairs. Partnerships were determined by grade level for which students are preparing to teach. Each set of partners were required to create a thematic interdisciplinary unit for use in their practicum. Copies of all units and activities were made for all class members to include in their personal teaching files. By the end of the semester, pre-service teachers compiled files of science units and lesson plans.
including numerous hands-on exploratory activities which they were able to access from the website as well as from their personal files.

Each student taught one lesson from the unit in a simulated peer teaching situation where students first microteach at Wesleyan. After receiving feedback from peers and instructors, students then refined lessons prior to presenting at practicum. Instructors found that peer teaching prior to delivering lessons was effective in preparing practicum students to teach more confidently during their field experiences. Peers reflected on these experiences and made suggestions for improvement.

Themes of the units came from any topic within the areas of technology, physical science, life science, or earth and space science. No two units may use the same topic. In this way the students gained exposure and materials for teaching as many topics as possible.

Following introductory sessions in which students experienced hands-on science lessons and review basic science concepts such as the metric system, measuring, observing, and data gathering and reporting, partners chose their unit’s topic. Students were expected to increase their knowledge base on the topic, to explore existing lesson plans for teaching the topic, and to create original lessons and activities to use in teaching the topic. Information that is gathered was included in the web page that each pair began creating the second week of the term.

During the last month of the semester, pre-service teachers were on-site at a culturally and socioeconomically diverse, K-6 school for two hours everyday for two weeks. Students visited the classrooms on three earlier occasions to build rapport with the students and the teacher, and to learn the classroom routines. Classroom computers, the school computer lab, and Nebraska Wesleyan equipment were used as the partners teach their science units and facilitate the children in creating web pages. The complexity of the children’s web pages was determined by grade and age level, the nature of the unit topic, and the computer skills of the children. These web pages were placed on previously created partners’ web pages. Practicum journals were kept by each pre-service teacher in which he/she was asked to relate events and episodes that occurred during teaching and to reflect on those experiences.

During the last week of the term, students ED 244 returned to campus. Partners shared their web pages in a “Celebration of Learning” with fellow students, parents, cooperating teachers and Wesleyan Education Department members as well as any other people whom students might want to invite. The main intention of the “Celebration of Learning” was to have students present and critique their units and websites while professionally discussing the strengths and weaknesses of their work. A rubric (developed in class) and based upon the Web Page Project Information. will be utilized to evaluate presentations and

Technology Instruction. During the second-third weeks of the semester, students met in the Wesleyan Computer lab and learned how to utilize Adobe PageMill, a webpage editor. Students learned the basics of HTML while initially designing a science-related website. At this point, students simply began designing their site—website scaffolding—and in the course of ED 244 conceptualized their unit topic while also collecting URLs for placing on the website. Students also viewed websites created by previous ED 187 students. The main intent was to teach how to effectively search the Internet for lesson plans while also acquiring skills to effectively utilize technology. Emphasis was on developing and utilizing hands-on science lessons through the use of students’ websites.

Students had the option to seek assistance through Sunday night labs and also sit in on ED 187 if they had not taken 187 and wanted added assistance. Periodic classes (2-3 throughout the semester) were established to provide continued assistance in developing the website/s.

Students also learned how to use a digital camera and scanner. Both multimedia tools were utilized in two main manners: adding personal and science related images to the website; and in involving practicum students at Huntington Elementary School through taking pictures and scanning artifacts of preservice students’ work. Each of these aspects modelled hands-on learning while also continually developing the initial website.

The websites were utilized in on-campus microteaching to provide opportunity to refine prior to utilizing at practicum. Refinements were made and students were shown how to save their projects to a Zip disc (allows storage of 92 MB) so that students could simulate a live connection while also establishing which URLS Huntington students could actually access. This consideration allowed students to individualize learning yet ensure that Huntington students fully learn the science-related information which was required by lessons.

All students websites were linked to one another so that students could learn from each other while also allowing Huntington students to link to more resources. Again, the concept of website scaffolding was modeled as students designed their own website while learning basic HTML elements. Ongoing development allows students to increase the complexity and capabilities of individual websites while also linking to website of fellow students. In turn, the maintaining of sites on the Wesleyan server (at least one year beyond graduation) allows students to access the websites beyond the formal practicum while extending into other practice and student teaching.

Students were required to utilize their website at their practicum while journaling about the experience and sharing with classmates about general effectiveness.
Students discussed the effectiveness of using their site by presenting at the "Celebration of Learning" that was held during Finals Week. Involved participants provided a 15 minute presentation which was evaluated by fellow ED 244 students and faculty. Each opportunity to present allowed students to develop enhanced professionalism and ability to reflect on pedagogy.

The flow chart in Table 1 illustrates the elements of the model and our plan for implementation. The model is being used for one 18 week semester.

Objectives of Model for Integration:
1) Students explore the Internet for science information and for lesson plans that can be used in teaching science to elementary students.
2) Students learn HTML and how to use a web editor, Adobe PageMill, to create web pages.
3) Students learn to use a digital camera and to incorporate pictures into web pages.
4) Students create science teaching units on various topics within the science curriculum.
5) Students create web pages which will be integrated in teaching science units and links to scientific information.
6) Students teach the science units to elementary or middle school students in a practicum experience.
7) Students teach elementary and middle school students to create themed web pages as part of their science units.
8) An overall web page links all web pages of pre-service students so that students can access fellow classmates' website information.
9) Web pages created by the pre-service teachers connected with an overall web page on the Nebraska Wesleyan Education Department server accessible to future practicum students and for use in student teaching.
10) Enhance collaboration between K-12 and higher education.
11) A repository of website-based activities for use in math and science classrooms established and maintained on the Nebraska Wesleyan University server. These activities continually developed and refined for use in preservice and inservice classrooms.

Evidence to Evaluate Project Success
The project utilized formative and summative evaluation to assess success. Evidence to judge success included:
1) Preservice students maintain journals during the course of the project. The journals provide general attitudinal feedback on the use of science lessons and effectiveness of integrating technology
2) The websites utilized in science classrooms. These websites maintained on a Nebraska Wesleyan University server will be accessible beyond the funding of the project thus sustaining the impact of the project. The websites were evaluated with a class designed rubric which will be based upon the rubric of "The Web Page Project Information" (http://206.252.190.23/tips/webpagerubric.html, 1997).
3) A mid-term examination administered over introductory science concepts and teaching pedagogy (information presented weeks one through eight).
4) The number of preservice teachers attending the Nebraska State Technology Convention provide informal assessment of teachers' attitude toward use of technology while also allowing students to gain ideas and network with inservice teachers.
5) Enhanced collaboration between Nebraska Wesleyan University and Huntington Elementary School and providing "in kind" support for the support of preservice students. Evidence determined from informal interviews by instructors.
6) A "Celebration of Learning" held during Finals Week. Involved participants provide a 15 minute presentation evaluated by fellow ED 244 students and faculty.

Dissemination of Plans and Findings
Instructors will disseminate plans and findings by submitting a proposal for presenting at Nebraska State Educational Technology Convention and encourage involved parties to attend. All websites and information is
maintained on the Nebraska Wesleyan University server so that preservice students and inservice teachers may access beyond the actual project. Project results shared with Nebraska Wesleyan University Education Department members. Preservice students encouraged to utilize websites and science-related materials in other practica, student teaching, and later in assisting overall school improvement in becoming inservice teachers.

TEACHER EDUCATION ONLINE: TRIALS, TRIBULATIONS, AND SUCCESSES OF COURSE DEVELOPMENT

Patricia A. McGee
The University of Texas at San Antonio

In 1998, the University of Texas (UT) at Austin, the University of Texas at Brownsville, and the University of Texas at San Antonio received a grant to collaborate and develop an online master's degree in educational technology. The grant allowed the universities, all in the UT system, to pilot four courses. The courses are delivered through electronic means and without regular, face-to-face meetings. Students enroll for a course through their own institution, although the course may be delivered from another, partner institution. Computers in the Classroom is one of these pilot courses offered through the University of Texas at San Antonio (UTSA). At this writing, the course is still under construction. Rather than describe the logistical and administrative aspects of the project, this paper focuses on the actual course development. It describes the process of course development and the course design, including considerations of the learner, content, activities, delivery and assessment.

Bigelow (1997) has identified six premises of learning which underlie a course of study and which can provide a basis for World Wide Web (WWW) course development:

1. "Learning as goal-based". The more clearly goals are stated the more likely a student will understand them and be able to engage in active knowledge construction. In a web-based course, goals must be stated in several ways and in several places to ensure that students read and understand them.

2. "Learning as resource-supported activities". Traditional activities, such as reading, discussion, or observations, often rely on materials that support learning. Web-based courses typically rely on web-based materials that may not be easily or consistently accessible. Instructors must be prepared for the unavailability of Internet resources. They must also provide ways to insure that all students have accessed materials and are accountable for using them.

3. "Conceptual thinking". Learning concepts requires study, practice, and application. Without face-to-face interaction, the instructor must find ways to observe and evaluate student's conceptual understanding on an ongoing and documented manner.

4. "Use of feedback". Regular and timely feedback is critical to student learning. The method of feedback may be a consideration of the individual student's preference or style and the instructor's skills (Thatch & Murphy, 1995). Students expect feedback to be immediate when using e-mail. This may not always be possible for the course instructor in asynchronous communication. It is important to explain feedback and response processes to students and to model them.

5. "Active learning". Students can develop learning skills and strategies by participating in selecting learning activities and sharing information with their peers. This requires some flexibility in the course design for the students to make decisions about what and how they will learn. Students are afforded a greater opportunity to participate in ways they might not in a face-to-face situation (Harasim, 1996). E-mail, web-based discussions, and discussion lists are asynchronous and provide more opportunities for active participation than a traditional course meeting.

6. "Learning motivation". An intrinsically motivated student will be more likely to be actively engaged in the learning process. To increase motivation, the instructor can help students make connections between the course content and the student's practical world. For web-based courses this may mean requiring students to write, observe, survey, or discuss local environments, situations, or policies.

These premises provide the framework for the course, one that would be taught differently, with identical content, in a traditional learning environment. Before determining goals, content, and learning activities, the learner must be carefully considered.

Starting with the Student

The student must be the focus of an online course. What the students already know and what they need to
know are primary concerns, just as they are in traditional course development. The critical difference is that for an online course the instructor must consider the technical skills of the students and the unique nature of computer-mediated communication (Mason & Kaye, 1990).

The students enrolling in this course come from three very diverse demographic areas with a wide range of social, academic, and work backgrounds. Some are K-12 teachers, some are full time graduate students who are not working or have never taught, some are librarians, and others are technology coordinators. One issue that concerned the UT partners about the differences among populations was the question of acceptable performance standards. These were not the same for the three participating universities. What might the standard at one institution was not at another. For example, not all partners felt that it was reasonable to expect sophisticated writing skills because writing expectations were lower at one of the institutions. Eventually, the partners agreed upon basic guidelines for performance, although assessment standards reflect the individual institutions.

During the advising period before registration, it became obvious that entry-level knowledge of the content varied enormously among students. One illustration of this disparity is student understanding of the Internet. Some students were well versed in Internet resources and functions, while a few had never used e-mail or a web browser.

In order to design a course that would match the learner’s needs, a discussion list was created to keep in contact with potential students. As the course evolved, students were asked for feedback. The students had similar questions about the use of computers. These questions and student feedback about course design were used in revising the structure and organization of the course.

The diverse nature of the student population means that there must be flexibility in the course, both in how the students work online and in the focus of their learning. To help less knowledgeable students, the course web site includes links to sites that might help students review and practice online skills before beginning the class. Students also have options in how they turn in assignments and how they interact with classmates. Printed assignments, telephone calls, and face-to-face meetings are encouraged if students are not comfortable in relying on the use of web-based resources and e-mail. The intent for these modifications is not to diminish the advantages of distance learning but rather to start the course where the learner is. After carefully considering the learner’s requirements and suggestions, course content can be designed and organized.

Organizing Content

The nature of the UT collaborative effort in of itself shapes part of the course content. UTSA does not offer this graduate course, although the other partner institutions do. UTSA does have an undergraduate course in which students learn the technical skills for using hardware and basic software, so the graduate level course more appropriately focuses on the application of and guidelines for computer use. The most important considerations for developing content were threefold: the learner, existing guidelines, and resources available.

With the support of a graduate assistant, Sarah Vinch, the author wrote goals, identified entry-level behaviors, analyzed content, and wrote performance objectives. Sarah also kept an ongoing list of terms and definitions that will serve as a student glossary in the web site. The author and Sarah also visited many other web-based course sites and read much of the literature about web-based courses. At first a textbook seemed unnecessary since there was so much information available on the Internet. After talking with students, however, the author decided that the students needed something concrete to which they could refer. After the basic objectives had been determined and correlated to the text, and web-based resources, the course content was organized.

A concept map helped to illustrate the relationship of identified course concepts. Major concepts for the course include: instructional purposes for computer use; technical skills and knowledge of software and hardware; curricular applications for computer use; cognitive theory as it relates to computer use; and guidelines for computer use. The questions generated by the students matched well with these broad topics.

Once the focus of the course was determined, related questions were clustered into learning modules. Objectives and questions were correlated and activities were developed. This question-based approach allows for flexibility in content. For example, one module focuses on the following questions: What computer skills are appropriate for certain ages? How can level of computer skills be determined? What existing guidelines support or limit or clarify the use of computers in the classroom? The district technology coordinators are interested in both teacher and learner skills so they look at these questions with the idea that they will be responsible for informally or formally evaluating teacher competencies and supporting teachers to integrate computers at a given grade level. The elementary school teacher sees these questions as relating directly to students and focus more on classroom applications. All course participants will answer the same questions from their own practical perspectives. Determining how students would answer these questions requires a careful analysis of the nature of the medium and the role of the course instructor.

Developing Learning Experiences

Harasim (1996) notes that computers can increase the participation of all learners through “expanded educational access”, “collaborative learning and teamwork”, “active participation”, and “fluid roles”. The role of the instructor...
must be that of a guide or facilitator rather than that of a director of activities. These qualities are incorporated into the course in several ways.

The purpose of the distance learning course is to provide expanded access of credit hours to a geographically remote population. Harasim (1996) believes that "networks are social places with the potential to be more egalitarian than other media for social interaction". There was, however, some concern among the UT partners that students would not have access to the technology required of a web-based course. As a means of addressing this possible limitation, students are informed of the minimal level of technical expertise and access they need to take the course. They are asked to take a web-based survey, which analyzes their skill ability and probability of successfully completing an online course.

Most students express an interest to work from home, even though most have high speed access to the Internet either at work or at their local university. The course 'place' is a web site with minimal graphics and no frames to allow students with slower connections to open the site without a time consuming wait. Collaborative activities are mostly e-mail-based, the lowest common computer-mediated denominator among students. A toll-free telephone number allows students easy and free access to the instructor. These technical factors can determine the degree of participation for students with disparate skills, computer hardware and software.

The course supports collaboration in several ways. Students have both independent and collaborative tasks to perform. Independent tasks involve readings, observations, and interviews, both on- and offline. Collaborative tasks involve discussions, mentoring, and group projects. An e-mail discussion group is facilitated by a different student each week. This helps the students get to know each other, ask questions, and get feedback or confirmation for their ideas. In online courses that require both e-mail and web-based materials, students often ask questions or request information that can be located in another electronic place (Campbell, 1996). An open forum area, discussion group, or an area of announcements and updates can help prevent replication. The web site used in this course includes a main calendar, which lists each module’s objectives, readings, tasks, and assignments. If a change is necessary, students are informed, via e-mail, to check the web-site.

Time management is another aspect of communication for both students and instructor. Students may be eager to know how much time they should spend on a task or how long a document should be (Campbell, 1996). Deadlines and number of words or text lines for documents may be one solution. Since this course is not organized on a weekly calendar, students must e-mail the instructor each week to explain what they have done and what they are planning to do in the next week. Each assignment includes required length and/or criteria of completion.

Time is also a consideration for the instructor. Most students find e-mail a non-intrusive medium and interact more frequently and more intimately with a course instructor (Campbell, 1996; Harasim, 1996). A computer-mediated course means that an instructor is on call 24 hours a day, seven days a week. In this UT collaboration the number of students enrolled must also be considered. Although this is a graduate course, each institution has a cap of 30 students for a course. This creates a potential problem or insecurities can be overcome. If work is not completed satisfactorily, students are given the opportunity to re-submit within a given time frame. If a student feels they have already mastered an objective they may choose to determine a substitution task at a more sophisticated level. Students may submit work as many times as necessary. If the learning activities connect with the student’s real world environment, they will be more motivated to revise and resubmit work.

Conclusion

In a study of students who had completed online courses, Campbell (1996) found students perceived many advantages to learning online:
- control over own learning
- independence
- sense of responsibility
- self motivation
- working at own pace
- ability to work at home

The proof of success for Computers in the Classroom will be measured by student learning.

References

Assessment

Learner assessment follows traditional lines and is viewed as a means of motivation and feedback. Assessment is based on student participation in online activities, completion of activities and assignments, and a final product that is negotiated between instructor and students. The final product reflects the student’s personal work practices or future goals. Objectives are clearly stated for each module and assignments are given for each objective. If a student feels they have already mastered an objective they may choose to determine a substitution task at a more sophisticated level. Students may submit work as many times as necessary. If the learning activities connect with the student’s real world environment, they will be more motivated to revise and resubmit work.

Problem of Developing of Mixed Computer and Non-Computer Methods for Science Teacher Education

Yuri Orlik
Javeriana University

Educational technology can provide teachers of science subjects with access to some different resources for use in the classroom. However, for traditional and modern science education, the computer is only one means of enabling teachers to improve students' knowledge. Thus it is very important to investigate the question of the place of computer- and non-computer methods in science education, because, as usual, the greatest benefit for better teaching and learning is in using the mixed methodology.

The first problem is to find a valid relationship between non-computer and computer methods in teaching, and an appropriate role for them during lectures, seminars and other academic activities. Traditional teaching methods in science are often: explanation with illustration, instruction with reproduction, heuristics and investigation methods, method of resolution of teaching problem etc. Each of these methods has two aspects: external and internal. The external aspect is easily seen in the class as the instructor displays it in his method of teaching and in the organization of academic activities. The internal aspects of the teaching method can be found if one observes in detail the teaching practice with respect to the organization of the cognitive process, methods for developing students' thinking, logical operations and other didactic functions of class activities. (Science Teaching Reconsidered, 1997).

Computers are used in science teaching in several aspects of this traditional teaching methodology. The first of these aspects is the facilitation of the illustration of didactic material; for example, in the form of the electronic blackboard. This is one good example of how computers improve the quality of the visual representation during the lecture. Modern graphic packets (Corel, Power Point etc.) allow designing teacher information and produce a corresponding increase in the understanding and perception of the information during the lecture.

Another method of using information technology is the application of simulation software. Teaching demonstrations are very important during lecture in the natural sciences. Modern hypermedia and multimedia software allows the direct demonstration of experimental phenomenon as a part of teaching material. For example, the software in CD-ROMs allows the teacher to show important chemical experiments during lectures on different themes of a chemistry course (ChemDemos Videodisc, 1995). In this case, the computer improves some drawbacks and difficulties of the actual chemical experiment and provides another method (such as a video demonstration) of instruction. Multimedia experiments can be cheaper and safer than the real ones. However, we can not be sure that students will know the material better in the multimedia case, as compared with the traditional live experiment. On the other hand, live demonstration of the experimental phenomenon can be better for developing knowledge and skills.

The next important problem is to find the same correlation of traditional and computer methods during science laboratory activities in physics, chemistry and biology. The first case of this computer application may be the simulation of some laboratory activities. For example, there are different examples of traditional software for analytical chemistry, which allow students to master titrations of different solutions before an actual titration. This independent student work allows them to prepare better for the respective themes of the course. Another common computer application is the processing of numerical data, using spreadsheets and other software, which allows one to calculate and do graphics easily. Both of these methods are very useful and give positive results in students' knowledge, as compared with traditional non-computer variants.

A third important problem is the evaluation of students in science subjects. Written exams involving traditional tasks or multiple choice tests are currently the main type used in classes at the moment. Modern software that evaluates students may ease the evaluation process for the teacher. For example, the program VizQuis contains different kinds of questions for the course of general chemistry and provides the opportunity to design new variants of control tasks for exams (VizQuiz, 1995). Software for knowledge and skills evaluation may have some of the same problems as traditional methods, such as...
the lack of variants which evaluate not only lower-order but higher-order cognitive skills (HOCS) (Zoller, 1993). Improving instruction and assessment of HOCS is a very important problem in science education. Thus it is often easier for teachers to utilize traditional evaluation methods of these skills rather than use computer methods.

A similar problem exists with modern Internet tools for learning and teaching science subjects. For example, virtual classes and schools have now become innovative methods of instruction. One of the main characteristics of this method is that students use intelligent software which can play the roles of an assistant and a tutor. It is also important that this software can provide tutoring help in simulation of a human collaborator. The strength of this methodology as compared to our traditional methods of science instruction is that it helps to integrate all modern educational technology resources in the same place (Leddo, 1997). Virtual reality is gradually becoming an important method in computer science instruction and has a direct application to teaching and training at many levels of education (Sims & Elson, 1997). Software for science instruction allows the penetration into nature through objects and scientific models and stimulates the curiosity and thinking processes, which are very necessary for developing students' creative skills. For example, the software iFlying through protein molecules of the University of North Carolina shows a good application which allows students to interact with large molecules and structures (Rheingold, 1991).

Examples mentioned above show that although computers and various software programs can be of great aid for science instruction, there are some essential methodological problems related to their application in classes. Thus it is important to consider further research in this area for both quantitative and qualitative approaches. By making these efforts, we can find answers relating to better development of knowledge and skills in students.

930 — Technology and Teacher Education Annual — 1998
Computer Assisted Instruction (CAI) covers a myriad of different programs. In the area of science education several types of CAI are being used including: drill and practice, dialogue and tutorial, simulation and modeling, “lab” data gathering/analysis/processing or microcomputer based laboratory (MBL), telecomputing, multimedia/hypermedia, and expert systems.

A review of the literature suggests that CAI studies in science education can be divided to two main groups; comparison studies which try to compare CAI method with traditional methods, and cognitive processing studies which focus on “how CAI affects learning processes. Early studies in the field focused on comparison of different kinds of CAI with the traditional method. However, it was concluded that CAI could no more be evaluated by a single outcome study as all textbooks, lectures, or films can be judged on the basis of a single comparison. “To draw general conclusions, it is necessary to take into account the results from a variety of outcome studies carried out in a variety of settings under different circumstances.” (Kulik, Kulik, & Shwalb, 1986, p. 236). Comparison studies, even in the meta-analytical form, can not tell us why students learn better with CAI than with traditional methods. The novelty of using the computer may be one factor. More research is needed that focuses on identifying the characteristics of effective software and the conditions for its effective use.

Studies comparing computer-based learning with non-computer-based approaches do not necessarily provide a link to or understanding of what is going on while students are learning using instructional technology. (Berger, Lu, Belzer, & Voss, 1994) Even the best pre-post and randomized designs cannot answer such questions. Although meta-analyses provide an overall average measure of how computers affect learning, they cannot provide some of the specific information indicating how certain programs have affected the learning process and the specific contexts in which CAI programs were successful. Most meta-analysis studies showed that the most effective type of CAI in science education are simulations and MBLs (microcomputer based experimentation)(Berger et al., 1994). However, not all meta-analysis studies showed the same results, sometimes they were contradictory. That is why there has been a shift in the kinds of questions asked in more current research. As Mayer (1977) noticed “The traditional question concerning the effectiveness of one medium over another proved to be an unproductive question, as have previous studies on media effects.” (p. 17) In most recent research studies the main questions asked are, How CAI can affect learning and do media influence students’ learning? or, as Clark (1983) has suggested, do media merely influence the way learning is delivered?

Generally, CAI programs have had positive effects on student achievement. However, these effects have been less than expected by their creators. Furthermore, the implementation of CAI in the school systems has been too slow. According to Baker and O’Neil (1994) reasons for this slow implementation and the lack of good quality educational software can be attributed to three major sources. First, CAI has not been embraced and pulled by real needs of the school system because institutional focus has been on maintenance of existing goals. Second, with few exceptions, serious commercial developers, inhibited by their own short-term expectations for profit, have rarely targeted education. Third, the poor quality of the available educational software is due to the lack of a theoretical framework in the design of the software and other technical weaknesses in the developmental process.

Historically, the focus of research, and goals and methods used in the field of education software development have been highly related to the advancement of technology, the societal situation and the dominant learning theory. With each advance in technology there has been a concurrent shift in CAI research. Similarly, the evolution of learning theories from behaviorism, through
Theoretical bases of the shift in CAI studies

It is now widely recognized that science education has failed to provide the majority of students with a real understanding of science concepts. Thirty years after Bruner (1960) introduced his cognitive approach in science and mathematics teaching, a large body of research has indicated that there is an urgent need for a new approach to science education. (Steen, 1987; Lochhead, 1983; Trowbridge & Bybee, 1990; Kruger, Palacio, & Summers, 1992).

Jerome Bruner's book The Process of Education (Bruner 1960) presented a theory that changed the whole system of education, especially in North America. Theoretically, the discovery approach or direct experience was supposed to be effective because students would do their own scientific processing.

In the 1960s, it was assumed that if the structure of the discipline was taught with an emphasis on inquiry students would not only learn the content and inquiry skills but would use and apply them to everyday life and to the problem solving in general. (Yager & Tamir, 1993, p. 638)

The most obvious drawback to the discovery learning approach is the amount of time required for students to make discoveries. Some educators (Mestre, 1993; McDermott, 1984) have suggested that it is necessary to reduce the number of topics in the school curriculum in order for the discovery approach to be effective. Given the amount and complexity of information, new fields of knowledge, and the realities of the information revolution brought about by information technology, this solution is impractical. Science education is not limited to traditional classroom instruction. For example, in distance-learning programs, student learning usually takes place away from the host institution. Today, a large amount of information is delivered outside of the school system through information technology such as television and the Internet. On the other hand, if educational systems make use of new models of meaningful teaching and learning, there would be no need to reduce the number of topics taught in schools. With the right approach, large bodies of knowledge could be learned in meaningful and effective ways.

Skinner (1968) queries how a teacher can arrange lessons so that every student makes discoveries. The quickest students in a class are likely to find solutions first; while the other students would simply copy the leaders. Therefore, less capable students may feel discouraged and lose interest. Also, interpersonal problems may arise as a result. That is why teachers have reported that the discovery approach has been boring for some students (Thijs, 1992).

After all, can one be sure that the students who answer the teacher's questions have really discovered the information or did they know it already. Moreover, answering the teachers' questions based on hands-on activities and even solving the related problems, does not guarantee that the concepts have been understood.

Another problem is that discovery learning may not be appropriate for all students. Some students do not have the patience to try different approaches to solving a problem, especially without receiving feedback from the teacher. Other students are not sufficiently motivated to function well in a relatively unstructured situation. Students who are highly anxious or compulsive succeed in more teacher-directed classes (Hamachek, 1987). Furthermore, students may lack the prerequisite skills or self-confidence to make discoveries on their own. This is in harmony with some findings indicating that a learner controlled program is less effective than a computer-controlled program in computer assisted instruction at elementary level (McNeil, 1991). Therefore, a more active role on the part of the teacher or through computer-assisted instruction may be necessary.

The discovery approach or the inquiry method is useful as a valid and comprehensive, evaluation of students' misconceptions. It is also very useful to show the students how their preconceptions are in conflict with scientific realities. However, this is only one step towards meaningful learning. Prior to discovery, the teacher should introduce the objectives of the lesson so that students can be shown where to focus their attention. This requires a bridge between prior knowledge and the content to be learned.

Ausubel (1968) developed a theory of meaningful reception learning called the subsumption theory. The main idea was 'how does a person's prior knowledge and its organization (constructs) determine learning'. Ausubel had two major contributions to the development of cognitive psychology. First, his focus on the importance of prior knowledge and the construction of knowledge which lead to constructivism; and second, the introduction of the concept of advance organizers (AOs) as a bridge between prior knowledge and the content to be learned.

Advance organizers are superordinate concepts within which learners can subsume the new material and relate it to what they already know. Students often have no knowledge about a topic. Organizers are introduced in advance of the material to be learned, and are presented at a higher level of abstraction, generality, and inclusiveness (Good & Borphy, 1990). Advance organizers are not conventional previews or summaries that briefly state the main points in a presentation. They constitute a set of ideas that act as a framework to which the student can logically anchor subsequent related learning (Bowd, McDougal, & Yewchuk, 1994).

As already mentioned, the discovery approach proposes that direct experience is the best way to change students' misconceptions. It assumes that students will see the difference between their preconceptions and the physical
realities and hence, alter their preconceptions. The discovery approach assumes that the conceptual structure of science is based on the generalizations from data obtained in hands-on activities. However, it has been reported (Neressian, 1989; Grayson & McDermott, 1996) that even if students recognize a conflict between their expectations and the data, they will often try to discount the data. Therefore, their underlying, often incorrect belief is retained, or even reinforced. Moreover, inspection of the transcripts of students' discussions in the science classroom fails to show dramatic moments of conversion (Thijs, 1992). Based on the above findings, it would appear that an alternative approach to science teaching is needed.

Recent findings in cognitive learning suggest the need for a more systematic and comprehensive study of the students' prior knowledge and misconceptions. Given teacher training and teaching constraints, it is highly unlikely that a traditional classroom teacher could perform such a systematic analysis. The inventive model of teaching may solve this problem.

The inventive model is a new model for conceptual change based on the advantages and limitations of the approaches discussed above and recent research in science education. This model can be considered as a constructivist model focusing on students' misconceptions and conceptual change. It provides a useful theoretical framework for technology-based instruction.

According to the inventive model, identifying student's misconceptions is not enough. It is more important to identify the underlying conceptions by exposing students to multiple problem situations. This systematic analysis of students' misconceptions can, and should be done, by computer. In fact, it is difficult, if not impossible, for a teacher to do such a systematic study of students' prior knowledge and misconceptions given class sizes and time restraints. Phase I of the inventive method begins with the systematic analysis of students' preconceptions in a particular topic.

Phase II introduces the content to be learned, in order to bridge students' cognitive structure with the new content. These advance organizers can include concept maps and simulations, and/or interactive videos.

Phase III is the essence of this model. The purpose of this phase is to give the students the opportunity to:

Test their preconceptions through hands-on activities or computer based simulations. Articulate and become conscious of their own thoughts by making predictions based on them.

Compare their pre-conceptions with the scientific reality and identify the conflicts between their misconceptions and the scientific realities.

Becoming dissatisfied with their misconception through a multiple problem situation and feel the need for a new concept.

Explore plausible alternatives by themselves or as suggested by the teacher and choose the more convincing alternative.

In Phase IV, the final phase, the teacher provides the advantages of the scientifically acceptable conceptions through a multiple problem-solving situation.

The inventive model provides powerful learning opportunities for students but can be extremely demanding on teachers; therefore, a method must be found to encourage teachers to use it. New instructional technologies have proven to be effective in many constructivist teaching situations. However, more sophisticated technologies must be developed to fulfill the requirements of the new inventive approach to science education.

The new trend

Computers could be used in different stages of the inventive model. Thijs (1992), suggests that classroom experiments are never fully convincing since they can only be performed with imperfect results. Computer can simulate activities that are difficult or impossible to do in most classrooms. For example, it is impossible to eliminate friction and air resistance in a live physics experiment. With technology, “students are placed in a situation where they control an environment by interacting with the computer.” (Carin, 1993, p. 313)

Computers might be used to simulate ideal situations as well as the abstract concepts and processes which are very difficult to grasp in reality. According to Grayson & McDermott (1996) computers combine the realism of animated motions with the idealizations of textbooks and lectures. Therefore, computers can be used both in evaluation of misconceptions as well as in other phases of instruction. Grayson & McDermott (1996) also noted that computer simulations are often much simpler to set up than laboratory demonstrations. Furthermore, a simulated situation is completely reproducible, requiring little intervention from the teacher. The same task may be presented in an identical way to every student.

Evidence shows that computer simulations are as effective as real experiments and save time. For example, McDermott (1984) observed that “the procedures the students used in typing to produce various motions in the computer environment closely resembled the procedures used by students in the laboratory investigations.” (p. 30) Today, computers are considerably more sophisticated than when she made her initial observations in 1984.

Simulations follow the constructivist idea that learners construct their own unique concepts through active participation. Theoretically, students should be more mentally active in the inventive model. Simulations have great potential as a CAI teaching tool and are invaluable in helping teachers to design and conduct experiments more effectively and the pace of instruction can be adapted to the needs of the student. An important aspect of CAI simula-
tions is that the student must constantly be active answering questions, relating concepts to each other, solving problems, and making decisions.

Modeling software differs from simulation in that the learner is an observer of a phenomenon rather than an active participant. Modeling is also powerful in that it allows one to investigate processes such as following the steps in the working of an automobile or observing the movement of magma under ground and climaxing with the eruption of lava (Carin, 1993). Simulations and modeling are effective at enriching minds-on/hands-on activities and discussions.

Minds-on/hands-on experimental activities using a computer and sensor gather, process, and display data directly from the environment have been given the name microcomputer-based laboratories or MBLs (Carin, 1993). MBLs turn the focus away from more trivial mechanical processes in laboratory activities to higher and more creative levels of scientific processes, that is, analysis, hypothesizing, and evaluating. With MBLs, data gathering/analyzing/processing is so easy that it motivates explorations and discovery. Students focus on thinking about data and not merely on gathering it. (Price, 1989)

According to Thornton & Sokoloff (1990) “There is strong evidence for significantly improved learning and retention by students who used the MBL materials, compared to those taught in lectures.” (p. 858) It should be noted that they did not compare MBLs with real experiments in their study. However, they believe that MBLs allow student-directed exploration without the time-consuming drudgery associated with data collection. Time is saved for more observations and multiple problem solving situations, and data are plotted graphically in real time so that students get immediate feedback and see the data in an understandable form.

This is in clear contrast with the discovery approach in which students receive no feedback until the end of the lesson. Thornton & Sokoloff (1990), observed that the immediate feedback supports collaborative learning, and collaborative work provides immediate feedback. Furthermore, because data are quickly taken and displayed, students can easily examine the consequences of a large number of changes in experimental conditions during a single laboratory period. Thus, MBLs have the advantage of using probes to measure real-world physical attributes, simulations allow effective control of the environment, and modeling allows one to see unobservable or time-constrained processes. It would appear that computers can be used effectively both in the first and the second phases of the inventive method.

Meta-analysis studies have shown that simulations and MBLs are the most promising applications of the computer in teaching science. These methods can discern and give guidance as needed so that students discover (construct/invent) as much as possible on their own. “Such techniques should foster the development of critical, original, and flexible thought. Microcomputers can be used by individual students to facilitate independent learning; some students can learn in one way and other students in a different way.” (Berger et al., 1994, p. 487) The importance of cognitive style in learning is now well documented in the literature (Riding, 1997). Such instructional diversity is very difficult to achieve in a classroom setting, where the entire class is usually doing the same thing.

A detailed analysis of students’ interactions with the computer (often by keeping log files of keystrokes and mouse moves) is an invaluable source of information on students’ cognitive processes. Berger (1982) and Dershimer, Berger, and Jackson, (1991) have shown powerful learning curves and teaching efficiency in first-year college chemistry. They also discussed, how log files can be used to describe the learning and the process of estimation in a gamelike environment.

Mayer (1977) states that “Instructional development is too often based on what computers can do rather than on a research-based theory of how students learn with technology. In particular, the visual-based power of computer technology represents a grossly underutilized source of potential educational innovation.” (p. 17) According to Mayer, computer-based multimedia learning environments provide students with the opportunity to work easily with both visual and verbal representations of complex systems. However, to fruitfully develop these potential educational opportunities, research is needed on how people learn with multimedia. He concludes that on the theoretical side, the results of an extensive series of studies using a variety of materials provide consistent support for the generative theory of multimedia learning. According to this theory, “coordinated presentation of explanatory words and pictures is effective because it helps guide learners’ cognitive processes.” (Mayer, 1977, p. 17)

CAI also has the potential to facilitate ‘learning how to learn’ and has been used successfully for teaching problem-solving skills and cognitive strategies. Friedler, Nachmias and Linn (1990), used science software combined with MBL activities on heating and cooling to show that problem-solving skills or scientific reasoning can be improved (as measured by a “scientific reasoning test”). With increasing use of expert systems and artificial intelligence, it is proposed that conceptual maps could be designed with computers which have access to students’ conceptual knowledge. Conceptual maps are strategies for conceptual change which can be used by teachers in all phases of the inventive model especially in the third phase.

In summary, the basic rationale of the inventive model is the belief that conceptual change does not occur simply because students see a conflict between their preconceptions and the scientific realities; rather, students, after testing their preconceptions will gradually realize the
advantages of scientific explanations. This will happen only if the teacher/technology supplies the required corrective feedback, and provides explanations of the advantages of the scientific conceptions through a variety of demonstrations. The effectiveness of different components of this model in science teaching have been well documented (Dykstra, Boyle, & Monarsh, 1992; Berger, et al., 1994).

Hypermedia/Multimedia software development tools such as Authorware offer a unique opportunity for research in science education (Berger, et al., 1994). An integral part of instructional technology is the automatic logging of student actions. Combined with hypermedia techniques they provide important tools for testing this new model and for understanding the cognitive processes underlying the learning.

At The University of Calgary, the research team is investigating the effectiveness of the inventive model in teaching physics at the high school level using technology to support the learning environment. Computer-assisted instruction is being designed to fit the model—theory in search of technology. If the model is accepted, then perhaps teachers will utilize the technology.

MULTIMEDIA CASES IN ELEMENTARY SCIENCE TEACHER EDUCATION: DESIGN AND DEVELOPMENT OF A PROTOTYPE

Ellen van den Berg
University of Twente

This paper discusses the design and development of a prototype of a case-based interactive system, delivered via CD-ROM and the WWW for use in preservice teacher education. The development of this prototype has been conducted within the framework of the MUST-project MULTimedia in Science & Technology). The MUST-project is a joint venture on behalf of three Teacher Education Colleges, the National Institute for Curriculum Development and the University of Twente in the Netherlands. The MUST-project aims at developing multimedia cases for the professional development of prospective teachers in elementary science and technology education. Multimedia cases are considered to provide a powerful learning environment that stimulates and facilitates the prospective teachers' reflection on learning and teaching. They consist of a combination of edited video-tapes of classroom events, as well as audio-taped information and text. The MUST developers employ an evolutionary prototyping approach, which combines input from theory and practice through the cyclic process of design, development and formative evaluation (in the field) of prototypes. This approach is facilitated, in part, by the authoring system used to create and revise prototypes: Authorware 4.0. This is a powerful, yet friendly tool which, for educational purposes offers two crucial advantages: a) educational experts (as opposed to ICT experts) can do the programming themselves, thus closing the communication gap between developer and programmer; and b) Authorware's flow-line authoring style makes it easy to cut and paste entire modules from one location to another, thus supporting true rapid prototyping.

In the next section, one of the main sources of inspiration for the MUST project is briefly outlined. Subsequently, the design and development of the prototype "Liquids in Test Tubes" will be further elaborated.

Cases and case based instruction: from linear structure via hypertext to hypermedia

Cases and approaches to case-based instruction offer curriculum materials and pedagogies to alter teacher education. Although they may be new to teacher educators, written cases and case-based instruction have been popular in professional development enterprises, such as law and medicine (cf. Lacey & Merseth, 1993). In general, cases bring the complexity of professional practice into educational programs, and thereby help to bridge the gap between theory and practice. Until now, the vast majority of cases for educational purposes have been given written form. They are crafted in compelling narratives with a beginning, middle and end, and situated in a specific event or in series of events (Shulman, 1992).

Written cases, however, are subject to a linear sequenced text structure. Hypertext, however, provides a nonlinear environment for organizing and displaying text. In such an environment, nodes of information are dynamically linked (McKnight, Dillon & Richerson, 1996). Stanton and Stammers (1990) give (partly empirically based) reasons why such an environment might be superior in supporting the learning process. They argue that nonlinearity:

- adapt to different levels of prior knowledge;
- encourages exploration;
- enables students to see a subtask as part of a whole task, and
- allows students to adapt material to their own learning style.

Hypermedia (or multimedia) can be perceived as an extension of hypertext. This concept refers to the integration of media such as audio, video, graphics, animation, spatial modeling and text, into one computer system (Cennamo, Abel, George & Chung, 1996; Jonassen & Reeves, 1996; Lacey & Merseth, 1993). Multimedia can stimulate more than one sense at a time and in doing so, may get and hold more attention (Jonassen & Reeves, 1996, p. 703). Particularly in teacher education, the use of video
recordings of classroom teaching in multimedia cases seems to be very promising, because they may capture the similarity of events occurring in classrooms with greater accuracy than written text: “a picture is worth a thousand words.” Kinzer (1997) paraphrased this maxim by saying that in order to capture the complexity of teaching one needs a thousand pictures.

Jonassen and Reeves (1996) have developed convincing reasoning as to why computers (and thus multimedia) should be perceived as cognitive tools for educational purposes. These tools refer to technologies that enhance the cognitive powers of human beings during thinking, problem solving and learning. In multimedia-based cognitive tools, information is not encoded in predefined educational communications that are used to transmit knowledge to students. Rather, such multimedia productions intend to actively engage students in creating knowledge that reflects their comprehension and conceptualization of information and ideas. In this way, multimedia cases fit into a constructivist vision of learning.

From this perspective, multimedia cases offer ample educational advantages for (prospective) teacher learning (Bliss & Mazur, 1996; Cennamo et al., 1996; Fitzgerald & Semrau, 1996, Harfield, 1996; Nicais & Barnes, 1996) as they:

- **Stimulate** an active learning attitude in a learner-controlled environment;
- **Yield** the possibility to revisit classroom events in order to make sense of them;
- **Show** the cases from myriad perspectives;
- **Offer** procedural support for instructional design and classroom teaching;
- **Lessen** the gap between theory and practice, by giving practice a more profound and integrated position into teacher education programs.

### Design considerations and decisions

In this section, the design considerations and decisions underlying the development of the MUST prototype are outlined. Beginning with prior commitment to case-based instruction, the aims and functions of the MUST cases are described; and finally, the design choices are presented.

#### Prior commitment

The MUST project’s prior commitment to case-based instruction impacts subsequent decisions about more precise characteristics of the cases. In the MUST-project, the cases are examples (cf. Merseth, 1996) of more constructivist classroom practice in elementary science. To avoid any misunderstanding, these examples are not meant to be followed uncritically. On the contrary, they intend to stimulate reflective thought and communication. The cases are being designed in such a way that they provide ample opportunity for analysis and reflection.

The cases are “layered”, which implies that different perspectives, in the form of additional information regarding the actual classroom teaching and comments, are included. Comments are particularly meant to bring about an internal cognitive conflict (Levin, 1995) and so stimulate students to in-depth processing of the information presented in the case.

### Aims and functions of MUST-cases

The aims of the MUST-cases are to stimulate prospective teachers’ pedagogical reasoning in elementary science and technology by situating learning in the complexity of classroom teaching. It is hoped that, through context-rich case descriptions, prospective teachers will be more able to construct and reconstruct their knowledge base by means of personal and collaborative reflection in a community of practice. In other words, the cases intend “to foster the three Cs: complexity, constructionism and community” (Lacey & Merseth, 1993, p. 547).

The MUST cases intend:

- **to demonstrate** exemplary practices in a realistic context;
- **to stimulate** reflection on pedagogical content issues;
- **to support** the design and implementation of high quality teaching;
- **to provide** a communication system for the exchange of ideas.

### Design choices

McKnight et al., (1996, p. 630) suggest conceptualization of usability issues underlying the design of hypermedia systems in terms of four basic factors: the users, their tasks, the information space in which the task is being performed, and the environment or context in which all these interact. Application of their suggestions to the MUST-project leads to the considerations presented below.

**Users.** In a multimedia system for teacher education, two user groups are to be distinguished: the teacher educators and the students. The computer skills in both groups vary from hardly skilled at all to very elaborated. This implies that the interface of the multimedia system must be very easy to handle without boring the more experienced users.

As far as the teacher educators are concerned, it must be recognized that there are differences in beliefs about quality science teacher education and science teaching. The MUST-project favors flexibility of use of the multimedia cases and does not want impose a prescribed path on teacher educators (or prospective teachers). However, this flexibility of use has its boundaries, as the full educational potential of the multimedia cases will only reached in a constructivist learning environment.

As far as prospective teachers are concerned, the MUST-project intends to develop multimedia cases that can offer a challenging learning environment for students just starting
the teacher education program, as well as for more ‘mature’
students.

**Tasks.** For teacher educators, the use of multimedia
cases will require a change in their current practice. Teacher
educators need to act as coaches of the students, and take
their ideas as a starting point for the learning process. The
MUST-project intends to support teacher educators by
means of workshops and written guidelines to be created
based on the implementation experiences of the teacher
educators involved in the project.

To support the flexibility of use by both teacher
educators and students, different types of assignments are
incorporated into the cases. Similarly, the system offers
flexibility in that the teacher educators are free to add
assignments (related to the cases) within the program.

**Information space.** Actually, the question about the
information space refers to the boundaries of each case. In
the MUST-cases, a distinction is made between the CD-
ROM-component and the WWW-component. As MUST
strives to incorporate the ideas of users, a WWW-compo-
nent serves as a “boundless” information base, to which
MUST users may contribute their suggestions for activities,
additional cases and practice work. In addition, the WWW
user has access to a broad domain of information via
additional Internet links. The CD-ROM-component of the
information space is limited to what the designers put into
case, but has the advantage that it may be run locally
(regardless of whether or not an Internet connection is
available at the moment). In addition, this also omits the
difficulties associated with (memory intensive) video
fragments having to be downloaded from the Internet. On a
CD-ROM, they may be accessed quickly and easily.

**Context.** Large-scale reform of Dutch elementary
teacher education has been planned and partly imple-
mented by the Ministry of Education. An important aspect
of this reform is to stimulate self-directed learning of
students, both individually and collaborative. Within this
context, the Dutch government advocates the use of
multimedia. However, policy regarding the integration of
media in teacher education programs remains sketchy, to
date. So, the MUST-project may also be able to contribute
to a greater clarity in terms of the possibilities and limita-
tions of multimedia cases in the larger scale reform of
teacher education in the Netherlands.

**Description of the MUST prototype**

In order to facilitate a better understanding of the
MUST project, a description of the prototype itself may be
useful. Entering the program, users encounter the opening
screen (Figure 1) which illustrates how this prototype will
be integrated into the whole program.

At this stage in the MUST-project, the users have one
option, to choose “Liquids in Test Tubes.” This is the case
that is being used for prototype development and evalu-

111

Figure 1. Opening Screen

After this choice, the users enter the main menu of the
case selected. (Figure 2).

Figure 2. Main menu for the case

A star has been chosen as a metaphor for the interface,
because it represents the nonlinearity of information.
Additional reasons include the notion that “stars” are part
of the science curriculum, and they are associated with
“brightness.” Clicking on the sun in the right corner of the
screen gives the user access to the MUST WWW homepage
(http:\www.to.utwente.nl\crc\mustweb).

Placing the video clip at the heart of the star emphasizes
that actual classroom teaching forms the core of the case.
(Due to budget constraints it was not possible to incorpo-
rate a new video into the current prototype. Instead, an
existing video clip was used, originally developed for
inservice education purposes).

By clicking on the word, “video”, the user enters the
screen pictured in figure 3.

The user may view the entire clip (17 minutes) from
start to finish, or skip through sections by clicking on the
particular lesson stage s/he is interested in.

938 — Technology and Teacher Education Annual — 1998
Background information is presented in order to contextualize the classroom lesson (see figure 4). This background information intends to help the user to interpret the video. It provides factual information about the school, but also about the school’s educational philosophy. The teacher page includes information about that teacher’s view on student-centered elementary science. The class page contains some general information as well as authentic student work.

The assignment component offers various forms of assignments created for the future teacher; the typology used is as follows: meaning, critical and practice. The “meaning” assignments ask users to formulate the way they comprehend the information presented in the case. These assignments may be especially appropriate for prospective teachers in their first year of teacher education, because at that time they have little practical experience. In the “critical” assignments, users are stimulated to reflect upon the information presented in the case and to formulate their own opinions about strengths and weaknesses of the lesson, why the teacher made certain decisions etc. In the “practice” assignments, the users are asked to take action, by developing and implementing their own lessons.

The users may also study and print the lesson proposal upon which the video was based. They have three options: the complete proposal, a brief outline and they may assemble a “tailor made” (custom) proposal.
Finally, the curriculum area illustrates how the lesson used in the video case fits into a complete lesson series, and into the Dutch national curriculum for elementary science.

**Final remark**

The MUST design team has experienced the design and development of a prototype to be a professionally rewarding enterprise. They would recommend to others intending to design multimedia to begin the prototyping phase(s) as soon as possible. Not only have concrete prototypes aided in the formulation of our main objectives, but actual prototypes have served to severely enrich the level and content of our design team discussions. Moreover, concrete prototypes (demos) provide an excellent means to communicate the (often otherwise abstract) aim of the project with others, such as sponsors (!) and intended users.

**Acknowledgement**

The author would like to express her gratitude to Irene Visscher and Susan McKenney for their expedient programming of the MUST prototype.

VIRTUAL INTERNS IN THE FIELD: PRE-SERVICE EDUCATORS AS ONLINE MENTORS TO AT-RISK MIDDLE SCHOOL SCIENCE STUDENTS

Joseph Winslow
Coastal Carolina University

Doug Smith
Coastal Carolina University

The World Wide Web has become a popular Internet technology for use in the classroom (Quinlan, 1996). Graphical browsers, such as Netscape or Internet Explorer, provide students and educators with simple “point and click” access to numerous types of online resources, including networked databases, publications, multimedia files, and various discourse media.

Of this last type, electronic mail is perhaps the most widely used. An asynchronous system, e-mail does not require message sender and receiver to be online at the same time, and numerous studies have noted that this technology can be used successfully in the classroom. Pitt (1996), for example, found that frequent use of electronic mail as a means for submitting undergraduate assignments facilitated assessment and improved class discipline. Anderson (1996) indicated that email was effective in managing group projects. Others have noted that the technology could be used effectively to build collegial relationships. Tannehill et al. (1995), for example, found that email was an efficient medium for exchanging information between doctoral-level physical education students and in-service physical education teachers.

A newer, related technology, computer conferencing, has also been found to benefit students and teachers in instructional environments, especially in writing-intensive courses (Essid, 1996). Like e-mail, computer conferencing is asynchronous, but the technology allows users to post messages in “threaded” discussion forums—centralized bulletin boards that group or “thread” together messages of similar content to provide a visual heuristic to the user. Another key difference is that most computer conferences require the user to come to the designated “board” or “news group” and post the message, instead of the message being sent to individual users via e-mail and list-serv. Shriner and Rice (1996) has indicated that this increased convenience of access has facilitated the acquisition of undergraduate composition skills. Yeoman (1995) found similar results for students involved in collaborative writing projects. Other studies have noted improvements in moral reasoning (Harrington & Quinn-Leering, 1996), oral presentation skills (Anderson, 1996) and critical reflection (Harrington & Hathaway, 1994).

Several studies have indicated that computer conferencing technologies can effectively build and sustain mentoring relationships; however most of these studies examined mentorship of undergraduate-level students by working professionals. Oneil and Gomez (1996), for example, found that conferencing software was useful to networking professional scientists with undergraduate science majors interested in a particular field. The working scientists answered field-based questions posed by students and critically reviewed assignments submitted via e-mail. In a similar study, Sanchez and Harris (1996) connected content experts with in-service school teachers to serve as consultants on student learning projects. No published studies were located on computer mediated mentoring relationships between pre-service educators and public school students.

The researchers intend to explore this under-investigated field using a new Internet discourse technology—world wide web based “chat.” Unlike conferencing and e-mail technologies, chat systems use a real-time synchronous messaging protocol that enables users to “talk” to each other by typing; dialogue appears as a screenplay, with user names highlighted and comments posted immediately adjacent. The researchers are interested in exploring the efficacy of this technology as it relates to knowledge acquisition, mentor relationship development, and concept visualization. Specifically, the following research questions will be addressed:

1. Does online mentoring facilitate the acquisition of science concepts (as perceived by participants)?
2. Does real-time chat technology facilitate the development of online mentoring relationships (as perceived by participants)?
3. What discourse patterns emerge as participants discuss visual scientific concepts using a text-based communication medium?
4. What topical patterns of content discussion emerge over time?
5. Are there any attitudinal changes among participants regarding their views of computer technology in the classroom?

Design and Methodology

Five undergraduates will be selected from an anticipated pool of 100 students enrolled in EDUC 204, an intermediate level educational technology course to be offered in the Spring of 1998. These students will be selected by the researchers based on written letters of application and screening interviews. The five at-risk students to be paired with the undergraduates will be selected by the researchers working in coordinated effort with Science teachers at Conway Middle School. It should be noted that one of the researchers is a University Supervisor to student-teaching interns of science at Conway Middle School.

Each of the five undergraduate mentors will be randomly assigned to one of the five at-risk students. Both mentors and mentees will undergo separate training, provided by the researchers on-site, in using the web-based chat system. Student mentees will use web-enabled computers available in the computer lab at their school. Mentors will use web-enabled computers in the computer lab at the CCU School of Education. For a period of six weeks, each pair of mentors and mentees will meet three times a week for 30 minutes in a preassigned virtual chat room accessible over the world wide web, password protected and unique to them, to discuss issues relevant to the student’s science curriculum. Mentors will have been briefed during training by the normal classroom Science teacher regarding curricular content to be covered during the six week period. Mentors will use this information to anticipate some of the questions that may arise during the online sessions. At the conclusion of the six week period, all participants will be exit interviewed and surveyed; in addition, mentors and mentees will be introduced “for real” and debriefed at a social gathering on site.

Data Collection and Analysis

Traditional qualitative techniques (including pattern and cross-sectional analysis) will be used to analyze data accumulated during this study. Data sources will include transcripts of mentoring sessions and exit interviews of all participants (including host teachers), as well as completed open response item surveys.

Significance

This study utilizes an Internet technology that has previously been underinvestigated, perhaps because it is relatively new. Results from this study could provide valuable guidance for future studies investigating its efficacy in the classroom. In particular, it may facilitate the design of specific interventions to be used as independent variables in future quantitative studies with larger samples and achievement outcomes. The study is also significant because it targets a population of students (at-risk) who statistically have limited access to these advanced technologies and underperform in math and science curricula. Study findings may indicate teaching strategies that increase students’ probability of success in science. Finally, the study has implications for guiding future research in distance learning applications, where remote or virtual contact with instructors is an essential part of distributed curricula.

Based on information and communication technologies TAMID (A Hebrew acronym for “Communications, Science, Knowledge and Teaching”), operating at the Open University of Israel, has developed a combined learning, training and support environment for the benefit of junior high science teachers aimed at improving the standards of science and technology teaching in junior high schools.

The model and methodology developed in the project are applicable to non-science teachers, and other professionals. Thus TAMID can serve as a model for information and communication-based training and support for the advancement of professional performance.

**Answering professional needs of teachers via computer technologies**

Interviews with teachers and teacher-training professionals, and a review of the literature, reveal the following needs of junior high school teachers:

- Opportunities to consolidate, refresh, expand and update scientific knowledge.
- Continued development of teaching skills - both general and specific to science teaching.
- Exposure to different teaching styles, classroom experiences, professional dilemmas, and available resources.
- Access to expert support in the fields of education and science, and constructive opportunities for dialogue with experts and with colleagues.
- Feelings of mutual commitment and professional responsibility through the sharing of information.
- Access to relevant information and contact with research and development facilities, as well as technology-based industries.
- Assistance in adapting to the new science and technology curricula being introduced in Israeli junior high schools.

In response to these needs, a learning and support system was established. This electronic teacher center offers a range of on-line courses. Topics are drawn from the Syllabus for Science and Technology in Junior High Schools, and virtual classrooms are the point of contact. For the most part, activities which take place in this part of the center are initiated by TAMID. These include:

- A team of experts, representing all the relevant disciplines, both scientific and educational, at the teachers’ disposal on the network, respond to questions submitted by teachers and provide professional and educational support.
- Discussion groups, which permit the teachers to converse with both colleagues and instructors in the exchange of relevant information.
- A database containing suggestions and ideas for classroom activities submitted for the most part by the teachers.
- A scientific news corner in which the teachers and experts can reflect upon scientific news and developments and how to integrate them in the classroom.

At present, more than 200 teachers participate in the program, learning and communicating on-line with tutors and experts.

**Electronic teachers’ center-The components:**

**Learners, instructors, courses, and technology**

TAMID holds the promise of serving as an electronic teachers’ center for all junior high science and technology teachers. It offers a range of on-line courses on various topics in science and education, and ongoing support relevant to the teachers’ day-to-day challenges and experiences. The courses can be readily adapted to meet changing needs.

**On-line Courses: Objectives, Methods, Content and Materials**

TAMID focuses on developing flexible and dynamic on-line modules for in-service training courses in science and science education, aiming to cover all subjects in the new Syllabus for Science and Technology Teaching in Junior High Schools in Israel.

- Each on-line course consists (more or less) of the following components:
  - A general survey of the main principles of the topic, plus notes explanations and relevant definitions.
  - A list of key words (in Hebrew and English)
• Study aids, including written material, databases and Internet sites.
• A compilation of questions, activities and assignments for students, which will be continually expanded.
• A compilation of recurring questions on the topic.
• Discussion groups which will clarify the topic and how to teach it.
• A list of experts and teachers enrolled in the course.

Each course utilizes a combination of written, electronic and visual materials. Study materials include text books (i.e. selected passages from Open University study units), databases, videos (including programs broadcast on Educational Television and on the cable TV Science Channel), papers from scientific journals, and items on science which appear on television or in the newspapers. The challenge is finding the best possible mix of materials and taking advantage of the most suitable technological means to deliver them.

Each course has its own "virtual classroom", where materials and bibliographies are available and the discussions take place. On-line discussions develop between the teachers and tutors in response to assignments, meetings, and issues that arise in the classroom, or items which appear in the media. Invoking participation on the side of the teachers is an issue in itself.

Courses are modular and adaptable, and can be linked to one another. Units developed for one course can fit and be integrated into another. Courses include team assignments, which are a combination of subject matter and pedagogical tasks.

In most cases, the assignment produces ideas for classroom applications of the principle being studied. These are added to the "Bank of Ideas" and circulated to all the teachers in the group. Face-to-face meetings are held about once a month and are devoted to hands-on laboratory work, field trips, guest lecturers, and discussions. These meetings play an important role in helping the group coalesce and develop mutual responsibility. Groups of teachers from the same part of the country meet locally. Satellite and video-conferencing are also being considered, particularly in the recruitment of lecturers.

In addition to the formal course components, teachers take part in informal discussions, which include current events, teaching strategies, motivational projects, and alternative evaluation methods. In this way, the learning process becomes both practical and relevant, allowing individual and general needs to be addressed when they arise. Teachers also submit questions on specific scientific issues to academic experts. These questions and answers are currently being edited, catalogued and listed according to keywords, and are to be added to the network as a resource for all teachers.

All the classrooms are open to all the teachers participating in the program. Thus students from different courses may "drop by" and get a taste of the material or participate in some of the discussions going on. This is expected to have certain drawbacks, primarily "interference" on the part of the "guests". If such interference becomes a real problem, we will revert to a system of "closed" classrooms.

A great deal of thought goes into planning and developing the courses. As our experience grows, so too do the issues: What do teachers need to know in order to teach? How can this knowledge be passed on to them? Many argue that teachers and students must be equipped to work in an information-oriented world where teachers are expected to guide and tutor rather than to simply convey knowledge. But what are the implications of this trend for teacher training? It suggests that learning should become more independent, and should be project-based and investigative. Turning the slogans into practical applications is no simple matter.

Until now, the main aim of all of TAMID's refresher courses has been for teachers to master a particular discipline, and the relevant teaching techniques. We believe that mastering the core of the subject matter enhances teachers' self-confidence and improves their performance, even in guiding projects. In any learning theory, it is the teacher's obligation to help their students understand the basic elements of a subject.

On-line Instructors

The educational and support team is composed of instructors, outside experts and colleagues:

• Instructors plan the course, prepare and mark assignments, lead on-line discussions with the teachers and offer suggestions and ideas for classroom activities. They are linked to the network and thereby maintain continuous contact with the teachers, answering questions as quickly as possible.

• The TAMID team includes a "representative" from all relevant disciplines, so the teachers have someone with whom they may consult on subject matter. This is particularly useful as the new science and technology curriculum sees science as one interrelated discipline, rather than a collection of subjects. Effective teaching requires that teachers work in teams within which there are different specializations, but this is not always possible within a single school. The chemistry and physics components of the curriculum are particularly problematic.

• The TAMID team includes a "representative" from all relevant disciplines, so the teachers have someone with whom they may consult on subject matter. interested in being involved in education but have neither the time nor the forum, an opportunity to contribute to the educational endeavor

• Colleagues also fill an important role. Sharing ideas in real-time is an integral part of the TAMID approach, in which everyone (instructor included) learns from everyone else. As in “real” life, several on-line discussions are usually taking place simultaneously.

The Technology

We use the First Class software package (translated into Hebrew) for interactions and discussions and the Internet for information and data retrieval.

Issues in focus

Proper Mix of Applications

Lack of appropriate equipment at the teacher’s site limits the ability to utilize the full potential of the technologies. By making more complete use of applications, such as sound, pictures, animation, video clips and link-ups to Internet sites, educational potential will be expanded. What is the “correct” combination? What is the connection between the new technologies and the cognitive functions involved in learning? What are the implications of these abilities to learning theories, and teaching methodologies?

Heterogeneity among learners

Teachers are by definition a group with varying levels of experience, ability, motivation, knowledge, and communication and thinking skills, their needs also vary according to the students they teach. Teacher training courses need to be tailored accordingly; a dynamic model, able to respond to their varied and changing needs, is required.

Databases

On-line databases are being put together which include a digital library, a bibliography of referrals to relevant Internet sites, and a record of activities on the network. Each database raises questions as to the type of material to be included, the quality of material and day-to-day management and organization.

On-line instruction

Virtual tutoring is a new and not obvious task. On-line teaching is very demanding for the tutor. Many participants hesitate to express themselves for everyone to “see”; some are “over producers”. Criticism and cynicism on the network are thundering, and so are silences. On-line teaching requires definition, training, practice and experience.

Technical Issues

In order to offer teachers readily available, nationwide technical support and inexpensive communications services, organizational and financial solutions must be found. Until then, achievements will be sporadic and with little influence.

Conclusion

TAMID offers a new model for in-service training for teachers based on information and computer communications, which is free of time and location limitations, and which is aimed at changing the way teachers prepare for their work.

The oft-repeated saying that teachers teach according to the way they are taught implies that teachers must be given a model for teaching that can be copied. But is this not deceptive? Can an average teacher in an average school attain the same standard of teaching as one in a center at which the best teachers teach with plentiful resources? A partial answer is that teachers should they be engaged in a constant process of learning and should receive support from a center which can offer expertise in all the required fields.

TAMID aims to confront these unresolved issues and to facilitate open debate on them among its staff and the teachers. Our hope is that what we learn through experience and deliberation will be of benefit to others with the same interest and goals.

Science—945
The simulation section of the SITE annual appears to have always represented a smallish group of researchers. This year is no exception. Six papers were received this year for publication, from four different universities and a representative from industry. At the very least, this indicates that no single school or company can claim a monopoly on the research effort devoted to simulations. At the worst, it may indicate that simulations are yet to rouse widespread interest. As an optimist, my impression is that simulations will soon stake their claim as effective cognitive organizers and learning/teaching tools.

As this year’s section editor, I had the distinct privilege and opportunity to read all of these papers thoroughly. I find them to be of high quality, and worthy of each attendee’s attention. Feel free to read these papers, attend the authors’ presentations, make comments and take some of the authors’ enthusiasm along home and share it with peers.

What follows is a very brief synopsis of the six papers and the last names of the authors. This year, the synopses are shorter owing to the presence of an abstracts book. If after reading a particular synopsis questions still remain, I encourage the use of the abstract book to clear them up.

The Papers

Kenton reported on the design and effect of a simulation used prior to formal instruction in middle school science. This simulation placed students into the role of simple circuit designers, attempting to make a bulb light with available materials. Students appeared to use the simulation to become aware of, or test their conceptions and thus to prepare for conceptual change.

Lewis investigated the use of a social studies simulation, in conjunction with World Wide Web resources, to produce an inter-disciplinary curriculum. Students would encounter the simulation in several classes, each emphasizing a different aspect of the program. Lewis’ work involved the use of MECC’s Yukon Trail simulation to interest students in the Yukon Gold Rush era.

Milbank describes the role of simulations in industrial training environments. The simulations described help to track the user’s action throughout the encounter, and provide feedback to evaluators. This feedback helps to indicate weaknesses in the user’s understanding of the phenomenon modeled.

Strang outlined the types of feedback available to students using the Teaching Decisions (TD) simulation. Students use the simulations early in their student teaching preparation. Different feedback types produced by the simulation are then used by preservice teachers to evaluate their performance in a simulated teaching environment.

Strang, Blackwell and Sullivan reported the effect of the Teaching Decisions (TD) simulation on the lesson planning abilities of users. The TD simulation provides feedback of various types to the user, who then uses the information to help plan a lesson.

Van Gorp described the use of a World Wide Web-based simulation of geometry with students in eighth grade mathematics courses. Teachers and students are able to engage in two-way communications, for the purpose of asking questions or submitting answers. The simulation models linear algebraic formulas of the type aX + bY = c, and plots the students’ manipulations of the model.

PREPARING FOR CONCEPTUAL CHANGE: A MIDDLE SCHOOL SCIENCE ELECTRICITY SIMULATION

Jeffrey M. Kenton
Iowa State University

Constance P. Hargrave
Iowa State University

Physics is one of the subjects studied in middle school science that students find difficult to understand. Difficulties in learning may arise because students construct their own understanding about how the physical world operates based upon personal observation or experimentation (Hewson, 1984). Electricity is one subject of physics that students have difficulty understanding (Slotta, Chi, & Joram, 1995). As with physics in general, student conceptions about electricity are often a result of personal observation or experimentation. Moreover, these conceptions are often built upon ontological attributes, on which students later bases their beliefs about electricity (Chi, 1992). If student-constructed conceptions about electricity are not supported by or consistent with scientific theories of electricity, formal instruction about electricity may not be understood or fully accepted by the student (Slotta, Chi & Joram, 1995; Hewson, 1982).

The purpose of this paper is to describe the role of an electricity simulation in preparing middle school students for conceptual change in science. In this paper, current practices in science learning are presented, followed by an overview of the conceptual change theory. Then a definition of computer simulations and their characteristics that make them appropriate for constructivist learning are presented. Finally, a discussion of the Workspace simulation used to help middle school students become aware of their conceptions and prepare for conceptual change is presented.

Science Learning

Physical science content standards for grades K-4 involve learning in the fields of object and material properties, position and motion of objects, and light, heat, electricity, and magnetism. For example, the standards explicitly describe students coming to know how electricity may produce light, heat, sound, or magnetic effects (NSE Standards, 1996). In grades 5-8, students are to build upon this knowledge to explain the use of electricity as energy and the transfer of energy (NSE Standards, 1996).

A student may have developed strong ideas about scientific phenomena prior to learning about them in school. The strength and persistence of these ideas increase as the ideas are tested and verified by the person (Rumelhart, 1980; Meyer & Woodruff, 1997). Often when students’ personally-produced ideas are tested under scientific conditions, they inaccurately explain the phenomenon (Hewson, 1981). Student-created ideas often persist despite formal instruction, even when formal instruction is intended to undermine a student’s support of inaccurate ideas. Meyer and Woodruff (1997) reported that students often consider laboratory environments to be artificial and separate from reality; moreover, students believe their own ideas were created in the real world. That is, students often refuse to accept the evidence provided during laboratory experiences because the environment in which the student developed the conception (i.e. a students’ personal observation) seems more real to the student than a science lab environment (Meyer & Woodruff, 1997).

Conceptual Change in Science Education

Posner, Strike, Hewson, and Gertzog (1984) described a theory (known as conceptual change) that examined the way students adopt or change their conceptions. The researchers suggested that the process of changing a person’s conception takes place in four stages. The stages are dissatisfaction with a conception, intelligibility of the new conception, plausibility of the new conception, and fruitfulness of the new conception.

Dissatisfaction with a conception occurs when a student’s existing conception is ineffective in correctly solving a problem. After several attempts to solve the problem with their existing conception, the student may become aware that the conception is unable to correctly solve the problem, and dissatisfaction with the conception is the result. After a student has become dissatisfied with an existing conception, he/she may seek a new conception that can solve the problem. To begin the process of conceptual change (the dissatisfaction stage), a student must be aware of their current conception.
Computer Simulations

Computer simulations have been used in all areas of science to enhance student learning. However, the instructional use of computer simulations to create environments for students to make meaning or test their understanding has been questioned (Thomas & Hooper, 1991). Purity of computer simulations to offer environments for students to become aware of and test their conceptions is discussed, followed by a description of Workspace and its use with middle school students.

A computer simulation can be defined as: “a computer program containing a manipulatable model of a real or theoretical system. The program enables the student to change the model from a given state to a specified goal state by directing it through a number of intermediate states. Thus the program accepts commands from the user, alters the state of the model, and when appropriate displays the new state” (p. 498) (Thomas & Hooper, 1991).

Thomas and Hooper (1991) defined a model as a set of parameters that control the process being modeled. As stated above, the system being modeled need not exist in reality (thus enabling the modeling of systems that are either too dangerous, expensive, or impractical to use in the classroom) (Gredler, 1996). Thomas and Hooper (1991) also described the existence of a given state and a goal state in a simulation. The given state introduces the problem to be solved, and the goal state is the desired result reached by manipulations of the model. Simulations are excellent agents for achieving transfer of knowledge (Thomas & Hooper, 1991), but are often used in instructional settings either to provide new knowledge or test previously developed knowledge (de Jong, 1991).

Purity is an important consideration when designing or evaluating the instructional uses of a simulation (Thomas & Hooper, 1991). Thomas and Hooper (1991) divided simulation models into two groups: pure and impure. The distinction between pure and impure simulations is categorical, based upon Thomas and Boysen’s (1984) Taxonomy for the Instructional Use of Computers. The five categories of the taxonomy (experiencing, informing, reinforcing, integrating, and utilizing) are based upon the relationship of the student to the information being learned. Pure simulations were defined as those that place students in experiencing or integrating activities. Thus, pure simulations place students in models where information is encountered for the first time (experiencing), or as a method to determine how the student solves an unfamiliar problem using information given in a different context (integrating). Impure simulations deliver information to students (informing) or test their knowledge of previously learned concepts (reinforcing).

Pure simulations include activities that familiarize students with unfamiliar content, giving these students an opportunity to explore and develop conceptions about the content prior to formal instruction. Pure simulations also may provide students with an opportunity to demonstrate how they may have transferred conceptual comprehension from one type of activity to another. That is, the student may use (integrate) the knowledge they have gained in one context to solve a problem encountered in another context.

Impure simulations are those that place students in informing or reinforcing activities. The informing activities teach the student about the process being modeled. Reinforcing activities test the student’s comprehension of information previously taught. Impure simulations seek to have students demonstrate their mastery of factual data, often within the same context that the material was learned.

Workspace

Workspace is a computer simulation of electricity designed for use prior to formal instruction about electricity. According to Thomas and Hooper (1991), Workspace is a pure instructional simulation in that Workspace places users in and experiencing role with regard to electricity. Workspace places users into the role of a circuit builder (Figure 1). Middle school students used Workspace to develop or become familiar with their conceptions of electricity.

Workspace provides users with an environment to discover electricity concepts and to build or test their existing conceptions. By confronting a challenge to their existing knowledge base, users either affirm their beliefs about electricity (if the circuit functions), or develop a sense of cognitive dissonance (if the circuit does not function). This cognitive dissonance can become dissatisfaction if the student interprets the circuit design flaw to an existing conception that is no longer valid. A limitation of Workspace is its inability to place more than two wires into a single bulb circuit. Users indicated that they felt the experience was real (Kenton, 1997).

Figure 1. Workspace Project Window
Workspace Data and Analysis

Workspace produces data of two types that may be utilized to assist identifying student conceptions regarding electricity: sequential mouse click record (adapted from Williams and Dodge, 1993) and screen captures made each time the student tests a circuit design.

Sequential Mouse Click Record

This record tracks each user’s circuit building designs. Workspace tracks several pieces of information for each mouse click. Figure 2 illustrates a sample printout of a completed circuit. Each mouse click is recorder in sequence from first action to final action in numerical order. A report similar to the example shown in Table I is produced automatically by Workspace when the user exits the program.

Table 1. Workspace Mouse Click Record.

Stack closed at: 9:34:57 AM
Total elapsed time = 288.93 seconds

From left to right on each line: (a) the number of the event, (b) the total elapsed time before the listed event, (c) the name of the card where the click occurred, (d) the general location on the card of the mouse click (such as a button or field name), (e) the elapsed time between the previous mouse click and the current mouse click, (f) the screen x coordinate of the mouse click (measured from the left edge of the screen), and (g) the screen y coordinate of the mouse click (measured from the top edge of the screen).

To analyze the data recorded for each event, a separate data checking program is used. For example, the circuit recorded in figure 2 progressed from action 6 to action 13 where the circuit was tested. Action was a click on the bulb button on the right side of the screen (coordinates 416, 212). Thirteen seconds later, the user clicked on the wire button (coordinates 404, 72). The next two actions describe the locations of the ends of the first wire. The first end was located on the right terminal of the bulb, as placed in the center of the screen (160, 157). The second end was placed on the right terminal of the power source (206, 262). Nine and a half seconds later, the user repeated this process for the wire placed on the left side of the circuit. One end of the wire was placed at the left terminal of the bulb (135, 157) and the other on the left terminal of the power source (85, 263). Twenty-six seconds later, the user pressed the test circuit button, resulting in the production of a screen capture (Figure 2).

Figure 2. Workspace Sample Tested Circuit.

Screen Captures

Screen captures are graphical representations of the material on the screen. On Macintosh computers, the key sequence Cmd-Shift-3 will produce a capture of the entire contents of the screen. This file is systematically named “Picture xx” where the xx stands for an integer starting with 1, and incrementing for each successive screen capture. Numerous utilities exist that perform the same function on other computers.

Workspace captures the screen appearance for the instructor to be able to review the conceptions shown within the capture. These captures may be evaluated according to Shipstone’s (1984) categories of electricity conceptions. However, screen captures alone may not fully convey a student’s conception. Thinking-Aloud protocols, using snapshot data as discussion material, were more effective at revealing the student’s conception than the snapshot data alone (Kenton, 1997).

Implications of Workspace on Middle School Students’ Learning about Electricity

Although Workspace is a very simple simulation of electricity, the data-gathering ability is quite powerful in helping to determine each user’s electricity conception.
Using Workspace's mouse click tracking records and screen captures were effective in identifying circuit design conceptions and strategies of middle school students (Kenton, 1997).

Thomas and Hooper (1991) and Hooper and Thomas (1990) reported that pre-instructional simulations are effective at acquainting or reacquainting users with their conceptions regarding the topic of study. This methodology was investigated by Brant, Hooper and Sugrue (1991) within lecture environments. Further studies are planned to assess Workspace's group use characteristics. These studies will investigate the effect of preinstructional simulation use and group discussions on student electricity learning.

DEVELOPING CRITICAL THINKING SKILLS THROUGH AN INTERDISCIPLINARY APPROACH FOR THE USE OF SOCIAL STUDIES SIMULATIONS AND THE INTERNET IN UPPER ELEMENTARY SCHOOL CLASSES

Bruce Lewis
Tennessee State University

This presentation will develop and evaluate ways to incorporate MECC’s simulation software into the upper elementary curriculum through an interdisciplinary approach to strengthen the critical thinking skills of analysis and synthesis, particularly through the use of MECC’s Yukon Trail. Activities will be demonstrated for use in social studies, mathematics, science, geography, literature and language arts classes. This approach may increase verbal fluency, vocabulary, and complexity in written expression as evaluated by writing assessments, such as the TCAP. Computerized simulations in multimedia, such as MECC’s software, may increase motivation and may promote authentic learning in the classroom (Agnew, Kellerman, & Meyer, 1996).

Critical thinking requires thought to be analyzed and assessed for its clarity, accuracy, relevance, depth, breadth, and logicalness. Since reasoning occurs within points of view and frames of reference, students need to be aware of an author’s approach to a particular problem, as well as their own. (Paul, 1997a; Biehler & Snowman, 1993).

An understanding of critical thought enables students to take basic tools of critical thinking they learn in one subject and extend them, with proper adjustments, to other subjects which they study. Students can be taught so that they learn how to bring the basic tools of disciplined reasoning into every subject they study (Paul, 1997a).

From the Critical Thinking Glossary come these important terms:

“Analyze: To break up a whole into its parts, to examine in detail so as to determine the nature of, to look more deeply into an issue or situation. Students should continually be asked to analyze their ideas, claims, experiences, interpretations, judgments, and theories and those they hear and read.” (Paul, 1997b)

“Perspective (point of view): Human thought is relational and selective. It is impossible to understand any person, event, or phenomenon from every vantage point simultaneously. Critical thinking requires that this fact be taken into account when analyzing and assessing thinking.” (Paul, 1997b)

A “strong-sense critical thinker is one who is predominantly characterized by an ability to question deeply one’s own framework of thought, an ability to reconstruct sympathetically and imaginatively the strongest versions of points of view and frameworks of thought opposed to one’s own, and an ability to reason dialectically (multilogically) in such a way as to determine when one’s own point of view is at its weakest and when an opposing point of view is at its strongest.” (Paul, 1997b)

Teaching for critical thinking enables students to explicate, understand, and critique their own deepest prejudices, biases, and misconceptions. Genuine fair-mindedness is achieved by developing critical thinking skills in dialog with others where they gain empathic practice of entering into points of view that students are fearful of or hostile toward (Paul, 1997b). Unfortunately, most assessments are based on lower-order learning and thinking. Chief culprits have been multiple-choice, machine-graded assessments which have focused on surface knowledge. Higher-order thinking, critical thinking abilities, is increasingly crucial to success in every domain of personal and professional life.

Research methodology: Approximately ten (10) public and private elementary schools, housing an approximate total of thirty (30) sixth grade classes, will be randomly selected from Metro-Nashville and surrounding areas. Of these thirty classes, ten (10) sixth grade classes, consisting of approximately 250 students, will be randomly selected.
for the treatment group, while ten (10) sixth grade classes, consisting of approximately 250 students, will be randomly selected as the control group. Each of the 500 students will be administered both a pre-test and a post-test of critical thinking skills.

Students should be able to demonstrate the ability to “distinguish clearly between purposes, inferences, assumptions, and consequences; discuss reasonably the merits of different versions of a problem or question; decide the most reasonable statement of an author’s point of view; recognize bias, narrowness, and contradictions in the point of view of an excerpt; distinguish evidence from conclusions based on that evidence; give evidence to back up their positions in an essay; recognize conclusions that go beyond the evidence; distinguish central from peripheral concepts; identify crucial implications of a passage; evaluate an author’s inferences; and draw reasonable inferences from positions stated” (Paul, 1992; see also Biehler & Snowman, 1993).

Jonassen (1996) identifies databases, spreadsheets, semantic networks, content expert systems, computer-mediated communications, multimedia and hypermedia as “mindtools”, selected application programs for engaging and enhancing thinking in students. The computer application programs that Jonassen identifies as “mindtools” can be used to represent knowledge in a variety of subject areas; they are “generalizable” and engage learners in critical thinking.

Jonassen (1996) further states that effective simulations require well-structured activities, such as those outlined in this presentation. Critical thinking skills such as evaluating and analyzing can be engaged by information retrieval, particularly through research on the Internet. Critical thinking skills such as assessing and identifying assumptions can be engaged by e-mail, while computer conferencing (using LISTSERVs, bulletin boards and newsgroups) involves analyzing and evaluating the issues being discussed. Computer conferencing engages participants in elaborating on ideas, analyzing opinions and perspectives, and then synthesizing various positions.

MECC allows using their simulation software (Africa Trail, MayaQuest, Oregon Trail, Oregon Trail II, Yukon Trail) in a variety of ways (as a review of curriculum, individually or small groups, or as a reward). The intent of this paper is to show how to integrate the simulation into the curriculum in a number of different areas. (While MECC states that “gambling was omnipresent during the Klondike gold rush”, for the educational purposes of this research the gambling aspect of the software will be disabled as per MECC’s instructions. However, I do regret losing access to the two-team dog sled race in Sheep Camp, which would provide an entertainment side to the real thing, the annual Iditarod Sled Dog Race in Alaska.)

Language arts classes can use the computerized journal for writing exercises and reflections about research and readings done by the students in the class. One of the characters the students will encounter during the simulation (at Dawson City) is Jack London, the author. Students may appreciate the class time oral reading of his book, “The Call of the Wild”. They may also enjoy the oral reading of Velma Wallis’ book, “Two Old Women: An Alaska Legend of Betrayal, Courage and Survival.”

Geography teachers may appreciate the map skills developed in the software program and through the readings of “The Call of the Wild” and “Two Old Women”. These map skills can be applied to tracking (via the Internet’s live coverage) the annual Iditarod Sled Dog Race. Mapping skills, strategy formulation, record keeping, and deductive reasoning are skills developed by game-type problem-solving programs and simulations (Biehler & Snowman, 1993).

Science teachers can review weather conditions for Seattle, Washington (where the journey to the gold fields begins), Skagway and Dawson, Alaska (some of the few cities of the region around the gold fields), and the Yukon Territory of Canada. The students can also monitor the weather (via the Internet) of the Iditarod race. Other projects of interest might include minerals (relative value of gold, silver, iron ore, etc.), mining techniques and methods (1897 compared with 1997), and materials and clothing production (1897 compared with 1997).

Math teachers could explore supply and demand economics (as supplies dwindle, prices increase). Distances between significant sites could be determined and the distance traveled each day in the Iditarod race could be charted.

Social studies teachers may want to use the K-W-L strategy. The Yukon Trail software program lends itself to cooperative learning, as most activities are best accomplished in pairs, but group size may be adjusted based on the availability of computers. Since characters in the software program who have both a first and last name are supposedly real people, teachers could have the students research a particular character via print text and/or the World Wide Web. The students could then give oral reports in their language arts classes about their chosen character. If done in pairs or teams, the group could provide posters and other types of visual presentations. Depending upon computer and software availability, multimedia presentations could also be accomplished.

A recent posting to the Listserv discussion list “Middle level education/early adolescence (10-14)” revealed that “in 1996, Internet access was available in about half (53%) of the schools in which 71% or more students were eligible for free or reduced-price lunch programs and in 58% of schools in which 31 to 70% of students were eligible. In comparison, 72% of schools with 11 to 30% of students
eligible for the free or reduced-price lunch program had Internet access, and 78% of those with less than 11% of students with free or reduced-price lunch eligibility were connected to the Internet.” Therefore, recognizing that not all schools will have access to the Internet, the proposed activities will focus on both text-based documents (books) and web-based hypermedia via the World Wide Web (KIRK_WINTERS, 1997).

DEVELOPING SIMULATION-BASED APTITUDE EVALUATION TOOLS: A NEW APTITUDE MEASUREMENT PARADIGM

Greg Millbank
Praxis Technical Group, Inc.

Simulation-based aptitude evaluation tools are a new type of psychometric device that takes advantage of the ability of high-powered desktop computers to simulate reality and to simultaneously measure the reactions of users of the simulation as they cope with scripted simulation experiences. Praxis Technical Group, Inc, a small Canadian company, has recently developed several such systems along with complex software for the development of these evaluation tools. These evaluation systems often provide extensive training to the user as a part of the evaluation process, and may, in fact, be used to develop certain skills and abilities in untrained users before testing for the acquisition of those skills.

Although the advantages of these new tools are considerable, their use is restricted to the measurement of abilities required in situations which are reasonably simple to simulate by computer. However, as the power of desktop computers has continued to dramatically increase, the ability to simulate a wider variety of events has grown proportionally. Thus, simulation-based aptitude evaluation tools are moving from a marginal and experimentally interesting measurement device to a potentially mainstream psychometric technique. New Java-based middleware will soon make it possible to train and evaluate teams of users over the Internet and to compare the abilities of team-trained users with those who do not have appropriate experience and skills in collective action. This paper discusses simulation-based aptitude evaluation tools, critical features of their design and construction, their advantages, and examples of their use.

Advantages and disadvantages of simulation based aptitude evaluation tools

The primary advantage of simulation based aptitude evaluation tools is that they provide a way of directly testing for specific skills and aptitudes with demonstrable high validity. This validity stems from the fact that performance is measured under circumstances which closely simulate the actual circumstances under which aptitudes or skills will be required, not from statistical inference. Furthermore, a properly developed simulation based tool will test actual performance of the required skill or aptitudes, and not abilities which are assumed to be analogous to, or which are assumed to occur in concert with the desired abilities.

Frequently the only alternatives to simulation based tests are pencil and paper tests for skills which are assumed to be analogous. These tests therefore often have questionable validity for the specific purposes to which they are put, simply because the assumption of an analogous relationship between the skills they were designed to test for and the skills desired may not be valid.

Furthermore, the high face validity of properly designed simulation based tools means that statistical validation over large populations is unnecessary. As a consequence, simulation based aptitude evaluation tools are not as expensive in comparison with other types of tests as they may initially seem. Even though simulation based tools are initially relatively expensive to develop, they are relatively inexpensive to validate. As a consequence, their overall cost is generally comparable or lower than the development costs of pencil and paper tests.

A secondary advantage of these evaluation tools is that they are completely computer-based and are therefore self-administering. As a consequence use of the tools is relatively inexpensive and trouble free and application of the tests is totally consistent. In normal use the test subject sits down to computer which gives all necessary instructions and required information through a multimedia computer-based training program. The computer presents the simulation as required, automatically observes the behavior of the subject, and at the end of the test sequence, the computer performs any necessary statistics on the collected data and presents a profile of the test subject.

The primary weakness of simulation based tools lies in the need to create a close simulation of the actual circumstances in which desired aptitudes and skills will be required. Even small differences may seriously hamper the
validity of the tests, or at least render that validity questionable to the extent that extensive statistical validation will be required.

**How do simulation-based aptitude evaluation tools work?**

Simulation-based aptitude evaluation tools use the power of computers to simulate situations in which specific skills, aptitudes or intellectual abilities are required. The use of these skills and abilities enables the user (i.e. the subject of the evaluation) to cause the simulated event to progress in a certain way. Users who lack the requisite abilities are unable to control the simulation in the desired way and thus develop an outcome which is easily distinguished from that developed by skilled users.

In practice, the presentation of simulated problem events and the tracking of the user's response to those events is completely automated. A complete evaluation generally consists of many simulated events, each one designed to elicit specific behaviors. Certain aspects of the user's response to each event in the series of presented events, trigger a monitoring system which records information in a database concerning the user's responses. At the end of a testing session, which may last several hours, the information collected in the database can be statistically manipulated (this is usually automatic) to develop a profile of the user.

Simulation-based aptitude evaluation tools have recently been developed and have been used to select candidates for such jobs as air traffic controllers, operators of computer-based process control systems, and similar jobs which require complex abilities and in which the incumbent employee will normally operate through a computer or a computer-like interface. However, simulations of business processes and other "soft" events such as negotiations, are raising the possibility of simulation-based evaluation tools for skills and abilities which do not normally involve computers.

A simulation-based aptitude evaluation system is considerably more than just a simulation. In fact, in some examples the simulator is the simplest part of the system. The essential components of such a system are as follows:

**Simulation engine**

The simulation engine is a mathematical or quasi-mathematical kernel which receives information from the event handler regarding the state of a number of variables (sometimes numbering in the thousands) and using that information and its own built-in mathematical structure, calculates outputs (i.e. new values) for all of the same variables. This output represents the state of the system at some future point in time. For example, the simulation engine which drives the simulation of a unit in an oil refinery receives information regarding the state of all the (simulated) devices in that (simulated)unit — the state of pumps, valves, levels in tanks, pressures in vessels, and so forth — as well as information regarding control moves establishing desired changes in values of variables representing the states of these devices. The simulation then calculates what the state of each device will be four seconds in the future (four seconds is the refresh rate of a typical refinery control system). It then transmits this information to the event handler.

**Event handler**

The event handler is more of a convenience than a necessity. It collects input from all sources and output from all sources and keeps this information segregated into its appropriate time steps. When any of the other components requires information or wishes to send information to another component, it does so through the event handler.

**User interface**

The user interface is the interface for communication between the user (subject, trainee) and the simulation system. For some kinds of simulations the user interface is a copy of the interface used in real-life. This is true of computer control system interfaces, air traffic control interfaces, and the like. Interfaces for other types of simulations are more problematic. Much of the initial or "face" validity of a simulation-based evaluation tool is intimately related to its user interface. If the interface and/or the means of manipulating the interface are not similar to the real-life task conditions for which aptitudes or skills are being sought, the validity of the test could be compromised. For example, instead of testing for skills necessary to control air traffic within a control zone, one might instead be testing for manipulative skills necessary for controlling a computer mouse. If mouse-using skills are among the skills necessary for an air traffic controller, then this is much less of a problem.

In many respects, therefore, the user interface is the factor limiting the effectiveness of simulation-based evaluation. One of the greatest advantages of simulation-based evaluation is its high face validity. If this initial validity is seriously compromised, the advantages of simulation-based aptitude evaluation may be lost.

**C. B. T. system**

The task of explaining the simulation based test and the collecting registration information is usually handled by a computer-based training program. Such programs are closely integrated with the simulation system, but provide information from a collection of multimedia files. Such programs may include short quiz sequences which ensure that the test subject understands critical information which may be necessary to his performance of the tasks required during the simulation sequence.

**Communications system**

Complex simulations may involve the simulation of communications between the test subject and simulated
members of a simulated crew. For example, in a simulation of a unit of an oil refinery or chemical plant, one of the most important skills is the ability to communicate effectively with operators running other units and with operators working outside in the plant. Furthermore, the simulation system may move from time to time be required to communicate with the test subject. All these communications may be done by selecting text items from pop-up boxes on the screen but it is questionable that the ability to select appropriate text is the same as the ability to communicate effectively by voice.

Recently, Praxis Technical Group has been experimenting with computer voice recognition and it is reasonable to say that voice recognition techniques have matured sufficiently in the last year that two-way communication with a computer by voice is now a possibility. As a matter of fact, this entire paper was dictated to a computer and converted into text by a voice recognition program.

Data collection system

A simple database is set up so that registration information and evaluation information can be collected. In effect, it matters very little what type of database is used. Data is collected from the event handling system. It is usually marked for collection by the scripting system.

Scripting system

The final and possibly most important component of a simulation based aptitude evaluation tool is a scripting system. The purpose of the scripting system is to control the simulated experience in order to provide test sequences which will elicit behavior for the evaluation tool to measure. Scripts control all aspects of the simulated environment to produce "scenarios" – chains of events which mimic real-life situations. These scenarios are generally half an hour to an hour in length, but may be much longer.

In practice, scripts not only control the simulation engine, but watch for specific behaviors and control the data collection side of the system. For example, a script may cause a pump in a chemical plant simulation to shut down. The simulator will then react in a way comparable to the actual plant. The script system will "watch" the test subject to see if he/she performs the right moves to select, set-up and activate an alternate pump. If the test subject performs correctly, evaluation scores are written into the database. If the subject is only partially able to restore the simulation to normal operation, the script may record appropriate marks or comments and then may restore the simulation to correct operation and at the same time launch a computer-based training program which explains to the test subject what happened and what the new situation is.

The scripting system is the most complex part of a simulation based aptitude evaluation tool. Praxis software developers have found it necessary to develop a special scripting language which is both fully conditional and fully parallel. It was also necessary to develop a special compiler and debugger. The need for a scripting language with these characteristics occurs because it is not always possible to know in which order things will occur, nor exactly how they will occur. Both the user and the simulation engine will react in unique ways to a situation as it unfolds.

As a consequence the scripting language must "watch" many different event sequences or "strings" simultaneously. In a most complex case the scripting system would have to watch every single variable of thousands of variables in a complex industrial simulation as well as all communications channels and any other sequences of events that may be generated through the user interface by the user. Each one of these "strings" would have certain conditions set for it. If the pre-established condition for any "string" was met, then the scripting system would act for that particular string of events, no matter what was happening to the rest of the system.

Types of simulation-based evaluation tools

Praxis Technical Group, Inc. has developed several simulation based evaluation tools. Generally these have been built around simulations of computer controlled industrial processes. Simulations of air traffic control problems have also been developed. These evaluation tools are currently being used to select candidates for industrial computer control system operators and air traffic controller positions. In both cases classes of selected candidates have shown dramatically increased ability to learn required skills and dramatically lower levels of stress during the training period than have classes of candidates who were not selected by simulation based tools.

The payout for both trainees and the training organizations has been considerable. Trainees are being selected for jobs for which they have a natural aptitude. As a consequence, stress levels during training and on the job are greatly reduced. It has been shown that only about 20 percent of the working population have a strong natural ability to perform these control related tasks. Operator stress and general safety are markedly improved if operators are naturally suited to the jobs they perform.

The payout for corporations and training organizations has also been considerable. In the case of air traffic control candidates it is not uncommon to spend approximately one million dollars per candidate to reach the stage at which the candidates ability can be assessed. It is not uncommon for approximately half of the trainees to be "washed out" at this stage. For each class, therefore, several million dollars are wasted. Indications are that costs in the process industries are proportional. The use of simulation based aptitude evaluation tools can cut these costs dramatically. Further
benefits result from the higher competence of selected candidates once they become full operators. These benefits show up in improved operation and improved safety.

Praxis Technical Group, Inc. has also begun to experiment with specialized simulators that simulate the process of negotiation. We are looking for specific skills and aptitudes that differentiate successful negotiators from unsuccessful negotiators. This work is still in an experimental stage. Similarly, Praxis has begun work with various types of business simulations. The simulations simulate various types of business environments. We will be looking for entrepreneurial skills and abilities.

Java and the simulation of collaborative environments

Praxis has recently developed a 100 percent Java-based simulation environment which can perform all the tasks of the environment described here with the additional abilities of being able to run several interacting simulators simultaneously across a network or the World-wide Web and the ability to combine the collaborative efforts of widely distributed trainees. It will be interesting to see if this Java system can be used to develop simulation based aptitude evaluation tools which can distinguish certain social skills necessary for effective team players.

FEEDBACK POSSIBILITIES IN A LESSON-PLANNING SIMULATION

Harold R. Strang
University of Virginia

Early in their professional training, preservice teachers at the Curry School are introduced to several fundamental aspects of lesson planning via a Windows-based instructional aid called the Teaching Decisions (TD) simulation (Strang, 1996). Each participant, assuming the role of a teacher, engages in a series of decision-making activities in planning a 30-minute lesson for a small class of pupils. The planning task comprises four activities, each defined by a separate work window. These activities include (1) becoming familiar with individual pupils by studying and taking notes on their academic ratings and their personality traits, (2) deciding where pupils will be physically stationed and with whom and what (computers, blackboards) they will work, (3) developing the lesson activities that individual pupils and/or groups of pupils will complete, and (4) determining what the teacher will do during the lesson. Later in the semester when all students have completed the interactive phase, 8-12 students gather for group debriefings. At this time each participant receives a printed report that presents personal information about that teacher's lesson-planning activities. During these 30-minute sessions, the students, with the aid of a series of computer-generated screen displays, compare their personal records with computer-generated composites derived from their class cohort and from experienced-teacher cohorts. These personal-group comparisons are designed to stimulate realistic student discussion on effective lesson planning.

Types of student feedback

Students may receive any combination of five types of lesson-planning feedback after they complete the TD simulation's interactive phase. The first three software-generated feedback printouts offer personalized information concerning the teacher's (a) step-by-step movement through the task, (b) recognition of individual pupil differences, and (c) planning focus, respectively. The fourth report offers a composite of both navigational and planning measures. The fifth instrument presents a graphical printout of factors that define the more global aspects of the teacher's lesson-planning style.

Feedback on step-by-step navigation

The Navigation Event Record provides an event-by-event description (including a time line) of all mouse and keyboard entries which the teacher has made during the simulation's interactive phases. During debriefing, this report is particularly useful in helping students to focus on the individual decisions and time commitments that they made as they planned each lesson component.

Feedback on the recognition of individual pupil differences

The Pupil Planning Profile provides numerical data on 10 major planning decisions that teachers rendered for individual pupils. Variables defining the teacher's evaluation of individual pupil academic and personality characteristics prior to initiating planning actions include (a) the amount of time spent studying a pupil's records and (b) the number of notes taken during this process. Additional variables tap pupil spatial and activity assignments as well as the proportion of time the teacher planned to spend with each pupil.

Feedback on planning focus

The Planning Outcomes Profile displays general decision patterns that the teacher exhibited while completing the simulation's interactive phase. A review of this report's numerical data reveals whether, in taking notes on pupils, the teacher focused on positive or negative traits or favored academic information over personality traits. Numerical comparisons also reveal preferences for blackboard or computer assignments, for personalized or standard lesson activities, and for working with individual pupils, groups of pupils, or the entire class.

Feedback on composite measures of navigation and planning

The Simulation Summary Profile offers a sampler of information concerning six navigation and planning activities. These activities include moving across work windows, selecting feedback windows, developing note lists for pupils, making pupil spatial assignments, deciding upon lesson activities, and allocating teacher time to pupil groups.
Feedback on decision-making style

The Planning Strategies Profile is the most recently developed feedback instrument. This graphical record allows participants to view their planning decisions within a broad context—a context defined by a global lesson-planning style. Work has begun on defining the major dimensions that define these styles.

Lesson-planning Style Scores for ID # 281

Figure 1. The Planning Strategies Profile

Factor analysis of the 1996 preservice cohort has yielded a clear factor structure. This structure addresses distinct decision-making factors that define four major TD simulation lesson-planning dimensions. Note that the vertical axis in Figure 1 depicts scores, and the horizontal axis depicts the four factors as described below. The cohort mean is 100; the standard deviation is 16.

1. Organizing the planning tasks. High scores on this factor indicate that the teacher was flexible in navigating the four tasks that collectively define the lesson-planning assignment; low scores indicate that the teacher exhibited a more conventional linear navigating style. The planning variables that define this factor consist of measures of how frequently the teacher (a) moved from one task to another, (b) revisited work windows that had already been accessed, and (c) initiated unconventional forward jumps across tasks.

2. Using information. During lesson planning, the teacher had immediate access to seven types of information via a single mouse click. This information, presented in a feedback window adjacent to the work window, included instructions for navigating the current work window, notes describing pupil characteristics, planning decisions recorded on work windows that were not currently visible, the lapse time spent in planning, and enlarged graphical representations of pupil faces. High scores on this factor indicate that the teacher’s approach to using information in lesson planning was defined by scanning a variety of feedback sources; low scores indicate that the teacher’s approach was defined by focusing on a specific source of information. Variables constituting this factor include the frequency of information-window changes and the number of different types of information that were accessed during the planning.

3. Relating to pupils. High scores on this factor indicate that in planning the lesson the teacher relied heavily on the needs of individual pupils; low scores indicate that the teacher did not. Variables that define this factor include the frequency of assigning pupils to work alone, the amount of teacher time allocated to individual pupils, the variety of equipment used for instruction, and the number of different activities assigned during the lesson.

4. Developing lesson activities. High scores on this factor indicate that the teacher exhibited a high degree of indecision in assigning lesson activities; low scores indicate that the teacher did not. Variables constituting this factor include the amount of time the teacher spent in assigning lesson content and the frequency with which the teacher reviewed program-defined content descriptions, authored personalized lesson activities, and reworked previously developed content assignments.

Student debriefing

A typical group debriefing session

The group debriefing sessions that follow the interactive lesson-planning task enable each participant to study personal lesson-planning records, to compare their personal performance on these instruments with that of peers and experienced teachers, and to use this feedback as a base for engaging in a discussion with their peers concerning effective lesson planning. Each 30-minute session begins with the distribution of one or two feedback reports. After having an opportunity to study their personal records, the 8-10 students attending each debriefing session can compare their personal performance with that of their peers and a cohort of experienced teachers. A Visual Basic tool allows the debriefer to read all cohort or other group data.
files and create a series of screen images (projected via an LCD panel) that display histograms and/or pie charts depicting the average group scores for variables listed on the current feedback instrument. Figure 2 presents information provided to the 95 preservice teachers comprising the fall 1996 cohort. This graphic includes both peer and experienced teacher comparative measures for that category of the Simulation Summary Profile that addresses teacher time commitments. The left bars depict averages for a cohort of 31 experienced teachers; the right bars depict averages for the cohort of 95 peers.

**Figure 2. The group display for teacher time commitments**

**Legend**
1. % uncommitted time
2. % individual pupil time
3. % pupil group time
4. % entire class time

**Student evaluations of debriefing**

Both ratings and comments gleaned from a questionnaire administered at the conclusion of the 1996 debriefing sessions affirm the instructional value of the debriefing feedback but also indicate that there is room for future improvement. Rating results reveal that 78.2% of respondents clearly felt that the debriefing experience was helpful. Rating differences, however, emerged across the sexes. The 65 women who completed the questionnaire exhibited a higher positive collective rating score for the three items that focused on helpfulness of the debriefing than did the 13 men who completed this instrument \((76) = -2.04 < .05\). Inspection of the ratings of peer and experienced teacher feedback reveal another important finding. While 51% of women and 69% of men indicated no preference for peer versus experienced teacher feedback, a substantial block of women (43%) and men (31%) rated the experienced-teacher feedback more helpful than the peer feedback. Only four women in the entire sample rated the peer feedback more helpful than the experienced-teacher feedback.

Student comments included on the questionnaires generally support the instructive value of the debriefing experience. Positive comments focused on (a) having the opportunity to practice lesson planning, (b) becoming more aware of the complexity and the time demands of the task, and (c) learning to balance class instruction with one-on-one instruction. The theme expressed by the minority of students who wrote negative comments centered on being confused by the amount of information presented in such a short period of time and being uncertain of what they had learned.

**Future applications**

Based on the questionnaire findings and on unsolicited information obtained through informal dialogue exchanges with students throughout the year, the Curry simulation team is currently considering implementing several changes to enhance the feedback value of the debriefing sessions. These changes include (a) devoting more time to the debriefing, (b) focusing on fewer and more clearly defined feedback measures during the debriefing, and (c) linking the entire debriefing experience more closely to the academic coursework that the preservice teachers complete during their simulation experience. Coupled with this movement toward better integration will be an increased effort to enhance the instructional efficacy of the simulation by involving the faculty teaching the parallel courses more completely in all aspects of project development.

DOES LESSON-PLANNING SIMULATION PERFORMANCE PREDICT CLASSROOM AND FIELD PERFORMANCE?

Harold R. Strang  Chadwick C. Blackwell  Amie K. Sullivan
University of Virginia  University of Virginia  University of Virginia

Over the past three years, almost 300 students at the Curry School have completed the Visual Basic Teaching Decisions (TD) simulation during the early phase of their teacher-training program. As described by Strang (1998), the feedback provided by this interactive experience allows participants to compare personal lesson-planning decisions with those of their classmates and with those of experienced teachers. The evolving software's lesson-planning measures have increasingly become more sophisticated and sensitive to individual participant differences. For example, Sullivan, Yeh, and Strang (1997) found that lesson-planning strategies of experienced teachers differed from those of their inexperienced peers. The present exploratory study focuses on a cohort of students enrolled in the Curry School's teacher-education program. The first research goal is to identify the major types of lesson-planning strategies that these teachers-in-training employ as they complete the TD simulation. The second goal is to determine whether the identified planning types relate to other simulation performance and rating measures, to demographic variables including age and sex, and most importantly, to performance in other areas of teacher preparation. These areas include (1) academic achievement in teacher-preparation courses and (2) future teaching performance in field settings. The underlying purpose of this research is to explore whether the TD simulation has diagnostic value. Most importantly, to what degree can TD performance scores be used by teacher educators to personalize preservice teachers' future academic and field experiences so as to maximize their effectiveness when they work with live students in the field?

Identifying types of lesson-planning strategies

Through the use of factor analysis, Strang (1998) has isolated four decision-making dimensions that define preservice teachers' performance on the TD simulation. The factors address how participants (1) organize their movement through the task, (2) use information during planning, (3) focus on the needs of individual pupils, and (4) demonstrate decisiveness in developing lesson activities. In the current study, an attempt was made to determine how these dimensions interact to produce patterns or types of lesson-planning strategies. An iterative partitioning method of cluster analysis (Aldenderfer & Blashfield, 1984) was employed to determine the clustering patterns of a sample of 95 preservice teachers who had completed the simulation during the fall of 1996. Maximum distance and iteration frequency played a strong role in determining that the following 5 clusters would be retained for further analysis.

**Type 1.** This cluster included 4 students who exhibited high flexibility in moving through the planning task but displayed relatively little concern with meeting the needs of individual pupils.

**Type 2.** This cluster included 32 students who exhibited low flexibility in moving through the planning task, focused on specific information rather than on scanning during decision making, displayed little concern with meeting the needs of individual pupils, and exhibited little indecision in assigning lesson activities.

**Type 3.** This cluster included 21 students who focused more on scanning information sources than on using specific information for planning, and exhibited little indecision in assigning lesson activities.

**Type 4.** This cluster included 4 students who exhibited high flexibility in moving through the planning task, focused on specific information rather than on scanning during decision making, displayed great concern with meeting the needs of individual pupils, and exhibited little indecision in assigning lesson activities.

**Type 5.** This cluster included 34 students who exhibited only one trait—a high degree of indecisiveness during the assignment of lesson activities.
Expanding our understanding of planning types

The next step in the research plan involved increasing our understanding of the 5 planning types by assessing their relatedness (a) to other measures obtained from simulation planning performance and post-participation ratings, (b) to key demographic variables, (c) to academic achievement in a learning and development course, and (d) to supervisor ratings of teaching performance in a field setting. Since this is an initial exploratory study and two of the planning types included only four students, relationships among the types and specific variables were established by simple observations of variable means and standard deviations rather than by more rigorous group statistical analyses.

Relationships with simulation performance and rating variables

Several relationships were gleaned from a review of simulation performance measures that had not been used to define the planning types' component factors and from a questionnaire administered immediately following the teachers' completion of the simulation debriefing session. The eight-item questionnaire addressed participants' motivation during the simulation's interactive phase and their perceptions of its user-friendliness and value as an instructional vehicle.

Type 1 participants generally took a long time to complete the task yet spent little time reading either initial instructions or instructions describing how to complete specific planning tasks. In preparing to interact with pupils, these teachers spent relatively little of their planning time studying the characteristics of their future pupils. They did, however, anticipate devoting much time during the lesson to interacting with pupils. Their planning responses suggest that these interactions centered on providing pupils with vocabulary and reading. Students in this cluster, however, reported relatively little experience working with children in diversified settings.

Type 2 participants engaged in the simulation-planning task for a relatively short period of time.

Type 3 participants exhibited one distinct behavior during planning; they were likely to try to exit the planning task prematurely.

Type 4 participants studied the initial simulation instructions for a relatively long period of time; they also tended to engage in the simulation-planning task for a lengthy period. They spent a relatively large proportion of this planning period in studying the characteristics of their future pupils, and they anticipated devoting a large amount of their time to interacting with pupils. Finally, they tended to rate the feedback that they received during debriefing as helpful.

Relationships with demographic variables

The following relationships were observed when demographic variables including age, sex, 4 SAT performance measures, prior experience working with children, and teaching area variables were compared across the 5 clusters.

Type 1 students generally achieved high SAT scores on vocabulary and reading. Students in this cluster, however, reported relatively little experience working with children in diversified settings.

The Type 2 cluster contained a disproportionately large number of physical education majors. Also, 3 of the 4 students who dropped out of the teacher education program were members of this cluster.

The Type 3 cluster contained a disproportionately large number of men.

The Type 4 cluster was comprised of 4 female elementary education majors whose verbal SAT scores were generally high.

Relationships with academic performance variables

The following relationships were observed when academic achievement in a learning and development course was compared across the 5 clusters.

Type 4 students tended to exhibit strong improvement from their midterm to their final examinations and generally earned high course grades.

Relationships with field experience rating variables

Supervising teachers used the following rating categories to evaluate the preservice teachers' performance in the field.

1. Professional responsibilities includes managing assignments, scheduling daily routines, and meeting attendance responsibilities.
2. Professional commitment includes seeking knowledge about the discipline of pedagogy, exhibiting appropriate practices in the classroom and school, and volunteering for assignments.
3. Professional relationships includes working cooperatively with mentor-teachers and other professionals, seeking feedback on assignments, and maintaining professional confidences.
4. Professional skills includes developing appropriate classroom skills, responding to instructional and emotional student needs, and displaying overall effectiveness during the field experience.

Inspection of supervisor ratings yielded the following 2 relationships.
Type 1 students were rated relatively low by their field observers on professional responsibility, professional commitment and professional skills.

Type 4 students were rated relatively high by their field observers on professional responsibility, professional commitment and professional relationships.

Type summaries and conclusions

The results obtained from this exploratory study provide interesting portraits of several types of lesson planners that appear to be anchored either to affective or cognitive foundations. The principal characteristic of Type 1 planners appears to be egocentrism. These teachers, reporting that they had had little experience working with children, were largely concerned with completing the lesson-planning task on their own terms and in filling up lesson time with what they deemed to be important academic information. Moving to the academic and field arenas, members of this cluster had extensive vocabularies and were strong readers. Their relatively low field evaluations may reflect the difficulty that these preservice teachers experienced when their self-centeredness hampered their ability to profit from the feedback provided by their field supervisors.

The principal characteristic of Type 2 planners appears to be the cognitive attribute of low commitment. These preservice teachers completed the lesson-planning simulation relatively quickly by following the preset linear decision-making template, by seeking out few information sources, by employing few options to individualize pupil instruction, and by exhibiting low indecision in assigning lesson activities. Interestingly, 3 of the 4 students in the preservice cohort that withdrew from the teacher education program were Type-2 planners.

The principal characteristic of Type 3 planners appears to be the emotional attribute of low motivation. In the planning simulation, these participants tended to isurf indiscriminately through both valuable and relatively useless (e.g., enlarged pictures of student faces) information sources, exerted little effort toward developing lesson content, and were likely to attempt to exit the planning task prematurely. It is interesting to note that this cluster, which is in part defined by information surfing, is also over represented by men.

The principal characteristic of Type 4 planners appears to be competence. These preservice teachers studied instructions carefully and devoted a relatively long time developing their lesson plans. They studied the characteristics of their future pupils very carefully before they began making actual planning decisions. During planning, they were flexible in moving across decision-making categories. They also tapped relevant sources of information in their decision making, focused on meeting the needs of individual pupils, displayed little indecision in assigning lesson activities, and anticipated spending a relatively large portion of lesson time interacting with pupils. Moving to academic and field settings, the four women constituting this cluster had high verbal SAT scores, demonstrated improvement across tests and earned high grades in the learning and development course, and received high field participation ratings from their supervising teachers.

With only one simulation performance factor defining it, Type 5 provides the least clear picture of a lesson-planning style. The principal characteristic of Type 5 planners appears to be indecision in responding to one of the planning tasks chief challenges—developing lesson activities for pupils. Illustrating this struggle, Type 5 planners spent a relatively higher proportion of their time engaged in making activity choices, frequently checked activity definitions, and repeatedly changed activity assignments.

Two major conclusions can be drawn from the results of this pilot study. First, effort needs to be directed toward making the simulated lesson-planning task more meaningful to a larger number of participants. Strang (1998) discussed the importance of post-planning feedback and debriefing and suggested several ways in which this phase of the task can be improved. Additional efforts must also address the breadth of the simulation's planning options with particular attention paid to the availability of realistic lesson activities.

The second conclusion drawn from the current study is that lesson-planning performance exhibited during the simulation not only provides helpful personal feedback to student participants, but it can also be used as a tool by professors and field supervisors to guide these students as they move from classroom theory to real-world teaching. For example, type information gleaned from simulation performance measures might (a) alert teacher educators as to the special needs of their egocentric preservice teachers, and (b) sensitize teacher educators to motivational issues in low-commitment preservice teachers.

In closing, it must be emphasized that the current study needs to be replicated to confirm the factor structure, cluster results, and variable relationships suggested in this paper. The replication cohort will include over sixty students currently completing their first year in Curry Teacher Education Program.

Capturing the Process of Thinking with Online Computer Simulations

Mark J. Van Gorp
Calvin College

Constructivist educators emphasize the process of thinking and learning. Bednar, Cunningham, Duffy and Perry (1992) state, "Constructivists focus on the process of knowledge construction and the development of reflexive awareness of that process" (p. 24). Jonassen (1996) writes that computers must serve as knowledge construction tools that "support, guide, and extend the thinking processes of their users" (p. 10). Further, constructivists stress the understanding of a particular student's thinking process over the observation of his or her correct answers (Confrey, 1991).

However, authors such as von Glasersfeld (1991, 1995) note that understanding an individual's thinking process is a rather elusive endeavor. He writes that "models we construct of other people's ideas and mental operating... are necessarily hypothetical because we have no direct access to what goes on inside other people's heads" (von Glasersfeld, 1991, p. xvi). Nevertheless, teachers must strive to make sense of and value the thinking of their students by constructing hypothetical models of each student's thought process (von Glasersfeld & Steffe, 1991; von Glasersfeld, 1995). This construction best occurs through linguistic communication with the student (von Glasersfeld & Steffe, 1991).

The ensuing paper, although not documenting a challenge to this claimed superiority of linguistic communication, presents an additional or perhaps complimentary approach to the exploration of student thinking. This approach is supported by a Web-based tool that qualitatively captures the process of thinking. After introducing the background for tool design, the paper will briefly describe the tool and illustrate its use in mathematics education. The paper will conclude by discussing the tool's strengths and weaknesses.

Background for Tool Design

By analyzing post-test results, substantial valuable research has addressed the learning effects of computer simulations (e.g. Brant, Hooper & Sugrue, 1991; Thompson & Wang, 1988). However, while this research often examines cognitive outcomes after simulation use, another smaller and important strand of simulation research examines cognitive processes during simulation use. This research examines what is often missed — the process of student thinking and problem solving. For example, by using computer simulations which automatically deposit student interactions (protocols) on a local disk, several investigators have explored patterns of student thinking by searching the stored data files (e.g. Hooper & Thomas, 1990; Upah & Thomas, 1993). Although examination of protocols can be time-consuming and tedious, these investigators found this task to be a valuable source in speculating about thinking processes which may not otherwise be observed.

Turoff and Hiltz (1995) further advance the ideas of simulation design. They believe a powerful addition to simulation use is the capability to 'record and playback' simulation input in virtual environments. Here, instructors could record their input to a simulation, and students could replay this input to "see how the problem solving process of the instructor unfolds as he or she goes through the process of dealing with some complex problem in [an] application domain" (p. 207).

When considering the ideas of Turoff and Hiltz and the investigation of student protocols, immediate research implications may hold for computer-mediated communication activities in teacher education. For example, Poole (1996) created an environment which connected preservice teachers with elementary students across the United States. Preservice teachers sent mathematical problems to their assigned students each week via e-mail, and the students responded with a solution and an explanation of their solution process. However, when the students did not clearly articulate their solution process, the preservice teachers "could only reply to the correctness of a response rather than [provide] more detailed feedback that might help the elementary students develop better problem solving skills" (p. 159). Although one of Poole's primary goals was to foster the preservice teachers' selection of appropriate mathematical problems, future networked situations may be viewed in light of protocol research and
Turoff and Hiltz's suggested design: These situations may be supported by representing a general problem in an online computer simulation and providing the capability to record, playback, and guide the process of student thinking and problem solving.

Tool Description

The background presented above, namely the value attributed to protocol analysis and the potential power of 'record and playback' functionality, motivated the design framework for a new computer-mediated tool. Furthermore, the impetus for creating this tool was spurred by the belief that preservice teachers could constructively use this tool to explore the cognitive and metacognitive problem solving processes utilized by elementary or secondary students — independently of time and space.

Thus, a tool manifesting the theoretical 'record and playback' functionality suggested by Turoff and Hiltz (1995) was created. Although not specifically duplicating their proposed design, this particular tool's functionality permits the storage and playback of user interactions with computer simulations. Additionally, because the tool is Web-based, the need for localized storage of simulation protocols is negated and the boundaries of protocol research are extended.

This tool is implemented as an assignment type built into a larger virtual classroom management system known as ClassNet (Van Gorp & Boysen, 1997). ClassNet is designed to support a growing hierarchy of Web-based assignment types such as tests, surveys, and instructor evaluations. One assignment type, termed cnet-java, allows retrieval of Java simulations from ClassNet and storage of interactions with those simulations inside ClassNet's database. Researchers and teachers can later analyze or playback these protocols.

Sample Protocol Session

The following sample session illustrates the playback of student protocols. The protocol figures, extracted over a period of 2 days, are taken from a recent research study which evaluated the use of protocol analysis in preservice teacher education. To reduce the number of figures needed, repeated "Step"s are combined; however, when using the actual simulation, a line is drawn or a conjecture is presented each time the teacher presses "Step". This gives a feel for the thought process of the student.

Session Context

Three preservice teachers were connected online with 2 pairs of eighth-grade boys enrolled in a pre-algebra course. The eighth-grade pairs had only previously graphed lines by creating and plotting tables of (x, y) points. Subsequently, the preservice teachers and the eighth graders cooperatively worked with a cnet-java assignment that extends the plotting of table points to the exploration of linear equations.
For approximately 1 week, each student pair interacted with Lesson Graph every afternoon. Meanwhile, the preservice teachers accessed Lesson Graph every evening, replayed and discussed the student protocols, and sent appropriate guidance for future simulation use. The purpose of this guidance was to constructively support students in their discovery of linear concepts and promote the use of metacognitive strategies.

Session Illustration: Creating Perpendicular Lines

The student pair highlighted in this illustration had already utilized an important metacognitive strategy to discover parallel lines: They held two variables constant (A and B) while changing the other (C). The preservice teachers emphasized the importance of this strategy and sent guidance that challenged the students to create perpendicular lines.

In response to the teacher's challenge, the students began exploring perpendicularity and eventually discovered how to create perpendicular lines by changing a sign on the A or B coefficient (see Figure 2). They then replied to the preservice teachers' original challenge (The preservice teachers' challenge is shown first):

Teacher > Do you know the opposite of parallel? If so try experimenting with that.
Student > Yeah! We did it.
Student > Look through our equations. 1x+y=1, 1x*-1y=1

Unfortunately, the students had failed to test their hypothesis with numbers other than -1 or 1. Later, in the same protocol session, the students also created perpendicular lines with 0's and 1's (see Figure 3), but they did not relate this discovery to the previous discovery of A or B sign transformation.

After playing back the protocol and thinking about the students' discovery, the preservice teachers sent the following guidance that evening:

Teacher > You found perpendicular very well.
Teacher > Can you find it using 1x + 2y = 3?

This was a valuable task for the teachers as they attempted to invoke cognitive conflict through the use of a counter-example: Changing signs of the A or B coefficients in this equation will not produce perpendicular lines.

On the next day, the students applied their newly found conjecture to the equation sent by the teachers. However, they now discovered that changing the signs of the A and B coefficients did not produce perpendicular lines (see Figure 4). To remedy this misconception, the students eventually brought previously constructed knowledge to the forefront (see Figure 5): They had used 0's and 1's to create perpendicular lines the previous day. The student pair now realized that changing the A and B coefficients also creates perpendicular lines and combined this knowledge with their previous hypothesis of changing the signs. At last, a line perpendicular to 1x + 2y = 3 was constructed (see Figure 6).
Discussion

Capturing and playing back remote student interactions with Java simulations provides an interesting arena of research. Its primary strength is that preservice teachers or researchers can easily analyze and discuss cognitive and metacognitive processes employed by the student users of a simulation. This is particularly important for preservice teacher education as impending issues of classroom discipline and organization may hinder preservice teachers from ever thinking about student thinking. Further, the asynchronous nature of protocol research gave the preservice teachers time to collaboratively construct optimal guidance to send.

Nevertheless, protocol capture and analysis in this study did have various weaknesses. These weaknesses were primarily due to the asynchronous nature of the study. For example, the preservice teachers could only hypothesize about the student thinking based upon the stored data (i.e., the graphed lines, conjectures, and replies to teacher notes) and could not immediately ask the students about their thoughts. Further, the students could have periodically benefited from immediate guidance that directed and enriched their exploration. Another drawback was the lack of non-verbal cues: The only means of determining levels of confusion or enjoyment was to ask the students through written notes. Finally, creating an actual simulation and connecting it with ClassNet was not a trivial task. It involved computer programming expertise.

These weaknesses lead directly into future research. For example, synchronous guidance may be included by either programming this capability in or by making use of commercial tools. Many commercial tools also support the synchronous transmission of audio and video. Thus, one
may conceivably observe remote students working with a
simulation, communicate with them by audio or type-
written chat, and view the student interactions with that
simulation - all at the same time. Although asynchronous
communication gives novice teachers the time they need to
construct guidance, more advanced teachers may benefit
from this synchronous challenge. Finally, future research
might also address the creation of tools that simplify the
storage and analysis of protocol data.

Conclusion
The strengths and future research ideas for the capture
and analysis of simulation protocols suggest that similar
activities should continue to be investigated. These
activities may potentially benefit not only the user of the
simulation but also the analyzer of the user's interactions.
Simulation utilization coupled with the advent of Java and
World Wide Web technologies is one means of permitting
new teaching, learning, and research opportunities that were
previously not possible. Similar web-based experiences
must continue to be envisioned and explored.

Social studies education has long suffered a malaise regarding its efficacy among teachers and students. What with debates centering around its very definition and goals, very traditional approaches to curriculum and instruction, and students stating that social studies is boring and irrelevant, there is no wonder that the discipline and its advocates suffer a confidence problem. The articles included in the social studies section each address these issues in their own way. The overriding theme of the papers as a whole can be described as suggesting that social studies education be transformed through technology and constructivist integration, and that teacher education is an ideal arena for the transformation to begin. Many state that the ultimate goal of social studies is to assist in the development of active citizens who are able to think critically and solve problems. If this truly is the goal rather than the perpetuation of the status quo and the continued facilitation of hegemony, then transformation is not only needed, it is required. The papers included herein offer ideas for such reform.

Jones and Bennett describe the establishment of The Jamestown Virtual Colony, a web-based online resource for teachers that includes plans, documents, outlines, bibliographies, and web links. The project is thematically organized and is designed to be interactive and possess ongoing development. The goal is to offer an improved strategy for integrating technology in social studies education for preservice and inservice teachers and their students. The authors utilize the web because of its tremendous potential in facilitating data gathering skills development. A model for social studies teacher education is also provided in the paper. True technology integration in preservice programs suggest email, personal web page, and Internet resource applications focusing on lesson and unit design and implementation. The paper concludes by including limitations and really suggestions for more collaborative web-based projects for social studies education. Projects such as this can only assist in the transformation of social studies education toward a more relevant, student-centered learning experience.

Dowling describes a collaborative project entitled The Community Discovered. The goals of the project includes the linking of art and technology through a constructivist framework and designed for disadvantaged students. The ultimate outcome of the project is the development of curriculum activities based on electronic museum materials. A variety of participants and projects have been employed in initial development. Also included is a review of literature regarding successful integration of technology and project-based learning in schools. Innovation diffusion literature is also thoroughly reviewed. The paper also includes a preliminary review regarding success of the project and suggests that constructivism is an appropriate strategy. A school wide technology focus is also suggested for successful implementation. The authors are quite upfront with early evaluations and provide very relevant ideas for project implementation that has generalizability for similar endeavors. The paper concludes with recommendations to facilitate broad-based implementation of the project. The thorough literature reviews that respectively integrate technology integration and innovation diffusion tied to the early evaluation of this project offer powerful ideas for future technology projects in social studies education.

Cole Slaughter and Jones suggest in their paper that the World Wide Web is an innovative tool for research and telecommunications for teachers and students in learning about different cultures. The paper describes the implementation of a culture box (or an electronic version called cyber cube) for inquiry activities regarding different cultures. Examples of culture box applications are included in the paper. The authors suggest that by including technology via the world wide web the culture box transforms into a cyber cube. Preservice teacher comments and reflections are included to give credence to the project. The culture box/cyber cube example provided is on Australia with several relevant web sites listed. The authors conclude by stating that culture box/cyber cube activities provide multisensory, multi-modal learning that enables the transfer of knowledge through a motivation inquiry and technology-based
project. Such an activity provides an innovative method for integrating technology in developing a community of learners and in developing a more meaningful global perspective.

Ledford and Peel state in their paper that the preparation of teachers requires the modeling of technology as a tool to provide relevant connection to the world for students. They suggest that the Internet offers access to current information and historical documents which enables active learning in the classroom. A number of web sites are listed that correlate directly with the ten thematic strands suggested by the National Council for the Social Studies. The listings include practical information such as the title of the web site, web address, and description of the site. The goal as indicated in the paper is to integrate technology in such a way as to allow preservice teachers the opportunity to apply Internet resources in developing curriculum and instruction.

Adamy and Madden describes a project that enhances social studies instruction by using the web to improve student awareness of social, historical, and ethical issues surrounding WWII. The authors discuss the importance of developing foundational knowledge and a sense of empathy for true historical understanding to occur. Prescriptive and constructive web sites are described with the paper suggesting that interactive sites possess the highest potential for learning. The project includes the development of a web site designed focusing on students’ interests with the Underground Railroad serving as the connection to WWII. The intent is that students should be allowed to interact in constructing knowledge and that technology can assist in this learning with students creating their own stories while placing themselves in the scenarios presented.

The papers in this section of the annual indicate that there is hope for transformation in the integration of technology in social studies education both at the K-12 and teacher education levels. We can now only suggest that continued efforts are made to nudge the disciplines of social studies education, information technology, and teacher education is ever more empowering directions for teachers and students.

TEACHING IN THE INFORMATION AGE: THE JAMESTOWN VIRTUAL COLONY

Raymond C. Jones  
University of Virginia

Clifford T. Bennett  
University of Virginia

Teachers genuinely hunger for resources to help them in teaching content. One need look no further than the eager cajoling of textbook representatives in conference exhibition halls, the frantic searches through book storage rooms when last-minute course assignments are announced in August, or the multiple visitors to ERIC gopher sites. If a workshop presenter offers good ideas, he or she will find every copy of the handouts snatched up. Starting teachers might be in search of any help as they confront content for the first time; seasoned teachers might be no less eager in the pursuit of fresh ideas. Good teachers are likely accustomed to requests from colleagues to share copies of their creations.

Programs in teacher education, and content methods courses in particular, are veritable lesson plan production factories. Semester after semester, students in teacher preparation programs develop units, identify resources, and write out detailed lesson plans that incorporate a range of engaging activities. And their well-organized notebooks all too often become another volume stored in a methods professor’s filing cabinet or are lugged from school to school during the early years of the student’s professional teaching career.

The Social Studies Program Area of the Curry School of Education at the University of Virginia has decided it is time to wed the productivity of its preservice teachers to the demand by practicing teachers for timely, useful, creative lesson plans and resources. It’s a marriage, of sorts, made possible by the advent of the World Wide Web. Funded in part by a grant from the Virginia Foundation for the Humanities and Public Policy, the Social Studies Program Area has created the Jamestown Virtual Colony to serve as an online resource for teachers whose content includes the founding and settlement of Jamestown, Virginia. Soon after its inception, the project was recast not only as a service to high school history faculty but as the organizing framework for a collaborative themed approach to the training of preservice teachers and the enhancement of licensed teachers’ leadership. The completed project represents the Curry School’s first of what should be many web-based teaching resource units for teachers of history and social studies.

The Jamestown Virtual Colony

The primary purpose behind the Jamestown Virtual Colony Web site is to offer teachable lesson plans through the instant and mass distribution of the World Wide Web. The choices of content and concepts, and the state and national standards that inform the lesson plans’ foci, are geared primarily to 11th grade United States History courses, although teachers of any level should find the site useful for creating and tailoring their own instructional activities. The lesson plans are integrated into a larger themed unit framework, which includes objectives, unit outlines, and annotated bibliographies. The content of the site is divided into five areas: Corporate Colonization, Development of Government, Organization of Society, Economic Matters, and Broader Themes of Jamestown. The daily lesson plans do not exist in isolation, but are supplemented by primary sources, images, maps, and reference works, as well as an exhaustive list of links to other relevant sites.

Teachers who access the Jamestown Virtual Colony will find more than the lesson plans and resources developed within our unit. They can also find lesson plans and guides developed by some of our Masters students for teaching with other online Jamestown resources. The site also provides some assistance with evaluating information found on the Internet, using search engines, and (coming soon!) a “virtual field trip” to Jamestown that permits online visits by those who would otherwise be unable to travel to the real Jamestown.

In keeping with the notion of the Web as a “dynamic environment” (Garland, Scott, & Boyer, 1995), and in seeking to take advantage of its interactivity, the area devoted to Links to Other Sites includes user-input forms so that visitors to the Jamestown Virtual Colony can add relevant links that they themselves have created or that they have encountered. A special section is devoted to class web projects. As more and more teachers involve their students...
in “intellectual skills” projects, the World Wide Web is increasingly the vehicle used to publish student work. Teachers can add a link to their students’ work directly onto the Class Projects page within the Jamestown Virtual Colony.

The Role of the World Wide Web

Educators of young children who wish to engage those children in the social studies must necessarily come to terms with the emerging roles of technologies in the development of society, and in the activities of contemporary teaching and learning (Goo ler, 1995).

Much has been written about the incorporation of technology, computers, and specific applications in social studies teaching. While a great deal of the research about the effectiveness of computer applications in enhancing student learning has yet to reach definitive status, it is clear that computers can—and should—occupy a role in the preparation of children to assume their roles as good and productive citizens of tomorrow. Classroom teachers and students “who have learned to use these tools effectively have increased their ability to solve problems, accomplish tasks, and learn about the world” (Moursund, 1995-1996). We cannot neglect our duty likewise to prepare preservice teachers to effectively utilize technology in pursuit of educative goals. Kovalchick (1997) notes that as “the use of technology in teacher education gains greater attention, it’s important that we continuously refine our models of technology instruction for preservice teachers.”

Social studies and the World Wide Web are natural partners in the educational endeavor. In fact, it is the advent of the Web, particularly after the introduction of Mosaic and, later, Netscape, that has best exemplified why technology must find a suitable home within the social studies. There is no doubt but that the “resources made available by Internet access have tremendous educational potential” (Boldt, Gustafson, & Johnson 1995). While many “social studies educators have been reluctant to integrate computers into their curriculum and instruction” (Berson, 1996), an increasing number are recognizing the Web’s particular value as a means for accessing information, a primary educative process in good social studies instruction. “Data Gathering,” which is first among four skills deemed essential by the National Council for the Social Studies in 1990, is perhaps the most common activity engaged in by students in social studies classes.

What is the Web’s beauty when it comes to gathering data? It has never before been possible to access the volume and array of primary sources as can now be found through a few clicks of a mouse button. And it is unfiltered content, without interpretation or revision by textbook authors or other third parties. In today’s world, the delivery of a single newspaper to a few lucky social studies classrooms seems almost laughable when held up against the hundreds of newspapers from throughout the world that can be accessed online. The instant identification, reading, and tracking of Congressional legislation through Thomas [http://thomas.loc.gov/] puts students in direct contact with the legislative process. “White (1990) has noted: ‘Interactive multimedia—the marriage of text, audio, and visual data within a single information delivery system [sic] represents a potentially powerful tool for teachers and students throughout the curriculum’” (cited in Martorella, 1991). Images, maps, speeches, music, and video abound, and the hyper-navigability of the Web allows students and teachers to seek directly the content in mind while simultaneously pursuing connected areas of interest in the manner befitting their search. In other words, students and teachers can circumvent the middlemen and brokers of information in the truer spirit of social science inquiry. And one of the most valuable shifts in the expression of students’ information-gathering skills might be, as Richard Diem put it, not finding the right answer but “asking the right question” (Diem, 1997).

Publishing the Jamestown Virtual Colony on the World Wide Web permits universal access to its resources. There is no reliance on traditional publishing and distribution systems of a physical product. The content can be updated and supplemented instantly, and sounds and images are as accessible as text documents. Teachers can hyper-navigate the site and thereby go directly to the target of their particular interest.

But what distinguishes non-technology-using teachers from effective users? There is reason to believe that better integration of technology training is needed in preservice teacher education. It is not only how tools are manipulated but to what end they are used that teachers should understand. The possibilities for technology in the hands of well-trained teacher education graduates “depends in no small measure on [having a] broad, deep, powerful, and empowering teacher education experience, supported by telecommunications technology” (White, 1997). Integrating technology into methods courses helps create the “cadres of reform-ready novice teachers who are able to harness technology’s potential to transform education and schooling” (White, 1997).

Further, teachers need to see the usefulness of the Web and other technologies, not only for their “own professional growth,” but also to see “how they can use these same resources to support the curriculum” (Fontana, 1997).

The Methods Component

Beyond the obvious benefits to United States History teachers that this online repository will represent, though, is the emergence of a renewable model for the methods training of preservice teachers that includes a component of collaborative leadership by experienced Masters level students. Based on a thematic team design, the graduate
students managed and directed the curriculum development work of students in the social studies methods course and created the unit framework into which the preservice teachers' products fed. This represented the first time we had ever combined Masters students with undergraduate preservice teachers in order to enhance the learning outcomes for the Fourth Year students.

Designing instructional materials for delivery by the World Wide Web forces emerging teachers to confront some very frank issues: What is history? What should United States History offer to students? What characterizes good instruction? What characterizes a good lesson plan? What are the attributes and pitfalls of the World Wide Web as a resource, information source, or repository? The preservice teachers did not merely practice the crafting of lessons for good learning but attempted to resolve how one best develops an Internet resource for history teachers that is accessible, meaningful, and useful. Authenticity took a more central role as students sought to demonstrate their emerging understanding of good lesson planning. Because the students posted their early lesson plan drafts on their own personal home pages, we were able to institute a peer review process that led to useful revisions by the lesson plan authors and which called on students to seriously grapple with the components and qualities of good lesson planning as they attempted to provide constructive criticism to their classmates. Most feedback was given via email, but each student also completed a detailed rubric review guide [see the Appendix] for at least three of his peers.

The divisional responsibility framework was a unique way to honor the expertise of our Masters students, all of whom were licensed teachers with experience ranging from recent graduates with only a student teaching field experience to eleven years of classroom experience in New York. Their roles as team leaders called for them to better understand and then articulate their accumulated knowledge about teaching. Their guidance of the undergraduates' work was accomplished in regular meetings and through email communication.

As White (1997) notes:
...in a teaching field that places a premium on primary sources and inquiry, future social studies teachers ought to explore the range of resources available for their students and their own further education that telecommunications technology makes possible.... The potential benefits in reaching out to a wider world of resources makes experience in using telecommunications technology in preservice education particularly imperative for social studies teachers.

Some Caveats Worth Considering

While the development of the Jamestown Virtual Colony occupied a central role in the first half of our social studies methods course, this inaugural run of the model came with some limitations. First and foremost, the students who developed these lessons have not been asked to also teach them in real classrooms. Certainly, a trial run with opportunities for feedback and revision would allow for reflective adjustment in the structure and implementation of the lesson plan design. Second, because they are only in the fourth year of a Five-Year Bachelor of Arts/Master of Teaching program, these methods students are essentially novices in lesson plan writing. By the time they complete the second half of the methods course, their skills will be much improved and will find richer manifestation. But for many, this project was a first attempt at serious lesson plan writing for well-defined content and with an intended audience outside the faculty of the School of Education.

Third, as a new project without antecedent, the development of this online resource for teachers followed an emergent design. It was clear that working towards a goal which did not exist in any example form was for some students an unsettling experience. In truth, the wide latitude for creativity and the open-ended nature of individual lesson development were a difficult concept for some of the more anxious students.

Fourth, not all classroom teachers have access to the World Wide Web. Those who do have computers, modems, and communications and browser software are not necessarily "well-connected." DOS or early Windows versions of software, modems that are 14,400 bps or slower, and unsophisticated dial-in systems make web-surfing a treacherous and frustrating activity. We have very deliberately kept our site as low-impact as possible so that interested teachers would not become frustrated waiting for fancy graphics and large images to load.

Finally, it is not our intention to continue active maintenance of the Jamestown Virtual Colony. It will be left to exist in the form made final with our spring revisions, and the students and faculty involved will move on to other pressing projects. As of this writing, a decision is still pending as to whether the files will be moved to the Anthology History and Social Studies Pavilion on the Virginia Public Education Network (VaPEN), or if the site will be offered to the Jamestown-Yorktown Foundation to become a part of their outreach and education programs. The real benefactors, though, are the teachers who will now find a wealth of resources for teaching about the Founding of Jamestown. From our vantage point, the Jamestown Virtual Colony is a fitting tribute to the 400th anniversary of this settlement.
Future Implications

We gained much as teacher educators from this collaborative web-based project. It is likely that it will be a regular component of future methods courses. Students not only studied the theory and models of good lesson design but became critical consumers of their peers' lesson plans. Further, because their products will be offered to a world market of over 20 million computers, students seemed more intent on achieving a quality result from their labors. And the technology component in their preservice training should not be overlooked. The students in the methods course were immersed in web issues ranging from searching the Web to critically evaluating Web sites. They also were invited to expand their notions about the instructional applications of the Web and Web design. The real beneficiaries, though, are the teachers who will now find a wealth of resources for teaching about the Founding of Jamestown. From our vantage point, the Jamestown Virtual Colony is a fitting tribute to the 400th anniversary of this settlement.

NAME of LESSON PLAN AUTHOR

TITLE of LESSON PLAN

THEME AREA that LESSON IS PART OF

NAME of REVIEWER

Lesson Components

The objectives are behavioral and measurable.

“Students will be able to...” do something as a result of, not necessarily as part of, the lesson.

The relevance of the lesson is clear and meaningful.

Involvement of the learners is well-connected to the activities which follow it. Its relevance is clear and logical.

The lesson plan functions to organize the content so that student understanding of new information can be enhanced.

There are central or pivotal questions that serve to get at the “heart” of the lesson, its big ideas, or its most important points.

Clear, specific, detailed, step-by-step instructions are provided to guide the teacher through each element of each activity of the lesson.

The activities of the lesson are engaging, creative, and innovative. They seem more “fresh” than “stale.”

The activities, if well-completed, will lead to student achievement of the lesson’s objectives.

A closure that brings everyone back together and which revisits the important points of the lesson is well-explained.

The closure encourages a “reflective” moment so that students may reexamine the important objectives of the lesson.

976 — Technology and Teacher Education Annual — 1998
The closure is composed of appropriate questions. 4 3 2 1

ALL necessary materials are provided. It is clear what materials are referred to in the lesson (rather than saying "the handout," it is referred to by name). 4 3 2 1

Excerpts and quotes are appropriately cited. 4 3 2 1
The sources of information are clear.

A bibliography of sources and resources is provided, with annotations. 4 3 2 1

Recommendations for evaluating or assessing student outcomes are provided. (These would tie directly into the objectives listed at the top of the lesson.) 4 3 2 1

The reviewer is not distracted by errors of spelling or grammar, unnecessary or cluttering graphics, or poor text presentation and organization. 4 3 2 1

**Web-Based Presentation Issues**

The layout and design of the lesson are orderly and sensible and adjust to varying screen sizes. 4 3 2 1

The presentation of the lesson online reflects the author/designer's knowledge of website evaluation (i.e., authorship is explicitly noted, date last updated is included, links back to main or referring page are provided, etc.). 4 3 2 1

All links work. 4 3 2 1

Navigation within and between lessons has been considered. 4 3 2 1

There are links for backing out of sub-pages and/or for moving forward to subsequent pages. 4 3 2 1

The title bar/top of page contains the title of the lesson, as opposed to "Lesson1.html" or "untitled." 4 3 2 1

Handouts, worksheets, etc., are included as separate pages which can be individually printed. 4 3 2 1

**Open-Ended Questions**

What is it about this lesson that makes it teachable?

What is it about this lesson that makes it difficult to teach?

Would you want to be a student having this lesson "done" to you? Is it engaging? Would it inspire you? Why or why not?

List at least four recommendations you would make about the appearance, design, and layout of this page.
The Community Discovered: An Early Review of One U.S. Department of Education Challenge Grant

Sherwood Dowling
National Museum of American Art, Smithsonian Institution

The Community Discovered is a collaborative project sponsored by the U.S. Department of Education’s Technology Innovation Challenge Grant Program. These grants are awarded for the purpose of developing and refining technological applications with the potential to make significant contributions to school improvement. The Community Discovered is one of nineteen projects awarded Challenge Grants in fiscal 1995. This Challenge Grant, awarded to Westside Community Schools in Omaha, is a project that links art and technology with integrated constructivist curricula designed to transform the education of rural and urban disadvantaged students. The project features a collaboration between Nebraska public school districts and Nebraska museums. The Smithsonian’s National Museum of American Art, the University of Nebraska at Omaha (UNO) and Prairie Visions are also principal partners in this effort. The Prairie Vision Consortium was established by the Nebraska Art Teachers Association and Nebraska Department of Education with support from the Getty Center for Education in the Arts, and includes over ninety public and private school districts in Nebraska. The Community Discovered builds upon and extends the impact of the Art and Technology Integration Project conducted by Westside, Grand Island, the National Museum of American Art, and the University of Nebraska at Omaha. The ATI project received a two year grant from the Nebraska Excellence in Education Council.

In addition to Westside Community Schools, currently participating Nebraska K-12 school districts include the School District of Grand Island, Lexington Public Schools, Winnebago Public Schools, and Omaha Public Schools. These participants represent a diversity of students including significant African American and Latino populations. Urban, suburban and rural communities that feed these school systems are comprised of families with a broad range of socioeconomic circumstances.

The U.S. Department of Education believes that the nineteen “Challenge Grant communities are likely to succeed because they have begun with a clear definition of the educational problems they want to address.” (U.S. Department of Education, 1995). This paper presents an early review of the Community Discovered project describing progress toward that optimistic prediction and offers suggestions for improving chances of success.

Basic Concept and Goals

The Community Discovered is a five year project designed to link the use of technology and the visual arts with other subject areas throughout the K-12 curriculum with special emphasis on service to rural and urban disadvantaged students. A principal outcome of the project will be development of curriculum models of engaged student learning featuring activity based use of museum source materials made available electronically.

The Community Discovered project has five goals: 1) to promote and encourage academic achievement, 2) to provide student equity in access to state and national museum resources, 3) to enable educators to effectively use appropriate technologies for teaching and learning, 4) to effectively integrate art into interdisciplinary curriculum projects, and 5) to create a national network of educators to support the development and implementation of appropriate learning strategies that integrate art and technology into other subject areas.

Five related activities are designed to enable educators within Nebraska to participate in the accomplishment of these goals:

1) The Electronic Museum in the Classroom - digital images of museum artworks are being made available via Internet with information about each work and model curricula using the work. The National Museum of American Art, the Joslyn Art Museum (Omaha, NE), the Sheldon Memorial Art Gallery and Sculpture Garden...
2) Computer-based Educational Strategies - educators are testing, using, and evaluating commercially developed software as part of an integrated curricula. Students use software as tools in the construction of meaning and as electronic portfolios to record their progress and demonstrate their understanding of content.

3) Professional Development and Support for Educators - selected educators participate in intensive summer workshops preparing them to use the visual arts and technology, to apply the constructivist theory of teaching and learning, and to integrate art resources into content areas.

4) Integrated Curriculum, Instruction, and Assessment Strategies - educators develop curricular units integrating Internet-based resources engaging students in an active learning process. Site-based coordinators will with development, implementation, and assessment. Project evaluation is proactive, providing guidance throughout the project.

5) Nationwide Community for Art and Technology Integration - in cooperation with Prairie Visions and NDE, the project is sharing curricula, the collaborative model, and pedagogical methods using ARTnet, a web-based resource developed to support the arts as a core subject in the K-12 curriculum.

Further information on The Community Discovered can be found at http://communitydisc.wst.esu3.k12.ne.us

An Early Review: What Are the Chances for Success?

The following discussion is not part of the project's formal evaluation being conducted by the University of Nebraska at Omaha. The formal evaluation is being conducted by the Office of Internet Studies, College of Education, University of Nebraska at Omaha. The UNO evaluation is an impact analysis focused on analyzing data related to the above project goals and to related project objectives. With a comprehensive approach to data collection, UNO is examining teacher survey data, electronic data such as website use, classroom observations and videotapes, teacher and student interviews, student progress reports and portfolios, and focus group discussions. Both quantitative and qualitative approaches are being used to summarize and analyze the collected data with conclusions and implications based on multiple sources of data.

For example - the UNO evaluation of Goal 1, "to enable students to achieve high academic standards in art and other core subject areas" is broken down into specific objectives such as Objective 1.1, "80% of students in classes using the modules will show evidence of improved academic achievement indicated by: a) decline in absenteeism, b) increased student self-concept, c) students performing at higher levels as determined by each school's assessment of student progress." Each sub-objective has associated activities such as "a) a longitudinal survey of student attendance records, b) an annual student attitude survey - open ended and Likert, c) standardized test information" identified instruments to measure the activities, and project staff responsible for data collection. For further information on UNO's formal evaluation, visit http://ois.unomaha.edu/.

While the work of the UNO evaluators has been incorporated into this review, the purpose of the subject paper is not to evaluate project progress for each of the above project goals. Rather, as pointed out by Donald P. Ely, a review of basic conditions that facilitate the adoption of educational technology innovations can help identify the need for new or changed policies (Ely,1990). By comparing more subjective information with informed observations from existing literature in educational technology and innovation diffusion, this review will provide an informed view of the project's overall chances of success as well as several recommendations for improving those chances.

The following review compares project progress and participant observations with criteria for success presented in Technology and Educational Reform by Barbara Means and Kerry Olson (1997) and by comparison with benchmarks found in innovation diffusion literature such as Diffusion of Innovations by Everett M. Rogers (1995).

What Factors Lead to Success in Educational Technology?

The following discussion is derived from Technology and Educational Reform (1997) by Barbara Means and Kerry Olson. This report is part of the ongoing Studies of Education Reform Program of the U.S. Department of Education's Office of Educational Research and Improvement and was based on case studies of nine schools that "emphasized education reform (rather than technology for its own sake) and that provide challenging, authentic activities for students." This emphasis is further explained by Means and Olson:

The experiences of our case study sites suggest that, in fact, the move to project-based work, without relying on lecture methods or following a textbook, is a more fundamental and difficult shift than the introduction of technology. Teachers who have learned how to design challenging activities in which students work on cooperative projects and who are able to manage multiple student groups working on different phases of their project activity find that the introduction of technology goes relatively smoothly. (Means & Olson, 1997, p. 68)
The report identifies the following characteristics as important in supporting such an environment: sufficient numbers of computers to allow for frequent access, strong leadership, a collaborative environment with shared instructional goals, extensive opportunities for teachers to learn and work with technology, and on-site technical support. A sufficient number of computers is defined as “enough for a quarter of the students working individually or half the class working in pairs.” Leadership at the district level was categorized as instigation of innovation and in ongoing support with important activities being support for grant writing, use of bargaining and purchasing power, and nurture of reform activities. Importantly, the report also noted the negative consequences of top-down decisions with respect to restructuring and technology when first line educators were not involved. The most important element of leadership was identified as that of the school principal in inspiring and coordinating activities, in serving as a program advocate and liaison with the district, and in making technology supported reform a school wide effort. A collaborative environment with shared instructional goals is cited by the authors as fundamental to the successful integration of technology as teachers will be motivated to incorporate technology when it supports school educational norms. The importance of leadership and a collaborative environment resulting in a school wide vision are emphasized by Means and Olson:

... our case studies suggest that the greatest difference between more and less successful technology implementations resides in their artfulness in creating a coherent school wide approach to using technology in the core curricula for all students.

(Means & Olson, 1997, p.116)

The authors identified these strategies for providing opportunities for teachers to learn and work with technology: create a cadre of innovators to start a snowball, seek agreement on technology role consistent with school vision, provide computers for teacher’s personal use, reward instructional uses of technology, adopt technology skills goals, provide supported time for learning to use technology and design of instructional applications. Finally, Means and Olson identify five kinds of necessary technical assistance: help in planning for technology uses and acquisitions, training in how to use new hardware and software, demonstrations and advice on how to incorporate technology into instruction, on-demand help when software problems or hardware failures arise, and low level system maintenance.

This excellent report also provides information on resources for technology implementations, ways that technology supports project based learning, effects on students and teachers, and much more. The last chapter, reporting implications for policy, practice, and research, identifies five features associated with success: time devoted to developing a school wide vision, adequate technology access for all students, time for teachers to learn to use technology and to incorporate it into their own curricular goals, easily accessible technical support, and rewards and recognition for exemplary technology supported activities. Means and Olson conclude with the following features associated with successful applications - the most fully developed projects: had strong curricular content and many components that were not technology based, provided a structure within which teachers could innovate, provided an opportunity for teachers to collaborate with peers, involved students and teachers already familiar with the project based approach, and involved use of technology across subject matters and classrooms.

For the purposes of this paper, information in Technology and Educational Reform by Barbara Means and Kerry Olson, as discussed above, have been abbreviated as the following indicators of success:

- preexistence of project based approach,
- sufficient numbers of computers to allow for frequent access,
- administrative support by district,
- nurture of reform activities by school principal,
- coherent school wide approach to using technology in the core curricula,
- supported time for learning to use technology and design of instructional applications,
- easily accessible technical support,
- rewards for exemplary technology supported activities,
- strong curricular content,
- use of technology across subject matters and classrooms,
- structure within which teachers can innovate,
- opportunity for teachers to collaborate with peers.

What factors lead to the successful adoption of an innovation?

While The Community Discovered is certainly an educational technology project as described by Means and Olson, it can also be viewed from a more general perspective as an “innovation.” Successful adoption of innovations is generally recognized by their “diffusion” throughout a target culture. The study of innovation diffusion, pioneered by Everett M. Rogers, is a relatively new discipline by academic standards. The following discussion is largely drawn from Roger’s seminal work Diffusion of Innovations (1983). Rogers defines diffusion as:

... the process by which an innovation is communicated through certain channels over time among the members of a social system. It is a special type of communication, in that the messages are concerned with new ideas. (Rogers, 1983, p.5)

Rogers defines four main elements of innovation diffusion: the innovation, communication channels, time,
and the social system. An innovation, per se, is an idea, practice, or object that is perceived as new by the potential adopter. The characteristics of innovations, as perceived by potential adopters, explain from 49 to 87 percent of the innovation's rate of adoption. Characteristics identified by Rogers include: relative advantage, the degree to which the innovation is perceived as better than the status quo; compatibility, the degree to which the innovation is perceived as consistent with existing values, past experiences, and needs; complexity, the degree the innovation is perceived as difficult to understand and use; trialability, the degree to which the innovation may be tested prior to adoption; and observability, the degree that adoption results are visible to others. Rogers states:

Innovations that are perceived by individuals as having greater relative advantage, compatibility, trialability, observability, and less complexity will be adopted more rapidly than other innovations. Past research indicates that these five qualities are the most important characteristics of innovations in explaining the rate of adoption. (Rogers, 1983, p.16)

Since diffusion is defined by Rogers as a special type of communication, communication channels are obviously an important aspect of successful adoption. Mass media channels are recognized as the most rapid and efficient means of creating awareness; however, interpersonal channels, particularly peer to peer, are identified as more effective in promulgating adoption. Rogers indicates that:

... investigations show that most individuals do not evaluate an innovation on the basis of scientific studies of its consequences, although such objective evaluations are not entirely irrelevant, especially to the very first individuals who adopt. Instead, most people depend mainly upon a subjective evaluation of an innovation that is conveyed to them from other individuals like themselves who have previously adopted the innovation. (Rogers, 1983, p.18)

Rogers breaks the time dimension of the diffusion process into five steps: knowledge, persuasion, decision, implementation, and confirmation. During this process, the type of decision (optional, collective, authority) influences the rate of adoption. For example, if the head of an organization decides to adopt an innovation, the adoption rate will be faster than one dependent on organizational consensus. From a system perspective, an innovation's rate of adoption is generally depicted as a traditional S-shaped curve, representing the number of adopters over time. The slope is characterized by Rogers as consisting of innovators, early adopters, early majority, late majority, and laggards.

The focus of much innovation diffusion research is the social system, defined by Rogers as "a set of interrelated units that are engaged in joint problem-solving." Actors within the social system, particularly those identified as change agents and opinion leaders, are generally recognized as key figures in effecting innovation diffusion. While rate of adoption is, to a degree, a function of change agent effort, success is also related to a change agent's client (service) orientation. Opinion leaders are those members of the social system who are consistently able to influence (formally or informally) other members attitudes and behavior. According to Rogers:

The greatest response to change agent effort occurs when opinion leaders adopt, which usually occurs somewhere between 3 and 16 percent adoption in most systems. The innovation will then continue to spread with little promotion by change agents, after a critical mass of adopters is reached. (Rogers, 1983, p.208)

Group norms, organizational structure, formal/informal communication patterns, mutual discourse, incentives, and involvement by an "innovation champion" are also recognized by Rogers as affecting an innovation's rate of adoption.

In summary, the key variables identified by Rogers as determining an innovations rate of adoption are: perceived attributes (relative advantage, compatibility, complexity, trialability, observability), decision type (optional, collective, authority), communication channels, nature of the social system, and extent of change agent's promotion efforts.

For the purposes of this paper, information in Diffusion of Innovations by Everett M. Rogers, as discussed above, have been abbreviated as the following indicators of success:

- relative advantage - economic, social, convenience, effectiveness, satisfaction, etc.,
- compatibility with existing values,
- ease of adoption,
- no risk testing,
- visibility of success,
- authority decision to adopt,
- information (reduction of uncertainty),
- reduction in change agent/client communication barriers (elimination/adoption of jargon),
- frequent peer to peer communication,
- extent of change agent effort in contacting clients,
- extent of change agent orientation to clients,
- adoption by opinion leaders,
- involvement of an innovation champion.

What Other Factors Lead to Success?

Subsequent to Rogers' initial publication of Diffusion of Innovations a number of researchers have contributed insight into the innovation diffusion process. In a meta study of knowledge diffusion / utilization generalizations, Thayer
and Wolf (1984) report that diffusion of educational innovations is largely parallel to innovation diffusion in other domains. Thus, a selected review of diffusion literature was undertaken to reveal additional indicators of success.

In a study of twelve schools implementing educational innovations, Huberman and Miles (1984) found several factors associated with early success: degree of preparedness and user commitment, sufficient resources and materials, understanding of the new practice, prior experience and ongoing aid. Of particular note, "ongoing aid and inservice training were instrumental at rough-starting sites and seemed especially beneficial at sites that turned out later on to be the most change-inducing and the best institutionalized." They also found that results improved when such assistance was associated with the original project design:

At our sites, adaptation always took place - but it was sometimes constrained by administrators' stout refusal to permit adaptations that would weaken or water down the innovation. Enforcing fidelity for substantial, good-quality innovations really paid off - if it was accompanied by effective assistance. When adaptation went too far because of administrative "latitude," what often occurred was blunting or downsizing, trivialization, and weak student impact. (Huberman & Miles, 1984, p.279)

In a later study of school improvement strategies employed in ten states, Anderson, et al. (1987), define high quality teacher training as theory driven and also recognize the importance of creating a "cognitive frame common to teachers and administrators," one that supports the principal as a knowledgeable leader.

In a much cited review of the diffusion of the use of tetracycline, Burt (1987) found evidence that diffusion was fostered by physician perception of innovation adoption as the action proper for an occupant of their position.

Ely's review of the literature reinforces many of the above findings, particularly those of Means and Olson. Ely does specify time as a distinct resource (1990):

Good time. Company time. Paid time. Implementers must have time to learn, adapt, integrate, and reflect on what they are doing. ... Teachers need time for inservice training; they need time to revise existing teaching plans; they need time to practice with new materials; they need time to try out and evaluate new teaching procedures. In short, time is a vital element in the total process of educational change. (Ely, 1990, p.300)

In a study of suburban elementary school educators, Albrecht and Hall (1991) found that communication about new ideas tended to occur within "strong, multiplex relationships" dominated by "elite" groups of individuals:

...talk about new ideas and innovations is simply not a widely shared experience among organization members, despite prescriptive admonitions to the contrary. (Albrecht & Hall, 1991, p.556)

Curry (1992) explains the thinking that innovative organizations are learning organizations in which members are provided information upon which they act collaboratively, members are minimally defensive toward others, mutually supportive group dynamics exist, and participants have high freedom of choice to engage in risk taking. Learning oriented norms and strong internal commitment are typical of such learning organizations.

In an extension of Burt's methodology, Kearns (1992) added frames of reference to the actor's position within the communication network to establish a "sociocognitive network approach" to the study of innovation diffusion. Kearns' frame of reference is the "cognitive map" of the potential adopter incorporating underlying assumptions, values, and belief systems. Consistent with Rogers' assertion that the perceptions of potential adopters are as important as the facts about an innovation and Burt's description of structural equivalence, Kearns argues that the best predictors of adoption are the actions of "boundary spanners," those people in the system who interact with people outside their system:

...strategies for disseminating new products and procedures should seek to take full advantage of sociocognitive boundary spanners, particularly sociocognitive brokers. These actors apparently are capable of speaking several "languages," and thereby providing an important link among a diverse group of innovation stakeholders. (Kearns, 1992, p.65)

In an analysis of cultural factors associated with innovation diffusion, Strang and Meyer (1993) suggest the importance of intellectual models that permit diffusion of theory rather than specific practices:

... diffusion should be most rapid where theorization is central to the construction of both units and specific elements, where partial theorizations articulate with each other, and where a network of congruent theories forms a hegemonic cultural frame. (Strang & Meyer, 1993, p.500)

In connection with institutionalization of theoretical models, Strang and Meyer also emphasize the empowerment of "actors" to carry the "ultimate values" inherent in the innovation.

While many of the above factors overlap and reinforce previous findings, for the purpose of this paper, the following factors for success have been added:
• inservice training consistent with and supportive of original project design,
• promotion of the attitude that innovation adoption is the professional thing to do,
• good time, company time, paid time for participants to implement innovation,
• expansion of group communicating about innovation,
• mutually supportive group dynamics that permit risk taking,
• support interaction with outside educators already proficient in innovative practice,
• explicit theorization is an integral part of innovation,
• inservice instruction in underlying theory for educators and administrators.

An Early Review of The Community Discovered

The Community Discovered, as an innovation, was compared with the above factors for success to determine areas where project partners could take action to strengthen diffusion efforts. Information was collected through participant survey, interviews and direct observation. While the following observations often pertain to all five school districts currently participating, it is recognized that Omaha Public Schools has been a participant for less than six months and the author has limited evidence to support specific recommendations in this respect.

Means and Olson identified the preexistence of a project-based/constructivist approach as the most fundamental and difficult aspect of educational reform. The Community Discovered is based on the premise that such an approach will be used; however, in only one district is such an approach widespread. Other districts have adopted a project-based approach to some degree, particularly in elementary grades; however, in one district classes are traditionally content driven. As one respondent reported; “sometimes I wonder if those high school teachers know there are k-i-d-s in the room!” Given the findings of Anderson, et al. as well as those of Strang and Meyer, it appears that the project would be well served by specifically emphasizing constructivist theory. This conclusion is supported by participants who rated the presentation by J. Brooks and the modeling and clarification of the constructivist approach as the most valuable aspects of the June ‘97 inservice. Unfortunately, it must also be reported that the same participants rated “too many theories” as a least favorable aspect; perhaps innovation theorization is best provided in small doses. The project director has initiated a newsletter and a modest article on the project’s underlying research base in each issue may, without being burdensome, reinforce inservice provided by recognized experts such as Brooks.

Means and Olson also indicated that the more successful technology implementations generally occurred where a school wide approach to using technology existed. Consistent with this finding, they also cited the leadership of the school principal as fundamental. The school districts participating in The Community Discovered all have district technology plans or rubrics; however, it is not clear that district plans have been implemented on a school by school basis. Many of the participants’ principals understand the project, a number of the principals support participant time and collaborative efforts, and many do not inhibit participant activities. Unfortunately, as currently administered, The Community Discovered does not engage school principals and, consequently, their support is superficial. Even in the district where the project-based approach is widespread, a respondent reported that upon observing students participating in small group activities, one principal left the classroom commenting that “I’ll come back to observe another time when you are teaching.” Respondents in another district reported that only one third, or less, of the districts principals even understood reform activities. It seems clear that even if the immediate goals of the project are met, no lasting impact will be achieved without the ongoing commitment to reform by school principals. To that end, participants’ principals should be invited to become active in the project, receive their own inservice training, and proactively collaborate in achievement of project goals.

While no participating school has one computer for every four students (as Means and Olson suggest), with the exception of one district where computers are limited to the media center, there appear to be sufficient numbers of computers. The level and quality of technical support varies from district to district, but does not appear to be problematic. Only one district explicitly rewarded exemplary technology supported activities (through a technology factor in merit pay); however, several districts paid registrations and/or conference expenses for teachers making presentations at educational technology conferences and intrinsic rewards such as having class projects featured at parents’ nights were widespread.

The above factors for success were inconsistently present from district to district and from school to school. However, there was one factor that was consistently lacking - time. Participants unanimously agreed that too much personal time was required to plan project-based activities involving art integration and technology. Even when funds are available for substitutes other factors often mitigate against supported time. Participants often used evenings and weekends for project related work and several respondents suggested that a portion of funding budgeted for substitutes be repurposed to compensate for those hours. Certainly, no activity is sustainable in the long run if people are expected to commit significant amounts of personal time on an ongoing basis.
Rogers indicated that the greatest response to change agent effort occurs when opinion leaders adopt the innovation. It appears that some Community Discovered participants, often characterized as “risk takers” during the first year of the project, can now be described, to some extent, as opinion leaders. Unfortunately, this transformation has been gradual. One explanation for the slow rate of adoption by opinion leaders is the level of effort by each district’s primary change agent, the “site coordinator.” Although supported by project funding, site coordinators often have numerous non-project responsibilities. The project’s rate of innovation diffusion should increase if school opinion leaders are identified and recruited and, to the extent possible, site coordinators are free from non-project responsibilities. To that end, an excellent suggestion by one member of the UNO evaluation team was for site coordinators to participate in creation of model curricular units and thereby “serve as a metaphor” for project participants.

Rogers identified interpersonal communication, particularly peer to peer, as most effective in promoting adoption. Subsequent work by Burt, Albrecht and Hall, and Kearns emphasize the need for “strong, multiplex relationships” involving “boundary spanners.” The Community Discovered is ideally situated to foster such peer to peer relationships. Participants in the June ‘97 inservice intuitively recognize this need citing the need for increased interaction with members from other locations. Given the distances between participating school districts, the use of communications technology is explicitly recognized as part of the model being tested by The Community Discovered and, currently, the listserv is the primary inter-district means of communication. While other technologies such as video conferencing should be explored to facilitate the building of strong multiplex relationships between participants from different districts, it should be recognized that nothing will replace the value of peers meetings face to face. Workshops at regional partner institutions, such as the recently adopted special interest group meetings, may foster the rich interrelationships that promote innovation diffusion.

Another aspect of communication that is a factor for success is the visibility of success framed as professional success. One UNO evaluator recognized many successful classroom applications and pointed out that “good models were not being disseminated.” The project director has addressed this issue and the newly undertaken project newsletter should serve as a means to recognize professional success and to disseminate model applications.

Comparison of The Community Discovered with factors for success resulted in the following recommendations:

- in each project newsletter include a modest article on the project’s underlying research base,
- work with each district to propagate district technology plans through each school, engaging the principals in substantive aspects of the project,
- seek technology partners that will provide additional computers and a local area network for the district currently limiting student computer use to the media center,
- ask each participating district to feature a classroom application in each newsletter - with these serving as “nominations,” recognize exemplary applications through annual awards presented at the spring meeting,
- with funding currently allocated for substitutes, give district administrators the option of compensating participants for evening and weekend project work,
- work with district administrators to free site coordinators from non-project related responsibilities and provide them with inservice specific to their role as change agent, and
- foster strong, multiplex relationships among participants through all available means - expand workshops at regional partner institutions, leveraging their capabilities and increasing their role in the project.

With the exception of the universal need for supported time to work on project activities, factors for innovation diffusion success were present/lacking to different degrees in different schools. Similarly, many of the above recommendations are more/less applicable to different schools. While this finding is a matter of common sense, it is also recognized in the innovation literature. In an extension of Burt’s model of structural equivalence, Strang (1991) incorporates a priori notions about social structure in an investigation of decolonization and argues that diffusion occurs within regions rather than empires or the world system as a whole. In terms of The Community Discovered, this hypothesis not only explains the differences in adoption patterns between school districts when other factors are consistent, but argues that project administration and resources should be applied differently in each district.

The Community Discovered is an ambitious project. With an activity-based/constructivist approach, integration of the visual arts, and use of technology as integral factors, the project has been characterized as three projects in one. Most participants recognized the importance of a holistic approach and changes to the project’s basic structure are not recommended.

Huberman and Miles point out that educational innovations that are adopted smoothly are generally “midgets making few local demands” in contrast with rough implementations characterized as “ambitious, change-inducing, and organizationally difficult.”
In terms of desirable outcomes, smooth early use was a bad sign. Smoothly implementing sites seemed to get that way by reducing the initial scale of the project and by lowering the gradient of actual practice change. This “downsizing” got rid of most headaches during the initial implementation but also threw away most of the potential rewards; the project often turned into a modest, sometimes trivial, enterprise. By contrast, most of the initially rough-implementing projects, including those that later produced the strongest outcomes, remained ambitious, change-inducing, and ill-fitting, all of which made for difficult initial use, but could deliver significant practice change. (Huberman & Miles, 1984, p.273)

This message is consistent with Ehrmann’s (1997) premise that to make visible improvements in learning using technology, you must undertake large scale changes in methods and learning resources and it bodes well for the long term overall impact of the project.

While the sometimes rough initial implementation of The Community Discovered has frustrated participants in different ways in different places, any overall assessment must recognize the project’s significant progress in moving from the conceptual stage toward broad implementation. The above review supports the project’s basic direction and has revealed no problems inconsistent with a review of educational innovation literature. Recommended changes are modest, intended to further diffusion efforts.

SOCIAL STUDIES CONNECTIONS:
EXPLORING CULTURES THROUGH THE WORLD WIDE WEB

Bernadette Cole Slaughter  
Indiana University of Pennsylvania

Thomas W. Jones  
Indiana University of Pennsylvania

Using the World Wide Web (WWW) as a research tool is an innovative and encouraging way for preservice teachers to make inquiries into and acquire information about different cultures. As a telecommunications tool, the WWW quickly connects people and ideas across distances and time via the Internet. That one can access information files, worldwide, is a novel idea to many educators and preservice teachers even if they understand the importance of computers in society. While computer hardware and software are available in classrooms, teachers and preservice teachers need time and the research skills to efficiently locate information relevant to a particular topic. For instance, students in a fifth grade classroom studying a particular culture, such as Aborigine, Cherokee, Ibo or Welsh, need guidance in locating information relevant for their research. In many ways, this is new learning for both students and teachers. From an inquiry perspective the need for information triggers a search based on the individual student's goal. Given the nature and scope of the WWW information sites, instructors must set parameters and provide guidance to enable learners to attain goals. This paper describes implementing a "culture box" activity designed to "identify different cultures" (Barth, 1991, p. 83) in conjunction with an electronic version of a culture box called a "cyber cube" (Jones, 1997), a useful method of inquiry via the WWW.

Telecommunications in the information age appeal to students because of their familiarity with digital technology and because of the easy access to information and people. A student having Internet access and a level of technical expertise can use hypertext commands to create links to files on machines all over the globe. Given the increasing volume of information and the wide range of sources accessible to students and teachers alike, an important responsibility of educators is to teach students to critically evaluate information (Gilster, 1997; Caruso, 1997; Cole Slaughter & Knupp, 1995). In teaching the integration of research skills into elementary social studies classes, I can observe preservice teachers' fascination and excitement as they use Internet addresses to visit specific WWW sites for information about a specific culture. One student's comments reflect two critical elements inherent in Internet use - discovery and enjoyment: "I just learned how to use the Internet this semester, and I am constantly looking for lesson plans and articles. The Internet for research purposes is an excellent tool." The same student, accepting an assignment to learn about a contemporary member of the Cherokee group through research, wrote her reflections:

When I began my research project, I had no idea of Wilma Mankiller. Usually, when I start a project, I have some idea about the research topic. Not knowing about my topic made the project more fun. I used my new knowledge of how to use the Internet to do my research. I really like using the computer because the information is up-to-date. Also, you can obtain either in-depth information or a brief overview of what you are researching. I also liked being able to get a picture of Wilma Mankiller so I could actually see whom I am researching.

Using the WWW to explore cultures provides preservice teachers the opportunity to participate in an inquiry and reflective process. It was discovered that students can visit the following sites to find information about Wilma Mankiller:

http://www.powersource.com/powersource/gallery/people/wilma.html
http://www.library.okstate.edu/about/awards/winners/mankill.htm
http://don.skidmore.edu/ptroscla/wilma.html

986 — Technology and Teacher Education Annual — 1998
Reflections about the Culture Box

Studying the language, messages, educational practices, customs, and ways of life of people from various localities deepens knowledge and understanding of social problems as well as similarities and differences among people and environments. In our social studies classroom we learn the meaning of culture through a culture box/basket activity and a videotaped presentation which deals with culture from an anthropologist's perspective. A culture box/basket is used in a learning activity that allows individuals to select from it information, artifacts or objects, and through these, to tell the audience something about themselves. The choice and discussion of culture box/basket contents illustrate a person's philosophy, beliefs, process of decision-making, reflective thinking, creativity and communication skills. Through these impressions of culture, elementary preservice teachers from a predominately white culture are exposed to cultural diversity as a human and environmental experience. Having participated in the culture box/basket presentations, a preservice teacher wrote the following journal entry:

This particular activity was very insightful because in a few short moments we were able to learn so much about all of our classmates. I think this is a useful activity to get people to know each other. Also, it could help to relieve any anxieties that people may feel when they are introduced into a new setting.

From an instructor's perspective, using a culture box/basket activity and group discussions about constructing the culture box/basket provide a learning environment that is non-pressured, interactive and multisensory. The preservice teacher continues to reflect in his journal about the value of this activity:

I think the most interesting things that people brought were items representing hobbies. This gives all of the students in the class an opportunity to actually see and touch something which is representative of that activity and that is better than just hearing about it. Also, I think this is an excellent activity to do in an elementary school because the students can learn so much while having fun and wouldn't even recognize it is actual learning.

Barth (1991) suggests that the social studies culture box designed for children in second grade enables learners to gain knowledge about different cultures through effective strategies such as integrating, reinforcing and accommodating information.

In a social studies classroom that integrates technology in the curriculum the transfer value of a culture box/basket presentation is substantial. When preservice teachers are given an opportunity to use the WWW to research a topic they develop knowledge and skills about culture and technology. The teacher is able to observe the ways in which learners can acquire information about different cultures through exploring the WWW.

For instance, by incorporating the information site - http://homepage.third-wave.com:80/educate/me.htm - created by a graduate student, elementary preservice teachers are exposed to new educational technology and concepts embedded in content, such as hypertext, links, integrated learning, critical thinking and cultural diversity. Using this strategy, preservice teachers can connect their learning experiences from presenting a culture box/basket to a different style of learning with the computer generated "cyber cube."

Individually, preservice teachers are able to assess their educational needs for professional growth. For example, a nontraditional preservice teacher said:

One of the more attractive features of the presentations is the kinetics of article illustrations - this way students can visually experience information. I realize I need more exposure to new technology. I learned that I have a great deal to learn about progressive technology to be effective in educating my students to meet the challenges of the Twenty-first Century.

The ability to self-evaluate and choose, coupled with the novelty of accessing WWW sites and links to additional information sources, is evidenced in reflective comments from a student who has "just learned to use the Internet."

It is pretty impressive to look at what people can create on the Internet. I thought the computer-generated culture box said a lot about the person. It said he is an intelligent and competent in the area of computers. This would not be an appropriate thing for me to do since I only know the basics about computers. I personally enjoyed the class presentations of culture boxes. To me, it is more intriguing to see and feel actual "stuff" than the images on a screen. I may use the culture box/basket to introduce myself in my student teaching experience.

Guided Resources

Having grasped the meaning of culture from the classroom presentations, preservice teachers use various Universal Record Locators (URLs) that lead to information about a specific culture. For example, studying Australian culture, and, in particular, the Aborigines with classroom Internet access, preservice teachers explored the following URL's to learn about language, art, prehistory, botany and geography:

Australia
Australian Aboriginal people language
Australian Aboriginal art:
http://www.geocities.com/Vienna/4259/abor-art.html
Conclusion

Making connections with culturally diverse groups using culture box/basket presentations and technology requires resources. Preservice teachers select the items about their ethnicity and cultural heritage(s) or travels to create a culture basket or a "cyber cube." For students unfamiliar with the idea of a culture box/basket, using the electronic version of a culture box provides a model to construct the contents for a culture box/basket. Just as important is the guided exposure to WWW sites. For some individuals, going on a computer journey is adventure some whereas others will find the process intimidating. In any case, educators cannot ignore the trend toward greater familiarity with new technology among today's students. This trend is supported by our observations of technology use among preservice teachers who integrate technology in planning instruction and classroom presentations.

We believe that exploring cultures through the WWW and encouraging preservice teachers to interact with an electronic "culture box" provide social studies multisensory, multi-modal learning. Preservice teachers are able to transfer knowledge from social studies coursework to the classroom and into the global environment. The proc-cess models inquiry methods and integrates technology in the content area. Each student produces information about a culture, analyzes connections across cultures, and uses links to world sites to enhance their knowledge.

Furthermore, students always choose the items to include in a culture box/basket. They choose the best way to organize family photographs, documents, maps and items that enable them to speak about themselves, their beliefs, relationships, environments and travels. For participants in the course, learning involves seeing, listening, touching, smelling, tasting, asking questions for more information, or making a comment. Because each student must think about the culture box contents, choose the items to share, organize an oral presentation or textual information in an electronic version, the classroom environment reflects openness. In the social studies classroom, preservice teachers explore shared ideas about a strong sense of family and community.

ADDRESSING THE SOCIAL STUDIES STANDARDS THROUGH INTERNET CONNECTIONS

Carolyn C. Ledford
East Carolina University

Betty B. Peel
East Carolina University

With the demands of the ever-changing society and the world, teaching social studies today is a challenge for teachers. Documents of reform like Goals 2000: Educate America Act and Curriculum Standards for Social Studies (1994) call for a different type of social studies than most of the preservice teachers have experienced in their own educational experience. Furthermore, the National Council for the Social Studies (NCSS) in its standards for the preparation of social studies teachers emphasizes the need for deliberate planning in the social studies:

"...courses in social studies methods should prepare prospective teachers to select, integrate, and translate knowledge and methodology from history and social science disciplines in ways appropriate to students in the school level they will teach and give attention to the goals unique to the social studies and those shared jointly with the other areas of the school curriculum. Students should also be able to teach social studies utilizing a variety of curriculum approaches and in different types of settings (1992)."

To prepare teachers for the future, we must model the use of technology as a tool to connect the social studies to the world in ways that are relevant to the students. To meet the current demands, the Internet provides resources to connect to the most current information in the field as well as direct access to historical documents.

What role can the Internet play in social studies classrooms? The value of the Internet lies in its user. The computer environment offers equal and sometimes greater control and flexibility to young children (Clements, Nastasi, & Swaminathan, 1992). Computer-based telecommunications through the Internet and online services afford a tremendous potential for social studies classroom now and in the future for students to become active learners. By providing this hands-on classroom experience with technology, students gain skills and knowledge necessary for personal, professional, and civic productivity. Using the Internet stimulates curiosity and eagerness to learn through immediate availability to infinite resources. By exposing preservice teachers to current potential of the Internet, access is available for up-to-date information and resources needed to teach social studies. The Internet provides unique opportunities for teachers and educators to collaborate, learn from one another, and to access and retrieve information. Connecting to the world via the Internet transports teachers and students beyond the traditional barriers of classroom or building.

Preservice teachers use the Internet to find resources for a thematic unit, a requirement in the social studies methods course. Since the preservice teachers are introduced to the Internet in a curriculum course that precedes the social studies methods course, they can further explore the possibilities for Internet resources of lesson plans, primary sources, virtual field trips, documents, and data collection. As the preservice teachers maneuver through the innumerable links, they interact with online resources. The preservice teachers then integrate Internet materials and/or activities found into their social studies units.

Internet locations to meet the ten themes that form the framework of the Social Studies Standards include resources for teachers and interactive locations for students to become involved citizens. Some examples of Internet resources that address the themes of the framework of the social studies standards are:

I. Culture

Through the exploration of web locations, students can compare and contrast the cultures of many areas of the world.

The Smithsonian
http://www.si.edu

This location links students to the 16 Smithsonian museums and the National Zoo as well as the history of the institution. The graphics help bring this online tour of the Smithsonian to life. The exhibits of the Smithsonian provide examples of culture from many areas of the world.

Indigenous Peoples of Latin America and South America
http://www.lanic.utexas.edu/la/region/indigenous

Investigate the customs, culture, and people of Brazil, Ecuador, Mexico, Chile, Bolivia, and other countries. Links
are provided to the Center for World Indigenous Studies and other international resources.

II. Time, Continuity, and Change
   Through exploration of Internet sites students can examine their historical roots and locate themselves in time.
   National Museum of American History Homepage
   http://www.siledu/nmah/
   The collection contains more than 17 million artifacts of the nation's heritage in the areas of science technology, and culture. Innumerable artifacts of everyday life including the Star-Spangled Banner (the flag), Edison's phonograph, early digital and electronic computing machines. A timeline is included that covers the history from 1500 to the present visually providing examples of history and technology throughout the history of the nation.

III. People, Places, and Environment
   The locations chosen for this theme assist students in relating to the past and to determine where they are located in relation geographically to other people.
   The Census Bureau
   http://www.census.gov
   Students can examine information about any city in the US. Census data helps students discover the needs of the people of the city which they might wish to address. Population data will answer questions for students about the number, ethnicity, and age of people. Relevant subjects include: county and city data book, county profiles, economic information, household economic statistics and voter registration.
   City.Net
   http://www.city.net/
   Check on cities all over the world by clicking on the region of the globe that leads to specific countries and major cities.
   Map Quest
   http://www.mapquest.com
   Children can visit the small towns and cities of our country. They can plot an imaginary school bus trip to each location from their own hometown by using Trip Quest. This feature provides city-to-city directions and interactive maps.

IV. Individual Development, and Identity
   Explore locations about culture, psychology, and groups to discover how we develop our personal identity.
   Interesting Dates in Black History
   http://www.ai.mit.edu/~isbell/HFh/black/bhist.html
   This source provides interesting facts about the history of African Americans.
   Native American Resources on the Internet
   http://hanksville.phast.umass.edu/misc/NAresources.html
   This comprehensive list of Native American resources on the Internet links to categories such as museums, artists, archaeology, legal, music and bibliographies.

V. Individuals, Groups, and Institutions
   Locations on this theme allow students to examine ways individuals, groups, and institutions play integral roles in people’s lives.
   League of Conservation Voters
   http://www.lcv.org/lcv96/
   The League of Conservation Voters has published a National Environmental Scorecard every year since 1970 to provide information about the voting records of the members of Congress. Scorecard represents the consensus of experts from 27 environmental groups who have selected the key votes on which members of Congress should be graded.

VI. Power, Authority, and Governance
   Web addresses that assist students focus on the historical development of power, authority, and governance.
   The Constitution
   http://www.1m.com/~cjp/whig/Constitution.html
   This location provides the complete text of the Constitution of the United States and the amendments. By using this site students can explore the document to make discoveries about the electoral college.
   The Jefferson Project
   http://www.voxpop.org/jefferson/
   The Jefferson Project is a comprehensive directory of online politics. Included are mailing lists of web pages for the White House and all members of Congress. Two features include Netgrams and The Zipper. The Zipper allows you to enter your zip code to determine the members of the House and the Senate that represent you. It also allows you to communicate directly with any member of Congress and the President via email or visit their home page.
   Thomas
   http://thomas.loc.gov
   This site is a service of the U.S. Congress through its library. Floor activities are published each week. Major legislation by topic and bills by number that are enacted into law, and bill texts from the 103rd and 104th Congresses are available. Committee reports and home pages for members of the U.S. House and Senate are included. Historical documents, such as the Declaration of Independence and the Constitution are accessible at this location.
   Welcome to the White House
   http://www.whitehouse.gov/WH/Welcome-plain.html
   The White House location provides a variety of information about the President and the Vice President, the Virtual Library containing White House documents, audio speeches, photos, and White House for Kids sections containing helpful hints for young people to become more active and informed citizens.
VII. Production, Distribution, and Consumption

Students can explore resources to gain information about the factors of production, goods and services, as well as gain experience understanding about the U.S. National Debt.

Economics Resources for K-12 Teachers
http://ecedweb.unomaha.edu/teach.htm
This economics location provides resources for the K-12 teacher.

Budget of the U.S. Government, Fiscal Year 1998
http://www.access.gpo.gov/su_docs/budget/index.html
Budget publications and reports are available online from this U.S. Government Printing Office site. Users can search budget documents and download sections for further study.

U.S. National Debt Clock
http://www.brillig.com/debt_clock
The clock continuously updates the amount of the national debt. Using figures from the U.S. Treasury Department and the Census Bureau, the population is figured along with the debt, showing each citizen’s share of the debt.

VIII. Science, Technology, and Society

Addresses available on the web allow students to evaluate new technologies to determine the benefits to society.

National Museum of American History
http://www.si.edu/nmah/youmus/hohr.htm
The Hands-On History Room provides examples of new technologies throughout our nation’s history.

IX. Global Connections

The World Wide Web provides innumerable locations for students to explore the realities of our global interdependence. International issues about a variety of topics including the environment, human rights, and economic competition can be explored through the Web.

International Environmental Agreements Online
This environment location includes an on-line tool for browsing and searching of text, summaries, and the status of treaties and other international agreements related to the global environmental change and sustainable development.

United Nations
http://www.un.org/
Collect information about the United Nations through audio, visual, and webcast. This address is divided into International Law, Human Rights, Economic and Social Development, Peace and Security, and Humanitarian Affairs.

X. Civic Ideals and Practices

Civic participation of individuals and groups can be monitored by exploring web addresses. Active civic participation can be developed using models found at other locations.

Give Water a Hand
http://www.uwex.edu/erc/
This location describes a watershed education program designed to involve students in local environmental service projects. With the information included, classes plan and complete a community service project to protect and improve local water resources.

Washington Post
http://www.washingtonpost.com
Students can access updated weather reports to examine the weather at a variety of locations. In addition students evaluate the latest national and world news. Stock quotes, other financial and business topics can also be accessed.

Yahoo News Summary
Students can read the top news story of the day by contacting this location. Yahoo News Summary includes ten news headlines and a paragraph about each.

If we are to meet the current challenges in education, we must provide preservice teachers with the skills and opportunities provided through technology. As preservice teachers create effective units using the Internet, they begin to take advantage of the possibilities its resources provide. It is therefore essential upon all educators to modify traditional social studies curriculum to reflect the increasing use of technology with the exploration of the Internet.

These days, the collective memory of teachers often does not encompass the World War II era. Consequently social, political, and historical contexts have become more and more remote for their students. This lack of reference has led to difficulties presenting certain aspects of social studies to children. World War II, for example, has become so abstract as to be almost unreal to present day students. This paper describes a design for using the World Wide Web as a tool for enhancing social studies instruction. The purpose of the project was to increase student awareness of some of the social, historical and ethical issues surrounding World War II. The specific goal was to help students explore three key aspects of the War in Europe: occupation, resistance, and sacrifice. An additional criterion was that the basic concept of the design would be applicable to other subjects and other grade levels.

The unit focused on German occupation of Denmark during World War II. Instruction centered on the novel Number The Stars by Lois Lowry. The book describes the adventures of a Danish girl, her family, and their Jewish friends in occupied Denmark. The instruction addressed the need to build prior knowledge of some of the issues arising from the German occupation of Denmark, so that students were aware of the social and historical underpinnings of the novel. It also addressed the need to relate the themes of occupation, resistance, and sacrifice to other periods in history and to other social contexts.

Empathy in Social Studies

Empathy involves the ability to identify emotionally or intellectually with another person. Fostering empathy has gained some prominence in social studies during the last decade (Farmer & Knight, 1995). Ideally, creating empathy with people from the past can help students better understand the choices that people throughout history have made by helping them identify and understand the emotional, intellectual, ideological, and contextual factors that were involved in those choices.

Farmer & Knight (1995) maintain that: [The] connection between learners' general thinking and their understanding of history can be seen when we examine the place of 'empathy' in school history. Learners apply their knowledge about people in the present to account for the actions of people in the past and use similar scripts to explain the actions of people in the past and life in the present. (p. 26)

It is therefore critical to help students to make connections between their contemporary lives and those of people who lived in the past, thereby giving them a basis on which to build understanding of situations that would otherwise lie outside their frames of reference, and therefore be foreign and uninteresting.

Brown (1995) and Ashby & Lee (1987) describe a seven step process through which students gain historical understanding. Empathy is an integral part of the process they explain, and consists of several levels with corresponding actions, knowledge, and assumptions needed to understand the past:
1. Abaffling past, in which students may be interested, but are unable to explain.
2. A ‘divi’ past, in which students view people in the past as morally and intellectually inferior, and thus uninteresting.
3. An ignorant past, in which people in the past are seen as inferior because of what they do not yet know.
4. Generalized stereotypes, where people in the past and their actions can be understood by an assumption that their lives were very similar to those of people today.
5. Everyday empathy, in which students see a point in empathizing, but still assume that people’s lives in the past were like those of people today.
6. Restricted historical empathy, where understanding of people in the past must come from examination of their specific situations.
7. Contextual historical empathy, in which students base their understanding on beliefs, ideas, values, and contextual situations from the past and today.
Ashby and Lee (1987) describe empathy as an "achievement", a place "we get to when we have successfully reconstructed other peoples' beliefs, values, goals, and attendant feelings" (p. 63); a place in which one can grasp entire structures of someone else's ideas, even those with which one disagrees, and take someone else's point of view.

Similarly, Portal (1987) discusses "projective imagination". Projective imagination allows students to bring their own intuitive way of observing and making judgments to the learning environment, allowing them to examine a new situation by applying their accustomed techniques for gathering and analyzing contextual data. He warns that this will not necessarily provide insight into the "authentic thoughts of the past," but it will allow the student to form hypotheses that will help explain peoples' behavior in other contexts.

Fostering empathy in social studies is thus a process by which students base their understanding of past people and events on present day experience, and achieve a state of mind in which they can consider the beliefs, ideas, and actions of other people. In order to build empathy successfully, students must eventually develop the ability to consider past and present contexts and values simultaneously in order to make informed, valid comparisons, and thus gain a better insight into the patterns of human behavior throughout history.

**Prior Knowledge**

The level of a student's ability to empathize with others in different historical, geographic, or social contexts is an aspect of the prior knowledge that all students bring to their education. This aspect of prior knowledge, to be sure, is underdeveloped in some and more developed in others. Although it may be tied to or limited by a student's psycho-social level of development or life experience, it can be enhanced.

Prior knowledge can be described as a combination of the learner's preexisting attitudes, experiences, and knowledge (NCREL, 1995). There is some debate about prior knowledge and its use in instruction. Seen from a constructivist point of view, some of the failings of computer-aided instruction may be blamed on inappropriate instructional design that does not properly take into account students' prior knowledge. These failings can be laid at the feet of computer-aided instruction that is produced according to a transmission-absorption, or behaviorists model (Kennedy, 1995). It is a durable model of education: prescriptive, controlling, and often unfeeling.

Other aspects of the debate about the role of prior knowledge in instruction center on the presence of a reified prior knowledge (Roschelle, 1995) rather than on building or enhancing the dynamic knowledge base or context in which to present new instruction. Roschelle frames the debate succinctly:

On one hand, educators rally to the slogan of constructivism: "create experiences that engage students in actively making sense of concepts for themselves." On the other hand, research tends to characterize prior knowledge as conflicting with the learning process, and thus tries to suppress, eradicate, or overcome its influence (1995).

While this debate may be a valuable academic exercise, onlookers might not sense from this argument that prior knowledge is something supple and changeable. The debate centers on what might be called weed control. What one side sees as undesirable, another might see as valuable or even necessary.

In constructivist learning different types and degrees of interaction are critical: "The constructivism asserts that the world is not found, but made through interaction with experience. The learner acts as a theorist who continually refines his own structure of knowledge based on experience (Connell & Franklin, 1994, p. 610). Seen thus, prior experience is a crucial tool with which the student shapes instruction.

Resnick (1987) speaks to "a general need to redirect the focus of schooling to encompass more of the features of successful out-of-school functioning" (p. 19):

Evidence is beginning to accumulate that traditional schooling's focus on individual, isolated activity, on symbols correctly manipulated but divorced from experience and on decontextualized skills may be partly responsible for the school's difficulty in promoting its own in-school learning goals (p. 18).

In the "learning communities" of Jonassen (1995):

"knowledge construction is not supported by technologies used as conveyors that prescribe and control all learner interactions." (p. 61)

**Social Studies and the Web**

The persistence of the behaviorist model also accounts for the types of World Wide Web sites that purport to be educational, but in fact only supply a lesson plan or a syllabus. There is no compelling educational reason for such material to exist in this context except convenience for the site administrator. These sites say, "Here's the material. Come and get it!" The site owners cynically reduce the educational transaction to a one-way street: "You pay. I give. I don't care if you learn anything."

These prescriptive WWW sites are functionally different from constructive sites. Prescriptive sites, both commercial and nonprofit, seek to present curricula, objectives, or other educational packages. They contain files that are designed and delivered as instructional tools. That is, they use the World Wide Web as a medium for the delivery of instruction itself, or to deliver prepackaged instructional material.
Constructive Internet sites leave it up to the learner how to understand and use educational materials. Constructive sites can be interactive sites where electronic tutoring takes place. For example, Calculus and Mathematica Distance Education programs (targeted at “nontraditional students working in homes”) can be offered over the Internet, with a sequence of electronic “notebooks.” Other examples include virtual field trips, like guided tours of colonial sites such as Williamsburg or Jamestown, online museums, and hyperworlds. Further examples of constructive sites include projects or “unit studies” like the Jason project in which students “take part in global explorations using advanced interactive telecommunications.”

Discussing the need for designers of educational interactive web sites to have empathy for their target audience’s prior knowledge, Roschelle (1995) and others have remarked that the burden is on the designer to cultivate a habit of attention to the needs of its intended audience, to, in effect, empathize in order to build empathy. Based on the way prior knowledge shapes learning, instructional designers must be sensitive to the different knowledge bases of their intended audience. They must listen and watch, and be attentive to the learners as they use the materials.
