The project outlined here began as an attempt to build a prior knowledge base for sixth grade students who were about to begin a unit of study on World War II. More specifically, the instruction was designed to help the students investigate the concepts of occupation, resistance, and sacrifice that are central to the plot of Number The Stars. Our needs analysis showed that students were lacking an empathetic understanding of what life was like for people who had endured hardships in the past. In order to build understanding and empathy with the impact of foreign occupation, the danger of resisting the occupying forces, and the sacrifices made by those who lived in these conditions, students were given an opportunity to experience their lives in a similar context.

We wanted not only to build an interactive site that would fill this particular need. We also wanted to be able to apply our basic design to a range of educational contexts. Accordingly, we designed an interactive World Wide Web site (http://poe.acc.virginia.edu/~pm68/Day1.html) where students could begin to understand the three themes on a personal level prior to reading Number The Stars. We provided a web form in which the student entered details of his or her own life, including name, age, favorite food, the name of a friend or classmate, and the name of a neighbor. These details were then inserted, via a perl script, into a story that was designed to exemplify one of the three key concepts of occupation, resistance and sacrifice, during the era of the Underground Railroad or World War II Denmark.

We chose the era of the Underground Railroad as an historical context because it is a time during which the themes of occupation, resistance, and sacrifice are woven into the retelling. The Underground Railroad, by virtue of being studied before World War II, also provided the material for the subtext (or deep learning) of applying basic historical themes to other social, political and geographic contexts. Even though they had studied it in the recent past, giving the students the tools for making this historical era accessible was a necessary first step.

By inserting details of their personal lives into the two social and historical contexts, the students developed a frame of reference for a more intimate understanding of what occupation, resistance and sacrifice meant. They directly connected the details of their lives to those of people in the past.

The activity was broken into two days. The first day covered the Underground Railroad, and gave the students the choice of three scenarios in which to place themselves: A runaway slave, a child of a conductor on the Underground Railroad, or a child of a southern planter. The second day of instruction covered World War II, and, similarly, provided three scenarios: A Jewish child in Copenhagen, a Danish child, or a Danish farmer’s child. The students placed the details of their own lives into the stories, and, in effect, became the characters in the stories. The resulting stories were printed out each day, and read to the class by the student who had supplied the personalized details. Each student’s story was then discussed, allowing the students to more fully explore their lives in these new contexts, and also allowing the class to understand how someone they see everyday experienced occupation, resistance, and sacrifice. The web site remains available for students to “try on” the lives of these ordinary people in other places and times.

Remarks

In order for students in social studies to connect with the past, they must be able to see other peoples’ struggles and triumphs as if they were being played out according to discernible patterns of human behavior. These patterns can best be uncovered by placing the students themselves in the picture. The great themes of world history will only be revealed to those who are able to see themselves as the people of the past saw themselves. Only by building empathy in the study of society can modern-day students construct a frame of reference in which historical figures are not images flashing across a screen or words in the pages of a book. Only by enhancing their prior knowledge of their own humanity can students add the depth of understanding in which history resonates, and the face of our shared humanity shines.

Once upon a time, not so many years ago as stories go, there lived a beautiful young woman, with her mean stepmother and two ugly stepsisters. This beautiful young woman, let’s call her Cindy, worked very hard doing all the housework, making the meals, running the car pool, managing the 401-K plan, and studying law during the day. At night, she ran a fabulous gourmet restaurant which served mainly vegetarian meals with an occasional retreat into New Californian cuisine. How did Cindy find the time to do ALL of this, you might ask? You’ll just have to wait! One day, Cindy and her stepmother and stepsisters heard that the Prince, who we shall call Fred (as that was his name), was going to have a giant party in order to find a bride so that he might be married. Well, as you can imagine, the stepmother was overjoyed, as she had long given up hope that her two daughters were ever to be married. Everyone was so excited, including Cindy, who had high hopes of getting to cater the party. Well, time passed, as it has a right to do, and Cindy had not heard from the catering manager at the palace, so she just basically just forgot about that job. Besides, she had other things to do. The night of the party, stepmother and her daughters left several hours early in order to get a good seat in the palace to talk about the people at the party. Cindy was not too happy to be left at home, but she decided that she would stay home and try out a new recipe for Caramel Flan that she had found in an old cookbook. As she lit the fire under her double boiler, WHOOSH, what should appear but the Wicked Witch of the East. “Can I help you?”, Cindy asked, since she was both beautiful and polite and had learned never to be shocked when she made flan. “I can help you go to the party at the palace if you like” said the Witch. Cindy thought a minute and replied, “No thanks, I’ve just got too much to do anyway.” So with that, the Wicked Witch bought some day-old gingerbread from Cindy (since she was expecting some children to drop by later that night) and popped off. “Now to get back to work”, thought Cindy. And so she did. Turning to her desk, Cindy began work on her latest novel, “Midnight In the Driveway of Good and Evil.” And so the candlelight fades slowly on our dear Cindy and her story. But wait. How did Cindy do accomplish this? Well, since this is only a fairy tale, she actually had to do it all the old-fashioned just plain old hard work. They didn’t even have electricity back then, much less technology. Do you think she WANTED to have to do her 401-k with charcoal and a shovel? I should think not. She would have loved to have had a computer. But she didn’t. And we do. And that’s the moral of the story.

Assistive Technology: Preservice Training for Special Educators

Evelyn M. Dailey
Towson University

Bob Wall
Towson University

Recently, the need for training special educators to work with students who use assistive technology has become recognized as a national priority (Behrmann, 1995, 1993; Behrmann, Morissette & McCallen, 1992; Flippo, Inge, & Barcus, 1995). However, much of this attention has focused on inservice programs for special educators and rehabilitation personnel; while little attention has been devoted to training preservice special educators (Bowser & Reed, 1995). Yet the Council for Exceptional Children, the largest professional organization for special educators, has included technology training as one of its many preservice competencies (CEC, 1996, 1994, 1990). Therefore, in response to preparing better preservice special educators, Towson University initiated a course design process in the fall of 1996. A faculty development and research grant was secured to purchase equipment and design the special education course called Assistive Technology for Students with Disabilities K-12. This course was subsequently approved by the university curriculum committee in fall 1997 and is slated to be offered in spring 1998. The purpose of this paper is to present a follow-up report on the initiative begun Towson University to design and implement a preservice course for special educators in the use of assistive technology. The first phase of this effort was presented at the 8th annual conference for the Society for Information Technology and Teacher Education (SITE).

Project Goals and Objectives

The current project is an important component in the design of an undergraduate major in special education at Towson University; however, the course Assistive Technology for Students with Disabilities K - 12 is an elective course. This course also represents a collaboration between faculty in the areas of special education and instructional technology and the Baltimore County Public Schools. This collaboration brings together expertise across disciplines and strengthens the relationship between the teacher education program at the university and the surrounding schools. It is hoped that this collaboration will eventually lead to an inservice course for educators of students who use assistive technologies and possible expansion of special education technology at Towson University. Future goals and objectives include a Masters Degree in Special Education and Assistive Technology for Students with Disabilities K - 12 will be a required course in this degree program.

Methods and Activities

During the spring of 1997, a special education faculty member applied for and received a summer stipend from the university faculty development and research grant committee totally $4600. The purpose of the summer stipend was to purchase equipment for and design the course Assistive Technology for Students with Disabilities K - 12. A total of $2500 was spent for equipment and the remaining $2100 was a salary stipend for designing the course. A list of the budget request, type of equipment purchased, cost, and vendors can be found in List 1. The following summer, a series of 10 lessons were created using the presentation software package Powerpoint and equipment was purchased. A list of the lessons designed can be found in List 2.

Successful Inclusion

With regard to the course design process. The special education faculty member submitted the proposed course for approval to the Department of Reading, Special Education, & Instructional Technology. After departmental approval, the proposed course was submitted to the College of Education Curriculum Committee where it was approved and then sent to the university curriculum committee in the fall of 1997 where it was also approved and is now scheduled to be offered spring 1998.

To ensure student enrollment in the course, the special education faculty member was awarded 3 hours of assigned time for fall semester 1997. During this assigned time, the faculty member presented an overview lesson of assistive technology to 11 sections of undergraduate students enrolled in Introduction to Special Education and 1 graduate section of Mainstreaming for the Classroom Teacher.

Special Needs — 997
Students in the classes were given a series of handouts generated from the overview lessons and a description of the proposed course. The potential audience was approximately 300 students. In addition, a flyer announcing the course offering was also created and distributed to students as well as teachers in the surrounding local education agencies (LEAs).

Outcomes and Impact
There will be several important outcomes of this project. First, the course will be offered in spring 1998 with an initial enrollment of 25 students. Second, if the course is successful based upon student evaluations, the potential exists to offer more sections of the course in the future. Third, there is the potential to offer the course to inservice teachers through a cooperative, outreach program with Baltimore County Public Schools. Finally, with the continued emphasis placed on technology and the direction of the strategic plan of Towson University, there may be the potential to design a minor or concentration in special education technology to complement the Bachelor of Science major recently awarded to Towson University. Future plans also include the inclusion of this course as a requirement for the Masters of Special Education degree.

Timeline and Completion Dates
Data analysis will be completed in spring of 1998 through student course evaluations. Based upon that analysis and faculty availability, subsequent offerings of the course will be determined. Based upon satisfactory student evaluations, a discussion with Baltimore County Public Schools will be initiated to offer the course in the future to their teachers at Towson University. Furthermore, in the spring of 1998, the special education faculty member will submit another faculty development grant to purchase additional equipment for the course.

Evaluation Plans
Quantitative and qualitative data will be collected via student evaluations of the course Assistive Technology for Students with Disabilities K-12. The preliminary course will be evaluated by the Facilitator of Assistive Technology for Baltimore County Public Schools also and comments from that office will be considered in the modification of the course.

Current dissemination plans include sharing of the course design process and course contents with the surrounding school systems of Baltimore City, Anne Arundel County, Howard County, Harford County, and others as appropriate. In addition, local, regional, and national presentations are planned for Maryland Association of Educational Uses of Computers (MAEUC), the Maryland Instructional Computer Coordinators Association (MICCA), the Maryland Association of Teacher Educators (MATE), the Eastern Educational Research Association (EERA), and of course Society for Information Technology and Teacher Education (SITE).

Summary
In summary, this presentation will provide participants with (a) an overview and timeline of the course design and implementation process (b) an outline of the course syllabus, (c) preliminary data from evaluations of an overview lesson for assistive technology, (d) outcomes and impact of the project, (e) timeline and completion dates for future course development and (f) evaluation and dissemination plans for the project.

Future educators participated in an online discussion of issues related to teaching students with disabilities. The 98 students subscribed to the SpEdExchange listserv and were enrolled in teacher preparation programs in Minnesota, Missouri, and Indiana. Messages were saved electronically and analyzed by topic. The participants were also given pre- and post-surveys to gain information on their computer usage, perceived level of Internet skills, and the benefits and difficulties of communicating via the listserv.

A process was established to ensure that participants began and ended their listserv experience at the same time. Academic calendar years varied and one institution was on the quarter system so data collection began when all participating universities were active. Message collection for the project ceased when the grading period ended for the first institution.

**Message Analysis**

The analysis of posted messages was completed by two preservice teachers and repeated by a post-service teacher and a professional outside the field of education to assure consistency in interpretation. All messages were saved electronically and hard copies were printed for future analysis. Duplicate and incomplete messages, and requests to subscribe or unsubscribe were excluded from content analysis. The 458 remaining messages were categorized according to major theme. Ten major themes were identified along with a miscellaneous category for messages that were not related to any other message. The messages in major theme areas were then further categorized according to topical area. Descriptive statistics were used to determine frequency of responses in each area and categories were ranked in order of most to least frequency of responses.

In the first category, Placement and Setting, messages dealt with the importance of student interaction in the classroom, preference for teaching students with special needs in a regular classroom or resource room, and identification of students with special needs due to a "label" or "different" treatment. Participants were especially concerned about the quality of interaction between peers and students with disabilities in regular settings and how the teacher modeled or promoted acceptance.

Messages with the topic of Educational Interventions included discussion of reading interventions, behavior management issues, and grouping students for optimal learning. Participants expressed anxiety related to managing difficult behavior and exchanged strategies for teaching reading and math.

Most postings relating to Philosophical Issues/Personal Reflections concerned reactions to poems, quotes, stories, and humorous anecdotes. Several poems were posted which stimulated discussion and appeared to help participants develop empathy for students with disabilities.

In the fourth most discussed category, Classroom/Administrative Issues, messages addressed advantages and disadvantages of team teaching, use of personnel and optimal class size to provide individual instruction, and viewpoints regarding the class within a class model of...
collaborative teaching. The importance and barriers to working collaboratively were also discussed.

Pre- and Post-Survey Analysis

Pre- and post-surveys were given to the preservice educators at each university. These surveys asked questions regarding computer usage and internet skills. The surveys also included questions about the benefits and difficulties encountered when participating in the listserve. From the pre-survey, the researchers found that less than 25% of the participants had prior experience with listerves. In the area of computer usage, the participants reported significant increases in using word processing, sending e-mail, and accessing the World Wide Web. They also reported significant increases ($p<0.0001$) in internet skills as a result of participating in the listserve.

The responses dealing with posting on the listserve revealed three results: (a) When asked to describe participation in the listserve the mean was in the frequent poster range. (b) Participation was significantly easier than the students predicted. (c) Though beneficial, participation was significantly not as beneficial as the students had predicted in the pre-survey.

Most comments made on the post-survey were very positive about participating on the listserve. Students seemed to enjoy sharing information and viewpoints and several attributed the listserve to expanding their view of Special Education. Some of the comments were the following: “Information, a variety of opinions, ideas, new things to think about, professional conversations, a variety of perspectives.” “Seeing others thoughts and concerns at being a Special Educator. You know that others are going through the same things.” “It helped me with strategies and basic questions I had.” “It allowed me to address questions I had.” “I enjoyed learning other opinions on certain controversial issues in the education field.” “I enjoyed seeing the many different opinions that were viewed on the listserve. It was interesting seeing alternative solutions to the different situations.” and “I learned a lot from the other students. I have learned about material that I did not know about and I have changed some of my viewpoints towards inclusion. I also had a chance to hear other viewpoints about Special Education.”

Recommendations

Several recommendations were drawn from the results of the analysis of messages and the participants’ responses. They included the following:

1. Messages tended to reflect a concern for the actual placement and equitable treatment of children with disabilities. Teacher education should continue to focus upon the impact of a disability upon an individual. It should also address the needs of the classroom teacher for strategies that will minimize this impact and maximize learning.

2. Messages often noted inventive strategies for academic learning and sought more strategies and materials which could be useful. Teacher preparation programs may benefit from direct provision of sources for materials and strategies. It may also benefit from allowing preservice teachers the opportunity to try the materials in hands-on situations.

3. The participants expressed the desire to practice more collaborative skills in regular settings. A training partnership between special and regular education programs may be beneficial in meeting this perceived need.

4. Many messages noted apprehension in the ability to deal with motivation and conduct issues. Confusion regarding implications of laws and policies was apparent. Preserviceteacher education may benefit from the greater exposure to policies and practices in behavior management.

5. Participants reported significant increased use of computers and increased levels of internet skills. Posting messages on the listserve seemed to increase the use of word processing, the World Wide Web, and e-mail. Teacher educators must keep in mind that integrating technology into coursework may or may not enhance the quality of instruction.

6. Participating in the listserve was perceived as beneficial by the preservice teachers but not as beneficial as had been originally predicted. The benefits listed by the participants in the post-survey fell primarily into two categories of sharing information and expressing opinions. Future educators appear to have a desire for all the information they can gather that includes resources, strategies, and materials. They were eager to express their opinions about issues in the field of Special Education and developed professionally by exposure to differing viewpoints.

NETWORKING SPECIAL EDUCATION TEACHERS: PROVIDING DISTRIBUTED RESOURCES ON SPECIAL NEEDS

Kevin Nguyen  
University of Toronto

Laurie Harrison  
University of Toronto

Greg Gay  
University of Toronto

Special Education teachers in primary and secondary school face daily challenges when working with special needs students. Teacher training and resources on special needs are usually scarce, and when available, are sometimes difficult or timely to acquire. Moreover, since the special education arena is very diverse, it is rare for a special education unit within a school, or even within the local area, to have the expertise and solutions for all issues. By forming world-wide networks between special education teachers at 1) the physical infrastructure level, 2) the information level and 3) the communication level, a special education community can be created with minimal distance, cost, societal and access barriers.

**Computer-Network Infrastructure**

When creating a distance education resource for special education the first thing required is a physical network infrastructure that links special education teachers and classrooms. The NII (National Information Infrastructure) initiative in the US, and similar government initiatives in Canada and other countries, ensure that a growing number of Internet-ready computers will be in the classrooms by the turn of the century (Brummel, 1994). A computer in every classroom is becoming a reality, and a computer for every student is becoming a new aim for some organizations. Because web browser software is ubiquitous, free for educational institutions, non-proprietary, and fairly accessible to those with disabilities, it is the ideal interface to a special education infrastructure. With the current availability of browsers and computers, and the low cost of Internet access, a web-based network is the most cost-effective, flexible and dynamic choice of network.

The student population that special education teachers serve has unique needs and equipment requirements for computer access. The computer interfaces to resources and learning materials should be accessible and adapted to accommodate students with special needs (Nguyen & Petty, 1997). Assistive computer devices such as screen readers for students with visual impairments, or alternative keyboards and mouse devices for students with motor impairments, are a necessary part of any web-based special education network infrastructure.

Specialized infrastructures may augment and complement a web-based network to achieve particular goals in delivering special education resources. For example, 56k / 64k ISDN videoconferencing can be used to bring experts and consultants from urban centers into more remote and resource-poor, rural schools for real-time consultation on specific issues. 336k / 384k ISDN videoconferencing can be used to bridge together American Sign Language (ASL) communities, where high-speed bandwidth is needed to maintain the video fidelity and frame-rate required for the nuances of sign language. The drawback of specialized networks is the increased cost, and the limited number of compatible sites one can communicate with. However, until consumer-level Internet access evolves to a more advanced state, specialized videoconferencing networks can serve certain purposes that web-based networks cannot.

The creation of an adapted physical computer networks is the first step before special education teachers and students can access distributed information or interact through on-line communities.

**Information Networks**

Web-based information networks should be designed to allow special education teacher to share resources with one another. Disparate resources, examples of best practices, lesson plans, teaching methodologies and digital libraries can be pooled together into a definitive clearinghouse on special education and related topics. Ideally, this clearinghouse of information would be easily updated, dynamically managed and disseminated to an unlimited number of teachers. Because the information is in electronic form, it is inherently more accessible for persons with disabilities than printed information; as the information can be enlarged, read though a speech synthesizer, or navigated without a page-turner, via assistive computer devices. Accessible HTML should be incorporated into the web pages to ensure that the information is usable by the broadest possible audience (Letourneau, 1996).

Not all information disseminated through web-based networks is text. Innovative web technologies can be exploited to deliver multi-modal information and resources.
Educational videos, or audio recordings from libraries for the blind, can be shared through an Internet based network. Such materials enhance the appeal to learning by being more dynamic and lively. Enticing and enriching materials will make a learner want to learn. Where possible, multimedia materials should also be adapted to meet the needs of special education teachers and their students. Videos can be captioned for those with hearing impairments and descriptive audio can be added for people who are blind. Text transcripts of all audio/video should also be provided to allow for easier review and navigation of the materials for persons with print impairments or learning disabilities.

Any information should be available at all times and easily located. Ideally, teachers should have the ability to submit new information entries to a resource clearinghouse that would go though a review committee to ensure appropriateness. As a resource collection grew, standardized processes for cataloging, organizing, and searching through the information would become necessary.

Interpersonal Communication Networks

There are several methods in which special education teachers can use network-based systems to communicate with one another. Listserves and web-based discussion forums bring together people with common interests to discuss specific topics. Synchronous forms of real-time communication are possible through web-based chat systems or 3D-mediated environments. Any of these on-line systems can be set up with restricted, secured access for scenarios such as mentoring, consultations, or testing and certification.

Interactive courses for professional development in the area of special education can be easily authored for the web using courseware development packages. These courses can provide opportunity equity for those who are geographically challenged (Paulet, 1989) or for those who wish to take highly specialized interest courses that aren't offered locally. Web courses can also act as a catalyst for on-line relationship building between teachers who share similar interests. These can become starting points for on-line communities built around SIGs (special interest groups).

An electronic classroom is a classroom without walls where cultural and societal barriers are eliminated. A person has the choice to reveal as much or as little about themselves as they want, allowing a new on-line persona to be constructed that can facilitate communication and learning (Gold, 1997). For example, a hearing-impaired student (or teacher) who is quiet around peers may be more participatory during on-line conversations. Also a student can choose to hide or disclose his or her race, sex, age or disability. T: anonymity that on-line communication networks provide can help eliminate pre-conceptions or prejudices that people sometimes hold against others who have visible differences. A more level playing field is introduced for a greater integration of a diverse population.

Web-based communication can also allow continued networking with colleagues beyond conference and special interest meetings. The building of professional contacts, links to experts in the field of special education, and the sharing of knowledge can all facilitate teachers in finding solutions to special needs issues.

SNOW - Special Needs Opportunity Window

Special Needs Opportunity Window (SNOW) is a pilot project funded by the Ontario Ministry of Education and Training. It is currently attempting to network together special education teachers throughout Ontario, and from around the world, utilizing the ideas and methods listed above. The SNOW project can be explored [http://snow.utoronto.ca]. There are several other projects in development at the Adaptive Technology Resource Centre that are also looking at ways to network special education teachers and students. These will eventually be linked through the SNOW web site as well. It is hoped that by bringing important issues of education access, community and technology to the foreground, other web-based special education programs can benefit.

Acknowledgements

This project was made possible through funding from the Ontario Ministry of Education and Training’s Technology Incentive Partnership Program (TIPP96-082). Thanks go out to Greg Gay, Laurie Harrison and Jutta Treviranus.

Papers in this section reflect the diverse ways that school districts, teacher education faculty, private consultants and school administrators are trying to help teachers better use technology in their classrooms. Collaboration seems to be the keyword. Schools, universities, government agencies and members of the private sector are teaming up to address the ongoing problem of providing professional development and support for teachers to integrate the use of technology with their instruction.

The first paper is a progress report of the implementation of a Technology Innovation Challenge Grant awarded in 1995. Marx describes the progress made over the first two years and outlines an Instructional Technology Master's degree program offered through the University of Texas at El Paso. The IT program was designed to help teachers in the 5 district consortium that received the grant: "... develop classroom teachers who are technologically literate, understand how to effectively and appropriately integrate technology into their lessons, are able to design and implement innovative technology-infused curricula, and act as change agents in their schools and districts."

Gershner and Snider also describe a school district/university partnership. In addition, one of the districts participating in their Community Collaborative Professional Development Center (CCPDC), Ysleta ISD, is also participating in the a Technology Innovation Challenge Grant project described by Marx. The CCPDC coordinates the preservice teacher-training efforts of Texas Women's University by linking teacher educators with schools in 7 local school districts to provide field placements for students and community business partners. The Center is supported by the Corporation for Public Broadcasting and has developed a Classroom Internet Integration Project that supports participating district's efforts to help their teachers develop technology skills, and the teacher training efforts of the university.

The Wunsch paper presents an overview of the evolution of the STAR project intended to provide integrated mathematics, science, and technology experiences for all secondary science and mathematics students in over sixty Houston Independent School District schools. She described how the project changed and developed over time and indicates the role of project participants including the University of Houston, Rice University, the Houston Museum of Natural Science, NASA, and Space Center Houston. The National Science Foundation provided funding for this project.

Nunn, McPherson, and Rust describe a partnership between Johns Hopkins University and the Baltimore Public Schools designed to train teachers to become school-based leaders in technology through a 36-credit graduate program in Technology for Educators. They outline the Master's program they designed and highlight the challenges associated with developing the program and challenges they faced in making it work. Breithaupt also describes a collaboration between a university and school district. He describes a project in which student teachers were paired with inservice teachers to work together to integrate technology with their instruction. Student teachers are a valuable resource for inservice teachers because they brought pedagogical innovation and technological expertise to the relationship.

Canipe and Parrish describe a federally funded project to provide training for teachers in five school districts. They present the underlying philosophy that guided their instructional focus and the relationship they are developing with LearnNC, housed at the University of North Carolina at Chapel Hill, to disseminate their materials on the Internet.

The Reesor paper is a bit of an anomaly in that it describes the efforts of a single school to integrate technology into the curriculum. As a small private catholic school, they lacked the resources and expertise available to the public school districts and universities described in the other papers in this section. Their efforts were supported by parent organizations, the local library, and Apple Canada; however, the development of the technology plan was
accomplished primarily through the work of teachers and administrators in the school.

The next two papers provide some general principles to help guide technology infusion efforts. Budin and Meier support a constructivist view of teacher development and encourage integrating technology skills training with relevant instructional activities, the use of integrated curricular projects, and providing a variety of instructional methods for training teachers. They focus on changing the culture of the school by individualizing change processes for specific schools and teachers and remind us to provide support over a sufficient period of time for change to occur. Barnes presents seven issues that should be addressed to increase the likelihood that technology integration efforts will succeed and sustain. He points out the need for administrative support, evaluation and accountability, and teacher access to computers to support meaningful curricular integration.

The final paper in this section addresses the key role of the technology coordinator in providing ongoing support and leadership for technology integration. The Marcovitz paper raises some interesting concepts about the work of technology coordinators through a mini-case study of one coordinator. The concept of “walk around support” is presented and its effectiveness with many teachers is explored. The visibility and interactivity that occurs when the coordinator walks around the school to complete various tasks promotes a high level of communication and technical support with the faculty. This allows the technology coordinator to serve in a policy making role because of his or her thorough understanding of technology needs in the school.

These papers provide some interesting insights into collaborative projects for enabling teachers to use technology with their students. The current trend toward school/university partnerships that draw on a variety of community resources provides a multi-level approach that may promote greater success for technology infusion projects.

Neal Strudler is Associate Professor in the Department of Instructional and Curricular Studies and the coordinator of educational computing and technology in the College of Education, University of Nevada, Las Vegas.
E-mail: strudler@nevada.edu.
In the Fall of 1995 El Paso was awarded a five year Technology Innovation Challenge Grant for $3.4 million. The goal of the grant is to create a community of 21st century learners by working with the three major school districts in the area (Socorro, Ysleta, and El Paso Independent School Districts) and fourteen partner schools within those districts. Technology is seen as an enabling force that allows students, teachers, and parents to overcome obstacles to success that exist in this low-income, low technology, primarily Hispanic region. The grant has five major components: connectivity, parent centers, e-mail mentors, professional development, and evaluation and sustainability. This section will examine each area of the grant in terms of its goals and the progress made so far. All elements of the grant are designed to work together to create learning communities in each school involving parents, educators, students, and other community members. Technology use is integrated in many ways but is never seen as an end in itself.

**Connectivity**

The connectivity portion of the grant is designed to aid the partner schools in providing Internet connectivity to their classrooms. Each school district is allocated $120,000 to be used in the partner schools as deemed appropriate by the district. This flexibility was necessary because different districts, and schools within districts, are in various stages of wiring.

Funding for this and other components was given first to the Socorro ISD, as the grant’s fiscal agent and most technologically advanced of the three districts. The Ysleta ISD got funds this year, and the El Paso ISD will receive these and other funds over the next two years, as they have six partner schools each, rather than the four each in the other two districts.

**Progress.** Connectivity is on schedule. The partner schools in Socorro have Internet connectivity in all classrooms; teachers and students are being trained in its use, and various types of Internet activities are being integrated into instruction. Ysleta received funds for 1997, and the partner schools are all wired and await final district action.

**Parent Centers**

Another major element of the grant is parental involvement. To this end, each partner school is required to set aside a physical space for a parent center. The grant provides equipment for the parent centers (again one district per year) once this location has been set aside. Equipment includes: a multimedia station including Power Macintosh computer, printer, scanner, digital camera, video camera, large TV/monitor and cart; and 15 Powerbooks (Socorro ISD) or e-mates (Ysleta and El Paso ISDs) for parent check out and home use. The technology is an incentive to help get parents involved in the schools and provide them with valuable training, but it is not the primary reason for the parent centers.

The parent centers are designed to increase parent involvement in the schools. In addition to technology training and laptop/e-mate checkout, a variety of programs are offered on each campus. These programs include citizenship classes, GED training, family enrichment programs, parenting skills, and visits from social service agencies.

**Progress.** All but one of the thirteen partner schools have parent centers up and running. The functioning parent centers have received their multimedia stations, and those in Socorro and Ysleta have received their check-out equipment; El Paso parent centers will receive their e-mates over the next two years.

As mentioned above, a variety of programs are in place at each parent center. Each center also has at least one person on staff as a parent educator; in some cases this person is a volunteer, while others are paid. The programs in the Ysleta and Socorro parent centers are generally very active, with good attendance and a variety of projects under way. A Parent Educator Association is being formed to share resources and provide staff development for all parent educators in the El Paso area. This program is having its intended effect of increasing parent involvement in their children’s education.
E-mail Mentors

The goal of the E-mail mentor program was to pair up students in the partner schools with business people in the El Paso area. This would give the children a role model and someone to provide encouragement and help. Due to difficulties encountered in finding enough business people to participate, University of Texas at El Paso (UTEP) undergraduate education majors were enrolled as mentors from a science methods course.

Progress. For a variety of reasons, this program has met with limited success and is being scaled back. While there was enthusiasm from some teachers and mentors involved in the program, difficulties included infrequent and inadequate mail from the students, lack of access, and lack of focus. Mentoring is ongoing with some of the original participants, but the program will not be expanded.

Professional Development

There are two main parts to the professional development program: professional development for K–12 teachers and professional development in technology for the UTEP teacher education faculty. The teacher development program educates cohorts of 15–20 teachers at a time in the integration of technology and standards into the curriculum. Teachers receive a Master’s Degree as an Instructional Specialist with an emphasis in Educational Technology; for those who already have a master’s degree or are pursuing a master’s in another field, an endorsement program is available where only the technology classes are taken with the cohort. The development and progress of this program will be discussed in greater detail below.

To help guarantee the integration of technology throughout the teacher education program, funds were also allocated for professional development of teacher education faculty in technology. After three semesters of limited success, this program has been suspended while other methods of implementing this development are investigated.

Progress. To date, two cohorts totaling roughly 30 teachers have graduated from the program. Four other cohorts, totaling approximately 70 teachers, are in various stages of progress. Initial results indicate high levels of satisfaction with the program and some progress in implementing the training. Future plans include observation of participant classrooms during and after their participation in the program and other forms of formative and summative evaluation.

The original plan for faculty development in technology was to give one faculty member per semester release from one class, paid by the grant, and that member would participate in a cohort’s technology class. For a variety of reasons including scheduling and different technological abilities, this plan did not work out. While limited progress has been seen in these faculty members use of technology, it has not been at the levels expected. The release program is no longer being used and other methods of faculty development are being discussed including: voluntary technology workshops during the semester on various topics; one-on-one mentoring of faculty; a combination of training and stipend to be used to purchase hardware or software for use in the classroom; and access to technology-rich teaching classrooms for faculty who participate in training.

Evaluation & Sustainability

While in one sense two separate components, evaluation of the success of the various programs and their sustainability after the grant money runs out are also connected. Various methods of evaluation are being used to determine the success of the different elements and these evaluations are, in part, designed to give feedback on the sustainability of these programs.

Connectivity

The success of this component is judged by getting schools Internet connectivity. Issues of sustainability involve maintenance and upgrading of equipment, and are outside the purview of this grant. They are the responsibility of the schools and districts involved. Thus far, this component has been successful. The Socorro district and Ysleta districts are both on track. The El Paso district, without grant funds so far, is making progress in the wiring of its schools for Internet access, and grant funds should allow the completion of this process in the partner schools over the next two years.

Parent Centers

Success of the parent centers is being evaluated in several ways. Physical locations have been established for all but one center. Numbers of program participants and parent volunteer hours in the schools are further quantitative measures being collected. More qualitative evaluation includes how parents are getting involved and volunteering at the schools and in their children’s education, and will be harder to measure. Sustainability is being ensured by the formation of the Parent Educator Association and school support for the centers and their staffing.

E-mail Mentors

This component has not achieved success, and no additional resources are being allocated to it at this time.

Professional Development

Evaluation of the teacher education component includes a Likert-type survey administered when students enter and leave the program. This survey addresses their knowledge, confidence, attitude, and use of technology. In addition, students make regular journal entries in the technology classes and will include observation of participant classrooms during and after the program.

Sustainability will be measured by whether the master’s program continues after the grant runs out. Participants currently receive partial scholarships paid by the grant.
while the faculty are either wholly or partially paid through grant funds. To measure interest from the teacher perspective, a self-paying cohort will be formed next fall; sustainability from the faculty perspective will be partly determined from interest in this cohort, and partly from the financial situation of the college. Sustainability will also be measured by the success of the faculty development program in integrating technology into the undergraduate teacher education program.

**The Instructional Technology Master's Program**

The goal of the Instructional Technology (IT) program was to develop classroom teachers who are technologically literate, understand how to effectively and appropriately integrate technology into their lessons, are able to design and implement innovative technology-infused curricula, and act as change agents in their schools and districts. The coursework consisted of four technology classes, taught by staff hired by the grant, and four general education classes, taught by both grant staff and UTEP teacher education faculty. In addition, there were two practica, one in mentoring and one in classroom action research. This section examines the model IT program we created for inservice teachers, the development of the practica into core components to ensure technology diffusion, classroom action research by teachers, and lessons we have learned from the process.

### The IT Program Model

One of our primary goals was to produce a model program that is aligned with the new NCATE-approved ISTE standards for teacher education programs. The program addresses the flexibility needed in an IT program due to the rapid changes that take place in the field of technology. The goal was to foster change in what and how teachers teach and students learn. These concepts were more important than learning about any specific technology. We divided the model into two halves because certain concepts, theories, and tools naturally come before others and build an important base for more advanced theories and instruction.

An important factor in the success of this program that does not appear in the model above is the role of the general education classes in supporting the technology classes. We have had mixed success in aligning the goals of these education classes with the goals of the grant. A schedule has been developed with most of the classes taught by members of the challenge grant staff. This seems to be an optimal solution. In classes taught by faculty not associated with the grant, the relationship between course content and program goals has depended on the faculty members. Clearly, teacher education faculty involved in an instruction technology program should be involved in the planning and implementation process as much as possible, and should be encouraged to adopt the goals of the program.

### Table 1.

**An Instructional Technology Program Model**

<td></td>
<td>Advanced applications; advanced multimedia authoring; group authoring projects; individual focus areas; more hardware; more networking</td>
<td>Dedicated graphics programs (2D &amp; 3D); sound programs; digital video; advanced Web tools (Java, CGI, etc.); advanced authoring programs (SuperCard, Director, etc.); web and file server software</td>
<td>Brain-based learning; curriculum reform &amp; design through use of technology; systemic change; mentoring; diffusing technology-based change throughout a school; classroom-based action research (measuring change).</td>
</tr>
</tbody>
</table>
The Practica

While initially both practica were designated for mentoring other teachers in technology integration, it became clear that this was unnecessary. In light of the growing emphasis in the program on evaluation and looking for classroom results, we decided to separate the practica into one for mentoring and one for classroom action research. We have developed formal models for both practica to ensure their consistency throughout the program and to facilitate their use by others.

Mentoring. One of the original program components, designed to ensure diffusion of technology integration throughout a school, was mentoring. Each teacher going through the IT program was required to formally mentor three other teachers. A model has been developed and is being tested whereby cohort teachers pick two or three other teachers in their school to mentor. Based on an initial needs assessment filled out by each mentee, formal Individual Education Plans (IEPs) are written up, a course of study is developed and carried out, and evaluation is done by both the mentor and the mentees. This evaluation should be formative and summative, and should focus on the impact of the training on classroom instruction and student learning.

Research. As a way of ensuring cohort teachers begin to implement innovative uses of technology in their curricula, and investigate for themselves what does and doesn’t work, we decided to design a classroom action research practica. One of the general education courses is on research, so this is a logical extension of that coursework. It also provides another method of evaluation for the grant, to determine if what is taught in the cohort classes is effective in the K–12 classroom. The specifics of this program are still being developed and will be tested in the spring of 1998 with one cohort.

Lessons Learned

While we have created a program we think meets the rigorous standards approved by NCATE and believe we are training our teachers to be change agents in their classrooms and schools, our successes have not come without difficulties. We have learned some valuable lessons that may be useful to those currently developing or revising an instructional technology program. Many of these lessons involved the initial setup of the program and include the importance of a dedicated lab for graduate students with sufficient computers, software, access, and peripherals. These conditions were not in place at the start of the program, and when we moved to our new lab, a marked improvement in teaching, learning, and attitude was seen. While it may seem a small point, the ability to darken the room sufficiently for an LCD panel or to have a high quality projector for whole class presentations is vital.

Aside from the physical location and setup for the technology classes, staffing was also an important issue. Because of the short time between getting the grant and having to start the program, staffing was not finalized until three semesters into the program. This was further complicated by one of the technology instructors leaving suddenly after the second semester. Classes are generally taught by two technology specialists and one curriculum specialist. It is essential that a curriculum specialist be involved in the technology classes. This person need not be a technology expert, it is sufficient that he or she be willing to learn the technology as necessary for instruction. The curriculum specialist has been key in keeping the focus of the technology classes on students and curriculum and on the appropriate uses of technology. The importance of having faculty in the general education classes versed in the goals of the program was discussed above, but is mentioned here to emphasize the need for an integrated program. An instructional technology program should focus on instruction rather than technology.

Finally, technology coursework should be based on the reality of participating teachers’ classrooms. All assignments in the technology classes are intended to be translated to the classroom. These assignments include lesson and unit planning with technology, software reviews, telecommunications activities, and multimedia authoring. Increasingly, classroom testing is a component of project assignments, further ensuring that teachers are focusing on their classrooms when completing assignments.

Conclusions

The use of mentoring to help diffuse technology use throughout a school is important for providing university instruction to a wider audience. Classroom research connects directly to the goals of the grant in increasing the use of technology in alignment with national standards and curriculum reform. Our work in formalizing these components is designed to ensure the success of the grant and provide help for other such programs.

The creation of a model scope and sequence for the program is vital for the same two reasons. One of the goals of the teacher education component of the grant was to develop a model instructional technology program. The length of the grant allows for extensive research on what does, and does not, work. The key is the translation from university instruction to K–12 classrooms, and as we have just started graduating cohorts, our research in this area is just beginning. But a concrete, yet flexible model that is aligned with new national standards allows others to look at what we’ve done and adapt it to their needs. Delineating the goals of the program, and a sequence for carrying out the program, makes it easier to align other education courses with the technology classes so that the program functions as a whole, rather than as separate parts.
After roughly two and a half years, we feel the grant is on track and on schedule. The connectivity, parent centers, and professional development programs are working together and creating a synergy among formerly disparate elements of the school communities. While some elements, most notably the e-mail business mentor program, have not been as successful as hoped, we have learned valuable lessons from all parts of the program. We are piloting models of parental involvement and professional development in technology that may be useful to others working in these areas. While we are at an early stage in terms of evaluation, we are piloting models for this as well. Overall, we feel we are fulfilling the goal of the OERI Technology Innovation Challenge Grants in creating innovative, collaborative programs to increase student success and community involvement, and using technology as a tool to help us reach those goals.

*Steven Marx is Visiting Lecturer with the Challenge Grant, College of Education, University of Texas at El Paso, El Paso, TX 79968. Voice: 915 747-5642, fax: 915 747-5755. E-mail: smarx@utep.edu*
CLASSROOM INTERNET INTEGRATION: A COLLABORATIVE ADVENTURE

Vera T. Gershner  
Texas Woman’s University

Sharla L. Snider  
Texas Woman’s University

The Community Collaborative Professional Development Center (CCPDC) coordinates the preservice teacher-training efforts of Texas Women’s University (TWU) by linking teacher educators with school districts which provide field placements for students and community business partners. The CCPDC includes eleven school districts that provide field training sites for hundreds of TWU preservice teachers including two urban districts (Dallas and Ft. Worth), three suburban districts (Denton, Keller, Lewisville), and five rural districts (Aubrey, Lake Dallas, Little Elm, Pilot Point, and Sanger). Each of these districts has unique characteristics and the CCPDC design provides preservice teachers with experiences in multiple settings during their teacher education programs.

In addition to the eleven school districts, the CCPDC includes Regional Education Service Center XI, the Texas Parent Teachers Association, Community in Schools, and the International Business Machines corporation. An Advisory Board with representatives from each of the partners establishes policies for collaborative projects. The CCPDC Director reports to the Advisory Board and to the Dean of the College of Education and Human Ecology at TWU. Eleven university professors serve as CCPDC University Liaisons to link the university with participating school districts. The CCPDC program was established in the fall of 1996 and replaces the existing TWU teacher education program in the fall of 1998. Funding was used to support district identified technology needs and technology instruction on the university campus.

Classroom Internet Integration Project Collaborative Partners

School Districts
The CCPDC has developed a collaborative project to integrate the use of the Internet into participating schools. The Classroom Internet Integration Project extends through K-12, and in all content areas, to address the needs of teachers in the Aubrey Independent School District (AISD). AISD enrolls 905 students on its three campuses. Thirty percent of the students are considered at-risk because of low SES. The teachers in this district all have computers on their desk and are quite computer literate.

This project includes an all-level effort for training and utilization of Internet in all classrooms in the district. This effort is timely and possible due (a) to the size of the Aubrey district, (b) its advanced status in technology, (c) its history of collaboration (d) its support of staff development to reach district goals, and (e) the support for technology provided by the AISD School Board. Current technology resources include a 4 to 1 ratio of computers to students, WAN facilities, Internet access in all classrooms, and links to TWU, the CCPDC, and the Corporation for Public Broadcasting (CPB).

Aubrey ISD is a rural district with limited local resources. However, they have community support for building a new high school and renovating other facilities and have state grant support for the installation of Internet in every classroom. Texas Woman’s University completed the classroom connections for Internet access the fall of 1997 and provides training in educational technology through the Department of Educational Leadership and Information Technology Services.

The AISD Technology Coordinator spearheaded the technology training efforts in the AISD. An AISD Staff Developer is also a member of the Research Team and led the training and implementation efforts for the elementary levels. The Webmaster is a doctoral student in School Psychology with strong technical and research expertise.

The Ysleta Independent School District (YISD) partners with the AISD in developing and evaluating project activities. The YISD includes El Paso which is urban with a 75% minority enrollment and is located in southwest Texas. The Program Coordinator of the Magnet High School coordinates implementation and evaluation in YISD. A network of elementary, middle, and high school teachers in El Paso are being identified to serve as partners to the AISD cadre of teachers for implementation of the WWW based prototype lessons.

Ysleta ISD is in the El Paso area which is markedly different from the Aubrey area. Aubrey has little ethnic
diversity, is rural, is in North Texas, and performs at a high academic level; El Paso is on the southern border, is urban and has a high concentration of minority students. This partnership provides an opportunity to share and evaluate lessons in two diverse settings. It also makes possible Internet-based communication between students in the two districts.

Over the past five years the Aubrey ISD has collaborated with TWU in the development of a new teacher education program. These efforts have focused on improving classroom instruction. With support from Texas Woman's University, a series of staff development sessions were implemented for AISD and other rural districts. An important additional benefit of this effort is the modeling and mentoring of effective instructional uses for the Internet provided by trained teachers.

**Texas Women's University**

The University Professors serving on the Research Team are instructors in educational technology and serve as University Liaisons to three rural districts. They have previously implemented technology-focused research in school settings and published and disseminated findings appropriately. The AISD Technology Coordinator, serves with them as the Texas CPB Summit Team.

The project provides outreach including sharing of experiences and products within the district, with the University and through Internet with a partner program in the El Paso area, the Ysleta Independent School District, and eventually with Summit Teams of the Corporation of Public Broadcasting.

**Corporation for Public Broadcasting**

University professors from TWU and school technology coordinators from AISD were invited to participate in their Fourth Summit for Educators held in Dallas during September of 1997 by the Corporation for Public Broadcasting. These Summits were co-sponsored by the National Council for Accreditation of Teacher Education (NCATE). This team was the only representative from Texas. This opportunity facilitated communication and possible collaboration with over 100 summit teams across the nation who participated in these summits. The summits focused on integrating technology into the curriculum. The partnership with Ysleta ISD grew out of the Dallas CPB Summit.

**Structure of the Program**

**Tasks**

1. TWU, AISD, and YISD design and implement the project.
2. Select, organize, and support a representative Expert Team. Define roles, responsibilities, and timeline to accomplish: (a) assessment of lesson plans, (b) selection of exemplary lessons from various levels and content areas, and (c) implementation of further utilization and evaluation within AISD and YISD.
3. Select and prepare cadres of university students to support classroom teachers during training days.
4. Establish a website to be linked to the Corporation for Public Broadcasting, Texas Woman’s University, and Aubrey Independent School District.
5. Prepare teachers at all levels in AISD to integrate the use of WWW resources into their classroom instruction in ten training days.
6. Implement and evaluate lesson plans developed by each AISD teacher who was trained.
7. Implementation of prototype Internet based lessons by an established AISD and YISD teacher team to encourage further collaborative efforts of integrating Internet resources into classroom instruction. This also encourages reflections on teaching and learning and possible classroom interchanges.
8. Share the new curriculum and the collaborative process at university, district, and conference events as well as electronically with other summit teams.

**Teacher Groups**

Three distinct collaborative groups of teacher participants were established: (a) identification of AISD teachers to be trained, (b) the Expert Team, and (c) Partner teachers for the YISD collaboration. The first group included all K-12 teachers, who were trained to utilize Internet resources in their respective classrooms. Some needed more training and assistance than others. Some did not wait for formal training to begin exploring the possibilities.

The second group was a seven member Expert Team which represented elementary, middle, and high school levels. This team, trained by Education Service Center Region XI, taught teacher inservices, and provided classroom support for teachers, evaluated lessons submitted after the first testing, identified peer teachers to utilize and evaluated lessons, and selected Partner Team members. The Expert Team also shared products in CCPDC seminars and with University content specialists.

The third group was comprised of partnering teachers. Pairs of AISD and YISD teachers communicated electronically about their utilization and evaluation of lessons as they were used in their classrooms. The lessons become available to others through the AISD, TWU and CPB/NCATE web sites.

**Implementation**

**Curriculum Development**

The first step in teacher training was a series of voluntary after school sessions for technology novices in February 1998. These sessions provided basic experience in connectivity including use of Netscape, bookmarks, and accessing some valuable educational sites. This orientation was followed by two inservice days. One day centered on lesson development and the other on analysis of appropriate Texas Essential Knowledge and Skills competencies for
teachers’ grade levels and content areas. The third training period provided opportunity for the teachers to develop lessons in their own classrooms with Expert Team members available in their building for specific help and encouragement. Each teacher was expected to develop, teach, and evaluate at least one lesson during this semester. As lessons were implemented, other teachers at their grade level or in their content area were encouraged to field-test them. The best of these lessons were identified as models for sharing with other members of the CCPDC, with TWU preservice teachers in technology seminars, and with teachers in the Ysleta Independent School District.

Teams

The Expert Team was responsible for design and implementation of training sessions. Others involved in implementation included the Research Team (university professors, AISD technology coordinator, AISD staff developer, and the WebMaster), the Partner Teams (teachers from AISD and YISD selected to share lessons and insights), technology professors from TWU, and university liaisons who share curriculum with other CCPDC districts.

The Research Team provided training seminars for CCPDC students on the integration of Internet and collaborated with other professors on enriching university classroom instruction. They also communicated with other CPB summit teams to share the process and products developed by the AISD Implementation Team. Products were posted on class web sites and the CCPDC web site.

Technology Utilization

The Aubrey District has been a leader in staff development and in technology. In May of 1997, AISD received a state grant which helped to provide the needed infrastructure and funds for staff development. Both the Aubrey Independent School District and Texas Woman’s University are committed to integrating technology into the classroom. With the support of an AISD small district grant and the 1997-1998 CCPDC grant both of these entities have the necessary infrastructure to support teacher training in effective utilization of WWW resources in classroom instruction.

This massive technological change in AISD was possible because of the small size of the district, its history of staff development and performance, the level of technology available, and the quality of the leadership team. The Superintendent and Technology Coordinator spearheaded the district effort and it was enthusiastically supported by the Principals and the Staff Development Coordinator. Teachers varied in their technological confidence and interest but comprehensive training and extensive support has resulted in significant classroom innovation.

Web page links between the CCPDC university liaisons, mentor teachers, student interns, student teachers has increased communication among participating groups. Telecommunication between Research Team Members and the Expert Team Members has also facilitated project management. Changes that seemed extremely difficult have become possible and easier as the project gains momentum.

Internet access has now been installed throughout the district. All AISD teachers have been trained to develop, utilize, and evaluate a lesson plan utilizing Internet resources. Each of these teachers will have implemented at least one such lesson during this school year. During teacher training, TWU students served as substitutes in classrooms providing support for the teachers and also gaining valuable experience for themselves.

Lesson plans have been assessed by the Expert Team and the best at each level or within each content area is being implemented and evaluated by a Partner Team which includes an AISD and a counterpart teacher from YISD. Both the implementation of the lesson and reflections on its effectiveness are facilitated and enhanced by electronic correspondence between the AISD and YISD teacher team.

Implications for Technology in Teacher Education

This collaborative effort supports the professional development of (a) preservice teachers at three levels, (b) the mentor teachers in two districts, and (c) the teacher educators at the Texas Woman’s University. Thus students, mentor teachers, and university personnel are enriched and sharing across the country is supported.

The TWU preservice teachers participated in field settings for two semesters as interns prior to becoming residents in a third placement. During this three semester period the campus technology seminars address connectivity, productivity, and integration. The opportunity to participate in field settings in active learning communities pursuing integration of technology is an important experience for them.

Collaboration of teachers across grade levels and content areas extended teachers’ professional development within the district settings. Their active collaboration with liaisons and other professors also enhanced teacher education in the university setting. In addition this collaborative adventure provided a framework for cross-cultural exchanges between teachers in contrasting districts and provided a context for collaboration among their students. This sharing of resources was expedited by access to communication technology.

Establishing connectivity between professors, interns, residents, and teachers is the foundation for ongoing electronic communication and individual professional growth. The AISD district-wide effort enhances the professional development of classroom teachers by supporting them in developing skills necessary to utilize Internet to enhance their teaching and to share their plans and reflections with their counterparts in distant classrooms. University seminar presentations by these mentor teachers expanded the learning of preservice teachers and university...
professors in the area of using Internet as a resource. The availability of these resources on the AISD, CCPDC, and TWU web sites supports dissemination and encourages reflective interaction between professional educators locally as well as nationally.

Acknowledgments

Drs. Vera Gershner and Sharla Snider would like to express appreciation to Dr. James Monaco, Superintendent; Deborah Sons, Technology Coordinator; and Marcia Johnson, Staff Developer for Aubrey Independent School District, Aubrey, Texas. Additionally, appreciation for assistance is extended to Diego Morales and the teachers involved in the project in Ysleta ISD, El Paso, Texas. The Director of the CCPDC at Texas Woman’s University, Donna Crenshaw, is applauded for her efforts in providing support for the implementation of this project. Funding was provided through the Corporation for Public Broadcasting and supported through the Ernest L. Boyer Technology Summit for Educators.

Vera T. Gershner is a Professor in the Department of Educational Leadership, Texas Woman's University, Denton, Texas 76204. Tel: (940) 898-2265, fax: (940) 8982224, E-mail: F_Gershner@twu.edu.

Sharla L. Snider is an Assistant Professor at the Department of Reading and Bilingual Education, Texas Woman’s University, Denton, Texas 76204. E-mail: F_Snider@twu.edu
PROJECT STAR: TEACHER-DESIGNED PROFESSIONAL DEVELOPMENT INTEGRATING MATHEMATICS, SCIENCE AND TECHNOLOGY

Gaye Wunsch
Houston Independent School District

In this era of rapidly changing technology, educational adaptation of technological innovations is creating a different role for the teacher. Inservice teacher professional development can no longer be a workshop forum in which teachers are handed “teacher-proofed” materials to take back to their classroom. The “one-size-fits-all” type of learning materials that grew out of the factory model of education has created a monotone in the classroom that students are no longer willing to accept. Modern technology has ushered educators into a new era where student learning can be individualized and integrated with a student’s needs, interests, and skills. This approach to learning can be threatening to teachers who entered the profession with traditional skills and expectations for maintaining a controlled, structured learning environment.

Retrofitting today’s technology into the traditional textbook-based classroom limits the potential for these new tools. A more constructivist model for education has emerged, but if teachers are to understand how to facilitate such constructivist learning, they must be allowed to experience it themselves. Teachers can engage in professional development opportunities that place them in the learner’s role, using technology in all phases of the process. Today’s teachers should view themselves as the head learner in their classroom, serving as a motivator and facilitator of student learning in a more collaborative environment.

Although students are expected to collaborate with peers on a regular basis, such collaboration is rare for their teachers. In the corporate workplace, especially in technologically related businesses, employees tend to work in project teams. Ironically, educators are not usually allowed the same opportunities that they are expected to provide for their students as they prepare them for future careers.

Initial Description of the Project

Project STAR (Students and Teachers Achieving Results) is a technology-based professional development program intended to provide integrated mathematics, science, and technology experiences for all secondary science and mathematics students in over sixty Houston Independent School District (HISD) schools. The project was funded in 1995 by the National Science Foundation (NSF) and Advanced Research Projects Agency, and is managed by the HISD.

Project STAR’s goals and objectives will be met through the implementation of a professional development program that was initially described as train-the-trainer model. After the project was underway, it became evident that a more collaborative approach was needed to provide a more suitable environment for learning. Acquiring technology skills was only a part of the process needed to achieve integration of technology into the curriculum. Eight classroom computer focus centers, containing five computer stations each, provided the opportunity for trained mathematics and science teacher-facilitators to model innovative teaching strategies for fellow teacher-participants. Project STAR is unique in that it is a pilot research project that operates within the HISD school system—the fourth largest district in the United States. Recent project growth is directly attributable to the coordination of area resources in response to teacher-identified needs and evidence of success from the first phase of the project. The project has survived many difficulties and shows great promise for promoting and supporting systemic change.

The development of Project STAR reflects a struggle to provide appropriate professional development within a rapidly changing environment, both inside the classroom and within HISD’s district structure. Although specific conditions and outcomes are beyond the scope of this presentation, the original project goals, objectives, and anticipated outcomes are provided for background information.
Initial Goals
1. Combine the use of telecommunications with model classroom-based science and mathematics professional development and preservice teacher education.
2. Involve the teachers in the continued development of appropriate instructional assessment models using resources available on a district wide network.

Initial Objectives
1. To increase students' academic performance;
2. To increase the quality of mathematics and science pedagogy;
3. To develop advanced telecommunications support and information nationwide; and
4. To provide telecommunications information infrastructure incorporating a wide variety of information technologies.

Initial Outcomes/Expectations
Project STAR participants will learn how to use telecommunication to:
1. develop curriculum units to be placed on-line that address national mathematics and science standards and use available Internet resources;
2. use effective instructional strategies in teaching science and mathematics to their students;
3. incorporate instructional strategies and assessment into the curriculum units;
4. develop teacher training modules using technology;
5. share and enhance curriculum units; and
6. access regional, national, and international sources of information.

Site visits by NSF representatives and HISD’s staff re-evaluation of existing conditions prompted revision of project goals and objectives.

Reconceptualizing the Project

Essential Question
In a comprehensive review of HISD’s existing professional development opportunities for the integration of mathematics, science, and technology, a pattern emerged. As stakeholders discussed conditions needed to fulfill the vision, the essential question for planning became: “How can Project STAR be used to enrich, focus, and extend existing mathematics, science, and technology programs through a variety of human and telecommunications infrastructures?”

Vision
A recent series of collaborative sessions with HISD staff, community corporate sponsors, and area institution representatives produced a vision statement that re-focused the project. It states:

1. As lifelong learners, visionaries, and risk-takers, students, teachers, and administrators live and learn in a technology-rich environment with unlimited access to virtual and actual resources. Students and teachers collaborate with peers and members of other generations while positively contributing to an advancing society.
2. As change agents, teachers and administrators model, facilitate, coordinate and coach individuals in the learning process supported through technology, to empower individuals as lifelong learners. As collaborators, teachers build collegial relationships and an evolving knowledge base so that teaching and learning communities are enriched through peer-to-peer, multi-aged, and intergenerational groups.
3. Administrators actively pursue and foster collaborations that cross boundaries and open doors among schools and the community so that the process of teaching and learning mathematics and science through telecommunications technology is enriched in a global world.

Support Systems
The original plan was for Project STAR to coordinate community input for teachers' professional development and classroom support. Those outside of HISD expressed a desire to help, but felt that coordination was best accomplished from within the district. In response to the essential question, the following infrastructures were identified and will continue to be developed.

Technical Support. To address existing technology support problems through HISD's help desk system, a Project STAR staff member will investigate the nature of support needs as problems are resolved. Data will be used to recommend changes to the technology support process currently in place.

Telecommunications. A district-wide area network of ISDN and T1 connections to all HISD schools provides telecommunications access for teachers to share their work. Through HISD's Wide Area Network, teachers have access to the Internet and e-mail. At least four secondary schools have videoconference labs and all middle schools have CU-SEEEME equipment. The Houston Museum of Natural Science and National Aeronautics and Space Administration (NASA) have established interactive contacts with some schools.

Peer Support. Teachers provide support for one another within the training program, and are showing initiative in working together in other training settings. They need more support in arranging time to work with their planning partners at school, to use the Internet and related computer applications in the development of their lessons, and develop and deliver inservice opportunities for their fellow teachers. Campus principals and administrative district superintendents will be included in the planning process to help teachers acquire training and subsequent planning.
support. For instance, Project STAR is assembling information to circulate one uniform application for all summer training that will be available to secondary mathematics and science teachers and relates to Project STAR’s program.

Organizational. Various departments within HISD and external organizations have begun to work together in addressing teacher professional development issues through Project STAR. A long-term process by which all areas of HISD and interested organizations can work together in an efficient, coordinated, constructive manner will be established with the assistance of upper level HISD management.

**Interim Evaluation**

The initial series of workshops served to improve nearly 300 participant teachers’ computer literacy and technical skills, but more attention was needed in the areas of:

1. Teacher-to-teacher collaboration;
2. Time, equipment, and support for practice;
3. Integration of mathematics, science and technology; and
4. Establishing a safe environment for risk-taking.

**Collaboration and Teacher-efficacy.** Although telecommunications were described in the original project goals and objectives, the role of technology in supporting the collaborative nature of the work was not specifically addressed. Processes for integrating mathematics, science, and technology were also not clearly developed. Initially, there were several hidden learning curves that teacher-participants were expected to navigate with little external support. They were rarely granted extra time during their teaching day to develop and practice new technology skills. Teachers were also fearful of straying from the traditional teacher-directed coverage of standardized test requirements. They were worried about wasting class time with complicated technology-based teaching tools in which they lacked confidence. Those who managed to attain the technical skill level necessary for publishing lessons were uncomfortable with sharing their classroom activities because they were uncertain of the quality of their work. Their confidence was further eroded when NSF site visitation team members criticized practice web home pages that teachers had generated during training sessions as “vanity pages.”

**Focus Centers.** Two focus center facilitators (one mathematics and one science teacher) were designated for each of eight campus research sites. At least one of the facilitators was located in a focus center classroom. Unfortunately, center facilitators were not closely paired by grade level or content. The lack of common students, common concepts, and common planning time made it difficult for the teachers to collaborate in the development of integrated mathematics and science curriculum. However, their shared commitment to provide technology and Internet access for administrators, teachers, students, and parents has made an impact, to varying degrees, on each campus.

**Revising the Project**

A project director was chosen from the original teachers trained to be facilitators in an effort to find solutions to the pedagogical and efficacy issues described above. The project director had previously served as a campus-based science curriculum and technology coordinator. She then developed a more teacher-centered training program using her project experiences, fellow teachers’ responses, in-depth conferences with project evaluators and key staff members, and an informal analysis of the district’s level of success with Project STAR training.

The refinement of Project STAR was guided by several teacher-driven factors:

1. HISD focus group discussions;
2. experience with the Coalition of Essential Schools (CES) Math/Science Fellows;
3. networking opportunities provided through NSF for the new director;
4. planning sessions comprised of teacher-trainers and local university professors; and
5. input from existing professional development programs within HISD’s mathematics, science, and information technology departments.

**Focus Groups.** As part of a restructuring of HISD central support services, HISD personnel from all levels were invited to participate in a series of focus group discussions to determine the district’s professional development needs. The teacher-related issues were closely aligned with the previous experiences in Project STAR. Ultimately, the general “lead teacher” concept developed to implement long term, campus-based teacher support became an element of the prototype for Project STAR’s “coach” training described below.

**CES Math/Science Fellows.** The director and two HISD teachers who were consulting on the project participated in an NSF-funded professional development initiative known as the Coalition of Essential Schools Math/Science Fellows program. The two-year CES training program is a nationally based, resident training model with provision for e-mail communication between participants being the only technology component. CES stresses collaborative and reflective skills for mathematics and science teachers who participate in integrated, investigative learning environments. The former director and lead facilitator for the NSF-funded project participated in a two-day planning conference with HISD and interested Rice University personnel to discuss effective ways to modify the CES model to suit a non-resident, urban setting with a technology-related focus.

**NSF Networking.** The NSF hosted two conferences in 1996-97 that brought together the directors and evaluators
of similar programs. The networking with technology-based research program personnel was instrumental in helping director gain a perspective on Project STAR's level of success and possible future activities. The importance of planned institutionalization was emphasized during these conferences.

**Project STAR Coach Model**

To assemble an effective team of teacher-trainers that functions in a collaborative work environment on individual campuses, mathematics and science teacher-pairs were recruited for a new form of training. The Technology Adoption Life Cycle (Geoghegan, 1994) indicates that teachers in the "early adopter" group have the most potential to be effective as change agents in their schools. Project STAR's application process seeks to identify early adopter teachers for participation in the revised program.

**Philosophy.** The basic philosophy of the training is based upon:

1. Teacher as learner;
2. Technology-rich learning environment for research and skills development;
3. Reflective practice, especially in examining personal professional growth;
4. Peer coaching, across the curriculum and between pairs;
5. Collaborative experiences as a learner and in curriculum development;
6. Investigations that foster the integration of mathematics, science, and technology while meeting HISD curriculum objectives; and,
7. Professional collegiality among participants, professors, and trainers.

**Pilot STAR Coach.** The 15-month Project STAR coach pilot training group began with a weekend planning conference, followed by a three-week summer institute at the University of Houston. The group then engaged in a yearlong follow-up training program. Activities include practice of peer coaching skills and applications of newly acquired content knowledge and skills with the use of technology.

**Summer Guidelines.** The three-week summer institute had three basic training components:

1. **Teacher-as-learner,** with guided technology-based investigations for mathematics/science pairs, led by professors or master teachers. Pre-determined outcomes were based upon sound curriculum guidelines and the basic integration of mathematics, science, and technology.
2. **Teacher-as-researcher,** with some freedom of choice in pursuing self-directed technology-based investigations at various locations throughout the community. Teachers learned how to write and pursue their own research questions in integrated investigative teams.
3. **Campus teacher-pair or team planning** to create classroom lessons using technology that reflect the new Texas Essential Knowledge and Skills (TEKS) competencies and to design campus-based professional development sessions. Teachers practice giving constructive feedback and using a tuning protocol process for refinement of their work.

**Technology Skills.** Training in providing technology-based teacher training on an individualized basis preceded the STAR coach training. The program allowed teachers to set their own pace, choose their particular areas to practice, and bring their own materials to develop. A teacher-curriculum advisor and a teacher-technical facilitator guided teachers in developing their own learning design. A printed guideline of skills provided the teachers with an overview of the types of computer technology skills considered essential to their technology needs.

**Final Products.** A final participant portfolio presented at the end of the academic year will demonstrate personalized professional growth and specific outcomes, including a published web-site lesson.

**Community Collaboration.** Members of the Houston area business and institutional community collaborated with HISD to increase the size and quality of the summer training program. Approximately 120 mathematics and science teachers are on track to become collaborative coach pairs. Some of the 30 pilot teacher-coaches will serve as teacher-trainers in the future. To implement the scaled up program, the University of Houston (main campus), University of Houston-Downtown, the Houston Museum of Natural Science, NASA, Space Center Houston, and SECME, Inc. (a national program to promote minorities in engineering) are joining forces. The University sites will be the main training sites, but teachers will visit the Museum, NASA, Space Center Houston, and City of Houston environmental sites to perform their self-directed investigations. Upon completion of summer training, selected teachers will develop technology-related classroom lessons to highlight the special technology resources at the Museum and at NASA. SECME, Inc. will join with Project STAR's summer training program to develop a new national model for their campus support team training program. Key SECME, Inc. personnel will incorporate Project STAR's technological and collaborative training into their vision for a new national training model for their program.

**Efficacy.** Teachers who have participated in the technology training and the more extensive coach training are very enthusiastic about their experiences. They express appreciation for the professional manner in which they
have been treated, and feel empowered to control their own learning. They have shown insight in the ways they now structure learning opportunities for their students.

**Pre-service Education.** The impact of this type of in-depth teacher development, occurring on the campus of major universities that are engaged in pre-service teacher education, is felt both at the public school and at the university level. Last summer's professors have been strong advocates of the project.

Preparation Teachers for School-Based Technology Leadership

Jacqueline A. Nunn  Sarah McPherson  William D. Rust IV
Johns Hopkins University  Johns Hopkins University  Baltimore County Public Schools

Futurists predict that for today’s students to succeed in the next century they must not only be technologically literate, they must also know how to think and use technology as a partner in their work. School district central office staff can no longer keep up with the demands of individual schools for technology planning, staff training and daily technical support.

Over the past decade, the number of computers and related classroom technologies has increased substantially. In 1987, there was one computer for every 37 students; now the ratio is one to seven (Technology Counts, 1997). While more than half of the computers are located outside of computer laboratories, only 15% of the nation’s teachers have had at least nine hours of technology training (Technology Counts 1997). What can school districts do to prepare teachers to take advantage of the new instructional tools?

This paper describes a partnership developed between the Baltimore County Public Schools and Johns Hopkins University. The purpose of the partnership is to train teachers to become school-based leaders in technology through a 36-credit graduate program in Technology for Educators. The paper is divided into three sections: (a) the setting and the institutions; (b) the development and implementation of the Masters degree program; and (c) the emerging impact of the training effort.

Partner Institutions

The Baltimore County Public School district is the nation’s twenty-fifth largest, comprised of 159 schools spread over an area of 610 square miles. Some of the schools are located in urban settings, others in the suburbs, and still others are rural schools. The district’s Department of Information Technology works with each of the principals to provide technical and curricular support to the instructional program in each of these diverse settings. The Department has established a system of Technology Liaisons, including a representative from each school, charged with providing local support for computer-related instruction.

Technology Liaisons were established for two reasons. First, local ownership of the technology is considered an effective link with the district’s site-based approach of governance. Each school develops and administers a school improvement plan that incorporates technology into the instructional program. In addition, the district office does not have sufficient personnel to maintain a constant presence in each school. The Technology Liaison helps fill the gap. The Technology Liaison approach is limited by the local representative’s technical capabilities and by the ability to encourage and support school efforts to effectively plan and use instructional technologies.

To help address these issues, Baltimore County engaged Johns Hopkins University as a partner in developing the local liaison into a true site-based leader in instructional technology. Located in nearby Baltimore City, the University was prepared to work with the school district to develop a cadre of technology leaders for the schools. The task was consistent with the mission of the University’s School of Continuing Studies, Division of Education which calls for graduate programs that prepare educational personnel to become leaders and change agents, and the development of partnerships with educational institutions. The University already had a well-established graduate program in Technology for Educators administered through its Center for Technology in Education and the existing program provided hands-on course work in technology as well as project-based instruction on curriculum integration.

Development of a Collaborative Cohort

Baltimore County Public School and Johns Hopkins University began work on a new master’s program in 1995. The goals of the program centered on three areas: (a) technical competence; (b) school-based leadership; and (c) the change process. The three areas directly addressed the expressed needs of district schools. Each school required on-site technical support and was charged with incorporat-
ing technology into the curriculum. Faculty needed staff development and support to effect changes in curriculum and teaching methods. The district and the University jointly determined competencies in these areas.

Competencies

Instructional technology administrators from the school system and faculty from the University collaborated to establish the competencies for the cohort students participating in this Master of Science in Education Technology for educators program. Selected competencies were based on guidelines for graduate programs developed by the International Society for Technology in Education (ISTE, 1991) and the Interstate New Teacher Assessment and Support Consortium (INTASC). Competencies were designed to prepare teachers to: (a) plan technology use and provide technology resources; (b) apply research-based principles as effective instructional leaders and master practitioners; and (c) be change agents for promoting school improvement and evaluating school change. Specific competencies are shown in Table 1.

Key Elements of the Partnership

Selection of Candidates

Each candidate selected for this program had to meet the regular requirements of admission into a Johns Hopkins University School of Continuing Studies graduate program, and also had to be identified and recommended by the district and school administration as a master teacher with leadership potential. Further requirements included a minimum of three years experience at the elementary level, advanced computer literacy and demonstrated competence in instruction and classroom management.

Role of Principals and School Improvement Teams

Principals with cohort members who worked in their schools agreed to participate in two seminars per year on leadership and technology. The principals and school improvement teams also agreed to support the implementation of participating teachers' projects within the schools. The seminars served as a vehicle for updating the school and district administrators on the scope and direction of the course content, as well as a forum for presenting projects that incorporated current research about effective technology applications for instruction in schools. Classes and seminars were held in local school facilities, contributing to the authenticity and relevance of course content because students used resources available in their schools to apply what they were learning in the program.

Applied Projects

Cohort members developed projects in each of their graduate courses. Projects were related to the program

</tbody>
</table>
competency areas, including: (a) development of school-wide technology plans; (b) school and district level staff development programs; and (c) evaluation of technology implementation in relation to goals listed in school improvement plans. Components of the projects included applied research, implementation strategies, and evaluation of student learning.

For example, cohort members developed comprehensive plans for opening newly networked buildings and/or wiring plans for distributed networks in renovation projects. The students' plans added the dimensions of examining the purposes and potential outcomes of increasing access to technology and how it would improve the school's instructional programs. The courses in the graduate program provided students with the expertise necessary to take a leadership role in planning for technology, that was critical to the accomplishment of school improvement goals.

Other student projects focused on the integration of technology into the curriculum. In these projects, students demonstrated a thorough understanding of the potential of technology to enhance the curriculum and to improve learning. Students mastered multimedia tools and the Internet, included these applications in instructional units and, trained colleagues in their schools to use these tools. Projects became the basis for school-wide, and often district-wide, staff development workshops.

Building-level administrators benefited from the expertise that cohort members developed as a result of the program. Cohort members reached a level of competence that allowed them to take ownership of technology innovations in their schools, and provide support for implementation of their innovations. The district plan calls for a cadre of trained teachers to serve as liaisons assigned at the building level to facilitate the infusion of technology into schools. The students in this program are prepared to serve in this capacity. They are now armed with skills to make a difference in their schools.

Implementation Strategies that Worked

The cohort program variations were designed to focus on school-wide technology leadership and to develop competencies that prepare teachers to serve as local experts and change agents for their schools and school districts. Several factors led to the students’ development as local experts and change agents. One was the location of classes. Most of the classes met in a local school facility. Field trips to other sites within the district were incorporated into the instruction. This required each of the graduate courses to use the resident hardware, software and network configuration available in district schools. Using the local schools also provided cohort members an opportunity to evaluate district-wide issues, such as: age and condition of building; feasibility for wiring, networking and upgrading equipment; expertise of administrators and staff; resources for procurement of wiring, hardware equipment, software and training; and parental expectations and support for technology in schools. District and building level support were key, not only for accessing the district facilities for course instruction, but also for providing information regarding plans for infusing technology in schools throughout the district. The district-level leadership for technology plans to use graduates of this program for key positions in Technology Literacy Challenge funds and Goals 2000 grants.

Personal characteristics of the cohort members was also a second factor that contributed to their ability to become experts and change agents in their schools. Demonstration of leadership potential was a criterion for an invitation to apply. Therefore, the students were highly motivated to become leaders, having already been identified by their principals as showing leadership qualities. Students were also intrinsically motivated and curious about the benefits of technology. They had the urge to be creative and the desire to be innovative—characteristics critical to technology leadership in schools. As evidence of the success of the program in preparing technology leaders, two students in the program have been recognized as Baltimore County Computer Educators of the Year by the Maryland Instructional Computer Coordinators Association for their site-based technology leadership.

Diverse thinking and leadership qualities of the students were the third and fourth factors in the success of the program. Although cohort members were primarily elementary teachers from a single school district, they used diverse applications of the theories and research presented in courses in their teaching environments. Courses were developed and taught by University faculty and adjunct instructors with experiences from districts outside of Baltimore County. Assignments were designed to develop new skills and understanding for individual students and to facilitate the application of those skills and knowledge in their own teaching situations. Cohort members exercised their leadership skills at the building level to obtain resources and the principals’ approval to complete the project assignments.

Challenges to Anticipate

Instituting a graduate program in partnership with a local school system brings a set of challenges to both parties. The university standards for admissions and tuition rates must be factored into the partnership negotiations. The university must be willing to customize a program and commit resources to deliver the instruction, as well as to establish and maintain collaboration with the district and building level administration. The school system must commit to providing the facilities and technology resources for the program. Both institutions expose themselves to the political implications of a partnership, as well as to internal political ramifications that may arise from the process of
selecting students, locating sites for classes and providing technology resources.

Time is another challenge for a cohort of students in any graduate program. To complete the program according to the schedule, students were required to complete 12 credits per year for three consecutive years. This is a rigorous pace, in terms of both time and money, compared to the typical master's student who is allowed, and often needs, five years to complete the 36 credit requirement. Classes were held after school when teachers are tired and in the summer when their families and colleagues are on vacation. The new knowledge the students acquired brought new demands on their time and responsibilities for technology advancements within their schools that competed with the program for the students' time and attention.

There is often mobility in assignments within school systems. Mobility presents challenges in that teachers get assigned to schools where they have neither the commitment of the principal nor the technology resources for carrying out their technology implementation plans. They may be required to work with novice staff to develop grade level team instruction that does not include the use of technology. The new school may have other priorities for school improvement initiatives.

These challenges routinely face districts and universities that initiate special programs for cohorts of students from a single district. A customized graduate program can address these issues and provide support to the students and to the partnering district. The problem-based learning format then becomes a solution to the challenges presented in the authentic context of working within a school district.

Collaborative Curriculum Development: Computer Education for Preservice and Inservice Teachers

David L. Breithaupt
North Carolina A & T State University

One challenge facing today's teacher education programs is how to teach student teachers to effectively use computers to support the curriculum. Equally challenging is the task of teaching inservice teachers to integrate computer technology into the curriculum. While computers have revolutionized business and industry, education has been left behind (Bell & Elmquist, 1992). Though many factors limit teachers' use of computers as an instructional tool, computer education for preservice and inservice teachers is a critical component of successful integration (Office of Technology Assessment, 1988, 1995).

This paper describes a project designed to help student teachers and inservice teachers work together to integrate technology with their instruction. In this project, student teachers and inservice teachers were, paired into student/mentor teams. Student teachers had some experience with their university coursework. Prior to participating in this study, secondary education student teachers completed a core computer course and a computer programming assignment during their teaching methods course.

During the junior and senior years of their undergraduate teacher education program, the student teachers were required to complete a core computer course in the use of computers in their curriculum. The core computer course introduced the student teachers to the operation of computers, software selection, and basic computer programming. During their teaching methods course, the student teachers received instruction in using computers in the curriculum, including instruction in the various types of educational computer applications, programming techniques, and the use of multimedia authoring systems. The student teachers then completed a discipline-specific computer programming assignment as part of a multi-disciplinary group of students (Breithaupt & Wentworth, 1996).

The inservice teachers did not necessarily have a background in computer-based instruction, but were selected because of their desire to learn to use computers to support their curriculum. Student teachers were paired with an inservice teacher and they collaboratively developed computer support for the curriculum during the student teaching practicum. The collaborative effort was support by faculty, staff, and graduate students at a large private university through the structure of a school-university partnership.

A resource team provided support to the student-mentor teacher teams' efforts. Participation of resource network consultants was unique depending upon the needs and requests of the individual student-mentor teacher teams. Most of the resource network consultants worked with one set of student and professional teachers, while a few assisted several of the student-mentor teacher teams.

Outcomes

Participation and experiences of each student-mentor teacher team was unique to that pair of teachers. While not every teacher became an expert in computer integration into curriculum, each made progress towards that goal. Teachers who did not use computers prior to this study learned to use them for classroom management and World Wide Web searches, and began discussing the use of computers for instructional purposes. Similarly, teachers who were already using computers as a management tool began assigning computer-based and web-based projects for their students and sought other methods for increasing the instructional use of computers in their curriculum. Finally, teachers who had already used computers to support their curriculum learned new programs, new methods, and launched development efforts for new computer-based curricula.

Support from the university was not limited to helping teachers learn to use the World Wide Web and multimedia authoring programs. Nor was it limited only to helping teachers understand and apply computer-based instructional methods to their curriculum. Support from the resource network and the university also included help obtaining grant funding for new curricula, site visits to help school and district media personnel support the new curricula.
technologies, and setting up and maintaining a listserv for teachers in the same teaching discipline.

An unanticipated outcome was identified by the inservice teachers. Because the student teachers began their student teaching practicum having already received a strong background in computer use and integration into curriculum, they became the more expert member of the student-mentor teacher team. The inservice teachers reported that, although they could not have done anything new with computers without the support of the resource network, they learned more about computers in the curriculum from their student teacher than from any other source. At the same time, the student teachers were benefited by receiving guidance from their experienced mentor teacher on using their computer skills in the classroom.

Not all teachers were willing participants in the project. A high school math teacher hesitated to participate in the study until directed to by district administrators. Despite the request by the district, this teacher refused to be contacted at school and attended only one meeting with a resource network consultant. The teacher discontinued participation near the end of the study, saying "I see no need for further participation [because] I really see no connection between computers and algebra."

Discussion

This project combined the development of computer supported curriculum with teacher education and professional development. Previous efforts to teach computer integration in curriculum have separated the education of student teachers and professional development of experienced teachers. Simultaneous teacher education and professional development has the potential to streamlining the process and yielding improved results.

Student teachers filled a valuable role in the Instructional Technology Integration Model. They brought the latest teaching methodology and their experiences using computer-based instructional methods to the student-mentor teacher teams. This helped the inservice teacher learn new skills and develop professionally. The inservice teachers brought their classroom teaching experience from which the student teacher drew guidance for the development of their computer knowledge and skills. The resource network consultants provide specialized knowledge and skills which were often beyond the scope of that required of a typical classroom teacher.

The results of this project indicate that collaborative curriculum development can be an effective method to teach student and inservice teachers to use computers effectively to support their curriculum. In addition, student teachers provide effective computer support to the inservice teacher they are working with. There appears to be promise for future work in collaborative curriculum development and instructional technology integration in the curriculum.

Organizing an Effective Multi-District Professional Development Program

Stephen Canipe
Guilford County Schools

Michael Parrish
Guilford County Schools

Conducting an effective staff development program that addresses the needs of a district's administrative guidelines is a difficult process. When you combine five school districts, each with their own individual needs, the task becomes gargantuan. The ABC Technology Consortium consists of five school districts and has, as its underlying foundation, the idea that students can achieve more when exposed to technology-rich lessons. What was needed was a program to train teachers how to create these lessons.

A program to address these needs was developed in the Summer of 1997 when representatives from five school districts (Guilford County, Person County, Stokes County, Surry County, and Wilkes County). In North Carolina, school districts are generally comprised of a county and all the towns and cities within the county. There is a large degree of state funding and state control and the State Board of Education has legal authority to replace a local principal of a school if students do not perform up to an expected standard. These five districts developed guidelines for summer training as part of the Federal Innovative Challenge Grant Program. The five districts formed a partnership called the ABC Technology Consortium and received a $4.9 million grant to be paid over five years. Phases of the grant included infrastructure creation, staff development, lesson development, and creation of a central repository of materials and best practices. Each aspect addressed one goal for improving student performance on North Carolina End of Grade Tests in reading, writing, and mathematics. Students in grades three to eight were the target audience. Results of the Summer of 1997 work can be found at: http://www.guilford.k112.nc.us/abc/home.html — under Thematic Units.

Planning Process

The first step was to get teacher representatives together to discuss and outline the nature of the summer program. Consortium districts sent key teachers and curriculum leaders to a session in April to begin planning. After much discussion and consideration of possibilities, these representatives came up with a tentative format for summer training that addressed issues of empowerment, networking, consistency, technology-rich learning, and the schools' professional environment.

Empowerment was deemed an important issue because there was a feeling that teachers are too often the last to know what is happening and why. The five counties encompass an area of about one-hundred and fifty miles from east to west. Teacher empowerment helped guide the discussion of how training sessions should be structured. The physical separation of project participants meant networking would be especially important to ensure communication among representatives from the different counties. Consistency also has implications with the multiple county nature of the grant. Technology-rich units were developed based on several factors: constructionist approaches, Gardner’s Multiple Intelligence Theory, and thematic integrated design.

It became obvious from discussions with the planning group that teachers who would participate had not had sufficient technology training to feel comfortable with either the process or the equipment. With this in mind, workshop training sessions were planned. Training consisted of general Internet sessions, sessions on HTML for creating web pages, and sessions on using a web browser (Netscape Navigator Gold). After they had received training, participants were instructed to create units of study that incorporated highly individual and interactive webpages for their lessons.

The issue of professionalism goes hand in hand with the empowerment issue. The planning team advised that teachers often have been called upon to perform a task without being treated in a professional manner. To address this issue, the current training included snacks, catered lunches, notebooks, and pens—items that are common fare in business training sessions. Effort was made to make the nature of training business-like and professional.

Underlying Concepts

Teacher representatives thought that each participating teacher should have a common understanding of the concepts underlying the training. From discussions it
became obvious that there was a wide gap in background knowledge even among the curriculum experts. Based on this input some background information was provided for each teacher.

Constructionism involves going from the general to the specific as students build knowledge structures. According to Harel and Papert "If one eschews pipeline models of transmitting knowledge in talking among ourselves as well as in theorizing about classrooms, then one must expect that I cannot tell you about my idea of constructionism. Doing so is bound to trivialize it. Instead, I must try to engage you in experiences (including verbal ones) that encourage your own personal construction of something in some sense like it. Only in this way will there be something rich enough in your mind to be worth talking about." An example of this process would be the study of circuits in a science class in which students are given bulbs, wires, and batteries and are asked to make the bulb light in as many different configurations as possible. After they have explored and constructed a personal knowledge base, they can then study serial and parallel circuits in a more formal manner. This approach allows hands-on, active learning.

Howard Gardner has defined intelligence as the capacity to solve problems or to fashion products that are valued in one or more cultural setting. This pluralistic view of intelligence suggests that all people possess at least seven different intelligences that operate in varying degrees of intelligence. The seven intelligences identified by Gardner are described below and the general characteristics associated with each of these intelligences were provided to the teachers.

1. **Linguistic intelligence** refers to an individuals capacity to use language effectively as a vehicle of expression and communication (Examples: poets & writers).
2. **Logical-Mathematical intelligence** refers to an individuals capacity to think logically, use numbers effectively, solve problems scientifically, and discern relationships and patterns between concepts and things (Examples: mathematicians and scientists).
3. **Spatial intelligence** refers to the capacity to think visually and orient oneself spatially. In addition, spatially intelligent people are able to graphically represent their visual and spatial ideas (Examples: artists, decorators, architects, surveyors, inventors, and guides).
4. **Musical intelligence** refers to the capacity to appreciate a variety of musical forms in addition to using music as a vehicle of expression. Musically intelligent people are sensitive to rhythm, melody, and pitch (Examples: singers, musicians, and composers).
5. **Bodily-Kinesthetic intelligence** refers to the capacity of using ones own body skillfully as a means of expression or to work skillfully to create or manipulate objects (Examples: dancers, actors, athletes, sculptors, surgeons, mechanics, and craftspeople).
6. **Interpersonal intelligence** refers to the capacity to appropriately and effectively respond to other people and understand their feelings (Examples: sales people, social directors, travel agents).
7. **Intrapersonal intelligence** refers to the capacity to accurately know oneself, including knowledge of ones own strengths, motivations, goals, and feelings (Examples: entrepreneurs, therapists, etc.).

Integrated thematic units involves integrating several subjects to cover a broad topic, with a focus on connections between ideas. For example, the broad integrating topic of differences allows a teacher to draw on several curriculum areas in addressing the topic. In mathematics, differences in numbers, operations, and functions could be examined. In science, the differences among the plants and animals, terrain, or climates could be covered. In social studies, differences in countries or people could be addressed. And in communication skills, the differences in parts of speech, readings about differences, and observations of different story types could be used. It should be apparent that this broad topic allows many different areas to be under the umbrella of differences.

Several thematic ideas were mentioned as possibilities for the participants to consider as they thought of their particular unit plans: conflict, leadership, continuity & change, communities, patterns, systems, relationships, beginnings, balance & stability, communication, interactions, and diversity.

**Implementation**

After all of the above factors had been considered it was time to actually select teachers from the various districts to participate in the program. Each county in the consortium had one representative on the Consortium Board who was instructed to select from their county those teachers who had the greatest curriculum knowledge in specific areas. Each county had teaching superstars and through a process of negotiation, the broad range of teachers and disciplines were selected.

Six days of professional development and lesson writing were planned. Part the first day would be used for introductions and expectations. One day would address Internet basics and the remaining time would be used for development of content and demonstrations. The introductory training was also used to secure free e-mail accounts for each participant. Ultimately each county would have an e-mail server as part of the grant, but these servers were not in place when training began.

Teachers were divided into grade level groups, 3-5 and 6-8. In these groups, they examined test results from previous years to see which specific objectives from the North Carolina Standard Course of Study (state prescribed
curriculum) were not adequately met. The groups then decided which units they wanted to write. At this point they had two options: (a) they could write unit plans first and go to the Internet to find appropriate links, or (b) they could use the Internet as a source for ideas and then incorporate these ideas into the unit plans. Each approach worked well and groups used one or the other based on personal preference and previous experience.

**Next Steps**

The next step for the ABC lesson development project was to interface with the Learners' & Educators Assistance and Resource Network of North Carolina (LearnNC). LearnNC is a professional development and support program for North Carolina teachers and administrators that is intended to help transform K-12 instruction, delivery of instruction, and learning. LearnNC is housed in the Institute for Academic Technology (IAT) which is part of the University of North Carolina at Chapel Hill. The task this group selected was to create a database of teacher lesson plans for teachers throughout the state to use. This project was funded by business and industry and by the NC Department of Public Instruction and will be available to teachers within the state free of charge.

LearnNC will also provide a communication network to support collaboration among public schools, higher education, parents, the community and business. LearnNC will help educators infuse technology into their teaching and learning by doing it, rather than by being told about or trained in it. It is hoped teachers will change the ways they think about learning and instruction and the ways they structure learning experiences. As teachers and teaching change, LearnNC will become an instructional and resource network.

The design of LearnNC simply stated is to:
1. Serve all schools regardless of their infrastructures.
2. Fit the work schedule of teachers.
3. Provide just in time access to materials.
4. Facilitate collaboration.
5. Accommodate different learning styles.
6. Become a set of community network services.

The goal of ABC is to utilize the LearnNC delivery system to make units of study available across the state and nation. LearnNC has agreed to allow ABC materials to be fully accessible to any browser. In addition, there will be a high degree of collaborative activity within the state and across the nation fostered through this relationship.

**Future**

One of the goals of ABC is to raise test scores among low performing students. Several things will need to occur for this to happen. One is the provision of new lesson materials that address different learning modalities. The second area is the availability of materials as needed. In other words, we must expand the school day. To do this we propose making our materials available on the Internet so that students can access them from home, public libraries, community centers, or wherever they can find an Internet connection. Our materials must be produced in such a way that they can also be transported home on laptops, PDAs, as CDs playable on home gaming stations, videotapes, etc. Multimodal must be our byline for all materials developed.

With the availability of increasingly complex technology, there will be a continuing need for staff development and training. The ABC Consortium has a goal of helping keep over 1,500 teachers abreast of changing and new technologies to help students learn. This is ambitious, but with teacher involvement and energetic trainers it is an achievable goal.

One of the ways that we plan to reach out to all the grant schools is utilize video delivery of staff development. The use of video conferencing collaborative professional development activities will be used for all the grant schools. This process will also enable the replication of activities in each school district and in each school whether a part of the grant or not.

Ongoing evaluation of the training process has begun and preliminary results indicate a high degree of acceptance of the process and a high degree of satisfaction with the results. Time will tell whether this degree of satisfaction and acceptance will be replicated in the entire teaching population of the grant schools.

For the past year, teachers, parents, and students at Our Lady of Grace School have identified technology as a curriculum focus and taken steps to collaboratively integrate technology throughout the school. The challenges and aspirations of this endeavor, with no extra funding and in a low socioeconomic area, will be shared in this paper. In a social context of cutbacks and restructuring, this has been a timely exercise which will be of particular interest to administrators seeking a comprehensive approach to using school-based planning to help teachers integrate computers into their instruction.

Our specific context is a school with a collective low self-esteem, yet with a deep spiritual commitment to children and to each other as a community. The pervasive mood that “we never get anything” was expressed in the Parent Council school-wide phone questionnaire that identified technology as a curriculum focus. It was at this point that I was called in an advisory capacity as the board Computer/Curriculum Consultant. I was later hired as Vice-Principal at Our Lady of Grace School.

We were “starting from scratch” with computer literacy. Our focus for the first year began with the basics. We needed to develop the expertise to pursue the identified school focus. We had been persistent in acquiring, over a period of three decades, a school gym, library and two new classrooms.

Given a vision this school had already proved it could be persistent.

Key Features of the Model

The key premises of this model are three-fold and are fundamental to the implementation of this initiative:

1. The plan is comprehensive and spans three years. One key premise centers on the integration of Computers Across the Curriculum (CATC). Using technology in a concept-based integrated curricula offers the learner meaningful connections between academic subject matter and the inquiry into a problem. This means that teachers are looking for ways to ensure that the use of computers is first and foremost connected to classroom curriculum.

2. The process, when using computers in schools, needs to be collaborative. Students and teachers can become more comfortable, and gain new perspectives, methods and shared materials, when usage incorporates partnerships and practical, hands-on activities.

3. The product needs to be integrated across the curriculum. Peer work that allows student experts to pass knowledge on to others enables them to better internalize, connect and understand.

School-Based Computer Planning

There are many components of school-based computer planning which cannot be addressed in this short paper. The components which are highlighted here were foremost in our planning.

School-Based Planning Initiatives

The first stage in planning school-based curriculum initiatives for the implementation of computers across the curriculum was to develop a school Computers Across the Curriculum plan. Collaborating with partners and in divisions around integration of computers and competencies, identifying student skills & learning outcomes and determining fit with in-class curriculum began intensively in August and September, and was ongoing throughout the following months.

Curriculum Continuum within Divisions

The primary division began with graphics. This lent itself very well to integration with other activities in their classrooms. Teachers incorporated student drawings with journal work and themes while encouraging exploration of the drawing software capabilities.

Junior and intermediate divisions identified word processing as a practical beginning point that would readily integrate with existing writing and research projects. Specific skills and sequential activities were used to bring our students through “the basics” of word processing. The activity also included a classroom application. For example, a skills activity included editing a piece using different fonts and styles. A follow-up would involve applying this in their own short story. The intermediate division also worked with graphics programs.

With much discussion, guided by the School CATC team, a three-year computer plan was fleshed out in late
November. Curriculum initiatives and student outcomes were identified in the plan. These were worded in terms of demonstrable skills which were curriculum-based, rather than software-based. We began to consider what our process for evaluation might look like.

We began implementing a student-based program and student progress became evident in their confidence and in the products they were producing. Parents were getting excited and thought “we had arrived.” But I had news for them! Two other components were beginning to emerge—teacher access/literacy, and hardware and software needs.

**Teacher Access and Literacy**

Professional development was tailored to meet the curriculum and teacher use initiatives identified in the school plan. Included were areas that all teachers would participate in (like word processing, graphics and desk-top publishing); areas of special interest to some teachers like curriculum planning and reporting; and areas to help students in the classroom like Internet usage and multimedia presentation software (see Lesson Plan page, http://libits.library.ualberta.ca/library_html/libraries/coutts/lessons.html).

We have developed several useful strategies to maximize inservice frequency and effectiveness such as frequent mini-workshops, held after school in conjunction with professional development days throughout the year; teachers becoming “teacher experts” in particular areas; and, on “snow days,” grouping children so that some teachers receive inservice while others supervised.

**Community Partnerships and Special Projects**

From the outset, we were on the lookout for special opportunities which could excite the interest and involvement of many people. We wanted projects that would tie in with our own local needs and would be authentic learning experiences for the students.

We were fortunate to be approached by Apple Canada and have been developing this relationship. We plan to share what we learn about how children use Apple’s new personal eMate computer in their daily routines. We placed two in the primary area and two in the junior area to try to provide access to all students in the school. In addition, this corporate partner will provide initial components of a multimedia and publishing workstation.

Our local community library invited us to participate in an application for Internet access which would be shared in community settings. I was most surprised to note how much more impact that invitation had on our Parent Council than did the corporate partnership. I was emphatically reminded of Chris Dede’s thesis that model of distributed learning, locally developed through the community, is in the very best position to meet the needs of the low income locality and to help districts leverage their scarce resources for innovation.

Parents play an ongoing role through the school-based computer planning process. Our Parent Teacher Association has been very active and became involved in one of this year’s key special projects. We are producing and publishing a school recipe book as a fund-raiser. Every student in the school is word processing his or her own recipe. Student experts then insert recipes from disks into a FileMaker Pro template which will allow students to record a voice message with each recipe. This recipe book will also be a slide show in which you can use a button menu to find and select a multimedia recipe. A cadre of parent volunteers from parent groups will provide much needed additional supervisory support throughout this lengthy process.

**Acquisition of Resources and Equipment**

Computers in the school were configured in a small lab of fifteen workstations. We had identified January as our target to begin Internet access and the use of our multimedia-publishing centre. We needed four workstations for our four ethernet drops and additional ethernet drops and a workstation in each of our new intermediate classrooms.

A target pupil to computer ratio has been set at 3:1 at the elementary level in the province of Ontario. Funds to reach these targets have come in the form of Ministry of Education GEMS grants to meet the needs identified in the school plans. We hope to get funds for additional computers through School Parent Council and CPTA fund raising.

It now became evident that in about one more month most of the students would be ahead of the teachers! We had one Powerbook to be shared amongst 14 teachers. Paul Gilster (1997), warns us that we don’t need a top-down decision to put a computer on every student’s desk, we need to put a computer on every teacher’s desk! We decided to make use of school budget program resources to plan for this need.

**Evaluation**

It was important that we establish clear criteria for the evaluation of the plan. What is success going to look like, who is going to measure it, when is it going to be measured and how are we going to follow up? We developed and set up a system of portfolios and diskettes for each student in the school from grade one to grade eight. These folders contained samples of the work each student did on the computer, both in the computer lab and during other computer times. Student evaluation also included a Skills Checklist with skills that were identified by teachers within each division.

An integration planner for each teacher or grade described the ways in which computer activities were connected with the classroom curriculum (themes, units, journals, research, inquiries, content and process, etc.). The integration planner also identified learning outcomes which were addressed.
Special Projects

Some of our special projects address technology use from a Christian perspective. We are a pilot project school working to identify appropriate and effective Christian Software. We are also forming an Internet subcommittee of the Parent Council to identify the most appropriate and effective Christian Internet sites.

In some ways, the current condition of educational computing is dishearteningly similar to what it was in the early 1980s. Now, as then, too many teachers have had little or no experience in using educational technologies. In spite of a constant flow of literature and advertising extolling the potential benefits of new technologies, teachers have not been adequately prepared to use them. Nor have most teachers been convinced that it is in their, and their students', best interests to do so. It may be true that many teachers have made great progress and are now using computers in wonderfully valuable ways; however, in almost every school we visit the situation is the same: the majority of teachers have not received even the minimal preparation necessary to operate their computers or use them effectively in their teaching.

A second similarity helps explain this lack of preparation. During the first few years, few microcomputers were available to schools and, consequently, most were placed in individual teachers' classrooms. Toward the middle of the decade, schools began investing more resources in purchasing computers and they tended to put all the computers in computer labs, moving those that had previously been in classrooms. This move has been explained in different ways: as an effort to ensure equitable use of the technology by all children; as the easiest way to deal with the problems of managing the machines and children's learning; or as a response to teachers' inability or unwillingness to use them in their own classrooms (Tucker, 1986).

Computer labs made the technology more manageable, but they also isolated it from the classroom, and decreased the likelihood that its use would be integrated with the rest of the school curriculum. Many teachers were unaware of what their students did in the computer lab. More recently, a combination of dissatisfaction with this separation, together with an ever-increasing number of computers purchased for schools, has given rise to a new push to "integrate" computers into teachers' classrooms. Many, if not most schools are now in the process of installing one to four computers in some or all of their classrooms.

The main challenge is that most teachers are no better prepared to have computers in their classrooms than they were in the early '80s. The intervening years, while computers were in labs where special teachers were responsible for them, did nothing to help educate classroom teachers about effective instructional uses of computers. Many have argued that the educational technology movement was likely to fail unless every teacher learned certain fundamentals about new technologies, including how to operate the machines, what software was available and what its potentials were, how software can be used to support the curriculum, and ways in which new technologies may transform school curriculum. In an October 1997 address at Columbia University, Vice President Gore clearly articulated the pressing need to educate not only those teachers already in schools but also the two million new teachers who will join the teaching force in the next few years—who are also poorly prepared to use technology in their teaching.

The challenge presented by the migration of computers from labs to classrooms is also a great opportunity for educating teachers. It becomes painfully obvious to teachers that they need all the help they can get to figure out what to do with these machines which have been placed in their rooms. Some supporters of classroom technology have recently presented theories of stage development in which simply having computers in the classroom pushes teachers from didactic to constructivist teaching (Sandholtz, Ringstaff, & Dwyer, 1997). But it seems much more likely that the machines alone are an insufficient spur, and that teachers need the help and support of others—peers, colleagues, administrators, and outside facilitators.

At present there is a broad consensus that we should invest heavily in wiring schools so that everyone will be attached to the Internet. Along with the push to acquire machinery for the classroom, this shows our national willingness to support educational technology, at least to the extent of supplying the hardware (McClintock, 1997). But there is (and always has been) less support for educating teachers so that they will be in a position to determine goals for instructional uses of technology. These goals should include not only how the technology can fit into, or
integrate with, existing classroom curriculum, but also how it can help shape curriculum in the future. For this task teachers need a certain degree of expertise.

We started the Center for Technology and School Change at Teachers College in order to work directly with schools and districts to help them achieve the goals of successful technology integration through knowledgeable teachers, and to study the ways in which technology is changing, or is likely to change, school life. Although our program has taught graduate classes and workshops in educational technology for twenty-five years, we felt that this mode of operation did not have enough of an effect on schools. We decided to work directly with schools through grants and contracts. We are presently engaged in projects with about twenty-five schools in the New York area: helping plan for the use of technology; helping elaborate educational goals and develop projects which will help them reach those goals; educating teachers about technology; assisting teachers in the classroom implementation of projects; and assessing the effect of technology in schools.

Schools of the future must plan for the effects of new technologies in at least three key ways. First, all students and teachers must become conversant with new meanings and uses of information so that they can take full advantage of information technologies. Schools should also create and foster their own technology cultures in which everyone shares the same general knowledge and usage of a commonly chosen set of tools. Finally, we should aim to use these tools to create a standards-based problem-solving curriculum, one in which students use sophisticated new technology tools to identify and solve meaningful and interesting problems.

Schools will benefit from university/school collaborations like the project we have developed. Although we do not want schools to depend on the efforts of outside facilitators, at this point in time and based on the historical evidence of the past fifteen years, it is clear that schools are not likely to integrate effective uses of technology themselves. Such collaborations are necessary and highly desirable because they can add a tremendous amount of excitement, energy, knowledge, and new perspectives to both parties in the collaboration. The primary question for us has been how best to work with schools to further our vision of the role of technology. In this paper we share some of what we have learned so far.

The Culture of the School

We begin with considerations about the school itself rather than with technology because the school is the more important. Although it may be true that, technology shapes our civilization, in our immediate world it is the inner workings of schools that determines the role of technology.

Schools have a long history of adapting instructional uses of technology to fit with existing practices. In spite of prophecies that film, radio, television, and other devices would revolutionize schooling, schools have instead managed to shape uses of technology and make them another tool to support what we now call traditional instruction (see Cuban, 1986). Despite the bandwagon type popularity of the Internet and its World Wide Web, what assurances do we have that schools will not have the same effect upon them as on past technologies?

For too long educational technologists have tended to assume that, because a technology had a certain set of potentials, simply dropping it into schools would actualize those potentials. As historians Carey and Quirk (1970) put it: "At the root of the misconceptions about technology is the benign assumption that the benefits of technology are inherent in the machinery itself so that political strategies and institutional arrangements can be considered minor." (p. 396) They were speaking of hopes and expectations for electricity at the turn of this century, but the same can be said about educational expectations for the radio or the computer.

The time has come for educational technologists to take the culture of schooling more seriously than we have in the past. Failure to consider this culture has been the cause of much of the failure of technology, as it will likely be in the future. The culture of the school encompasses many elements including the expectations and political skills of its leadership, the overall educational philosophy, personal relationships among those who work there, the nature and expectations of the student and parent body, and much more. All of these affect how technology will fit into the daily life in the school.

Moreover, each school is unique. It is true that schools in a given district, or perhaps even American schools overall, tend to resemble each other in many ways. Nevertheless, beneath this veneer, exist numerous and often subtle differences. Each school has its own history of how it deals with innovations, its own patterns of relationships that determine how and if innovations succeed or fail. Further, schools are not static entities — changing relationships, new leadership, and a myriad of new conditions, help determine how a school evolves.

There are several implications for those engaged in planning for technology innovation in a school. First, one must clearly understand the conditions that contribute to the school's culture (including the educational culture, moral culture, interpersonal culture, etc.). A second implication, is that we are in need of research that shows how technologies get integrated into the life of the school—particularly observational, ethnographic studies of classroom and school life. We need to understand more about the personal and inter-personal dynamic that accounts for success of new technology in some cases and failure in others.

A third implication has to do with a school's curriculum and pedagogical practices. These are at the core of a
school's culture, often so deeply embedded in its fabric that they seem nearly impossible to change at all. Yet, many school districts have placed computers in teachers' classrooms and expected "systemic changes" to occur in curriculum and instruction without other interventions. What can districts reasonably expect except the subversion of the technology into the existing practice of schools? How can administrators, district officials, technology coordinators, or outside facilitators work to change this culture? The answer lies first in understanding the existing culture and studying carefully the possibilities of new technologies for affecting the desired change.

**Curriculum and Technology Goals**

Since the microcomputer entered the school in the early 1980s, many educators have placed great hope in the possibility that it would transform teaching and learning. Several software applications were supposed to effect this revolution including: LOGO and the teaching of programming, the use of simulations, and students becoming mini-scientists by collecting and analyzing information with database managers. Each little cycle of hope and subsequent disappointment led to questions of when, or if, computers would ever fulfill their potential.

It is important to be clear about just what this potential is supposed to be. The excitement generated by technology in the minds of educational reformers has rested on a vision of schooling that emphasizes that students are active learners, and that teachers are moving from a reliance on lecturing to more of a facilitating role (see Sandholtz, et al., 1997). This is a constructivist vision in which students take initiative in asking questions, gathering information, solving meaningful problems, communicating with others, and constructing their own knowledge of the world. This occurs with the help of teachers, other students, and the environment.

From the beginning, there have been problems in connecting technology with this vision of schooling. First and foremost, it ran head-on into a reality of schooling that was much different. Our dominant "factory" model of schooling proceeds from diametrically opposite assumptions and tends to apply technology in ways that reinforce it, such as drill and practice programs that are similar to workbooks. Further, the vision and its assumptions were never articulated clearly enough, so that it has been easy for schools to blend elements of the constructivist with the factory model so as to defuse any transformative power the technology might have.

The result has been that teachers are unclear about what it is that the new computers are supposed to accomplish, or why it is important that they be used. What they read or hear about does not fit with the reality of their classrooms, and so teachers' first reactions are typically to send children to the back of the room to use a math or language drill program.

Those of us who espouse a constructivist vision of schooling must be clear that what we need to focus on is not just the question of how to use a computer, but what we want education to look like and what is best for children. We can come at this question from two sides. If we begin with a clear vision of what we want education to be, then we can think more clearly of what technological applications can support it. But it is also possible that technologies support a constructivist view of teaching, and that teachers will come to a constructivist view through using computers in their classrooms (Sandholtz, et al., 1997).

In either case, we must work both sides of the equation. We need to show teachers the power of computer applications and also link these applications with clear curricular and learning goals. We must do a better job of fusing curricular goals to technology applications in ways that begin to demonstrate the power of the technology to implement new visions.

**Working with Teachers**

Based on the above considerations, we offer a set of strategies for collaborating with schools. We do not present these as definitive, but as a set of working strategies based on our experience and our study of technology in schools.

**Developing a Common Culture**

To the extent that a school works to create a common technological culture, its chances of institutionalizing technology-based change are enhanced. One of the ways in which outside facilitators can best serve the interests of a school is to provide a holistic, relatively objective, look at the school—its culture, history of successes and problems with technology, and configurations within the school that offer promise of desired change. This can provide a solid basis for helping a school assess itself (as far as technology is concerned) and develop a realistic plan for integrating technology. This plan can provide a process for educating faculty and students in the use of a common set of tools.

**Integrating Technology Skills with Curriculum.**

Teaching teachers necessary computer skills has loomed large in the brief history of educational computing. Teachers are thought to lack skills including managing an operating system and using tools like spreadsheets and desktop publishing programs. Too often; however, training in these skills has proceeded in a curricular vacuum, with little or no reference to how the skills are relevant to what teachers do. The consequence has been that teachers rarely transfer skills learned in isolation to classroom instruction. For example, teachers need to see how a spreadsheet can be used to manipulate numbers and charts to promote sophisticated thinking and problem-solving strategies. This approach not only motivates teachers to learn how to use tools, but helps them think about how they can enhance their curriculum.

**Projects.** Planning for implementation of technology can begin with designing interesting and worthwhile
projects. Projects can be interdisciplinary and should involve the use of several kinds of technology-based tools including programs for planning, data gathering and analysis, production, and creation. For example, some students have developed projects on immigration and family histories using tools like hypermedia presentation programs, spreadsheets, and audio and graphics software. Other good beginning projects include creating a school store, publishing a newspaper, or creating a virtual class zoo. Some of these were existing projects or ideas, which have been enhanced through technology. For some teachers, this use of technology may help them consider new ways of structuring curriculum. In either case, a project approach can help teachers see the value of technology.

Individual Planning. In politics and environmental work, we have heard the phrase “Think globally, act locally.” The same is true at different levels of introducing technology to schools. The school can be thought of as the global unit of planning and implementation and individual teachers seen as the local factor. Not only is each school unique, but each teacher within a given school is unique. Each teacher has an individual level of knowledge about technology, attitude toward technology, and methods and beliefs about teaching and learning. Real success with technology ultimately comes at the level of individual planning and one-to-one relationships with teachers.

Varying Methods of Educating Teachers. Because teachers are different from one another, their responses to different ways of learning about technology vary. For some teachers (and for learning about some software applications) direct instruction may be effective. At other times, in different situations, one-to-one tutoring may be much better. It may be effective and efficient for teachers to learn from students, either directly or simply by watching students work with software. And some teachers might prefer to learn alone, following written or on-line instructions. It is not that any one of these methods can be matched to individual teachers. In some cases, a given teacher might prefer to learn all software in the same way. But more commonly, factors such as the school environment, time available, the type of application, and the disposition of the teacher will combine to determine the best method in a given situation.

Process and Time. A common misconception about technology is that it is a thing or an event, something which can be “implemented,” and is then in place—similar to the common belief in learning as something which can be delivered and has then happened, obviating the need for further learning. Many schools and administrators have tended to think of technological change as more or less instantaneous, as something to be taught to teachers in a few semesters which would then be “in place.” In reality, technology is a process that occurs over time, a process of continual change and growth. Not only does the technol-
Seven Stars That Shine or Seven Tacks to Step On: Making Technology In-service Programs Work

William G. W. Barnes
Choate Rosemary Hall

Technology in-service programs in secondary education rely on many factors to facilitate teachers' use of computers with their students. To promote a constructivist perspective, in-service programs should enable students to produce models, gather information, carry out simulations, and interact with software for learning concepts (Paakkanen and Viteli, 1996). This paper addresses conditions and factors that impede continuous professional development of teachers who need to learn skills for teaching with technology. These intervening factors; however, have little to do with the classroom. They reside in the culture of the school. The following descriptions and conclusions emerge from my experiences working and consulting with schools in Denmark and in four states in the USA.

Supporting the Technology Initiative
There is no substitute for charismatic school leadership that is well informed about integrating technology into the curriculum. Administrators must articulate their goals, organize the learning environment, and patiently withstand negative reactions of teachers who dislike the current emphasis on the use of computers in instruction. If a school's leadership does not address these issues, traditional teachers will argue that expensive resources are tied up with technology. To head off these claims, the school leader must take three steps:

1. A plan must be put in place for getting technology in-service programs organized by departments.
2. After the in-service program is under way, the administration must develop an annual evaluation system that includes documentation of how faculty are using technology for teaching.
3. School administrators must speak about technology goals repeatedly before teachers, parents, and students.

Other school issues may drive principals to seek political accord with conservative teachers by not taking these three steps. However, until school leadership commits itself to change by acting on technology goals, faculty utilization of technology will be slow. Reducing the funding for in-service programs or reassigning training personnel is the first sign that an administration does not have the resolve to reshape a school with technology. Nevertheless, my experience suggests that as administrators are replaced by new leaders who are committed to technology and can articulate a clear vision of how it can be used, there is a dramatic surge in new teaching competencies.

Continuous Professional Development
An ambitious professional development program is among the chief strategies for reaching the school's goals with technology. Regular workshops, personal coaching, and in-service sessions for large groups must be arranged within the school program (Bowers, Budd, Campbell & Rodriguez, 1997; Hannafin & Savenye, 1993; Rushcamp and Roehler, 1992; Sheingold and Tucker, 1990). However, the culture of the school may hamper this effort. Coaching duties, team try-outs, drama practices, and other non-instructional work assigned to faculty, may interfere with regular attendance at technology workshops. Family responsibilities may interfere with arrangements for training faculty after school. Regular offerings at in-service programs must be repeated and offered at different times to ensure all faculty can attend.

Successful in-service programs should involve department chairs who can help plan objectives and activities. Three or more teachers from a large department should be chosen to teach their peers in separate sessions. Teachers can sign up for specific workshops and attend three out of four offerings during a morning in-service. It is a mistake to group faculty in workshops without reference to computer literacy skills so additional workshops should be organized according to the proficiency of participants. In-service programs that provide one-to-one coaching can have a great impact on students' learning (Andrews, 1997).

Four major categories in support of constructivist learning in the classroom with technology include: communicating, researching information, structuring knowledge, and modeling of complex processes (see Table 1). These topics can be divided into many sessions for teacher in-service. Skill acquisition is a time consuming...
process for faculty who are learning to integrate multimedia production into assignments for a course. A teacher venturing into this area for the first time may wish to join forces with the technology coordinator who can handle the technical details of creating a multimedia document while the teacher manages the instructional activity. Ownership resides with the instructor for the class and this type of team teaching can be flexible and of short duration.

Table 1.
Topics of Technology In-service

Communicating
1. Drafting in a Paperless Classroom.
2. Engaging in Collaborative writing via e-mail.
4. Using white board software to brainstorm ideas.
5. Placing research results on a website.
6. Planning a project via e-mail with attachments.

Researching Information
1. Researching topics on the Internet, in library collections, and from reference works.
2. Identifying specimens from field study by sending images to a university.
3. Writing oral history from interviews of veterans and posting on website.
4. Videotaping visits of resource persons and digitizing video segments for a multimedia document made into a CD.
5. Posting a survey on a web page and reporting on responses after analyzing results with a database.

Structuring Knowledge
1. Organizing ideas into a concept map.
2. Structuring data categorically or chronologically in an outliner.
3. Making a timeline.
4. Organizing a lab report with headings for figures, tables, graphs, and appendices for images and scanned photos.
5. Importing images from electronic cameras for cataloging.
6. Producing a multimedia program with menus that branch to specific headings of interdisciplinary research.
7. Producing a website that allows users to move through research organized by families of the animal kingdom.

Modeling Complex Processes
1. Simulating forces of an avalanche.
2. Making molecular models.
3. Making a concept map of the factors leading to World War I.
4. Simulating microeconomic activity.
5. Changing values, coefficients, and exponents of an equation defining windmill blades to maximize grinding torque.
6. Simulating chemical reactions that are too lengthy, too expensive, or too dangerous to create in a lab.

The Value of Needs Assessment
Most school technology coordinators already know the competency level of the faculty with respect to computer use. The tech staff notices which faculty fail to sign up for lab use and do not make use of computers in their classrooms. Each school should develop an annual needs assessment instrument for determining how well faculty can use e-mail, spreadsheets, and word processing software. To tap more advanced skill levels, the survey should query teachers for knowledge of web page construction, multimedia authoring, content specific software, and use of collaborative groups and paperless classroom strategies. Stages of concern surveys are particularly valuable for analyzing patterns with large faculties. Once the technology staff has analyzed these results, the coordinator can use a table to summarize each teacher's need for training in each software category. The data will suggest classroom organizational workshops for problem-solving and collaborative grouping.

Adequate Time for Learning
Innovators invest a large amount of time in learning to use software effectively. To move to an equally high level of proficiency, teachers need to move out of workshops into more concentrated one-to-one training. Even after receiving intensive personal coaching, teachers must work individually with the software by studying the manuals, the tutorials, and the template files furnished with the program. New users must try to create programs and files that run. Most complex software has a learning curve requiring five or six hours of practice spread across two days. The confidence to use some software well with a class may take a teacher ten or more hours of exploration. It also requires time to create student handouts and determine how the software will be used to accomplish course goals (Bowers et al., 1997). Therefore, to transfer skills to students, professional development programs must build in adequate training and time for teachers to learn new methods (Andrews, 1997).

As mentioned above, supervisors delivering in-service must contend with the responsibilities of teachers outside of regular class hours. During the week, regular E-mail announcements can be used to alert faculty to workshops that will be offered that afternoon. If the workshop is not mandatory, E-mail responses often indicate that teachers can not attend because they lack the time. Many allude to childcare logistics. A precondition for successfully integrating technology into course content is the requirement that teachers address the areas revealed in the needs assessment by attending group workshops and one-on-one coaching sessions, and investing personal time to master software for application in the classroom.
Annual Evaluation

Technology use and its effectiveness should be included as part of the annual evaluation process. Few schools use teacher evaluations as a means of promoting technology integration in the curriculum and wise usage of computer resources. Evaluation is often viewed by teachers as a capricious science in the hands of administrators. It is also difficult to change one's teaching repertoire when assistance with technology is not readily available in many schools.

Evaluation should assess whether a faculty member demonstrates progress toward personal goals with technology. School administrators should first examine needs assessment data to help the teacher form personal goals. Assignment letters should describe the personal objectives that the teacher should address to match school goals in technology for the year. These expectations should be written with the full participation and consultation of each teacher. This increases the ownership of the teacher in the process. Goals should coincide with the scope of the in-service program and be realistic regarding time demands and access to computers. Personal goals should strike a balance between the needs assessment results and the larger school goals.

Once goals are in place, school leaders should provide an in-service program to help faculty acquire new skills from a broad schedule of topics. The goal of this training is to promote skills for integrating technology into content teaching. In-service evaluations of each session should examine how well training supported teachers, and whether a rapid transfer of new skills to classroom teaching occurs. Workshop leaders should use this information to refine the scope of topics and the delivery of instruction.

At the end of the evaluation cycle, teachers can organize the documentation for how they integrated technology into their teaching. Portfolios should include a brief description of professional growth in the academic year. Evidence of software use can be documented through syllabi, handouts, assignment sheets, instructions, outlines, concept maps, printed webpages, multimedia documents, and samples of student work. The educational leader's task is to determine whether each teacher has met the school, department, and personal goals as set out in the assignment letter.

The Key Role of Department Head

The collegial approach to evaluation described above hinges upon the supervisor's ability to conduct this work openly and in a manner that fosters trust. The evaluation effort may fail when a department head does not model appropriate uses of technology. This situation is not unique to education—the CEO of a large designer clothing corporation requires a vast amount of technology training across all divisions of his firm, but that he was barely able to operate a computer and had never learned to type. When an academic leader cannot teach with technology, there is a parallel disinterest among his or her colleagues. In addition, department heads are rarely willing to evaluate teachers for technology integration when they lack computer expertise themselves. To increase the competencies of department heads, schools must choose individuals for these posts who have the willingness to learn new skills and are committed to supporting the larger school initiative of technology integration.

Participation of supervisors in afternoon workshops or attendance at academic conference sessions can aid in building new awareness of how to use software in each subject area. Ten days of paid attendance at workshop sessions over the summer can greatly increase the likelihood that teachers will use technology in their teaching. For example, the department chair of an English department requested training for him and his colleagues on how to make multimedia hypertext documents for their classes. After a four-day workshop, the teachers learned to include sound, graphics, and digitized movies in expository texts written by their students. Students were so highly motivated that they worked far beyond the expectations of the assignment. Department heads need to develop technology skills and experiences and demonstrate leadership for securing training for their faculty. In addition, one workshop day should address procedures for the evaluation process and the construction of portfolios to document progress.

Providing Computers for Teachers

To make all the other provisions of a well planned technology professional development program work, each member of the faculty should have a personal computer. Without one, teachers will have difficulty internalizing the information presented at in-service workshops and finding time to use software effectively (Sandholtz, 1991). Schools can rarely buy all the instructional staff a computer in one year, but a long range program should be developed to spread funding for these purchases across several years.

Some teachers adjust their schedules to provide time for learning new software routines. For example, innovators tend to use computers in all spare blocks of time between family and teaching responsibilities. Laptop computers are effective for enabling teachers to work at home or the office and can also be used in the classroom for teaching. Portable computers can be used for electronic mail, word processing, spreadsheet, webpage, or concept mapping programs. However, more powerful workstations and desktop computers should be made available for faculty who create large multimedia projects. If administrators fail to provide these resources, professional change will come more slowly because faculty need to spend large blocks of time learning to work with computers and software at their convenience.
Summary

A program of continuous professional development in technology depends on many factors. As student involvement and interest rises, teachers use of technology may enhance the reputation of the school. Addressing the seven factors described in this paper can help promote a culture for learning and using technology in the school. When these steps fail to fall in place, technology supervisors responsible for staff development are often discouraged because there is inadequate transfer of skills from the workshop to the classroom. If top level support for a comprehensive plan is missing, it will be difficult to deliver a coherent in-service program across the school year and summer. The integration of technology with subject matter hinges on the long term issue of teachers having access to computers, workshops, and the time to master software routines. This work is best accomplished in the context of collegial annual evaluation that guides the process. Many schools have not yet addressed these issues. Until they do, technology integration will appear only in the classrooms of self-taught innovative teachers (Brunner, 1992; Polin, 1992; Wagner, 1993).

Supporting Technology in Schools: The Roles of Computer Coordinators

David M. Marcovitz
Loyola College, Maryland

In this paper, three areas of importance to computer coordinators in the schools are discussed: support by walking around, nuts-and-bolts support, and the computer coordinator as policy maker. I also analyze a day spent following a computer coordinator around an elementary school. That single day is examined in the context of a larger qualitative study in which various aspects of support for technology at Burnham Elementary School (all names in this paper are pseudonyms) were observed for a little more than one school year.

The computer coordinator may serve several roles, but the most dominant is meeting the immediate needs of teachers. This role is facilitated by a style of support which I call "support by walking around." Support by walking around includes any support given by virtue of being in the right place at the right time. Support by walking around was the computer coordinator's main method of serving the immediate needs of the faculty, and it was his best avenue for gathering information about technical and policy issues.

The computer coordinator felt his work was mostly "nuts-and-bolts." Nuts-and-bolts activities include tasks that require the expertise of a technician, which typical educators or administrators lack. The issue of nuts-and-bolts activities is significant because it consumes the majority of the time of the computer coordinator. On the surface, this would seem to imply that technicians should fill the role of computer coordinators. However, many activities, like training, are enhanced by someone who understands the classroom and the needs of the classroom teacher and can tie the activity into the context of the larger curriculum. Support by walking around also helps computer coordinators become knowledgeable about technology related issues in the school and helps them understand school-wide policy issues relating to technology.

This leads to the last area of concern for computer coordinators—computer coordinators as policy-makers. Although no major policies were made the day I spent with the computer coordinator, many of his activities were impromptu discussions about school technology policy. While many of the functions of the computer coordinator could be performed by a technician, the computer coordinator as educator and policy-maker has an opportunity to make a significant difference in the way the school uses technology to enhance the learning environment.

This study is an examination of the roles of computer coordinators and the ways that those roles go beyond technical nuts-and-bolts support. As a case study, this paper does not answer this question for all situations, but it helps to build an understanding of how a computer coordinator can function.

The Computer Coordinator in the Literature

Change processes and change agents in schools have been widely studied (e.g., Hall & Hord, 1987; Firestone, 1989; Fullan & Stiegelbauer, 1991). Others have looked specifically at computer coordinators. Strudler (1991) studied three elementary school computer coordinators and their roles as change agents. In his study, the computer coordinators ran programs in a laboratory separate from the regular classrooms; Burnham's computers were distributed among the classrooms. In each case, the goals were the same: integration of the computer into the teachers' curricula. The goal was better achieved when the computer coordinator became involved in the curriculum of the classroom and helped teachers see the value of teaching with computers. Most of the computer coordinators' work centered on immediate needs: for Burnham that was nuts-and-bolts activities, and for Strudler's cases that was the separate curriculum of the computer classroom.

Moursund (1985) also discusses the job of the computer coordinator. He emphasized a variety of skills necessary to be an effective computer coordinator including: general dedication to education and good managerial skills; specific knowledge of the educational system—including good teaching skills and an understanding of educational change; communication skills—with an emphasis on being a good listener; and technical knowledge in computer science and computer education—including knowledge of...
teaching and learning theory as they relate to the computer field. While nuts-and-bolts knowledge is hinted at in several of the areas, Moursund’s emphasis is on educational and managerial skills. Loucks and Zacchei (1983) discuss support for innovations in schools. They state that a successful innovation requires a local facilitator, acting as “... cheerleader, building commitment early and maintaining it through constant encouragement; linker, bringing in outside building commitment early and maintaining it through expertise and ideas and linking resources and expertise within the district; and trouble-shooter, helping teachers solve problems and maximize their efforts....” (p. 29) The local facilitator is a school-based contact for a single project or innovation that involves many schools. The computer coordinator assumes this role for a wide range of computer-related innovations. In Burnham’s case, Robert mainly saw his role as trouble-shooter, but the greatest success with the computer was achieved when someone, either Robert or the classroom teachers, took on the other roles.

Research Methodology and Procedures

This paper describes a case study that was part of a larger ethnographic study which looked at various aspects of support for technology in Burnham Elementary School, concentrating on three 3rd and 4th grade classrooms. I spent most of my time with these three classes and their teachers. I also looked more broadly at the 3rd/4th grade of Burnham Elementary School, the school in general, and the district.

Burnham Elementary School is a midwestern, public K-5 school with 19 classroom teachers and approximately 400 students. The school had an unreliable connection to the Internet, one computer in most of the 3rd, 4th, and 5th grade classrooms, a few computers shared by the 1st and 2nd grade classrooms, one older computer in each of the kindergarten classrooms, and one higher-end computer in the library with a networked printer and a scanner.

My qualitative methodology was shaped by situated-evaluation (see Bruce, 1993). In situated-evaluation, innovations are viewed as part of existing situations. Instead of viewing the innovation as a separate entity, it is part of the existing social system. Situated-evaluation techniques help us understand why support does not always meet its objectives. A situated-evaluation approach might find that the support was inadequate because the designers of the support did not account for the contexts and constraints of the situation, or it might bring about a better understanding of how the situation and the support interact to provide different support than what was originally intended.

Data for this case study came from a day that I spent with Robert, the part-time computer coordinator of Burnham Elementary School, during the 1993-1994 school year. I took notes about what I observed and expanded my notes through reflection over the next couple of days. As I read and reread the notes, I became aware of certain themes of interest, including: nuts-and-bolts support, support by walking around, and policy issues. I carefully coded each interaction for these themes, and I reread the notes several times, keeping these themes in mind.

The data from the single day with Robert was bolstered by the larger study. Before and after the day with Robert, I was able to observe him for brief periods and discuss issues relating to the computer coordinator job. Discussions were held with Robert, and other teachers in the school, and included formal interviews and informal conversations. The near-1000 pages of field notes from the larger study were coded, to enable extraction of any notes that related to the computer coordinator and analyze them in conjunction with notes from the day of observation.

The data from the larger study was supportive of what I saw during the day with Robert; however, at Burnham Technology Committee meetings, I was able to gain a better understanding of the potential impact of the computer coordinator on school policy.

A Day With Robert

Robert worked 15 hours per week as the part-time computer coordinator for Burnham Elementary School. I spent a day with him on Tuesday, December 7, 1993. In this section, I will discuss my observations and impressions of Robert’s activities during that day and highlight the issues of: nuts-and-bolts, support by walking around, and the computer coordinator as policy maker.

I arrived at Burnham Elementary School at 8:15 a.m. and went to the library to meet Robert. He does not have an office and his desk in the library serves as a “home base.” The library is frequented by teachers and students and is a convenient place for him to interact with others. Being situated in the library is also useful because it enables him to spend time discussing technology and school-related issues with Jackie, the librarian.

Before beginning his tasks, he talked to Jackie the librarian about the technology items that had been discussed at the faculty meeting the previous day. Then, they talked about other technology policy issues, including what to do about a modem that two teachers needed as part of the Global Schoolhouse Project. They discussed whether the modem should go in the classroom that the two teachers shared or in the library to be accessed over the network.

After Jackie left, Robert explained to me some of the issues involved with this double classroom. These teachers have four computers and will be getting more as part of the Global Schoolhouse Project. They do a lot with technology, but there is some resentment on the faculty about all the “goodies” that they have. Robert explained that part of the technology comes from grants, and part of it comes from the fact that their classroom is separated from the rest of the school by a small staircase, making it more difficult to share...
equipment (such as a computer on a cart) with other classrooms.

Robert then tried to check his e-mail. Since the school’s Internet connection was not working, he needed to use a modem, and for that, he lacked a piece of software. He thought that Cheryl, a 4th/5th grade teacher, might have the software. This afforded him the first opportunity to walk around.

Another item on Robert’s agenda was an inventory of all the hardware in the school, including locations and serial numbers. Completing the inventory gave him a second opportunity to walk around.

The Burnham Technology Committee had decided to buy a hard drive for the secretary in the front office and two AppleTalk cards to allow two printers to be shared over the network. Robert was responsible for this, and it required him to go talk to the secretary in the front office a few times—yet another opportunity to walk around.

At about 8:45 a.m., Robert left the library to go talk to the secretary in the front office about the equipment he needed to order. On the way, he bumped into a teacher and told her that he would be getting some shareware for the computer she had just gotten in her classroom. He also spoke briefly with the chair of the school Technology Committee. When he got to the office, he discussed the paperwork necessary for buying the parts he needed. On the way out of the office, he spoke to another teacher who told him that her computer had not worked since Friday. He accompanied her to her classroom and fixed a simple problem. She also told him that she had just taken a computer workshop about ClarisWorks, and asked if she could get it installed on her computer.

During this brief period of time, Robert went to the office to work on one problem, and addressed issues with three teachers. In the first case, he reminded a teacher, whom he had not seen in several days, that he would be helping her in an effort to bolster her enthusiasm about her new computer. He then connected with the chair of the Technology Committee to maintain his awareness of what was happening in the school. Finally, he solved a problem that could have persisted for several days had the teacher not made him aware of it.

On the way back to the library, Robert walked by a 5th grade teacher outside her classroom. They discussed some personal matters and talked about the ClarisWorks training that she and another teacher had attended. She said that the training was at ESC (a state-funded regional training center for schools) and funding for ESC was changing so ESC might not offer as much training the following year. This encounter helped Robert in his role as policy maker and as local facilitator.

Robert continued on his way back to the library and again talked to the chair of the Technology Committee. They walked together down the hall and discussed some network software. When he had made it back to the library, he called a computer store to find the price for the parts he needed. He then spoke with the librarian for a couple of minutes and went to the front office to give the secretary price information about the needed parts.

At 9:25, Robert returned to the library. He sorted through some things on his desk, putting some things in a folder he had created for articles of interest, including a magazine that contained a review of some of the best software. He said that he intended to make this folder available for all the teachers.

Robert told the librarian about the teacher who wanted ClarisWorks. They discussed looking into how many copies they had and who was using it. They also discussed getting copies of the handouts from the ClarisWorks workshop that two teachers had attended and make them available to other teachers.

This interchange between Robert and the librarian brings out an important role of the computer coordinator that goes beyond nuts-and-bolts. Teachers have a limited opportunity to interact with other teachers and with the district office. Some teachers, such as Jennifer, feel more isolated than others:

She said that she feels like she is alone with these problems. She’s not sure if anyone else is in the same position as she is with the computer. She said she knows Sarah and Cindy [two other teachers at her grade level] are more advanced than she is. (field notes, 1/13/94)

One role that Robert played was to be a liaison between teachers and teachers as well as between teachers and the district. Jennifer might have little opportunity to communicate with many other teachers, but does communicate with Robert due to the nature of his role.

During the rest of the day, Robert was engaged in a variety of activities in which he:
1. walked around the school collecting data for the hardware inventory;
2. worked in the library on the software inventory;
3. ate lunch with several teachers and discussing technology;
4. loaded shareware on a teacher’s computer;
5. discussed policy issues with the librarian and chair of the Technology Committee;
6. went to a classroom to look for some software he needed and helped the teacher fix an E-mail problem;
7. answered a technical question for the principal;
8. discussed the status of the network with a teacher;
9. found a printout at the printer that included several blank pages and discussed ways to prevent this from happening;
10. arranged times to provide individual training for two teachers;
11. helped schedule the use of the computer in the library;
12. told a teacher how to fix a software problem when she came to the library to pick up her work from the printer;  
13. arranged to help out as a technical consultant for a special program in the school; and  
14. answered questions over the phone for a teacher who was home sick.

His day was filled with nuts-and-bolts, discussions with teachers about various things and at various levels of importance, walking around and talking with people, and working and talking with people in the library. Most of the things he did were not of great importance when viewed individually, but taken as a whole, his pattern of contact with teachers—finding out about their needs, fixing their problems, and discussing their policy concerns—was very important.

**Discussion: Nuts-and-Bolts, Walking-Around, Policy-Making**

I looked carefully at the ideas of nuts-and-bolts and walking around. Nuts-and-bolts included things that a technician could do like: fixing equipment, installing hardware or software, ordering hardware or software, and cataloging hardware or software. Other activities included setting or discussing policies and developing curriculum (from planning lessons with or for teachers to finding appropriate technology for teachers). Training has elements of nuts-and-bolts, but can involve instructional and curricular issues. Teaching basic computer skills and basic word processing can be considered a nuts-and-bolts activity; however, when a curriculum-oriented person includes suggestions for classroom applications, basic training can go beyond nuts-and-bolts.

Walking-around support included any support given by virtue of being in the right place at the right time. This included meeting people in hallways or at mailboxes, teachers who came to the library for another reason but relayed a need when meeting the computer coordinator. Non-walking-around support included planned activities in which the supporter or the supported goes to a place for the specific purpose of giving or getting support.

Robert started the day by reminding me that most of what he does was nuts-and-bolts. On that day, I counted 50 specific instances of supportive activities. Of those, 37 were classified as nuts-and-bolts activities. Most of the other 13 activities could be broadly defined as nuts-and-bolts as well.

Although Robert spoke about an interest in being more involved in curriculum, his most significant non-nuts-and-bolts activities involved influencing policy at the school level. His main influence came directly from his position on the Burnham Technology Committee, but his unique policy influence came from the insights he gained as he discussed policy issues with people from around the school.

In terms of policy, and in terms of direct support, personal contact is very important. Robert could better discuss these policy issues because of the personal contact he had with teachers. In addition, he was able to provide more direct support because of the personal contact he made; that is, he was more aware of the teachers' needs and better able to help them.

Of the 50 supportive activities on the day I followed Robert, I classified 22 of them as walking-around. That is, nearly half of the supportive things he did that day were unplanned. Several of the planned activities were a result of finding out about needs from earlier times when he had walked around. Many of the examples above showed Robert on his way to perform a task, encountering someone who discussed a policy issue with him or told him about a need for support.

Walking around and working directly with many teachers helped him to understand what was relevant to them. This included school-wide policy issues like equitable distribution of equipment, and specific concerns of teachers like the need for student typing skills and assistance. Typing skills is an example of an issue that is not necessarily obvious without continuous contact with teachers. This lead to issues that affected the entire school like when, if ever, keyboarding and typing skills should be taught.

Although Robert's work was mostly nuts-and-bolts, it went beyond that, especially in the area of policy. For some teachers, the nuts-and-bolts work was critical to maintain inspiration. In particular, teachers who were not very inspired to use technology, such as Jennifer, required nuts-and-bolts assistance to use it at all. Some teachers will find ways to get around minor technical problems and remain inspired in the face of adversity. Walking around becomes critical for less inspired teachers who may ignore the problem and refrain from using the computer until the solution comes to them.

**Conclusion**

Robert's work consisted mostly of nuts-and-bolts support, including solving technical problems and basic training. Although advanced training and curricular support were goals, the most significant support beyond nuts-and-bolts was in the area of policy. All of the support that Robert offered was helped by walking around the school and informally supporting teachers who needed help or wanted to discuss issues with him.

The computer coordinator can be technician, trainer, curriculum consultant, curriculum designer, and policymaker. Support by walking-around can facilitate all of these roles by making the computer coordinator aware of technical problems and training needs, providing suggestions for how the computer can support the teachers'
curriculum, and the effects that policy decisions can have on different teachers.

We can learn a great deal about the potential of the computer coordinator from Robert. He maintained the technology infrastructure of the school and helped with basic training of teachers. His influence on curriculum and policy was not substantial, largely limited by his part-time status. He was in the best position in the school to understand the technological needs of the teachers, bring them new ideas, link teachers with each other and with resources outside the school, and discuss policies that affected all teachers at the school.

As teacher educators, we need to understand that computer coordinators need strong technical skills and the ability to provide basic training because these roles are likely to be significant parts of their jobs. If we want computer coordinators to influence policy and curriculum, they must have experience in these areas. Computer coordinators with an understanding of curriculum can link ideas from within and outside school. A computer coordinator with a good understanding of the change process can help to set policies that enable technology to help change schools in positive ways.

David M. Marcovitz is Coordinator for Technology in the Educational Environment in the Education Department, Loyola College in Maryland, 4501 North Charles Street, Baltimore, MD 21210. Tel: (410) 617-2250, fax: (410) 6175097, E-mail: marco@loyola.edu.
The range of instructional uses of online resources continues to expand with the number of online computers in schools and universities and the speed with which text, images, and sound are transferred. SITE, a forum for teacher education and technology, features presentations that focus upon helping teachers use electronic resources to improve teaching and learning. The articles in this section all use Internet/World Wide Web (WWW) as their technology-based learning software.

Two grant-supported activities are reported upon. Beth McGrath and Joshua Baron of Stevens Institute of Technology, NJ, describe a nation-wide, public-private staff development program to help teachers effectively use the Internet and to integrate these resources into their curricula and teaching. The project is supported by the United States Department of Education. Neal Topp, Neal Grandgenett, Robert Mortenson, and Elliott Ostler, all of University of Nebraska at Omaha, and Constance Hargrave of Iowa State University, present an Internet-based in-service model, work sponsored by the Helena Foundation. The program covers eight phases: partnership planning, program design, participant selection, awareness level instruction, experience level instruction, classroom integration, project closure, and dissemination.

Three articles address on-line communications. Beth Chandler and Cleborne Maddux at the University of Nevada, Reno, investigated students’ usage of instructors’ web sites. They present responses from 300 students at five colleges in the university that includes a discussion of the Web site components students found most useful. Sue Espinoza, Sharon Chambers, and Madeline Justice, of Texas A&M University-Commerce, describe experiences in using the WWW for meeting and providing on-line support for secondary pre-service teachers. Also discussed is the global educational community that emerges when produced resources are publishing work on-line. Jiang (JoAnn) Lan, University of Alabama-Birmingham, introduces a Web-based project through which across-the-curriculum professional development opportunities and continuous support for K-12 teachers has been provided.

Three articles discuss web-based graduate/in-service courses. Mark Stanbrough and Bill Stinson of Emporia State University, KS, describe the issues and awarenesses involved in developing a distance learning approach to graduate teacher education. Bob Gillan and Frank Fuller discuss a developmental structure they have devised for delivering college courses on the Internet. Morris Beers and Mary Jo Orzech, State University of New York- Brockport, present Educational Structures, a K-12 Internet-delivered curriculum tool that encourages use of the Internet in the classroom. Training on the use of this service constituted an in-service course.

Last, are two articles that look at different aspects of WWW use in education. Glenn Becker, of Thomson Technology Labs, MD, describes the creation of an Internet catalog that serves as a front end for student project, school resources, and approved Internet sites. Gertrude (Trudy) Abramson, Nova Southeastern University, FL, addresses issues related to the quality of articles found on the web. Suggestions for evaluation and methods of citing are included.

Sharon S. Brown, is Faculty Assistant, School of Computer and Information Sciences, Nova Southeastern University, 3100 SW 9 Avenue, Fort Lauderdale, FL, 33315. Voice: 954-262-2032.
STARTING A COMMUNITY-WIDE INTERNET TURNKEY TRAINING PROGRAM FOR K-12 TEACHERS

Joshua Baron
Stevens Institute of Technology

President Clinton's 1996 State of the Union address stressed the need for access and teacher development on applications of the Internet: "Our challenge is to provide Americans with the educational opportunities we'll all need for this new century. In our schools, every classroom in America must be connected to the Information Superhighway with computers and good software and well trained teachers" (President Bill Clinton, Jan. 23, 1996). His May 1996 announcement of the "21st Century Teachers" initiative set a goal to train 500,000 teachers in the use of innovative educational technology tools such as Internet-based resources (President Bill Clinton, May 29, 1996).

With movements such as Net Day helping to wire classrooms and the explosion in Internet connectivity in American homes and schools, more and more teachers, parents, and students are learning to "surf the net." Yet, little happens to actually change the way teachers teach and students learn without: carefully-crafted curriculum materials that meaningfully integrate compelling Internet-based resources; a long-term view of professional development that takes into account content, pedagogical, and assessment issues as well as technical mastery; and ongoing support for schools by organizations able to keep pace with the dynamic rate of change in the technologies themselves. One observer notes that teaching teachers how to surf the "Net and expecting them to create wonderful Internet-based curricula is akin to teaching someone word processing and asking him or her to write a textbook. Experience demonstrates that using Internet in the classroom, without thoughtful preparation, structured lesson plans, a sound foundation in the content discipline, carefully-considered classroom management strategies, and detailed assessment strategies, often is a time waster for students and teachers alike.

How, then, can schools and school systems prepare their teachers and students with the capability to utilize this remarkable resource in ways not possible with traditional tools? How can teachers capture the power of this technology to engage students, to involve them in interdisciplinary explorations that stress content as well as collaboration, critical thinking, and mastery of information technology tools? And, above all, why pursue the expense and investment of time necessary to help teachers become proficient with Internet technology and integrate it into the curriculum?

Based on work at Stevens Institute of Technology over the last three years through a National Science Foundation-sponsored grant (the New Jersey Networking Infrastructure in Education project or NJNIE), it has been demonstrated that thoughtful integration into the curriculum of Internet-based resources has enormous potential to improve teaching and learning. We've taken the approach that the Internet should be considered a "value-added" classroom resource; that is, one which empowers teachers to pursue activities not possible with other tools or strategies. We contend that, where another medium will suffice, a CD-ROM, a piece of software, or even a textbook, it makes little sense for schools to undertake the expense, technical difficulty and the teacher development required to successfully use the Internet.

For example, a sixth grade class might study whales. With an Internet connection, a teacher could have students go to any number of whale web sites to look at pictures of whales, find "whale facts," and even listen to a whale song. Yet this same exploration could just as easily have been conducted using a textbook, audiocassette or CD-ROM. However, the Internet can bring a distinctive advantage, beyond these other educational tools, to this study if it is used to acquire "real time" data on where the whales migrate. Students can track, through the Journey North (Journey North, 1997) and WhaleNet (Welcome to WhaleNet, Nov. 29, 1997) web sites, the migration patterns of whales in the spring and fall and see actual daily movements of whales by plotting their position using data from satellite transponders with which the animals have been tagged. They can combine this migration data with real time data on concentrations of phytoplankton in the world's oceans which comes from the SeaWIFS project web site (SeaWIFS Project, 1997). Using this new data they can link the whale's migration to its feeding grounds which are indicated by high concentrations of plankton, the whale's...
primary food source. All of this work can be guided by a marine biologist who may reside thousands of miles away but who can be in contact with the students using email. Clearly, these classroom experiences cannot be created using CD-ROMs, software packages, or textbooks because of the inherent static nature of these resources.

In the NJNIE project, we have observed that the Internet has a singular advantage in those explorations which can't be accomplished using traditional tools: where access to "real time" data and information enlivens the study of traditional topics (like looking up the location and magnitude of the earthquakes and volcanoes that have occurred within the last 24 hours around the world and plotting them on a map); where global collaboration with other students and content experts provide opportunities for student involvement in a real scientific exploration (like measuring the boiling point of water with students and scientists in Miami, Mexico City, and Mt. Everest and discovering how altitude affects the boiling point, or emailing a marine biologist to answer a question about seals that the teacher doesn't know); and where an interdisciplinary approach not possible with traditional tools can be facilitated by this technology (like a global water sample project in which students compare the microorganisms found in pond water in cities in New Jersey, South Africa, Japan, and England, and discover through email exchanges what life is like in those faraway places). See the NJNIE web site http://k12science.stevens-tech.edu for more information on these actual projects.

These projects and other unique and compelling applications of the Internet which utilize "real time" dynamic data and global collaboration to model, predict, and discover geographical and cultural differences have been the foundation of all the teacher professional development and curriculum initiatives in the NJNIE project. With $2.9 million in NSF funding and additional corporate support, NJNIE has reached 3,000 teachers from 700 schools in New Jersey. Because our partner schools see this focus on data as a compelling reason to undertake Internet connectivity and teacher professional development, we have been overwhelmed with requests from schools for workshops and collaborations.

For this reason, we sought to find opportunities for multiplier effects. Our new project, "The Alliance for Training K-12 Teachers in Instructional Technologies: A National Internet-in-Education Teacher Training Program," combines and builds upon two types of outreach programs initiated in New Jersey: partnering with community colleges to provide teacher professional development, and developing turnkey trainers or "mentor teachers" to become staff developers in their schools and districts. We see the Alliance partnership program as a viable model that can be implemented in communities in every state in the U.S. It presents a method for schools and school systems to provide wide-scale staff development in content-based applications of Internet technology and to bolster their staff development resources through collaboration with community colleges.

The Alliance aims to provide professional development (equivalent to a 30-hour graduate course) to a minimum of 2,400 teachers in three cities over three years through a network of local organizations utilizing exemplary curriculum materials and a turnkey training approach to staff development. We believe that this model is both replicable and scaleable, and can be initiated in additional cities with local corporate and foundation support. Educational Testing Service of Princeton, NJ will evaluate the efficacy of this model and its impact on strengthening and institutionalizing partnerships between schools and community colleges as well as its impact on the extent to which teachers and students make substantive and effective use of Internet-based resources in the classroom.

The Alliance project is funded with a seed grant of $909,000 from the U.S. Department of Education over three years. Started in fall 1997, the Alliance seeks to demonstrate a "proof of concept" working with local organizations in Cleveland, OH, Miami, FL, and Phoenix, AZ. Project partners include: Stevens Institute of Technology, which has developed the curriculum materials and packaged them into 10 three-hour "hands-on" workshop modules, and which will be providing support and guidance on the workshop series, curriculum, and development of the mentor teachers; the League for Innovation in the Community College, a consortium of the country's largest and most pioneering program-oriented community colleges, which will collaborate with the three community colleges to initiate and sustain school-college collaborations; and Thirteen/WNET, the flagship station of the Public Broadcasting Network, with extensive experience in educational programming, which has provided video documentaries of classroom applications of the Internet in instruction.

The community colleges selected for this demonstration phase, Cuyahoga Community College (Tri-C) in Cleveland, Miami-Dade Community College, and Maricopa Community College in Phoenix, are all members of the League for Innovation with a strong technological infrastructure and extensive experience collaborating with their neighboring K-12 schools. In each city, different strengths and conditions exist. The Alliance program aims to build on existing collaborations and overlay a set of exemplary curriculum materials that can be adapted to local needs. The model also fosters the support mechanisms to initiate and strengthen collaborations between partner schools and community colleges.

In the fall of 1997 during the project's organizational phase, Stevens and the League met with local leadership in the three cities (including school superintendents, district-level science and technology coordinators, and staff developers, as well as community college presidents, vice presidents, faculty and other administrators). At these meetings, partners shared detailed information about
existing K-16 collaborations, current local technology and staff development initiatives, and the needs and challenges of implementing the Alliance model. In each city, a strong focus by school districts on curriculum-oriented Internet professional development combined with recertification movements have rapidly moved the Alliance model forward.

In January 1998, core teams from each city met at Stevens Institute of Technology in New Jersey for a one-week institute. This intensive institute provided a detailed orientation to the 10-part workshop series, feedback and discussion about specific local needs and adaptations, and models for ongoing support and institutionalization of these new modes of collaboration and professional development.

10-Part Workshop Series

- Introduction to the Using the Internet - Getting Online for a Reason
- Internet as a Communications Tool - Using Email in your Classroom
- Collaborative Projects - Linking up Around the World
- Real Time Adventures on the Internet
- Identifying and Integrating Compelling Web Sites into your Curriculum
- Strategies for Finding Educational Web Sites and Searching for Information
- Unique Resources for Social Science and Language Arts
- Creating a School Web Site
- Classroom Management and Training Strategies
- What Have We Learned? Final Presentations

Between January and June 1998, each community college, serving as the locus of activity for that city's initiative, will provide professional development to teams of between 20 and 40 K-12 mentor teachers. These mentor teachers will participate in 10 three-hour hands-on workshops in order to prepare to begin giving workshops in September 1998. During the fall term, the community college teams will support the mentor teachers (working in teams of two) as they provide staff development to 200-400 colleagues. In this model each team of two mentor teachers will present the 10 part course to 20 teachers. In the next cycle (spring 1999), the community college core team will reach out to another group of mentor teachers, and then support them the next term in their outreach to their colleagues. At the conclusion of this three-year project, it is expected that each city will have provided staff development equivalent to a 30-hour graduate course for a minimum of 800 teachers.

The advantages of this model are obvious: it build upon local strengths and infrastructures that already exist and provides a mechanism for institutionalizing partnerships between community colleges and K-12 schools (given the rapid rate of technological change, this is of particular appeal to schools); it builds capacity within schools by creating mentor teachers who can serve as school-wide and district-wide staff developers; it puts Internet training in the context of sound curriculum applications which have been created with practicing teachers and which are keyed to national content and technology standards; and it satisfies a variety of local needs for recertification and graduate credits for teacher professional development.

Though the benefits of this initiative are clear, the Alliance model is not without challenges. In fact, the special strengths of this model—the ability to forge new relationships between community colleges and schools, the involvement of a variety of stakeholders in planning and implementation, and the use of school-based mentor teachers to provide quality ongoing staff development—also make this a complex and formidable program to implement. Particular care has been taken to involve all the appropriate school and district-level administrators in planning meetings, and their input and feedback has been sought at every stage of implementation. Selection criteria for the community college core team and for the initial group of tunkey trainers/mentor teachers has been developed, and district administrators are choosing these representatives as much for their leadership and motivational potential as for their content background and their technological proficiency. And an ultimate measure of the success of this project will be the extent to which classroom teachers are able to and enthusiastic about using Internet-based resources in the classroom. This requires districts to support the mentor teachers and the classroom teachers as they begin implementing Internet-based lessons in their classrooms. It will require them to rethink how they evaluate teaching and learning. And it will require schools to be flexible and adaptive to the constant changes in technology and the changes that the technology catalyzes in the teaching/learning dynamic.

The success of the Alliance model rests on three complex and interdependent elements: (1) exemplary curriculum materials that present applications of the Internet that enhance, enrich, and strengthen traditional lessons and provide opportunities for problem-solving and collaboration not possible with other tools; (2) a collegial, equal, and deepening partnership between K-12 schools and teachers and community college faculty and administrators that helps schools keep pace with and plan for dynamic technological change; and (3) school system support for the mentor teachers, the professional development services they will provide, and experimentation of classroom teachers as they integrate new Internet-supported instructional technologies into their classrooms and lessons.

Much learning has gone into the development of the Alliance model. We expect much more will result from this three-year experiment to capture the best that schools, community colleges, local organizations, and project partners can pool to achieve a national imperative—helping
teachers nationwide to exploit the power that these emerging technologies can offer to enable students to achieve their potential.

The purpose of this research paper is to report on an innovative Internet based in-service model called Project TEAM - Internet (Technology in Education Advancement Model). The project was supported by the Helena Foundation and was conducted by the University of Nebraska at Omaha and the Metropolitan Omaha Education Consortium (MOEC).

The project sought to enhance the use of the Internet by involving 20 educators (with both K-12 teachers and college professors) in a comprehensive and extensive year long Internet training program. There were eight phases in the program: partnership planning, program design, participant selection, awareness level instruction, experience level instruction, classroom integration, project closure, and dissemination. This paper describes each of these eight phases and their specific role in the overall structure of the project, as the project evolved from initial meetings to classroom based integration activities.

The use of information technologies in education is indeed increasing, and many institutions across the United States are beginning to plan and initiate steps to facilitate access to the "Information Superhighway," as represented currently by the Internet. In part, a vision for this effort has been identified and encouraged by the federal government. As stated by Vice President Gore, in an address to the communications industry:

"Today, we have a dream for a different kind of superhighway that can save lives, create jobs and give every American young and old, the chance for the best education available to anyone, anywhere. I challenge you...to connect all of our classrooms, all of our libraries, and all of our hospitals and clinics by the year 2000."

(National Institute of Standards and Technology, 1994, p. 57)

The "information superhighway" described by Vice President Gore, as represented by the Internet, has continued to expand commercially as well as internationally, and has now entered all aspects of our society, including K-12 education. The strong national emphasis on ensuring that our students are truly technology literate and ready for the future is continuing and has been recently reinforced by a new initiative from the federal government called "America's Technology Literacy Challenge - 1996." The initiative seeks to ensure that students will indeed have the communication, math, science, and critical thinking skills, that will allow them to thrive in the Information Age. This national mission is based on four "pillars" which include the following:

1. Provide all teachers training and support they need to help students learn through computers and the information superhighway;
2. Develop effective and engaging software and on-line learning resources as an integral part of the school curriculum;
3. Provide access to modern computers for all teachers and students;
4. Connect every school and classroom in America to the information superhighway.

Many educators at both the K-12 and college levels are beginning to show considerable interest in being a part of this effort. For education at all levels, Internet access offers the potential of "breaking down the classroom walls," and linking a classroom microcomputer with any computer on this international network.

Yet the very rapid rate of change related to the Internet is making it difficult for educators at both the K-12 and college levels to keep up and to address the training pillar of America's Technology Literacy Challenge. In particular, educators who are responsible for the technology training of...
other educators are becoming aware that they are no longer knowledgeable of, and able to teach, all types and aspects of the Internet. In essence, they are finding a need to collaborate in the technology training of the Internet by relying on others for particular topics and aspects of in-service activities. There is also a recognition that training on the Internet will never truly be “completed” and the educators at their institution will need to be periodically brought up to date in new advances as they become available for classroom instruction.

Thus, along with new technologies, a new approach is emerging related to in-service training related to the Internet. This approach involves extensive collaboration between curriculum and technology specialists and institutions, to help meet the changing needs of their faculty. This paper describes a specific model for this new collaborative approach to training teachers in educational technology called Project TEAM - Internet (Technology in Education Advancement Model), which has been used successfully for an ongoing in-service project in the Omaha, Nebraska area.

A Collaborative Environment

In the metropolitan Omaha area, the College of Education at the University of Nebraska at Omaha (UNO) and the seven urban school districts have banded together to share resources, ideas, concerns, and effective practices. This cooperative approach between and among the seven urban school districts and the UNO College of Education is fairly unique in the United States. The result has been the formal establishment of the Metropolitan Omaha Educational Consortium (MOEC). The scope of the combined school districts in the Metropolitan Omaha Educational Consortium encompasses more than 82,600 students and 4,500 teachers within 155 schools.

Prior to Project - TEAM Internet, the existing collaborative structure of MOEC provided an environment for the design and delivery of two earlier Project TEAM projects which followed the in-service model described in this paper. The Dartmouth-Nebraska Partnership project, which was the first Omaha Project TEAM, was offered in 1991 and 1992. This initial Project TEAM was financed through a partnership with Dartmouth College and brought teachers from the local school districts to team with professors from the university to design curriculum packages that integrated educational technology into regular classroom instruction. Both the teachers and professors prepared curriculum materials from their respective classrooms as well as being active learners in the same workshop.

From this first project emerged a second TEAM project entitled Project TEAM - Secondary Mathematics, which was offered in 1993 and 1994 and was funded by the Helena Foundation. This project was specifically designed to provide in-service teacher education for mathematics educators. The collaborative in-service program focused upon integrating advanced educational technologies into the traditional secondary mathematics curriculum.

The success of both of the earlier TEAM projects, encouraged the development of Project TEAM - Internet, which was also supported by the Helena Foundation, and was offered during 1995 and 1996. This year-long project sought to enhance the educational use of the Internet by involving a group of teachers and college professors in extensive collaborative Internet training program.

The Technology in Education Advancement Model (TEAM)

Effective teacher in-service has been identified by numerous researchers as a prerequisite to the effective integration of any technology into an educational institution (Friedman, 1991; Wood & Smellie, 1990; Jones, 1988; Crowther, 1983). Merely supplying educators with technology often does little good unless the teachers are also carefully trained to use the technology through an appropriate in-service program. However, teacher in-services need to be well planned and delivered to be successful (Boe, 1989; Hoffman, 1988; Rawitsch, 1981). A few hastily offered training sessions are usually not enough to encourage the active integration of technology into instruction. Instead, in-service programs need to be systematically planned and structured. Most importantly, in-service programs need to concentrate on gradually changing participants from technology learners to technology users and be structured to emphasize and assist ongoing curricular goals (Hubbard, 1989; Hoffman, 1988; McMeen, 1984; Moursand, 1984).

The model for collaborative in-service training in the Internet represented by Project TEAM Internet was divided into 8 distinct phases: 1) partnership planning, 2) program design, 3) participant selection, 4) Internet awareness instruction, 5) Internet experience instruction, 6) Internet classroom integration, 7) project closure, and 8) dissemination. For the institutions involved, the multiphase approach recognized that collaboration takes careful planning and time. Thus, phases 1, 2, and 3 were dedicated to the need to build a collaborative environment and structure; phases 4, 5, and 6, represented a systematic process for building expertise in the in-service participants; and phases 7 and 8, brought the Internet in-service activities to closure and facilitated a wider range of student impact and spin-off projects through dissemination.

The eight phase model was designed to be implemented within the period of 1 year, with instruction of participants occurring during the full 12 months of the project. The eight phase approach was essential to the success of Project TEAM. Each phase is now described in more detail.

Phase 1: Partnership Planning

During the initial partnership planning phase, project partners met and discussed the collaborative potential for
the sharing of resources and expertise. A Project Director or Directors were chosen, who then worked to implement the eight phase in-service model (TEAM). A Project Evaluator was also chosen, who monitored all phases of the project. To enhance joint planning, the Project Directors worked with a planning committee comprised of master teachers, local business technology experts, and university faculty. This committee made a commitment to participate in the in-service project and provide input into the design, delivery, and evaluation of the project.

Each of the member institutions represented by the committee also contributed at least one or more topic with an instructor to the three instructional phases of the project. The actual in-service instruction was planned for delivery at the resident institution of the expert instructor, so that integration of the topic into the classroom environment could be examined more effectively. By receiving instruction from daily practitioners at the actual classroom site, in-service participants received tutelage that focused directly on classroom application and represented demonstrated success.

Phase 2: Program Design

During the program design phase, the specific in-service activities and schedule were planned. Project partners met to discuss the basic and advanced Internet related topics that would be included, as well as identify the instructors and locations for each activity. These planning sessions were usually held in conjunction with breakfast or lunch meetings and included as many of the members of the business community, master teachers, university professors, and administrators as possible. A conceptual focus to the in-service design was essential. For example, in Project TEAM - Internet the basic design of the project centered on the concept that students must be prepared to use Internet related technology to help accomplish curricular related tasks in other disciplines (such as math, science, etc.). To accomplish the above objective, the planning group identified a schedule needed to facilitate instruction related to the curricular and technological constructs that were identified for the project. In the Project TEAM - Internet activities were spread over a twelve month period and required participants to attend the following training periods:

- Two Monday evening sessions per month
- One Saturday morning session per month
- A two day state educational technology conference
- Several Internet related field trips (school site visits, etc.)

Phase 3: Participant Selection

Participants for the in-service training were competitively selected out of a pool of applicants. To increase the number of applicants in the offerings of Project TEAM - Internet, participants were provided with several project related benefits. These benefits included a $750 stipend, $200 of hardware or software money (typically used for a modern or external hard drive), a university computer account, and 3-6 hours of university graduate credit.

Applicants were selected primarily on their potential contribution to their particular institution upon completion of the in-service training. To facilitate the selection process, and to maximize the quality of participants in the project, applicants were asked to answer questions related to the following topics:

- How training would benefit the individual applicant.
- How training would benefit the applicant’s colleagues.
- How training would benefit the applicant’s school.
- How training would benefit particular students in the school.

Participants were selected by a committee representing all involved in the project by a thorough review and discussion of the applications. All participating institutions had a relative number of “slots” for project participation. Representatives from each of the institutions made individual recommendations for participation, but the selection committee had the final decision as to which applicants were selected for the limited number of participation slots.

Phase 4: Awareness Level Instruction

Approximately 25% of the project instruction was devoted to “awareness level” instruction, where participants explored general possibilities of Internet application in the classroom. Awareness level activities included such overview activities as practitioner presentations, guest speakers, and general demonstrations of Internet related curriculum applications. Local vendors also could participate at this time by making group presentations related to their new Internet related products. However, sessions presented by practicing educators were the most interesting and helpful to the participants. For these sessions, it was found that it was sometimes best to meet at the school site of the presenter, to help get a solid look at how the presenter was using the Internet with students, as well as how they were dealing with particular hardware and software constraints. Such on-site visits were much richer experiences, since basic questions such as classroom organization, room configuration, networking structure, etc., were also addressed during the presentations and meetings.

The awareness level instruction served to build a fundamental knowledge in the participants as to how the Internet could be successfully used in education and sparked their interest in particular applications which were useful in their own classroom. It was found that it was helpful to keep awareness level activities as casual as possible, allowing participants to become comfortable with the project training and their ability to be successful in the project.
Phase 5: Experience Level Instruction

The second 25% of the project instruction was devoted to hands-on “experience level” instruction, where participants worked individually at an Internet accessible computer in a workshop setting. In Project TEAM - Internet, the initial focus of the experience level instruction was to help participants become competent in basic tool related applications, such as electronic mail, gopher, FTP, and the use of the World Wide Web. In addition, other more advanced topics were also included, such as authoring World Wide Web pages and working with virtual reality related (VRML) applications. Building a solid base of practical hands-on experience was essential for the participants' willingness to use and incorporate the more advanced applications and it was found that the basic tool instruction should not be rushed.

We also found that instruction during the experience phase should not try to teach everything about a particular topic, such as World Wide Web page authoring, but rather enough of a topic to allow the participant to eventually explore and continue work on their own during the later integration phase of the project. Participants had the opportunity to focus on a particular application that they found useful or interesting during the integration phase of the in-service instruction.

Phase 6: Classroom Integration

The final 50% of instruction time in the project was devoted to helping participants develop a personal integration project that incorporated the Internet into classroom instruction. A significant amount of instructional time during this phase was devoted to “open lab” where instructors with special expertise in specific Internet applications were available to help individual participants with their personal projects. It was also essential to help participants build their own personal network of individuals which they could draw upon to receive technical assistance and advice. This personal network was a continuing resource that they could draw upon once the project training and support was completed.

To help build the participant’s “personal network,” social activities were also built into the training, such as brown bag lunches, field trips, or periodic presentations that were open to the local experts and at times the community. These social activities helped build relationships between the participants and local experts, and the participants themselves. In addition, informal talk time, such as extended breaks or lunches, were built into all the structured training sessions that allowed some informal conversation time for the general sharing of ideas and problems. It was found that this informal time among professionals was where some of the best integration ideas came from and was essential to the successful brainstorming of solutions to many technical problems as well.

Awareness and experience level activities were also offered periodically during the integration phase, to help brush up on general skills, and to continue to learn about successful applications of technology in the classroom. However, topics during the classroom integration phase primarily focused on assisting participants in developing and refining their particular classroom integration project.

It was important to note that the three instructional phases were structured to facilitate a gradual development of technical and professional expertise in the participant. During these three phases, participants moved from a general awareness of what Internet applications existed, to hands-on experience with certain tools, to a very focused integration of the Internet into their classroom instructional activities.

Phase 7: Project Closure

Following the project instructional activities each participant reported on the project they designed that integrated the Internet into the design and delivery of classroom instruction. This reporting was done through a computer aided presentation by each participant to the entire group of participants and numerous invited leaders from the local school districts. In addition, each participant prepared formal documentation on their respective project, so that the projects could be replicated for implementation in several classrooms.

During this time, the formal project evaluator viewed the presentations as part of the overall evaluation of the in-service project. This allowed the evaluator to observe the integrated Internet based curriculum projects that reflected the overall goals and objectives of the general in-service project. Further, this phase of the project allowed the project directors to report back to the planning partners initially involved with the project. The actual integrated curriculum projects and the final report from the project evaluator constituted the major components for reporting on the effectiveness of the project.

It was anticipated that the participants would expand their Internet integration activities and continue to interact with each other and the project instructors. Additional funding sources were then explored to assist in the continuation of project activities, and to facilitate replications of the project with other participants and possible spin-off projects related to the participants own integration projects.

Phase 8: Dissemination

The purpose of this final phase of the project was to share information gained in the project with a wide base of educators. First, there was considerable dissemination among participant institutions regarding individual integrated curriculum projects throughout the year long training program. In addition, in Project TEAM - Internet, each participant had access to a computer, an electronic mail account through the university, and access to receiving information from the World Wide Web. This allowed project participants to continue to share information with
the project directors, other participants, and interested professionals via the Internet system.

Traditional dissemination methods were also used. Formal papers could be submitted to professional organizations for inclusion in local, state, regional, and national meetings and manuscripts could be submitted to professional journals. Dissemination not only reported on the project’s eight phases, but also on the integration projects developed by the participants themselves. Thus, dissemination included both internal and external audiences, and described individual as well as group successes as they reflected the eight phase model.

**Conclusion**

The eight phase collaborative in-service model, called TEAM, worked very well during the three offerings of Project TEAM in the Omaha. All the institutions involved have agreed that it was indeed more effective to approach technology in-service through a collaborative environment where resources and expertise are shared. One of the most impressive aspects of this collaborative approach was the emergence of a committed and energetic network of individuals who continued to share their expertise and collaborated beyond the two initial projects. This network of knowledgeable individuals is still a substantial resource to all initial partners in the project. Many of the individual integration products developed by the project participants were truly remarkable, and several of the local school districts even adopted individual participant projects as part of their overall school or district curriculum.

In the third Project TEAM - Internet, the training program strove to prepare these participating educators to assume a true leadership role in the effective integration the Internet into education. The project attempted to take a very practical and comprehensive approach to in-service training by involving participants in extended and well planned instruction that was carefully focused on classroom impact. It was hoped, and expected, that the Project TEAM - Internet would be an important first step for these educators in helping to locally realize the dream voiced by Vice President Gore and to initiate the training related pillar of “America’s Technology Literacy Challenge.”

Perhaps what was most encouraging in this project, however, was the change in the individual participants themselves. Most, if not all, of the participants are now actively helping others to integrate and learn about the Internet, and have become local experts themselves in particular Internet applications. Project TEAM seemed to have provided these participants with the technical skills and general enthusiasm to help others use the Internet confidently and effectively in the classroom. It appears that collaboration is indeed a possible key helping educators keep current with Internet related technology. In essence, we are adding additional evidence to support the old adage that sometimes all it takes for success is a little help from a friend, or in this case a “TEAM” of friends.

Telecommunications: Graduate, In-Service, and Faculty Use --- 1055
Advances in telecommunication technology and computer hardware have made access to the Internet available to more and more people (Kahn, 1997; Maddux & Johnson, 1997). One would be hard pressed to find a campus that doesn’t offer students and teachers alike access to the World Wide Web (Web). This hypermedia format provides a unique opportunity for educators to create a variety of rich online learning environments (Dringus, 1995).

Many instructors are taking advantage of this popular medium and creating Web pages for their classes (Quigley, 1994; Dringus, 1995; Young, 1995; Kahn, 1997). These Web sites vary from a simple posting of the course syllabus to multiple pages that include lecture notes, homework assignments, links to other sites, interactive quizzes and password protected grade postings. The advantages of having a course Web site include reduced photocopying (which includes eliminating the expense and the handling of paper); the ability to modify the syllabus any time during the semester; and posting new and pertinent information regarding topics discussed in class. (Young, 1995; Partee, 1996; Starr, 1997) For the most part, it is relatively easy to maintain and update Web pages. (Partee, 1996; Maddux et. al., 1997)

However, the rapid proliferation of Internet resources has resulted in a great deal of useless information being posted to the world. In fact, much of what is transmitted on the Web is self-promotional or commercial. For example, Wilkinson, Bennett, and Oliver (1997) site research done by Debashis in 1995 where an analysis of 1,140 randomly selected Web sites found that 21.93% of the material was public relations and another 20.70% were advertising.

It is reasonable to assume that if students don’t find useful information at their instructor’s Web site, they won’t use it. Accordingly, lack of use makes it difficult for a busy instructor to justify the time and effort needed to create and maintain a Web site. To make matters more complicated, the scarcity of design guidelines creates a great diversity in the quality of school Web pages (Maddux & Johnson, 1997). Both students and teachers would benefit if essential features of a useful Web site could be identified.

**Purpose of the Study**

The purpose of this descriptive research study was to investigate issues relating to college students’ use of instructor Web pages and features found on a Web page perceived by students as most useful. Student use of instructor Web pages was identified by the following factors: the amount of time students report they visit their instructor’s Web site, and the students’ recollection of features found on their instructor’s Web site.

**Delimitations and Limitations of the Study**

This study is confined to surveying the students at the University of Nevada, Reno. While the sample size (n = 249) is large, it is not a true random selection. The survey instrument did not control for students who had previous computer experience nor make any provisions for those students who had limited exposure to computers. The number of times students visited the instructor’s Web site was self-reported and may not accurately reflect the actual time students spend at the instructor’s Web page.

It should also be noted that the primary purpose of the instructors’ Web sites was to provide information to their students. More precisely, the Web sites were not created to exclusively deliver instruction nor to conduct on-line courses. This delimitation is important as the complexity of Web site design and implementation for on-line instructional Web sites exceeds the scope of this research study.

**Significance of the Study**

The study of students’ use of instructor-created Web sites is important for several reasons. First, by understanding the issues related to effective Web page design, teachers outside the subject area of computer technology could pursue the use of Web-based syllabi. Second, identifying and capitalizing on specific Web page design elements frees up time, a limited resource for instructors. Third, by identifying Web site features preferred by students, i.e., the ability to preview test questions and to see homework solutions, instructors can develop more effective Web sites for their classes.

**Methods**

**Research Design**

In this descriptive study, 12 instructors were randomly selected from five different colleges at the University of Nevada, Reno. The points of interest include student use of instructor Web pages and features found on a Web page perceived by students as most useful. Student use of instructor Web pages was identified by the following factors: the amount of time students report they visit their instructor’s Web site, and the students’ recollection of features found on their instructor’s Web site.
Nevada, Reno (UNR). The instructors were identified from UNR’s faculty Web page and departmental Web page. However, this was a sample of convenience as surveys were distributed only to those students whose instructors agreed to participate in the study.

**Instrumentation and Materials**

The survey developed to elicit students’ use of their instructor’s Web site consisted of 10 items requiring yes/no, multiple choice and open-ended responses. The survey items were designed to generate students’ perceptions of the Web site in terms of ease of use, aesthetic appeal, navigation problems, and usefulness of provided information. The survey was administered in paper format. The students completed the survey once for each class; however, it is possible that a student might have participated in completing the survey for different classes.

**Discussion and Remarks**

Surveys were distributed to ten instructors, which represented five colleges and approximately 300 students. Three instructors did not return surveys, leaving one college without representation. Table 1 shows the distribution of the returned surveys by college and department. Of the 300 distributed surveys, 249 completed surveys were returned, for an 83% response rate. Surveys were considered completed if the students answered any questions, even though some surveys appeared to be incomplete. The largest number of students participating was from the Computer Information Systems department, which accounted for 38.2% of the returned surveys.

Partee (1996) says that “the success of using communications technology in class depends on the swift and uniform introduction of all students to this form of interaction.” That almost 86% of the surveyed students had seen their instructor’s Web site is not surprising. In follow-up interviews with the instructors, everyone had made some attempt to encourage their student’s use of the class Web site. One instructor posted class assignments on the Web site, requiring students to retrieve the assignments on their own. Another instructor had created an activity that not only required the students to retrieve their assignment from the Web site, but also required they do so in the computer lab and to have the lab assistant sign off that they had indeed done so. Other instructors conducted class demonstrations on how to get to the Web site and navigate its contents. Only one instructor had not required the students visit the class Web site.

Table 2 show the affirmative responses to the “Have you seen the Web site” question by department. As one would expect, all the Computer Science and a good majority (83.2%) of the Computer Information Systems students had visited their instructors’ Web sites. Interestingly, the poorest visitation rate (Math, 50%) was for a Web page that offered incredibly useful and unique information. This Web site included password protected posting of grades, solutions to homework problems, interactive demonstrations of math theorems, and interactive quizzes to help prepare for classroom tests. Perhaps as a reflection of many of the Math students, one student commented “Sorry, but for the most part, the ‘Web’ doesn’t do much for me.”

More importantly, 96.3% of the students who had visited their instructor’s Web site knew how to get to the Web site on their own. The assumption is supported by the fact that 70% of the students reported visiting the Web site any where between a “couple of times this semester” to several times a week. In addition, the students remembered with a fair amount of accuracy that the instructor’s Web site contained the class schedule (76.6%), the instructor’s office hours (76.6%), and homework assignments (69.2%). The results of all the survey questions are reported in Table 3.

Partee (1995) also said “Any student lacking access to the network labors under a real disadvantage relative to other students regarding general course policies, assignments, and lecture information.” This is particularly true if the instructor does not provide this information in printed form. However, survey results show that over half of the students (53.6%) used the computer lab provided by the school to access the Web site so access to the Internet doesn’t appear to be a problem. In addition, 39.1% of the students said they visited the Web site from home; all of

1062 1057
which supports the literature that says more and more people have access to the Internet.

The most popular items on class Web pages seemed to be the homework assignments (49.1%) and the class schedule (40.2%). While none of the students made any comments regarding the posting of the class schedule, many students had something to say about the assignments. They asked that assignments be posted “in a timely manner”, at least a week before they were due, and contain information such as what is expected, due dates, and grading criteria. One student even suggested that the instructor post “an example of some prior papers.” Another frequent request was for homework solutions. Some frustration must have occurred as many students commented that they needed more instruction on how to retrieve the homework assignments.

Links to other relevant sites was also a very popular feature (34.6%) and rated the third top feature for improving the Web site. One student commented, “I think his Web site is extremely useful: especially the links he enables us access to at other relevant sites.” Only two students commented on links that didn’t go anywhere. Table 4 shows a selected sample of other student comments.

Lecture notes was another popular item (23.3%). Some of the comments included “explanations of lectures”, “more concise groupings of topics”, and “put the lecture notes out earlier, not the day of class.” More importantly, lecture notes was the item that most students selected (26.2%) as feature that would make the Web site more useful.

There did not appear to be any problems with the appearance of the instructors’ Web pages as there were no specific comments regarding this issue. The students recalled that they contained graphics (58.4%) and a variety of colors (52.3%). These features also ranked high in both the most liked and the least liked features. Moreover, these were not features that could be improved upon to make the Web site more useful. However, many students commented that they didn’t like waiting for graphics to download. The least liked feature was sound (21.0%).

Construction of the Web pages didn’t seem to be problem either. Most of the students (73.8%) responded that they were able to navigate to and from information links with relative ease and convenience. Most of the comments suggested the problem was the students’ lack of experience and knowledge in how to use the Web browser. Another frequent complaint was the amount of time the server was down, thus preventing the students from even getting to the Web site.

In summary, students are using the class Web sites created by their instructors and they are doing so from either the schools computer lab or home. While many are frustrated by their lack of experience with using Web browser, overall they understand its potential usefulness. To make the most of class Web site, instructors should require students to use the Web site very early in the class and perhaps not provide printed copies of information that they have posted. In construction of the Web page, graphics and sound should be used appropriately, as students don’t like to feel their time is being wasted on “frilly” extras. Lecture notes and homework solutions are the two features students determined would make the Web sites more useful.

While Dringus (1995) was primarily concerned with online courses, her recommendation that instructors conduct a usability evaluation is still applicable to course Web sites. This can be done as a survey to a sample of students during the design phase, as the course evolves, or at the end of an academic term. The results should assist the instructor in determining design improvements for the course Web site.

Implications for Further Research

The responses recorded in this study support the finding of many other researchers regarding student and teacher use of the Internet. That is, instructors are increasingly taking advantage of the resources made available through the Internet and are finding an interest in creating Web sites for their classes. Also, students as a whole seem willing and able to use instructor created Web sites. However, actual usage by students still seems elusive. As this could be attributable to a variety of factors, this survey should be conducted again with a larger and more randomized sample. Further experiments could be done to determine specifically how students are using their instructors’ Web, i.e., only for assignment retrieval, homework solutions, or lecture notes. Other items that might be explored concern the appearance of the Web pages such as screen layout, color, navigation options, and feedback options.

5. Which of the following features are available at the Web site?

- Graphics 125 (58.4%)
- Variety of color 113 (52.3%)
- Sound 26 (12.2%)
- Animation 28 (13.1%)
- Lecture notes 73 (34.1%)
- Homework assignments 148 (69.2%)
- Class schedule 164 (76.6%)
- Instructor’s office hours 164 (76.6%)
- Links to other relevant sites 105 (49.1%)
- Other 21 (9.8%)

6a. What do you like most about the Web site?
- The colors 44 (20.6%)
- The sounds 13 (6.1%)
- The graphics 50 (23.3%)
- The animation 18 (8.4%)
- The lecture notes 63 (29.4%)
- The class schedule 86 (40.2%)
- The homework assignments 105 (49.1%)
- The links to other relevant sites 74 (34.6%)
- Other 15 (7.0%)

6b. What do you like least about the Web site?
- The colors 37 (17.2%)
- The sounds 45 (21.0%)
- The graphics 28 (13.1%)
- The animation 35 (16.4%)
- The lecture notes 19 (8.9%)
- The class schedule 11 (5.1%)
- The homework assignments 15 (7.0%)
- The links to other relevant sites 12 (5.6%)
- Other 17 (7.9%)

Are you able to navigate to and from information links with relative ease and convenience?
- Yes 158 (73.8%)
- No 31 (14.5%)

9. What would make the Web site more useful to you?
- Don’t have an opinion because I’ve gotten by without it 41 (19.2%)
- Better graphics 14 (6.5%)
- Different colors 11 (5.1%)
- Animation 9 (4.2%)
- Sound 9 (4.2%)
- Lecture notes 56 (26.2%)
- Class schedule 10 (4.7%)
- Homework assignments 19 (8.9%)
- Instructor’s office hours 7 (3.3%)
- The links to other relevant sites 22 (10.3%)
- Other 34 (15.9%)

Table 4.
Students’ (S) Selected Responses to Survey Question 10:

“In what other ways could the Web site be improved.”

- S14: The titles in the homework should match the titles in the book.
- S49: Smaller fonts.
- S54: Reduce size of page – too much scrolling!
- S75: Make it more mandatory in the curriculum of the class. Maybe if we were required to use the Web site in order to access certain material pertinent to class.
- S85: It’s for a class and because of time constraints there should be less graphics. All I want when I go to the site is the written material I can print for reference!
- S108: Graphics, animation, homework assignments dated on a more timely basis. An example of some prior papers.
- S110: Better display - clear presentation of assignment and due dates. Whether assignments need to be handed in etc.
- S122: Make it clearer as to how the student accesses other informative links and sites.
- S132: Clearer access instructions
- S138: By giving students practice quizzes or tests to focus on main points of lecture.
- S147: Because I use it for school and time is limited I would like less graphics for faster download times.
- S168: Since it is a computer class, it should showcase technology, i.e., graphics, colors etc.
- S223: With a new picture.
- S233: Put notes and homework.

Technology integration — growing numbers of educators are suggesting that this should be the role of technology in today’s educational system. Computers, at the heart of this technology, should no longer be used as dust-catchers in the corner, or merely as rewards for those students who finish assignments early. They should be more than electronic workbooks or electronic flash cards where traditional educational activities are simply transferred into digital format. Key to this issue, though, is whether teachers have the skills, knowledge, time, and access to allow them to partially or fully integrate technology into their classes.

Technology standards and competencies are being developed to identify specific skills and issues that will facilitate this technology integration throughout the educational arena. The most well-known set of standards has been prepared under the sponsorship of ISTE (the International Society for Technology in Education), and is available both in print (Weibe & Taylor, 1997) and online (ISTE, 1997). Technology competencies are being compiled by a variety of bodies at various levels in the educational system. One of the more extensive listings of technology skills and knowledge is the North Carolina Competencies for Educators (1997), which is available online. With this growing attention to the use of technology within today’s schools, it is essential that educators be prepared to integrate this into their classroom learning environments.

Where do teachers learn about this technology? How do we prepare the teachers of today and tomorrow to use technology as an integral tool in their classrooms, as well as in educational endeavors outside the classroom and for professional development?

Colleges of Education are in a unique position to assist with the development of technology skills and knowledge for both preservice teachers, and those who are already teaching. Preservice teachers are often often required to take one or more technology courses, and there is a definite move to integrate technology into instruction throughout the content and field-based courses. Teachers who come back to school as graduate students may elect to take educational technology classes (or entire degrees), or they may find that they are using or seeing modeled some of the newer technologies, in the course of their studies.

Rationale

Schools have been acquiring technology, often in the form of computer hardware and software, but many teachers are not using these effectively or at all to enhance the learning environment of their students. Currently a primary addition to many schools and classrooms is Internet access, along with the related computers, if needed. Will this, too, go the way of many advances—where only some teachers use them, and not all of these do so appropriately?

Teacher education offers one approach to preparing current and future teachers to effectively use technology in their classes. Undergraduate students (preservice teachers) can see the appropriate use of technology modeled, can use it in their university classes, and can also be expected to use these techniques in their K-12 classroom teaching assignments. These students need a broad base of skills, especially since they do not know where they will be working.

Colleges of Education also work with current teachers—graduate students enrolled in degree or additional certification programs. These individuals are looking for ideas to implement in their classrooms, and may be able to get specific technologies for use in their rooms. They come with specific needs and desires, but are often open to suggestions of new approaches, including those involving technology. Currently, the greatest interest is in the use of the Internet to expand the classroom, and to enhance instruction. Teachers have heard that this is possible, but they may not have any idea of what it means.

One Approach

Colleges of Education include both undergraduate and graduate students, both preservice and current teachers—either on their own, or in conjunction with other institutions. This provides them with a unique opportunity, to have both groups work together, sharing their expertise, and gaining new perspectives about the use of technology in the schools. Opportunities for real-world experiences related to current professional activities, for mentoring/networking, for the
development of a sense of professionalism, and for on-going personal and professional development abound.

The authors, College of Education faculty members — two working with preservice teachers, and the other with graduate students who are K-12 teachers, have made a commitment to provide students with experiences that will contribute to the development of these ideals. They have worked together to provide students at both levels with appropriate experiences related to each specific course, that will also promote the ideas of networking and sense of professionalism and professional development that will provide educators with tools to use to enhance both their professional and personal lives. Students have found and used Internet resources (including lesson plans), 'published' lesson plans and other resources on the web, and participated in virtual teaming activities. They have interacted with students from their same, as well as different semesters, through the information that has been published on the web.

The Classes

The undergraduate students are in the final year of their preservice program, enrolled in either the intern (in the schools 2 days a week, and in class weekly) or the resident (in the schools full-time, with seminars every other week) semester. Prior to these classes, students have completed a basic computer literacy course (not part of the professional course sequence, as well as an educational technology course (with an emphasis on integrating technology into instruction). Students (other than transfers) already have their university Internet accounts, and have used e-mail and the web in both technology courses. The major stumbling block at this point is the lack of Internet access in the schools where students are serving as interns and residents — although the schools may have Internet access, they are not always open to these students using the Internet from their campuses.

The graduate students, during Fall '97, were enrolled in a special topics class (ETEC597), within the Educational Technology (ETEC) program. The course was titled for the text that was being used — Knapp & Glenn’s (1996) Restructuring Schools with Technology. All students (except one) were either teachers or administrators in public or private schools. The one exception has experience with Upward Bound, and is completing certification—in her communications during the course, she fit right in with the other educators, and her lack of classroom experience was rarely evident.

The Graduate Course

In Fall, '96, two of the instructors attended a distance education training workshop. As a result, they were able to apply for (and received) a grant to hire a graduate assistant to help with online course development. The course to be designed was a graduate course which would provide support for preservice teachers in secondary education. The graduate assistant, who had successfully completed both the intern and resident semesters as an undergrad, was able to provide valuable input about how the graduate and undergraduate programs could support each other, and worked well as a team member, with the two faculty members.

The course was offered in Fall 97, in an online format, with fourteen students examining ways to use technology as a tool in the classroom. One of the grad students was a Graduate Teaching Assistant, working with the preservice teachers, and she described the undergrad program (the intern and resident semesters) to her classmates, and was available to answer questions throughout the semester. Having her in the class was a great assistance, in helping the graduate students understand the undergrad program, which had changed dramatically from when they had done their student teaching.

To further prepare the graduate students to work with the preservice teachers, the students were asked to submit reflections on what they would share with preservice teachers (PT's), based on the weekly readings, discussions, or experiences. Meanwhile, the (PT's) were using e-mail and the web for communication and information seeking and retrieval. They were also reviewing and critiquing resource pages prepared by previous graduate classes. The critiques were thoughtful, offering valid suggestions, and they were encouraged to share their comments with the original page creators.

Virtual Teams

After midterm, Virtual Teams were formed. For these, students were divided into seven groups, with an average of six people (divided evenly among grad, interns, and residents) per group. Students exchanged introductions, with the graduates describing what they considered to be the role of technology in the schools, sharing specific instances of their use of technology , and asking for input. Despite some technical and other problems (server down, no access in some schools, mis-addressed mail that was returned, etc.), there were some quite valuable (and interesting) exchanges

A sample dialog, centered on one graduate student and her communications with preservice teachers, demonstrates the foundations in networking and professional activity that are among the goals of the program. In the following, GRAD indicates the graduate student, an elementary teacher, and the Preservice teachers are indicated by Pre1, Pre2, etc.

GRAD:

Dr. E. has great plans for you’ll. 597 has an assignment to search the net and find “the site” we think would help you the most when you begin teaching. This will be added to a list that has already been started. There are so many great sites with truckloads of information it would be helpful if we knew the grade and subject you plan to teach so that the site we pick for you would be most beneficial.

1062 — Technology and Teacher Education Annual — 1998
Thanks,

After students sent her their information, she replied:

GRAD:

Pre1, Thanks for responding to my e-mail. :-) 

I have asked the band teacher at my school to bring me her list of sites that she thinks she has in an educational music organization mag. I will send these to you as soon as I get them and I will surf as well. If nothing else, we should be able to find music types from different countries. This would add a cultural flair.

The band teacher said that many instruments have web pages. She may be getting web pages and newsgroups mixed up; but, either should work for you.

Wish me luck.

GRAD:

Pre2, I was searching the net for technology standards and found this site I thought you might be interested in: http://www.etc.bc.ca/lists/nuggets/english.html

GRAD:

Pre1, Today I have been looking for technology standards (another assignment) and found a site that I think you might like: http://www.etc.bc.ca/lists/nuggets/art_mus.html

There are many music links.

Pre1:

Wow, I checked that site out and it was incredible. I was only able to look at a couple links but have it bookmarked for future reference. That was exactly what I was looking for.

Thanks

Other comments reflected agreement with the original sender, and by reading about and replying to messages describing successful technology use in the classroom, we hope that our preservice teachers will become technology-integrating teachers in their own classrooms, willing to request (and hopefully expecting to find) appropriate technologies available for their use on a daily basis. The following response from one of the undergrads (and similar comments from other students) will hopefully be indicative of that outlook when these students begin their own teaching careers.

I enjoyed your information regarding technology in the classroom. I agree that it is important and relevant. I believe that it will be a necessary tool to implement in all classrooms in the future.

The graduate students were all champions of the value of using technology to promote learning in the classroom, and their enthusiasm was often contagious. The following is from a preservice teacher is amazed at what the grad student is able to do with old computers, and who obviously appreciates and agrees with the grad students positive outlook about the values of integrating technology into the classroom.

I think it is amazing how much you are able to accomplish on your 286s. You sound like someone is really excited about technology and will be ready to use the new technology at the new building. I am a student teacher at a new school, and the technology at this school is outstanding. There are two computer labs, one for each grade, and each teacher has his or her own computer.

The Future

As we await the final student reaction to the project, we are already planning for next semester. The graduate course will be different (Computer Assisted Instruction), and some of the residents will have participated as interns this semester. We will include student activities that relate to various other classes, where grad and undergrad students can use and respond to resources that our previous students have created. Some students from this fall have already mentioned wanting to keep in touch with other members their Virtual Teams, and we will be watching this. In addition, to facilitate this as well as other joint interaction, we will be setting up conference and chat space where current and former students can meet and maybe even collaborate on projects.

Summary

The opportunity for graduate and undergraduate students to work together provides all involved with a broader perspective on ways (and reasons) to integrated technology, as a tool, into the schools. As students networked, they acquired and enhanced skills that will promote their professional development in ways specific to their needs now and/or in the future. Virtual teaming promoted personal and professional exchanges in which students shared experiences and visions for the integration of technology into a variety of educational situations.

Helping Teachers Teach Better: Reinforcement of K-12 Content Instruction through Web-Based Instruction

Jiang (JoAnn) Lan
University of Alabama at Birmingham

Educators throughout the nation are challenged and frequently frustrated in our efforts to deliver on the great promises of technology to the improvement of education. This situation is particularly true among Alabama K-12 teachers. Although the number of computers in Alabama K-12 schools and postsecondary institutions is proliferating, computer-managed instruction (CMI) and computer-assisted instruction (CAI) have not been an integral part of the general curriculum. Studies have found that the only personal attribute that was a consistent predictor of technology adoption was the technological orientation of the instructor's discipline (Hirschbuhl & Faseyitan, 1994; Lan, 1993). For teachers who use technology, frustrations are many. One of them is that they haven't been provided with sufficient training and support for the use of computers in their disciplines. For those who do not use technology, as well as for many who do, a vision of what the technology is bringing into the teaching profession is yet to be created, much less realized.

To realize the vision of bringing technology to our classrooms, technology resources, training and support are needed. Professional development efforts are needed to provide training for practicing teachers in the utilization of subject-specific software to access resources which are available on the Internet in the subject areas of the core curriculum. Teachers require the basic skills to use technology to achieve the vision of teaching professions in the 21st century.

The absence of technology integrated programs and curricula indicate that the schools are not preparing students adequately for the 21st century workforce. This is particularly true in schools where resources are meager, and students are often under prepared. In a meeting of the UAB School of Education (SOE) Dean's Board of Advisors, members of the business community, when asked to describe their concerns regarding the status of education for students in the State of Alabama, stated that greater availability and skills to use technology are necessary for all students.

Since the ability to use technology will be a prerequisite for workers of the 21st century, the Dean's Advisory Committee expressed the belief that it is essential that schools prepare students to be users and consumers of technology, and that up-to-date equipment, including sophisticated use of the Internet, should be expected in all Alabama schools. Programs must be available for the training of teachers to assist them in use of these technologies in the classroom. To that end, adequate budget support for ongoing training in cutting edge technology for teachers must be established.

Education reform can be more successful through a partnership between the university and the community. Previous studies have indicated that collaboration between higher education institutions and K-12 schools brought two related paradigm shifts — structural and instructional. Instructional shifts include teaching and learning, ways of organizing teaching and learning, school and community interaction, and outcomes of schooling. In each of these categories, technology plays a vital role (Fountain, 1993). The Internet/Web-based instruction has drawn more and more attention from educators in both higher education and K-12 schools. Web-based instruction provides students and teachers with the opportunity to be engaged in dynamic instruction as well as providing opportunities for user integration of already developed Web-based instructional components. The use of computer technologies seems to hold the potential to make education more responsive to the needs of under prepared youth by fostering competence built upon unique cultural resources and individual skills already possessed (Thomas, 1992). This is particularly promising for Alabama students given the demographic and economic composition of the population.

By virtue of its faculty and resources, the UAB School of Education has considerable potential to provide outreach services, technical assistance and training, and thereby, to serve its area, region, and State as a leader of educational reform and the integration of technology into the schools and the community. The importance of taking advantages of available technology in in-service teacher education is recognized by the leadership of higher education institutions and at the K-12 schools. However, although hardware
(computers) are present in most Alabama K-12 schools, and the UAB SOE has computer labs for students and provides computers for its faculty, faculty/teachers knowledge and skills to use technology and discipline-specific instructional software to enhance teaching and learning in the core curricula have too often been lacking.

Overview of the Web-based Instruction Project

Through the funding of a Dwight Eisenhower Grant, the School of Education of University of Alabama at Birmingham (UAB) is implementing a five-year Web-based Instruction for K-12 Teachers Project to provide training opportunities to selected teachers from the State of Alabama.

The purpose of this project is to provide statewide across-the-curriculum professional development opportunities for teachers in Alabama K-12 schools to enhance their teaching effectiveness specifically as it relates to the Alabama Courses of Study guidelines applicable to subject areas through incorporating current (existing) and state-of-the-art (emerging) instructional technologies.

The project was initiated at the end of 1996. The middle school was chosen for the first year of the project because the middle school concept is new to Alabama teachers. Until recently, Alabama middle school teachers were prepared in either elementary or high school programs. With 4x4 requirements and the new middle school graduation exam, substantive learning must begin in middle schools.

In the second year of the project, the training will focus on using web resources to facilitate the instruction of high school core curricula. Web-based instruction for elementary curricula will be the focus of training workshops in the third year. In the fourth and fifth years of the project, training will be provided for school administrators and librarians/media specialists.

It is anticipated that after the five years envisaged for this project’s implementation, UAB will continue to build a cadre of technology oriented K-12 teachers who will carry out, using the training curricula and format developed through this project and field-tested to prove its success, the task of preparing more technology savvy teachers who in turn will lead and train their colleagues in their respective school districts.

Project Activities

Summer Workshop

The design of the summer workshop curriculum took into consideration the discipline-specific needs of the participants. It focused on Web-based teaching and technology oriented K-12 teachers who will carry out, using the training curricula and format developed through this project and field-tested to prove its success, the task of preparing more technology savvy teachers who in turn will lead and train their colleagues in their respective school districts.

The curriculum development process included consultation with curriculum specialists, and collaboration with UAB Schools of Business, Medicine, Arts and Humanities, Natural Sciences and Mathematics, and Social Behavioral Sciences, where necessary.

During the first-year program, 37 teachers from 22 schools located in 13 counties participated in two-week long summer workshops at the UAB School of Education computer laboratories. The curriculum of the workshops was planned to be both hands-on and guided by instruction. Workshop activities were designed to improve teaching effectiveness and to increase productivity through incorporation of computer and other information technologies in specific subject areas in which participants are teaching.

The following is an outline of the activities of the five-day workshop:

Day 1 - Web-based Instruction - Getting Started:
- E-mail setup
- Retrieving information on the Internet
- Communicating with others on the Internet

Day 2 - Web-based Instruction - Beyond the Classroom:
- Desk-top conferencing - CU-SeeMe
- Distance learning
- Video digitizing - QuickCam

Day 3 - Web-based Instruction - Build Your Own Site:
- Internet publishing
- Web page construction

Day 4 - Web-based Instruction - Curriculum Integration:
- Curriculum integration
- Web Whacker and Zip Drive
- Cultural pluralism

Day 5 - Web-based Instruction - For Those with Special Needs:
- Adaptive and assistive technologies
- Government policies and databases

Follow-Up Activities

In order to ensure that the participants continue to use the skills learned in the summer workshop to enhance their teaching and to benefit their students' learning, it was critical that the participants be provided with on-going personal assistance by project staff. In order to reach that goal, it was necessary to build a rapport between the instructors and the participants based on continuous, timely, and meaningful interaction. Several strategies were developed to facilitate the process.

1. “Tele-Mentoring”. A “tele-mentoring” system was developed and used to provide personal interaction and assistance to all participants in the project. Several project personnel served as “tele-mentors”; each “mentor” assumed responsibility for 4-5 participants as “tele-mentees”.

The responsibility for “tele-mentors” included:
2. Periodically (e.g., at least every two weeks) send messages to “mentees” about new developments in technology, new practices in the field, and new applications available, etc.

3. Ask “mentees” to share what they have been practicing in the class using what they learned from the workshop.

4. Provide consulting and advice as problems are identified.

5. Encourage the sharing of practices and problems among participants and with project staff directly or through the project Web-page.

Exemplary practices are displayed on-line on the project Web-page as examples for next cycle of project. Problems are collected and summarized, so that as we plan for the next cycle, we will be able to anticipate problems and deal with them ahead of the time.

2. Site Visits. Site visits were made either in group sessions at schools and ASPIRE Regional Training Centers, or at participants’ individual schools. Site visits were made by both the project director and the project evaluator.

The activities for site visits include:

- Observe classes using web-based instruction, e.g., WebWhacker, CU-SeeMe, e-mail, etc.
- Interview students in class about their experience with technology.
- Assist participants with application and technical problems.
- Take pictures and videotape class activities.

During site visits, project participants were asked to:

- Share with the project director problems encountered.
- Share with the project director improvements in student learning.
- Share with the project director student portfolios related to the use of Web-based instruction in class (e.g., on-line and cooperative research projects; on-line correspondence with scientists, educators, and other students outside of the school; on-line publishing; on-line database creation; virtual field trips; on-line social action projects; etc.)
- Share student portfolios they collected.

3. “Mini-Retreat”. As part of the continuous reinforcement of skills for Web-based instruction, a “mini-retreat” is planned in the winter of 1997. This will provide an opportunity to bring all project staff and participants together. It will be a working session as well as a “show time” for all participants.

During the summer institute, participants learned to search the Internet to find already developed instructional tools and resources. They also learned to use WebWhacker software to download Web-based information to a diskette for use in classrooms not connected to the Internet. Alabama SDE is planning connectivity for all schools. However, it will not result in connectivity for all classrooms. Thus, the use of WebWhacker will allow teachers the advantage of using Web-based instruction without having to be connected to the Internet. Other advantages to teachers include no waiting time for information to be transmitted on-line, eliminating inappropriate sites, and more easily keeping students on task. A second skill obtained by participants was that of video conferencing using CU-SeeMe with cameras and the Internet.

Participation Guidelines and Incentives

Participation guidelines were included in the initial Web-Based Instruction Project announcement to schools with criteria for participants’ selection and suggestions for participating schools. It was suggested that schools select highly motivated teachers whose teaching field was related to the Alabama Courses of Study applicable to the subject areas, and that they send at least two teachers from each school so they could reinforce each other’s efforts in using technology and help others in the school benefit from their experience. It was suggested that schools provide professional development credits and other incentives for teachers mastering technology goals. Selection priority was given to applicants who were in a qualified minority group, or teaching in economically disadvantaged or rural areas.

Some of the software and peripherals purchased through the project were available for participants to take back to their schools (e.g., WebWhacker, the Internet Camera, Zip drive) so that they could continue to reinforce the skills they learned in the workshop.

The Commitment of the Participants

The schools/school districts and individual teachers throughout the State have provided strong support to the project since the beginning. After the project was announced in May 1997, we received more than 80 applications from middle school teachers throughout the State. In June 1997, project director Dr. JoAnn Lan made a presentation about the project at the Alabama Educational Technology Conference (AETC) at Birmingham-Jefferson Civic Center. Another 40 middle school teachers signed up for the workshop at the conference. Unfortunately, due to the number of computers available in UAB SOE’s computer lab, and because the nature of technology training requires intensive teacher attention to students, and we wanted to provide the best experience possible for our participants, we determine that workshop size would not exceed 20; this resulted in 40 summer workshop participants in 1997.

The large number of applications received is evidence of strong interest and urgent need for the project. In order to keep the workshop size manageable, we have developed clear selection criteria which provide congruence between the project participation and the national objectives of the Dwight D. Eisenhower Grant. For example, selection priority will continue to be given to teachers who 1) teach in...
core curricula area (math, science, social studies, and language arts, 2) from schools that are located in traditionally minority, economically disadvantaged, or rural areas. These criteria clearly demonstrate our intent to keep in alignment with the applicable Alabama Course of Study, and to provide service to the under represented population.

The commitment of the participants is evident also in their contribution of their personal resource of $1,000.00 to upgrade the Internet camera. Through the grant, the participants were provided with an Internet camera as an instructional tool. Ten participants contributed $100.00 each to upgrade the camera from Black/White to color.

Evaluation of the Project

An external evaluator was contracted to conduct the evaluation of the project. Evaluation of the project indicated that only approximately 25% of the participants had used an e-mail account or WWW prior to attending the summer workshops. However, many participants had or have had a computer in their rooms. The lack of both Internet experience and connectivity in schools provides evidence that this project is meeting an urgent need both in training Alabama school teachers and in using existing hardware to provide Web-based instruction (via Web Whacker).

The initial evaluation of the summer workshops was very positive. Content analysis are being used to analyze the “Tele-mentoring” component with the goal of finding “themes” in the communications between mentors and mentees. Use of the “themes” can provide information for program improvement and planning.

During site visits made by both the project director and project evaluator, field notes describing both accomplishments and problems were collected. Data from student interviews are being analyzed using qualitative methodology. A report describing the evaluation data obtained from the classroom will be provided to the project director by the project evaluator at the end of 1997.

Continuation of the Project

Following the first-year summer workshops and during the site visits, we have received many requests from project participants to provide advanced training opportunities. It is apparent to the project staff that teachers not only see the need for technology training, but also are highly motivated to learn more about Web-based instruction and computing technology applicable to their specific fields. To meet this need, beginning in the second year, advanced programs will be offered to bring interested first-year participants back for a 2-day workshop for knowledge and skill reinforcement training. Included in these sessions will be training for participants who will become trainers in their geographic areas.

Jiang (JoAnn) Lan is an assistant professor in Educational Technology in the School of Education, University of Alabama at Birmingham, Birmingham, Alabama, 53294-1250. Voice, Office: 205 975-8867, Fax: 205 975-7494. E-mail: jlan@uab.edu
Alternative teaching methods and delivery systems have become a focus of educational programs. Massy & Zemsky (1995) observed two trends emerging with distance learning. The first trend is the new demand for information technology-based teaching and learning, and its substantial growth in the next decade particularly as an economical means of providing more readily accessible post-secondary education and credentialing. The second trend is the profound change in teaching and learning. Institutions can reap the benefits of the great potential that distance learning offers if they transform themselves in fundamental ways.

Whether or not one agrees that today’s colleges and universities have a worthwhile core of values that should be protected or that technology should be in part substitute for faculty labor, the potential for increased learning productivity through technology is too great for higher education to ignore. If colleges and universities fail to adapt effectively, other kinds of institutions will take up the challenge. (Massy and Zemsky, p. 11)

We need to not only make teachers aware of the latest technologies, but how we can learn through them and implement them into our classes (Milet, 1996). Viau (1994) stated that minds of tomorrow must be open and able to deal with information that is always changing and increasing. Educators must realize that tomorrow is here today with respect to developing innovative teaching techniques for keeping up with informational changes.

Marketing Strategies for Distance Learning Courses

Marketing strategies are extremely important in the development and implementation of distance learning courses. Since distance learning courses require a great deal of advanced planning and authoring on a website, costs in terms of time and technological applications are high and possibly wasted if enrollments do not materialized. Marketing is a topic that is not talked about much in distance learning yet plays such an important part in the success of your program. In developing our first distance learning courses, we discovered various things to do and not to do in marketing and publicizing our course offerings.

Define your population. Is there a certain professional group you are designing your course or curriculum for? Possibly this group as a whole participates in certain conferences or belongs to the same organizations. This knowledge helps in getting names and addresses from membership rosters. A list of previous on-site course enrollees is another example of potential students.

Determine the awareness, needs and technology available of your population. Is your population aware of what a distance learning course is? Do these professionals need certain courses for certification or for the performance of their responsibilities? What technologies are available to them for taking the course and how comfortable are they in using them? Recently, we administered a survey to 200 professionals at a conference in our discipline. We discovered that they had very little knowledge of what a distance learning course was yet they wanted to know more about it, their schools/agencies were requiring more use of computer technology in their curriculums and administration of duties, and that certain training topics were being endorsed by the state credentialing agencies. Obviously, this information was invaluable in designing brochures, courses, and technologies for our offerings.

Website and hard copy information sources. Even though accessing websites for information is usually very easy for the technology literate, additional hard copies tend to reach more individuals and reassure others considering the move to using technology in taking a distance learning course or who may not have current access to the internet.

Designate a contact person. Being able to contact someone who is knowledgeable and part of the course is an important asset for answering everything from course requirements to what kinds of technical skills are needed for just being in the course.

Use listservs. Professionals into the use of computer technology invariably get involved in listservs which address their disciplines and professional interests. Listservs contain a ready made audience of potential enrollees.
Conference presentations and exhibits. Presentations and exhibits allow you to show the technology involved and the potential of delivering pertinent information to professionals in a distance learning manner. Also, they create question and answer opportunities for those desiring more information.

Support systems. The delivery of a course is only as good as the systems creating it. Cooperative efforts with various departments such as instructional technology, continuing education, and the course discipline involved are necessary to not only carry off the course itself but to publicize it in the most effective means available. Our instructional technology unit showed us the strengths and weaknesses of different technologies in delivering course materials while continuing education related how to make mailings and material distributions more effective.

Marketing is more than just bulk mailing. Consult with individuals who are knowledgeable in the promotion of products. Journal advertisements and stories involving your materials while continuing education related how to make continuing education, and the course discipline involved are various departments such as instructional technology, good as the systems creating it.

There will be lots of questions before the course ever starts way of course taking and thinking for many individuals. There are some common questions as to how do I find the course site to what do you mean by downloading, etc? The time, simplicity, and patience you take in answering these questions will directly correlate with who enrolls now and for later courses.

Do not rely on others to promote it. Other professionals and support people do not have the vested interest in this course you do. With the time and energy you are expending to put this course together, it is only natural that you would want to self-promote this course as an important offering.

Avoid being an elitist. There is no such thing as a trivial question involving distance learning. This is a new way of course taking and thinking for many individuals. There will be lots of questions before the course ever starts and during the course on everything from what’s the internet to how do I find the course site to what do you mean by downloading, etc? The time, simplicity, and patience you take in answering these questions will directly correlate with who enrolls now and for later courses.

Start early. We discovered the planning and developing of a distance learning course takes somewhere between six months to a year, surveying and marketing are a must in determining if the course offering was worth the time and energy to produce let alone assure the minimum enrollments to actually conduct it.

Student Responses

In considering the World Wide Web as a teaching and learning environment, ongoing student responses are a critical tool in fine tuning a distance learning course. According to the student responses to our courses, we have compiled a series of concerns that should be addressed in planning and conducting a distance learning course.

In the asynchronous virtual classroom, students and instructors come and go at all times. The attractiveness of distance learning lies in the fact that students do not have to be at a certain place at a certain time is described as asynchronous learning. Many students with hectic professional/personal schedules such as family obligations, as well as students who are not within easy driving distance find distance learning a very attractive alternative to the traditional classroom learning environment. Scheduling problems are circumvented by allowing students to make choices as to where and when they study and participate in class. This approach can be a disadvantage to some students. Asynchronous learning may not be for everyone, at least not initially. Some students are synchronous learners. They enjoy the atmosphere and learn best in the traditional classroom with regular meeting times and an instructor leading class discussions. With the freedom that technology provides, it becomes very easy to put off study. Our distance learning students indicated a high degree of time management skills are needed for a successful distance learner. Overall, assignment deadlines were very helpful to students in managing their time.

The teacher’s role is changing in education. We are evolving from the teacher being an “authoritative figure” to the teacher becoming a “guide by the side.” Thanks to the informational technology age and a wealth of information at hand, it has become increasingly more important to be able to find information as opposed to “knowing it all.” Computer mediated instruction makes the student more responsible for self-learning, with the on-line student being guided by the instructor with more responsibility in finding his or her own way. Sharing technical skills and information websites with students motivates their use of online educational pursuits. This makes distance learning courses very attractive to teachers enhancing their knowledge or skills.

Another factor to consider is whether a course is cohort-based (taken with a group of students) or self-paced (open entry and open exit). Cohort-based courses have scheduled beginnings and endings with specific assignment time windows for forums. An assignment time window may be a ten day period in which students respond and discuss a topic. At the end of the ten day period a new forum assignment is given. While the old assignment is still accessible, it is no longer the current topic in focus. A Web-based discussion forum allows students to interact with fellow students as well as the instructor and become a virtual classroom. Students have noted that Web-based discussions can lead to more participation in class with discussion requirements for all students. Therefore, all students receive a chance to speak and the wide range of experiences, job responsibilities and various geographical locations seem to enhance the discussion forums.

The process for beginning a distance learning class includes a learning curve. The size of the curve may depend upon the technology background of the individual. Many students may initially feel uncomfortable with the technological processes being utilized. A two week period to get
everybody “up and running” is recommended. Many students make comments such as, “I am getting an internet connection”, or “I am getting a computer”; however, the process may actually take longer than expected. Using a variety of technological methods such as World Wide Web, e-mail, discussion forums, computer software, etc., create various responses from the learner. The more user friendly the technology, the less difficulty our students had in participating in course activities. Using a “one site does all” is recommended over the use of multiple software programs. The fact the World Wide Web is standardized allows instructors to place information on the World Wide Web for easier access and fewer problems. When students are “up and running” instructors can get to the “meat of the course” and focus on content-rich lessons.

Not only is the information more easily accessible to the student in a distance learning course, the necessity of clear and precise instructions are critical to student comprehension and performance of course activities. This makes creating online content the most difficult part of developing a viable web-based course. It is not simply a process of translating your basic lecture notes to the web. Information posted on the class website should be very precise and clear. Information should include the syllabus, announcements, assignments, as well as interactively designed questions for the bulletin board. Supplementary materials such as a course manual and videotapes can also help understanding of a desired assignment outcome. Students appreciated the clarity of instructions and deadlines expressed at the onset and during the course. Students’ questions and comments about assignments and instructions shed a great deal of light on how well you have expressed the course content and what corrections are necessary in the future.

Communication between teacher and student is extremely important. The process of technology implies we are available anytime and anywhere. Many students come to expect faculty to immediately respond to their e-mails. Our bodies and minds move slower than the technology available. A reasonable response time may be 24 hours. However, there are certain times when the 24 hour response time may be suspended because of weekends, vacations, and conference excursions. Announcements of these times are a simple matter of courtesy; and relieve much negativity and stress which could happen if not known by the student. Students appreciated being informed of equipment failures on the course site system. This notification eased their anxieties concerning the possible failure of their own computer equipment.

Professional Networks
Developing and maintaining a professional technology network can be a very enlightening and enriching experience for its membership and the clientele it serves. Several years ago, we established an annual “Sharing Day” workshop for our state professionals. Its idea was to invite professionals to a site for a Saturday to share their best teaching activities, ideas for classroom management, and their common interest in becoming better teachers in their profession. Also, it was to be an opportunity to become acquainted with other professionals around the state in their discipline. It was hoped that through this meeting, the professionals would discover each other’s talents and create a network of individuals which could be contacted when specific needs or questions came up regarding professional issues. These “Sharing Days” were a huge success for several years. As professional and family responsibilities became more evident, attendance at these sessions began to drop. In the meantime, technology became more and more commonplace in our schools. With the development of distance learning courses, an electronic masters, and summer intensive workshops in technology, we decided with encouragement from our distance learning students to use technology in re-establishing our professional contacts in the state? Thus, the Kansas Health and Physical Education Network was born.

Ground work for a network. A network needs boundaries to start from to assure its success. Geographically, the state of Kansas was a starting point because of our familiarity with the schools, their technology systems, and their teachers. Professionally, common interests must exist. Personal contacts were made with various health and physical education teachers geographically dispersed across the state to determine those individuals with an interest in a technology network and who had the available technology to participate equally with others in our initial undertakings.

The beginnings of a network. A small, manageable number of 20 professionals were identified to pilot this network with the idea of adding and encouraging others to join as the network progressed. E-mail communications with these individuals were established and a website was linked from our state professional organization’s home page so not only the network group but guests as well could access it. Our professional organization, the Kansas Association of Health, Physical Education, Recreation and Dance (KAHPERD), gave us a grant to travel to four schools sites, one in each professional district of the state, to visit teachers and survey their technological capabilities. This gave us an opportunity to become familiar with the technology in our state schools. Teachers from neighboring schools were invited to attend these meetings for information on the network and the use of technology in our profession.

The network’s future. With the network now in place, brainstorming was initiated through our website forum to determine and prioritize possible functions of the network. Clearly our first functions were to develop information sources on our network website to alert professionals to legislation affecting our programs and the sharing of lesson...
activities for various grade levels. Also, the forum discussion initially pursued technical ideas on producing web pages for the school programs of network teachers. On the horizon, it is planned to have spreadsheet applications and other software orientations relevant to the teachers' needs in their programs. Also, integration with other disciplines/teachers will be discussed. The recruitment of other teachers to network is an on-going process. Collaborative presentations for our next state KAHPERD conference to help other professionals with the advent of technology in their schools are being planned.

Visions For the Future

University teacher education programs must realize that technology-based education is here and is rapidly changing each day. Our intent was to relate how we have met the challenges of recent trends in education which suggest that the demand for information technology-based teaching will grow in the next decade and this technology will change teaching and learning profoundly. Our paper has discussed how we are utilizing educational technologies in innovative ways for teacher excellence, and improving the delivery of our teacher education system to a wider professional audience.

All courses undergo regular examinations to insure that they are current, theoretically supported, and consistent with the rest of the curriculum. In addition, many faculty members discover the necessity of examining their offerings for technological currency. The pressure to offer courses through distance media and with a variety of optional technologies makes it difficult to limit revision to simply updating bibliography. Such curriculum development has proven to be as troublesome as it has been necessitated by innovative departmental administration or clamoring students.

This investigation is predicated on the assumption that the instructor’s task is not to invent an Internet course, nor to make a single adaptation of an extant course that will make it, once and for all, instruction on the cutting edge. College instructors develop their courses gradually, over three or four iterations, in a way that allows continuous effort to produce an evolving product. Consideration for the abilities of incoming students and the technical infrastructure (that of the institution and of the participant students, as well) will guide the rate of development. Instructors’ general level of exhaustion will have a role, also.

The stages of Internet course development for teacher and student follow a life cycle that describes and may predict a pattern of instructional development that moves the course from a traditional classroom to a completely Web based asynchronous offering. In each instance, the instructor makes three kinds of choices: instructional design (goal sequencing, lecture strategy, for example), student expectation (read text, go to library), and instructional material (text, article, chalkboard). In the process of developing a previously taught course for the Internet, the instructor makes a series of decisions concerning the instructional value, the academic integrity, and the institutional efficiency of the methodology used.

In the relationship of the individual instructor to the subject matter of a course and to the individual students in a class, the research is not extensive. The individual choices of how to teach, how to evaluate, and how to be fair to each student remain unreported, perhaps because these matters have always been dealt with by instructors individually. They are decided as a result of institutional policy, but not interactively with it.

Designing and delivering instruction consists in choices: selections every teacher makes that begin with deciding whether to engage in detail or in span of subject matter and end with wondering whether individual progress or achieving an absolute benchmark of information is the proper criterion for grading.

Student activities mirror instructor choices. The three student categories are attention to class (listen, memorize lecture), analytical skills (read critically, write brief essays), and response (take tests, write book reports).

Classes that move gradually to the Internet can follow a progression that involves both teacher and student in changing skills. Here is an outline of the way the instructor can lead both one self and one’s students along that progression. Earlier stages of this development should be familiar to everyone. Later stages are richly displayed at Internet instruction collections like The World Lecture Hall http://www.utexas.edu/world.lecture/edu/.

Classroom instruction is the starting point: the traditional model. It employs lectures, handouts, and visual presentations on the board, with assignments of critical reading from text, library, and journal sources. Supplemental presentations are made, in class, with chalkboard or transparencies.

In some ways, this is the most flexible system of instruction. With the door closed, no one but instructor and students knows what occurs in class. An outline or a graph written on the blackboard can be changed to need the apparent needs of the class at the moment it is being drawn. Class discussion changes from section to section, but lectures or examples may change as quickly. Certainly, large classes or an instructor’s dependence on notes will diminish the interactivity of a class. Nevertheless, the traditional classroom always involves a lecturer looking at students, and students expressing their degree of attention by expression, body language, question, or comment.
Lectures and demonstration are truly evanescent, and (barring a tape recording) the interaction cannot be recaptured or duplicated in future.

Media-conscious classes tend to supplant lectures with projects. Instructor handouts begin to be supplemented by URLs and information available on-line.

Chalkboards become supplant by sets of prepared transparencies. And those transparencies are replaced by PowerPoint presentations. Indeed, the transition from writing on a chalkboard to designing a presentation often has designed transparencies as an intermediate step, lasting several semesters. Seasoned instructors, distrustful of projectors' reliability, routinely include static transparencies as part of their preparation, even when they desire to use only a projected presentation in class. Examples and assistance are available at The Campus Café http://www.presenteuniversity.com

Slideshows software does not lend itself to correction during a presentation, of course. Hoping to maintain a degree of student self-direction, instructors tend to use the presentation to set up situations, establish rules, or introduce broad outlines. Students find themselves encouraged to elaborate on the outline, rather than attending to didactic detail in a lecture. Thus does the technology begin to change the role of students within the classroom.

The existence of presentation equipment in a classroom suggests access to computing resources of other sorts. Instructors with PowerPoint have, by the nature of their exploration, gained access to other electronic instructional tools. As Compel can replace a chalkboard, databases replace indexes, URLs supplement tomes, and tutorial tools become part of re-teaching strategies.

Text-intensive Internet courses begin as a migration of the lecture and student discussion to a distance education medium (Moore & Kearsley 1996). This is the first realization of a class that can actually be exported to students at a distance who attend class electronically. In some ways, the text-intensive Internet course represents a retrograde step in instructional delivery. E-mail, newsgroups, MOO and MUD environments all lend themselves to instruction. However, they do not accommodate graphics or video (presumably) visually appealing presentations available with a projecting computer or a well-designed transparency.

They do provide a realization that any interaction among students must be accommodated — encouraged — by the instructor through the media that propel the class. The first Internet class is often the first collaborative class, as well (Berm & Bugbee, 1993) The University of California Extension demonstrates a wide variety of media at http://www-cmil.unex.berkeley.edu

Internet classes share with other distance education programs an unpredictability of uniform resources outside class material. A true distance offering can make no assumptions about library, laboratory, or archival resources, except those available through the Internet itself. Therefore, the technology forms a change in instructor expectation and student behavior as Internet resources become the core of student investigation.

The Web Course replaces the Internet course when visual tools and instructor skills outstrip text's limitation. Lectures (texts), presentations (graphics), and resources (links) become integrated. Please note several examples posted at http://www.tec.npsla.edu

Student activities become differently arranged, as well. Traditionally, a student is asked to prepare before a class, engage in class activities in the same order as other students do, and assimilate or apply the class activity in assignments or research. In the Web class, students are in control of their counterpart to "class time." Instructional material may be consumed at a rate suitable to the student's learning style and schedule. More important, preparation, instruction, and response cease to be discreet activities. A student can receive a lesson, read the assignment in the light of the level of understanding the lesson requires, and construct an assignment or pursue research at the same time the parts of the lesson are being received. Time management and study habits lose the structure required by the preparation/attention/response sequence of scheduled classes.

The result of this progression can be seen, not only in technological sophistication, but also in the learning and instructional activities of the participants: instructor and learner alike (Roberts & Keough 1995).

Every technological choice affects the learners in different ways, and is intrinsic to the subject matter of the class and the expectations of the instructor. Teaching people at great remove from campus, and expecting them to interact with each other and with the intellectual substance of the class without seeing one's self or each other, requires a reexamination of dozens of instructional decisions that were made for the classroom. Continuous revision of instructional strategies requires a parallel revision of the assumptions about the way students receive, respond to, and retain the material of every class. Revision also requires evaluating feedback carefully. Changing so much in teaching methodology is a little frightening. Changing it without being able to see or hear students' reactions to the changes can, and probably should, terrify any instructor.

Detailing the choices being made, and examining those choices in light of student feedback and other people's experience, seems the minimum price of this degree of innovation.

Internet-based communication has become a staple of academic communication: the whole system was invented to allow academics to work and talk at a distance. Not offering instruction in this medium deprives students of the opportunity to become comfortable in this central frame of discourse. And not allowing — requiring — this kind of access should be more disturbing than innovation at any level.

INCREASING USE OF THE WORLD WIDE WEB IN K-12 CLASSROOMS: AN IMPLEMENTATION PROJECT

Morris I. Beers
State University of New York at Brockport

Mary Jo Orzech
State University of New York at Brockport

The Department of Education and Human Development of the State University of New York at Brockport is in its third year of a Goals2000 funded project to increase teacher knowledge and use of technology in K-12 schools. The project has involved placing hardware in individual schools, training teachers to use the hardware, networking the schools, setting up a listserv, and having periodic meetings and mini-conferences. SUNY Brockport has been involved in both the in-service teacher training and primarily in the pre-service training of future teachers.

Each year the number of schools involved has increased. The first year, 1995 – 1996 involved the placement of hardware and training of a core of teachers in four schools on the use of the hardware, e-mail, and list-servers. The focus during the first year was for each school to develop an operational definition of professional practice school as it would be implemented at their site. The technology was used as a support to communication among schools and SUNY Brockport.

The second year of the project, 1996 – 1997, involved the addition of four more schools and a focus on multimedia applications in the classroom. Teachers in participating schools were trained in the use of HyperStudio and encouraged to use it in their classrooms and with their students. Each of the participating schools continued to use the provided technology both for communication with other members of the project as well as for the development of multimedia presentations. During this second year a core of teachers at participating schools were also introduced to the Internet, the World Wide Web, and Netscape as resources for their teaching.

In an attempt to encourage more use of Internet resources in the K-12 classrooms, the third year of the project, 1997 – 1998, added 1 more school bringing the total to nine, and focused on introducing teachers to a World Wide Web subscription service developed by American Cybercasting, called Educational Structures. Teachers at each of the nine participating schools were trained on the use of this new tool and encouraged to use it in their classrooms. Pre-service teachers at SUNY Brockport were also trained on the use of Educational Structures in their classes at the college so that they could serve as resources to teachers and students in the schools in which they were participating. The third year of this College — District Learning Community project serves a total of 180 pre-service teachers, in-service teachers, and college faculty from SUNY Brockport and Monroe Community College.

Educational Structures

Educational Structures is essentially a subscription service which uses the World Wide Web as its resource as well as its delivery system. Educational Structures is designed for use by both K-12 students and teachers stated to be “a K-12 Internet-delivered curriculum service for both educators and students.” It is organized into the subject areas of Social Studies, Science, Math, Language Arts, and Health. These subject matter subdivisions are called “wings,” using the metaphor of a large library. In addition to wings devoted to specific subject matter areas, both students and teachers can access the Media Center wing for additional resources. Teachers have tools available only to them through the Main Office part of Educational Structures which requires a user name and password for access. In the Main Office teachers can find lesson plans, assessment ideas, and a roster of other teachers who are using Educational Structures.

Student use of the Educational Structures system allows for subject exploration and tutorial type lessons, self assessments, and collaborative projects with students from other schools, districts, and states. Students can access dozens of publications including newspapers, magazines, and journals all of which allow free copying and distribution of articles through prior copyright agreement with Educational Structures.

Each wing of the Educational Structures organization has the same appearance to users to facilitate ease of use. Each wing provides four to six different specific subdivisions of the wing, appropriate to the subject matter repre-
sented. For example, the Language Arts wing provides the subdivision areas of Reading, Writing, Speaking, and English Language; each with its own "Information Stations." These "Information Stations" guide and facilitate student or teacher exploration of the specific area of the chosen wing. In addition, each wing as well as each area subdivision of each wing contains specific tools for users. These tools are: Search, Activities, Publications, and Joint Ventures.

The Search Tool allows the user to search Information Stations, Newspapers and Periodicals, or Webster’s New World Dictionary. This tool is a highly specific search engine for easy use within Educational Structures environment. Searches are further facilitated by the user typing in specific terms or phrases and/or specifying time periods for the search.

The Activities Tool is subdivided into the same areas as the wing and provides the user with learning activities which are color-coded to indicate the appropriate grade level. Teachers can use these as activities for the entire classroom and project information onto a screen or students can use them individually. The learning activities are much like lesson plans in that they contain objectives, materials needed, and instructions. The activities differ from lesson plans in that a student or group of students can do them without the intervention of a teacher.

The Publications Tool provides the user with a list of periodicals. The user can access the entire list or can look for periodicals collected by month. Once the user chooses a periodical and selects it, a full listing of articles is displayed. Choosing one of the articles displayed provides the full text of that article.

The Joint Ventures Tool is a unique one in that it taps the full capabilities of the Internet. Joint Ventures are initiated by teachers or students through a teacher Educational Structures provides assistance to the teacher in posting the joint venture in an appropriate format. These joint ventures vary from collection of temperatures around the country to writing poetry about your particular location. In short, the Joint Venture Tool provides students with electronic pen pals with a purpose and structure.

The Main Office Wing, open only to teachers provides tools which allow teachers the ability to incorporate Educational Structures’ wealth of information and activities into the classroom. Available are: lesson plans and interdisciplinary units written in a common and standard format, interdisciplinary thematic activities and enrichment opportunities, custom lesson plan support, related Internet sites, a counselor’s corner for information related to teen problems, and a user’s roster to provide a list of other users Educational Structures so that teachers can share ideas and ask questions.

Educational Structures provides both students and teachers with an organized window on the Internet. In addition to a safe and organized interface, users are supplied with lessons, activities, units, related sites, and other related resources. The key is related, so that the teacher or student does not spend endless hours searching the Internet with no concrete results.

Implementation

To encourage and enable teachers to use the Internet and the World Wide Web in their K-12 classrooms, each of the nine schools involved in the Goals 2000 project were provided with 20 licenses for access Educational Structures. Internet access and hardware were provided where schools did not yet have access.

An informational meeting and kick-off session was held in May of 1997 to introduce teachers, administrators, and college faculty to Educational Structures and the objectives of the third year of the Goals 2000 project. Beginning in the summer of 1997 and continuing into the fall, half-day training sessions were held for teachers in the nine participating schools. Follow up training sessions were held individually in each of the participating schools. These training sessions were led by the school district technology implementation teachers.

In August of 1997, just prior to the beginning of the fall semester for SUNY Brockport, a half-day training session was held for the faculty in the Department of Education and Human Development. Because of the excitement generated by Educational Structures 10 additional licenses were purchased so that faculty could have access in their own offices and not only in the Educational Computing Lab, which has 20 licenses. Faculty were encouraged to incorporate Educational Structures into their existing methods courses during the fall and spring semesters. The goal was to supplement material already taught in those courses, not create a separate mini-course on Educational Structures.

The use of Educational Structures was implemented in two different elementary methods courses, the secondary English methods course, the secondary Mathematics methods course during the fall semester of 1997. During the spring semester it will be incorporated into the remaining two elementary methods courses, and the two remaining secondary methods courses.

Students from the methods courses using Educational Structures are involved in school participation while in those courses. Many of those participants, mostly in the elementary methods courses, are able to use their learning of Educational Structures in the schools in which they participate. The numbers of the students doing so will increase in the spring semester.

Evaluation

In order to evaluate the effectiveness of training in-service and pre-service teachers in the use of Educational Structures, the authors are developing a series of questionnaires, interview protocols, and indicators of World Wide
Web use by K-12 teachers and students in target schools and at SUNY Brockport. The evaluation process will involve students as well as teachers in K-12 schools and at the college.

Survey questionnaires will focus on knowledge of Educational Structures and the World Wide Web in general. One survey will focus on student use and will be in three different versions, one for elementary school students, one for secondary students, and one for teacher preparation students. Another survey will focus on instructor use and will also be created in three versions, one for elementary teachers, one for secondary teachers, and one for college faculty.

In addition to surveys, random individual interviews will be conducted with a sample of students and instructors from each level.

Data will also be collected on number of times and length of connect time for each station connected to Educational Structures. Since Educational Structures is provided by IP address, collecting data regarding usage can be traced to individual classrooms or offices.

**Preliminary Observations**

Even as the surveys are being developed, feedback on Educational Structures is very positive. Teacher preparation students at SUNY Brockport as well as faculty find the service extremely easy to use. The college faculty was particularly impressed by the ease of use and many who had been very reluctant to use the World Wide Web have now begun to do so on a regular basis because of the introduction through Educational Structures.

Students in the Dimensions of Teaching course, the first level elementary methods course, were required to use Educational Structures to find and print out three lesson plans; one in science, one in mathematics, and one in either social studies or language arts. One of the professors team teaching this course then based a lesson on critiquing and improving lesson plans on these plans. The step is a big one since last year students were asked to write their own lesson plans.

The general feeling among students and faculty alike is that Educational Structures is a good tool in the teacher training program at SUNY Brockport, and one that is likely to remain available.

---

Morris I. Beers is Professor and Chair of the Department of Education and Human Development at the State University of New York at Brockport, Brockport, NY 14420. Voice, Office: 716 395-2205, Voice, Home 716 637-0085. E-mail: mbeers@po.brockport.edu or mbeers@frontiernet.net.

Mary Jo Orzech is Director of Academic Computing Services at the State University of New York at Brockport, Brockport, NY 14420. Voice, Office: 716 395-2368, Voice, Home 716 637-0809. E-mail: maryjo@acsprl.acs.brockport.edu.
The primary goal of this project is to find a way to make more effective use of the computers and Internet access available in our K-12 schools. With the cooperation of the administration, faculty, and students at the Anthony T. Lane Elementary School in Fairfax County, Virginia, we have begun building an Intranet (internal Internet) to catalog school resources, student projects, and Internet sites that are useful in the daily learning and teaching process. The system is called the Internet Research Center (IRC).

To begin building the IRC, we organized a group of 14 fifth and sixth grade students that meet once a week after school. With guidance from the faculty, these students select topic areas, research the available resources within the school and on the Internet, and then develop HTML pages that catalog what they have found. The HTML pages are categorized into a hierarchy of People, Places, and Things. Many students were interested in taking on this extra research, because they were able to learn more about the Internet and present their work in the interactive multimedia format supported by HTML.

Although the students are learning more about computers, HTML, image scanners, and the networks, the emphasis is on education supported by the technology, not education about the technology. For the IRC to be successful, however, students and faculty members have to be able to easily add and update information in the system. To facilitate these updates, a set of HTML templates have been built. These templates are generic HTML pages that a student can select and then populate with their text and images. The templates reduced, and often eliminated, the need for students to format their work with complex HTML tags. The templates also give a more uniform look to the many diverse topics included in the IRC.

Lane "Internet Research Center" Project

The IRC system's interface was designed to be simple enough for students in second and third grade to use, while offering the breadth and depth of information needed by students in fifth and sixth grade. The interface encourages exploration through reference materials and entices the student to take the initiative and explore related materials. The top level of the IRC has all topics categorized as People, Places, or Things. Figure 1 shows the top level People page. From here students can link to comparable pages for Places or Things, or drill down to see pages on specific people, like to one shown in Figure 3 on the Egyptian pharaoh Sneferu.

The hierarchy of topics is fairly shallow (only a few links deep) over most of the materials. A student can link directly to a specific page from the top level in many cases. Other topics, like Our Solar System (shown in Figure 2) can be linked to from the Places page, but they contain too much material for a single page. In cases like this, another level is added to the hierarchy.

The IRC uses the flexibility of HTML to form links among pages with related materials. For example, the page on Sneferu, shown in Figure 3, can also be linked to a page on his son Cheops and a general page on pyramids. The Sneferu page is also an example of a template that is used widely for biographies in the People section. This template includes the person's name in bold in the top left corner. The dates they lived between under the name and a picture embedded in the free text on the right side. Most templates have areas for Internet references and internal school
resources (such as videotapes and library books) at the bottom.

Figure 2. Table of Contents for Solar System

Our Solar System

Figure 3. IRC page on the Egyptian Pharaoh Sneferu

Challenges

The four main challenges facing the development of a system like the IRC are:

1) getting the basic tools in place, including the computers, software tools, and network facilities;

2) overcoming the cultural hurdle of introducing something new and turning it into something necessary;

3) finding and tracking useful resources on the Internet; and

4) maintaining the system as it grows.

With the first challenge, we were fortunate that Fairfax County had already provided the computers and network to the school. In addition, the school had also been furnished with a flatbed image scanner and two digital cameras for digitizing images that could be quickly incorporated into IRC Web pages. The one software tool we were missing was a WYSIWYG HTML editor. The HTML templates we developed greatly relieved the need for an HTML editor, because the students could edit the HTML templates in a simple text editor. We, however, need to identify an HTML editor soon so that the system is more accessible to everyone.

Overcoming cultural hurdles takes time. The overhead of using computers in schools is formidable and can not be overlooked. Teachers and administration are already under time pressure with their traditional duties. Adding computers to the classroom, lab, and library that require maintenance, software installations, and reconfiguration, without new staff to perform these tasks, simply overburdens the existing people. Even though the IRC is seen as a useful tool, the time required to maintain it can not fall solely to the teachers. For this reason, we worked hard on student and parent involvement in the development. Teacher involvement was, however, still critical. The IRC must support the program of study to be useful in the classroom and the teachers were instrumental in keeping this on track.

Finding and tracking Internet resources can be a time consuming task. Sometimes the best Internet resources are the hardest to find. Some sites are well indexed and leap out of search tools, while other sites are like buried like fossils (invaluable, but requiring great effort and some luck to find them). The Internet is also a dynamic resource. Web pages can change addresses or disappear without notice. Many sites are abandoned and out of date. As the IRC grows, it needs to take advantage of some of the new Web page maintenance systems that help track links that no longer work. This is, however, only part of the problem. Teachers and parents need to monitor the links included in the IRC to make sure that they are relevant and current.

As any experienced software developer can tell you, building a new system is the easy part. Maintaining it over long-term use is the most significant effort. One way to reduce the cost of this long-term maintenance is to use standards whenever possible. Standards reduce the cost of upgrades because there are competitive solutions to choose from and standards are more likely to maintain backward compatibility. Because we were building Web pages that would be seen on both Macintosh and Windows computers, we built all of the pages using standard HTML. We avoided extensions that were not supported by all browsers. Even as the Web migrates from HTML to the more powerful XML standard over the next few years, HTML will still be supported by browsers and will still be used by many Web developers.

Conclusions

We hope that as a result of the IRC, teachers will encourage students to browse the school’s internal resources, knowing that relevant materials are readily available. Teachers know where the materials are so that the
time spent using the Internet is more productive and predictable. Although students still have access to the “Wild West” of the Internet, teachers are more confident that they can supervise this access, because most of the student’s time is spent on internal Web pages and pre-approved external sites.

The interface has been designed to encourage short web pages that are linked to related topics. Not just reading on a computer screen, the IRC is an on-line, organized reference to previous projects, reports, and resources for further research. Students seem to be less inhibited to explore and review one-on-one with a computer than in a classroom setting.

The long-term success of the IRC depends on getting everyone involved. Teachers need to use it as a teaching device and as a resource for their own lecture materials. Exemplary student projects can be archived in the IRC and used to teach others and serve as an example to others. As a Knowledge Management System, the IRC can only succeed if the teachers and students feel a compelling need to use the system and have a sense of ownership and control over it.

Technology, computers, the Internet, distance education - all are words heard with increasing frequency, and ones that are influencing our personal and professional lives, as well as the very fabric of our society. In education (as well as in the business world), there are many examples of how time and location are no longer barriers to collaborative endeavors, as the new technologies enable us to work together in environments without either time- or distance-limitations. At the other end of the spectrum is the growth in classes and workshops designed to provide people with opportunities to learn to use computers (and other technologies) at all levels, from beginning to advanced. Not to be forgotten are those people who have no knowledge of or skills with computers, some of whom because of a conscious decision they have made, but others because of lack of access to the technology.

What does this mean for teacher education programs? We are already seeing some of the effects of the increased numbers of computers in K-12 schools, as many students enter higher education with computer skills that surpass that of their instructors. With Internet access at home and/or at school, many of today’s students are also experienced in the area of on-line communications. Does this mean that teacher education programs can jump right in and join the movement to on-line activities?

The papers in this section provide some insight and guidance in a variety of areas related to telecommunications in teacher education programs. These include some actual distance activities (via video teleconferencing or the Internet), as well as suggestions for training and support activities that will promote effective use of the Internet. The technologies this year include video conferencing, web conferencing, along with web training and use, with themes of telementoring, collaboration, information seeking and retrieval, and others. These may be included in combinations within various papers - a recognition that technology is just a tool, and that the various technologies can be combined as appropriate to provide the most effective teaching/learning environment for our teacher education students and faculty. Many of the following report data from formative and/or summative evaluation of the various projects, providing the rest of us with some suggestions and guidelines that we may use when designing our own telecommunications activities.

Joyce Lynn Garrett and Kurt Dudt describe a high-tech way to minimize the cost of supervising student teachers while adding diversity to pre-service teachers’ classroom experiences. Their program uses video conferencing to supervise student teachers who are at distant sites. Video equipment in the classrooms allows the university supervisors to observe, and then to meet with the individual student teachers and their cooperation teachers. Despite some technical problems, the response has been positive, and the program will be expanding.

A different type of video conferencing experience is reported by Carole S. Rhodes, who describes the use of distance education in a pre-service graduate teacher education program. Originally designed in a traditional one-site format, the course was changed to a video distance education format when six students from another campus wished to enroll. Rhodes reports the reactions of students at both ends (sending and receiving), and suggests some key themes and issues that must be addressed when using this method of instructional interaction. An interactive-web site and an emphasis on the importance of reflection, were also course essentials.

Reflection and the web both are included in the project reported by Charoula Angeli, Lauren Supplee, Curtis Jay Bonk, and Steve Malikowski. In this study of preservice teachers’ use of an asynchronous web-based conferencing program during their early field experiences, research questions included the areas of dialogue (topics), help (requests and given), indicators of effective mentoring on the web, student attitudes, and the relationship between conferencing tools and new expectations related to teaching and learning. Quantitative and qualitative findings are discussed, and the authors mention a follow-up study that will be forthcoming.

Jean Casey’s paper also addresses the issues of the web and student teacher reflection. She describes the current
status of TeacherNet, a project that involves student teachers in telecommunications. Student teachers, having Internet skills before they go into the classroom, are important resources, as they "lead the way by working side by side with other teachers and helping them acquire the necessary skills for information evaluation and retrieval to use in their classrooms and to model for their students." E-mail facilitated communication among student teachers, university supervisors, and each other, developing some networking that continues as support even after graduation.

Barbara Brehm describes a study of another type of Internet activity for teacher education students. NetWorkPlace was developed to provide a visual component to support on-line communications. Pre-service and in-service teachers were involved in a mentoring relationship, with the mentors enrolled in a graduate Language Arts and Technology graduate class. Brehm addresses topics discussed on-line (classroom management was discussed most), perceptions of the experience, and suggestions for those planning future research on telementoring of preservice teachers.

A still different approach to using the web is described by James M. Laffey, Dale Musser, and Thomas Tupper. An interactive shared journal system was created to facilitate the reflective learning process from field experience. The authors describe and illustrate the system, discuss its use by faculty and students, and conclude that the program does promote reflection.

Robert Lucking and Marc Childress also describe a project using telecommunications to promote interaction between two distant groups of persons. Theirs is a tutoring/telementoring activity between prospective teachers and elementary school students, using an advanced distance learning system that included individual work stations with audio, video, and video board capabilities. Preliminary reactions are included, as is a list of questions for further consideration.

The next four papers look at various aspects of using the World Wide Web in instruction. Nancy A. Tate describes a hands-on web-learning experience for elementary teachers, "designed to familiarize then with the resources available on the World Wide Web so that they could use the Web as a tool to enhance their teaching." A key factor was the curriculum connection. Tate discusses the preparation, as well as specific activities for implementation, and some evaluative comments. Of special interest is the list of Critical Success Factors which might be consulted when planning other such activities.

The papers by Raymond S. Pastore and by Roy Tamashiro both examine the use of the web for research. In the first, Pastore addresses several questions related to resources given to students to conduct Internet research and describes a study of 250 elementary and secondary teacher education students and their required Internet research activities. In the second, Tamashiro provides specific guidelines for teaching secondary and university students to conduct web-based research. Suggestions relate to everything from infrastructure to selecting and focusing a topic, through searching, finding, compiling, and publishing. Ideas for minimizing plagiarism are also included. With the increasing use of the Internet for research, it is essential that pre-service teachers have, and are prepared to teach, the required skills.

Roberta K. Weber and Perry Schoon look at the web from a navigational viewpoint. They address several issues identified in two independent studies (at one university) when using the World Wide Web in instruction. The findings indicate that there are specific barriers that inhibit the students' efficiency when using the web for learning, and some of these are related to difficulty in navigating through the web while searching for information. Weber & Schoon suggest that, to minimize frustration of web users, there is a need for instructional design considerations (of web sites and pages) that support learning.

The next paper describes a program that provides students with a very concentrated "boot camp" approach to learning various technologies to use in support of education. Abbie Brown explains how this intense two-week session was preceded by three-weeks on-line, for students to get to know each other and to begin some of the organizational activities to prepare them to come to campus and to participate in the "boot camp" computer activities. This model of combining on-line course activity with an on-campus intensive-study component is one that might be considered as we search for new combinations of delivery methods, in an attempt to find the most effective and efficient way to provide educational experiences for our students.

We often hear that telecommunications and distance education are the way of the future. As with other educational practices, though, it is essential that if and when these are used to promote teaching and learning of students at any level we examine them carefully to make sure that they are the most appropriate, efficient, and effective means with which to accomplish our objectives. The authors of the papers in this section are doing just that. They are innovators, sharing their experiences and findings with us.

USING VIDEO CONFERENCING TO SUPERVISE STUDENT TEACHERS

Joyce Lynn Garrett
Indiana University of Pennsylvania

Kurt Dudt
Indiana University of Pennsylvania

The cost of supervising student teachers has become a concern for colleges and universities across the nation. The impending teacher shortage means that already large programs will grow even larger. Already overwhelmed local schools will feel the impact even more seriously. In addition, the demand for more diversity of experience means that most teacher education programs, especially those of universities located in rural areas, find it necessary to place student teacher farther and farther away from their main campuses. The idea of supervising clinical experiences of pre-service teachers using video conferencing grew out of a need to reduce costs associated with teacher education. It takes about $14000 a year to educate each teacher candidate at Indiana University of Pennsylvania (IUP). Costs will escalate as demands for less reliance on local schools and more diverse experiences continue to increase.

IUP places student teachers in 150+ school districts from Pittsburgh to Philadelphia and from Bedford to Erie, an area of more than 60,000 square miles. It has also developed partnerships with Indian reservations as far away as North Dakota and Arizona, and has partnership schools in Great Britain and Western Europe. Supervision in these distant sites is both costly and time intensive. In most cases, the faculty must be away from regular duties for two or three days; but in some cases, supervision requires them to be away for extended periods and they must arrange teaching and research activities accordingly.

Attempts to reduce financial burdens to the College of Education and ease faculty stress by using site-based supervisors from local colleges and universities have fallen short. In the best situations supervisors may not be fully familiar with the teacher education program at IUP so supervision does not meet desired standards; in the worst instances, contracted supervisors have failed to visit their student teachers even one time during the 14 week experience, which is unacceptable at a university noted for a quality teacher preparation program.

One solution that has shown promise is use of video conferencing to supervise student teachers in distant locations. The College of Education at IUP received a three-year grant from the United States Department of Education, Fund for the Improvement of Postsecondary Education (FIPSE), to conduct research and evaluate video conferencing as a tool for reducing costs of supervising clinical experiences at the teacher education program at IUP. The goal is to determine whether quality supervision can be achieved and high levels of student teacher achievement maintained.

Millcreek Township School District in Erie, Pennsylvania seemed an ideal place to launch this work. Millcreek is an Apple School of Tomorrow and a technology partner with IUP. The district was involved in many technology exchanges with IUP, from meetings to in-service education for teachers to "teach-ins" by secondary science students; but no student teachers had been placed there.

The District had the potential of providing an outstanding experience for student teachers from IUP, but the District's location, about two and one-half hours away from IUP, was a limiting factor. Placing student teachers in this highly desirable setting was especially difficult because traditional supervision was nearly impossible given winter weather conditions in northwestern Pennsylvania. Discussions of ways to resolve the problem gave way to planting the seeds for this project.

Equipment and Networking Needs
What does it take to make supervision by video conferencing work? It takes dedicated work of professionals and technical staff, plus equipment and a network. The facility includes three essential elements: a CODEC unit, a network, and a room (Brooksby, 1994).

One CODEC unit must be installed at each of the two or more sites in the video conferencing network. The CODEC digitizes and compresses video and audio signals for transmission (Brooksby, 1994). Working together, each CODEC sends and receives signals.

Compatibility between different manufacturer's CODEC units has been a problem. Users had to have the same manufacturer's CODEC unit at all sites to communicate. Recently, the industry has established standards of compatibility (H. 320) to permit communication world wide.
between different manufacturer’s CODEC units. Also, video conferencing equipment now combines key components into a single system. Cameras, microphones, monitors, speakers, and control panels are integrated into one easily moveable unit. When considering video conferencing CODEC units, make sure that it has the international video conferencing standards of ITU-T H.320.

Support equipment needed to obtain maximum usage from a system should include a document camera, wireless clip-on microphone for instructors (or student teachers), table or ceiling mounted microphones for participants (classroom students), an auxiliary camera (for more than one camera angle), and a VCR designed to tape or show videos. Additional monitors may be used also to facilitate the interactions of large groups.

The network transmits information to and from CODEC units. A variety of formats can accomplish this task, including fiber optics, ISDN lines, and T1 (T-one) lines.

Fiber optics—A communication medium based on laser transmission. Glass or plastic fiber carries light to transmit video or audio data signals. Each fiber can carry 0 to 150 megabits of digital information per second or 1,000 voice channels. Transmission can be simplex (one-way) or duplex (two-way) voice data and video service (Portway, 1994).

ISDN lines—The Integrated Services Digital Network is a set of standards that transform an ordinary telephone line into a high speed data line capable of carrying information at 50 times the speed of conventional phone service. ISDN lines can carry extraordinary amounts of information (Hetrick, 1994).

T1 Lines—These high-speed digital data carriers deliver very high quality visuals, but are more expensive to use than ISDN lines.

ISDN lines were chosen because of their availability in Western Pennsylvania. Three lines provide a transmission rate of 386 KBS, an acceptable speed for transmitting video signals. Lower compression levels have a lower price tag for each hour of video conferencing; but the cost is slower transmission time with poorer real time representation.

ISDN lines at low levels of compression, however, can produce satisfactory quality video, especially for visuals without significant amounts of motion. Motions appear jerky, with a “tail-like” appearance. Experience has shown, though, that slightly lower quality visuals do not negatively affect viewer’s participation for educational purposes.

ISDN lines are also fairly inexpensive to operate. They are roughly equivalent in price to two times the cost of a long distance phone call to the same site (each ISDN line has two channels).

The most significant way to reduce the cost of operation is to do careful planning. Events should be preplanned, carefully timed, and based on clear objectives. Using these tips will mean moving smoothly from point to point in video conferencing activities ranging from group discussions to the supervision of student teachers.

Research and Evaluation

This project is designed to occur in three phases. The first was a pilot study to provide feedback for modifying and expanding the second and third phases. During phase one, three student teachers, three cooperating teachers, and two university supervisors volunteered to participate. Phase two, currently underway, involves 14 student teachers and their respective university supervisors and site based cooperating teachers. In phase three the number of “wired” sites will increase to three and the number of participating student teachers will increase to at least twenty-four. In each instance, a control group of carefully matched cohorts, who are participating in traditional site-based supervision, are providing data also.

Data were collected from participants in each of the three categories: student teachers, cooperating teachers, and university supervisors. A control group matched on all salient characteristics provided comparison data for the study. Pre- and post-experience data were collected about participants’ attitude toward, use of, and satisfaction with technology-based supervision of student teaching. Although a cost analysis was also conducted, the analysis of those data is not complete.

These data were useful in guiding the planning process for Phase II of the project. Project staff have elected to report them, because they could be helpful, as well, to others considering the use of video conferencing to accomplish activities not normally associated with the technology.

Analysis of Attitude, Use, and Satisfaction Data

University Supervisors

Data for follow up evaluation were collected from two university supervisors, three cooperating teachers, and three student teachers. Each was asked to complete 14 questions on a written questionnaire. The outside evaluator for the project reviewed the questionnaires for completeness, clarity, and comprehensiveness. Questions were designed as closed-ended, open-ended, and Likert-type. All participants responded to all questions, making all data usable for the purpose of analysis. The small N for Phase I limits reliability of the conclusions and generalizability of results, however.

Two university supervisors, with 12 and 9 years of experience respectively, reported supervising between 25 and 30 student teachers to date. Both reported this experience as their first using video conferencing to supervise student teachers. Each reported using it to supervise her student teacher over five times during the semester. Observations lasted between 30 and 40 minutes.
Video conferencing was also used to conduct planning conferences, pre-conferences, and post-conferences. The 2 to 5 planning conferences for each supervisor and student each lasted about 10 minutes. Pre-observation conferences also numbered between 2 and 5 and lasted between 10 and 15 minutes. Between 2 and 5 post-observation conferences were held and lasted between 10 and 20 minutes on average.

One supervisor held both midterm and final evaluations using video conferencing. The other only the final one—she felt compelled to make her midterm in person due to perceived problems with the use of video conferencing in a special education classroom setting.

Both report many positive aspects of using video: (1) it saved time; (2) they liked being part of an innovative project; (3) they developed skill in using video conferencing for future activities; and, (4) they like the collaborative nature of the IUP/Millcreek partnership. One also identified these: an otherwise unavailable site was made available, a definite schedule of observation was established, comfort and confidence levels increased with use of technology, and information from the experience was incorporated into a methods of teaching class.

Some less positive aspects of using video conferencing to supervise student teachers were also noted. Both suggested the audio quality was not adequate, a finding consistent with those from evaluation of the pre-student teaching experiences reported in an earlier annual report. At least one reported that technical difficulty with the ISDN lines and the ability of the local telephone company to deliver service affected her satisfaction rating.

Both university supervisors reported high levels of overall satisfaction with the system to supervise their student teacher. On a scale of 1-5, (5 was high), respondents were rated: overall effectiveness, quality of feedback they were able to provide students, and overall satisfaction with video conferencing.

One rated the overall effectiveness as 4 and the other rated it as 5. One rated the quality of feedback given using video conferencing as average (3), while the second rated it excellent (5). Both rated overall satisfaction with the use of video conferencing as high, One as 4 and the other as 5 and said they would use it again and would recommend it to others for student teaching related activities.

Finally, both made open-ended comments to explain their ratings:

US1: "I will be using video conferencing again this fall. I was very pleased with the experience."

US2: “Conferencing is sometime(s) awkward with video conferencing, especially when I haven’t met the cooperating teacher in person. The conversation is sometimes stilted and seems a little artificial. I think that’s probably unavoidable because this first semester held the awe of new technology for the student teacher, the cooperating teachers, and me.”

Cooperating Teachers:

Three cooperating teachers responded to the same questionnaire. All are experienced female teachers; one with 18 years teaching experience and two with nineteen. Their involvement with the student teaching program is 1 year, 4 years, and 10 years respectively, with between 1 and 6 student teachers among them. This is the first time any of them have had an IUP student teacher.

Like their university supervisor colleagues, this was the first time they had used video conferencing as part of the student teacher supervisory process. When queried about their use of video conferencing during the semester, one said she used video conferencing one time for about 45 minutes. One stated she used video conferencing between two and five times during the semester for an average of 30 minutes; and, one reported using it over five times for an average of 45 minutes each time.

Cooperating teachers also used video conferencing for planning conferences, pre-observation conferences, and post-conference activities. One reported she did not use video conferencing for planning purposes; one reported using it for planning one time for 15 minutes; and, one used it for two to five times for an average of 45 minutes. Uses of video conferencing for pre-conferencing were also varied. Two reported never using video conferencing for this purpose. One used it two to five times for 45 minutes. One cooperating teacher used video conferencing during post-observation conferences two to five times for an average of 45 minute; two reported never using video conferencing for this type activity. Two cooperating teachers reported not being involved in the midterm or final evaluations; one reports she was involved in both for about 45 minutes each time.

Data reported by one cooperating teacher regarding her use of video conferencing for the purposes of planning and pre- and post-conferencing were inconsistent with data reported by university supervisors and student teachers. There is no explanation at this time for these inconsistencies. The questionnaire has been revised, however, in hopes this will address the problem.

Positive aspects in the student teacher supervision process were also reported by cooperating teachers. Three cooperating teachers reported as positive the fact that (1) an otherwise unavailable site was made available; (2) they got to be part of an innovative project; (3) the university supervisor was made more available; (4) they became more comfortable and confident in the use of video conferencing as the project progress; and, (5) they developed skill to use video conferencing for future activities. All three also noted the collaborative nature of the IUP/Millcreek partnership as a positive aspect of their participation in the project.
Two of the three cooperating teachers reported time saving and knowing the schedule of observations in advance as positive. One supported the positive of advanced scheduling by reporting that establishing a definite schedule of observations was a positive aspect of using video conferencing.

Open-ended remarks by cooperating teachers suggest making video conferencing available for other activities. Another commented about the positive relationship between IUP and Millcreek and suggested that the system might be used as a way for Millcreek students to observe university classes in session (to help alleviate their anxiety about attending college—important for first generation college students).

Finally, two cooperating teachers stated they would use video conferencing again. The third one reported she might use it again, but did not list the conditions that would sway her one way or the other.

Areas which cooperating teachers thought could be improved were: scheduling of observations and meetings (2), video quality (2), audio quality (2), increasing the number of observations (1), more preplanning of the entire video conferencing experience (1), more mobile equipment (1), and making the equipment more available. One cooperating teacher expanded the close-ended questions by stating:

CT2: “The microphone situation is clumsy. Stationary mikes [microphones] and one clip on [microphone for]...[make it difficult] to hear pupil answers and [student] teacher needs to repeat responses for the [university supervisor].”

Overall, cooperating teachers report video conferencing effective for the supervising student teachers. One rates it 3, another 4, and another 5 on a scale of 1-5 (5 is high). They rate the quality of feedback they were able to give or receive via video conferencing high. Two rated it 4 and one rated it 5.

Cooperating teachers’ overall satisfaction with using video conferencing in the supervisory process was also high. One rated it 4 and two rated it 5.

Additional open-ended comments to support these ratings were provided by several respondents. Below is a typical quote:

CT1: “This proved to be an exceptional experience for all student teachers. Our child development/distance learning project received press from local news that created public awareness. Parents were impressed and proud that their high school students were offered [the opportunity] to participate.”

Student Teachers

Three student teachers participated in the pilot project begun in the Spring Semester 1996-97. Two were students in the Family and Consumer Services Education Program (Home Economics) and one was a student in the Department of Special Education.

One student reported between 2 and 5 observations by the university supervisor using video conferencing equipment; one reported over 5 observations. Observations averaged about 40 minutes each. Planning conferences were reported also by this group as an activity in which they engaged. One person reported a single planning conference of about 40 minutes, while two colleagues reported between 2 and 5 conferences averaging 25 minutes each. Pre-observation conferences were conducted for all three student teachers; one student reported participating in one conference and two reported participating in between two and five conferences of 15 minutes each. Post-observation conferences were reported as well. Two students reported one post-observation conference each. One stated the conference lasted about 10 minutes, the other reported a conference of 30 minutes in length. One student reported over 5 conferences averaging 10 minutes in length. Midterm evaluation conferences occurred for two students, and averaged 15 minutes in length.

Two student teachers reported they would both recommend and use video conferencing again as part of their student teaching activities given the opportunity. One stated s/he might use it. Reporting technical problems, need for more technical support, and problems using the equipment with students who had not used it previously.

No further explanation was provided and no follow-up interview was conducted. Project directors do know this response came from one of the student teachers working with special education students; and, though not reported, it is believed the respondent is referring to concerns also expressed by the university supervisor (moving special education students to a new environment where video conferencing capability was available).

Student teachers agreed that use of video conferencing was positive because: (1) it made an otherwise unavailable site available; (2) it made it possible to be part of an innovative project; and, (3) of the collaborative nature of the Millcreek/IUP partnership. Two said it helped them develop skill in the use of video conferencing for future activities. At least one reported it: (1) made the university supervisor more available; (2) made possible the establishment of a definite schedule of observations; (3) made it possible to know the schedule of observations well in advance; and, (4) made the participant more comfortable with the use of technology as the project progressed.

Areas that could be improved were also noted by student teachers. All three reported the need for more preplanning for the entire experience. One student suggested a dry run or pre-training experience. Two student teachers thought the scheduling of observations and meetings needed to be improved and that there needed to be more preplanning for each observation. One student reported that the audio
quality needed to be improved. One student also reported s/he would like to see an increase in the number of observations.

The following data were collected using a Likert-type scale of 1 to 5 (1 is low and 5 is high). Overall, two student teachers rated effectiveness of using video conferencing as 2, one reported it as 4. All were very happy with the quality of the feedback they received from supervisors using video conferencing; one rated feedback as a 4 and two rated it as 5. All three student teachers report their overall satisfaction as 4.

Student teachers provided several additional comments. One student stated:

"I appreciated being a part of this innovative project. If any further assistance is needed please feel free to contact me."

Another stated:

"The video conferencing was great, however it would have been more effective if the students were not taken out of their usual lrg [learning] environment (especially special ed)."

Summary Statement:

Project directors learned a number of things to help modify the project. Although very preliminary, significant findings about what works suggest that:

1. Video conferencing for student teaching supervision is effective.
2. Video conferencing works across settings and disciplines.
3. With minimal preparation, students, cooperating teachers, and university supervisors are able to use video conferencing in the supervisory process.
4. Currently available technology is sufficient to provide effective supervision of student teachers in distant locations.

Information from Phase I of this project suggests:

1. For participants, involvement in an innovative project and the availability of an otherwise inaccessible site seem to outweigh the minor technical problems.
2. Equipment location should not dictate usage, especially for students who may have special learning needs.
3. There is a need for well-planned pre-training/orientation to the use of video conferencing for supervising student teachers.
4. Human aspects of planning, scheduling, and conferencing may be more important to the perceived quality of distant supervision than technical aspects of using the video conferencing equipment.

This project was made possible with a grant from the U.S. Department of Education Fund for the Improvement of Postsecondary Education.

MULTIPLE PERCEPTIONS AND PERSPECTIVES: 
FACULTY/STUDENTS’ RESPONSES TO DISTANCE LEARNING

Carole S. Rhodes
Pace University

Technology has dramatically changed the way people interact and communicate. Many educators have readily embraced the idea that technology will, to varying degrees, alter their teaching. Technology lets educators explore multiple delivery systems and varying means of communication between teachers and students. Research conducted during the past five decades found no significant difference in instruction offered in traditional classroom contexts and those offered by forms of remote transmission such as television (Russell, 1992).

The use of technological advances has been an easy accommodation for some educators. For others, this has not been the case. Any change or paradigm shift comes with attendant concerns and frustrations thus it is necessary for educators to look closely at the process as we engage in varying delivery and communication systems. Reflection on the teaching/learning process, then, is crucial. Richardson (1990), in calling for an “individualistic, psychoanalytic approach” to teacher education, recognizes that lack of reflection leads to “an idiosyncratic view of teachers. That is, the teacher teaches as he or she is. How then, are we to think about affecting change?” (p.13). In order to facilitate such change, reflection was an integral part of the course.

In Psychology of Personal Constructs, Kelly (1955) notes that people use experience to create constructs through which they create new experiences and then verify or modify other experiences. We build each experience, then, upon experiences that are, in turn, modified through future experiences. This process is one in which we view the participants as “explorers” investigating their own historical landscapes (Pope and Keen, 1981). Through this exploration of self and one’s educative experiences, the educational context and perspective continually evolve. Kelly refers to this “permeability of constructs” as the working through ideas not rigidly held but open to change through new experiences.

Participants and Setting

The participants in this study were all pre-service graduate teacher education students at a large urban university. The participants were enrolled in a degree program leading to a Master’s of Arts in Teaching. All of the students were “career-changers” who, after several years in various professions, were now pursuing careers in teaching. Formative and summative qualitative data was gathered on the expectations, experiences and impact of the distance learning component of this course on the participants.

Context

The University has several campuses within a forty-mile distance of each other. I was scheduled to teach a course entitled “Language and Meaning” during a six-week summer session on one of the University’s campuses in Westchester, a suburb of New York City. Approximately two months before the beginning of the course, six students from the New York City campus requested that this course be offered on their campus too. Due to many factors, this was not possible. In trying to accommodate these six students, the idea of teaching the course via synchronous distance learning technology was born.

When I was asked to consider this prospect, I was intrigued. I have always been interested in technology, and I try to be innovative in my teaching. Nevertheless, here I was, a relative newcomer to the University, teaching a new course for the first time, considering embarking on this new adventure. As a teacher educator, I felt that it was important to take risks and try new teaching strategies, and I believe that technology, increasingly, will play a role in the lives of my students, all of whom are future teachers. Knowing very little about the “mechanics” of distance learning, I agreed with the proviso that the New York City students would agree to meet with me at least twice during the six-week course.

Implementation and Discussion

The course was offered via an interactive two-way audio and video delivery system in which participants on each campus were able to view each other. I taught the course on-site in Westchester with real-time transmission to the New York City campus. I also set up an interactive web site in

Telecommunications: Preservice Applications — 1089
the hope that this would facilitate communication between and among the students (Rhodes and Flank, 1998).

On the first day of class, I explained to the Westchester group what we were doing and why. The New York City group which had grown to ten students, knew about the distance learning situation. Many students in the Westchester group were uncomfortable with the prospect. They were concerned, confused and worried that they would not learn. We spent a great deal of time talking about the logistics of the course and the concerns of the students. We talked extensively about technology and its role in teaching and how this course could provide a demonstration of such a teaching/learning situation. We talked about taking risks as teachers and as learners. The students in New York City were much more comfortable with the situation, apparently recognizing that this was done to accommodate them. Three of the Westchester students seemed resentful and said that they might not have registered for the course if they knew that it was being offered this way. Although they were assured that they could drop the course with no penalty, they ultimately decided not to.

Initially, there were some problems with the transmission across locations. Initially there often seemed to be too much “down time” because the technological glitches interfered with the normal flow of a traditional class. Students at the remote site could not see things written on the chalkboard. Sometimes students could not hear each other. We forged on though. The interactive web site was active but only five students logged on during the first week.

Since this was a course for future teachers, we decided to focus not only on the content of the course but also on the process of being engaged in this distance learning situation. We explored the research on teachers as reflective practitioners as we navigated through the course. Students were asked to reflect on their experiences. I did too. After the first class I wrote:

I wonder about this experience . . . how will I ever manage this situation. I pride myself on knowing my students, but how am I ever going to get to know the NY group. They seem so remote—they are! This may not work for me. I’ve got to find a way to acclimate myself and my students. While I understand their discomfort, I hope that they realize that this will be a valid educational experience. Why are the Westchester students so uncomfortable? We’ve got to talk about this and relate it to their future professional lives. They too will be confronted with students who are angry or resentful or merely afraid. They need to see that this can be a great experience and their struggles will help them better define themselves as teachers. I need to help them.

After our second class, Kathryn and Paul, both Westchester students, decided to write their reflections on the web site rather than on paper. Most of the New York students discussed their feelings of being in a University setting which clearly was responsive to students’ needs. During this first week, none of the New York students focused on the content of the course or on the technological aspects of the course.

Honestly, I wasn’t sure after the first class, whether I would like the distance component to the class. I’m still not convinced but I think that this class went smoother and I don’t feel as much like I’m going to miss out on the content because of the technology. I couldn’t imagine myself taking a class by distance learning. As discussed at the end of the class, I feel that both the students and the teacher lose the personal contact and body language which I feel is invaluable in communication. I can see the value in a distance learning class, but I hope that it is not the wave of the future. (Kathryn-Westchester)

The jury is still out on the conferencing between the two campuses. So far it has worked out well for me, but I’m assuming that is because I’m in the class with the teacher. I feel strongly that conferencing is not the way to go in Education. There is just too much that students and teachers miss out on when they are not in the same room. How can we pick up on the body language? (Paul-Westchester)

By the second week of the course, we all became a bit more comfortable with the distance aspects of the course. Interestingly, some issues that arose out of the technological inclusions were interspersed within the course content. Students pondered language and meaning in varying contexts. They looked at various forms of communication, they questioned how people construct meaning and as they began to use the web site more, they pondered whether written communication was more meaningful than verbal communication. Often, the dilemmas posed by the technology formed the impetus for closer connections to the content of the course. The students began to look at the course as teachers rather than just as learners.

From a Westchester point of view, this is an interesting experiment to be a part of. I do not mind being a guinea pig from this perspective, and can personally put up with anything for a worthwhile common good. However, I still “feel sorry” for the NY people. I do not think they will get as much out of this class. I view them as “passive learners” - just like kids watching TV vs. being in a real hands-on learning situation with interpersonal feedback. They are listening, but are they tuned into the dynamic professor? They are not voluntarily responding, only responding when directly asked questions. It will be interesting to see if they become more active participants as the class progresses or not. Then again, maybe the NY people are happy being in a passive situation, where demands to participate are psychologically less, because they do not have the physical presence of the professor or eye contact with the prof to prompt them to respond. Some of them might be content
just sitting there anonymously, soaking up what information they choose. Others might be frustrated, but not express it, because they simply feel very self-conscious being on the TV screen or talking into the microphone, just as many people do not like their picture taken or voice recorded (Nadine-Westchester).

Just a few comments about the video hook up system we're using. It seems to force us to engage in "report talk" rather than "rapport talk" more typical of other classrooms. Sometimes it feels like I'm speaking over the PA system at Yankee Stadium. In N.Y., the fact that we each have to find the microphone, then turn it on, then interrupt the discussion in Westchester of course limits the spontaneity of our comments. As for the web site, this is a first for me. My initial thought was that this was interesting to witness on a one-time basis, but "we want Carole back." (Nadine-Westchester)

I was feeling much more comfortable. The students were engaged in thoughtful discussions and were better able to communicate across campuses. But, as I read Nadine's and other Westchester students' reflections, I realized that many of them were trying to figure out what it might be like to be on the receiving, rather than broadcast site. I decided that experiencing both situations was important for them and I arranged to switch sites and broadcast from New York rather than Westchester. Again, the Westchester students expressed concern. However, we were able to discuss how this would enable them to more clearly see some pedagogical issues and more closely identify with their NY classmates. I ultimately taught on-site from New York three times during the six-week course.

It will be interesting to see the participation level of the NYers vs. the Westchester people, on the evening(s) when the roles are reversed. I believe youngsters, in general, especially those in grades K-8 would have less trouble and even eagerly embrace the concept of long-distance learning more readily than adults. These kids have grown up in a technology age (Diane-Westchester).

I happen to be enjoying this class very much. However, when you made the visit to the New York Campus for the day, I felt as if you were not part of the class or our professor. During that session the class seemed to be longer, more drawn out, and our attention spans were far less than the regular classes that occur with you present. As a result, I am very glad that I am on the Westchester campus, and I do feel for those on the New York campus, because I can understand how they can become annoyed when they cannot intervene on the spot, instead they have to pause and wait for the microphone, or if they cannot interact as they would like to. This class is one of a lot of action. (Shelly-Westchester)

As some of us anticipated, the unanimous feeling in Westchester was that we did not enjoy being on the opposite end of the camera and microphone. The consensus was that this was interesting to witness on a one-time basis, but "we want Carole back." (Nadine-Westchester)

I happened to enjoy the broadcast from the Big Apple. I was glad to get a chance to see it from "the other point of view." I know that some of you aren't comfortable with it but I think this experience is a valuable lesson that can be utilized in many ways. One thing I think we all should work on is giving NYC a chance to speak more. I commiserate with you all in NY regarding the "back burner" feeling that is sometimes felt while being on the receiving end. (Rick-Westchester)

As the semester progressed, the technological aspects of the course became secondary. Seven of the students from both campuses decided that they too, wanted to switch sites occasionally. They felt that they wanted to more fully engage in the experience and they also wanted to get to know their classmates more. We added a telephone linkup and were able to do inter-campus group work. With the exception of one student, ironically a New Yorker, all seemed to be at ease with the remote transmission and were readily able to move beyond the technology and focus more deeply on the content. By the fifth session, students on-line comments rarely dealt with issues of technology and mostly dealt with content specific issues. I wrote:

It feels like it's all coming together. The content of the course has always been intact, but the polarity of the two sites seems to be diminishing. People on both campuses have fused into one class. There is a cohesiveness, a bonding.

The students continually reflected on their experiences, focusing on themselves as learners and as future teachers. Except for one NY campus student, all reported positive feelings about having been involved in a distance learning situation, though more than two-thirds of the students did not feel that it was something that they would like to use in their teaching.

I do appreciate the opportunity of being in this class and experiencing distance learning first hand. I have become much more comfortable on the Internet and have gotten to know people on two campuses. The course stands
as a lesson to us all and I think we are all better for having been a part of it. (Alice-Westchester)

As part of their final project, the students were asked to reply to the topic “Where I was, where I am now?” Perry’s reflections parallel those of most of the participants:

My final thoughts about distance learning: On the first night I was skeptical and considered surrendering, but I’m glad I hung in there. It was indeed an interesting experience. It remains undoubtedly preferable to be on site with the teacher. Because it extends a course’s reach, allowing students to take those they otherwise might not be able to take, it’s a positive development. It should lend itself well to lecture courses, not interactive courses like ours. Where am I? Much more enthused about technology and much less scared of it.

On the last night of class, we all met in a restaurant midway between both campuses. While several students had transversed campuses and therefore met each other, many of them had not. Over dinner, the conversations centered on typical topics, but interspersed were discussions of connecting with a teacher, limitations of technology, teaching and learning and the desire to continue to relate to each other.

Conclusions

Analysis of the formative and summative data gathered from the participants reveals key themes and issues including: the need for interaction among students; the need for student-teacher interaction, pedagogical concerns of distance learning courses; the impact of interactive-web sites in education and the role of reflection on one’s learning.

Overall, most of the students indicated that they had never reflected on their own educative experiences. They noted that while doing so now, they learned about themselves in ways they had not thought about before. Most of the participants noted increased self-understanding. Many participants noted that they were better able to get in touch with their own learning processes.

One outcome of this research is to encourage teachers to reflect on their educative experiences as a way of better understanding their classroom practices. A second outcome is the generation of questions about the effective incorporation of distance learning.

A CASE-BASED ELECTRONIC LEARNING ENVIRONMENT FOR PRESERVICE TEACHER EDUCATION

Charoula Angeli  
Indiana University

Indiana University

Lauren Supplee  
Indiana University

Steve Malikowski  
Indiana University

This study took place within a teacher education program at a large Midwestern university with vast field observation placements around the state and world. In the first field experience of this program, preservice teachers study for 20 hours with nearby public school teachers. Here, students experience varying degrees of isolation from their instructors, cooperating teachers, and peers. Not surprisingly, many students are lonely and unsure of their responsibilities, while cooperating teachers only have a vague idea of what is expected of the visiting student. Fortunately, as Singletary and Anderson (1995) point out, there are a number of emerging computer conferencing technologies to support beginning and inexperienced teachers with specialized training and consultation.

The purpose of this study, therefore, was to discover whether preservice teacher electronic conferencing on the World Wide Web (WWW) about early field experiences can have an impact on their learning of educational psychology and general apprenticeship within the teacher education program. In building on an earlier comparison study of synchronous and asynchronous conferencing, favoring the latter, this follow-up second experiment was conducted in the spring of 1997 using student-generated cases and an asynchronous web-based conferencing tool called Conferencing on the Web (COW). In a nutshell, this study combines the power of asynchronous conferencing with case-based reasoning and peer and mentor collaboration to electronically apprentice student learning.

Technology Meets Learning Theory

Cases have been used in law, medicine, and business to ground student learning into the context of these disciplines (Riesbeck, 1996). According to Williams (1992), the case method has been used to anchor classroom activities in complex situations wherein students can reflect on the utility of knowledge while understanding the conditions of use. However, she also points out that cases can vary in their authenticity, complexity, engagement, and underlying format. In terms of format, cases can be presented as simple narratives, cases with embedded flaws, cases with expert commentaries, and cases with alternative or counter cases (Silverman, Welty, & Lyon, 1992).

According to Copeland (1989), technology-mediated laboratory experiences might enhance the level of preservice teacher reflection and clinical reasoning about such cases. The time independence of asynchronous web-based conferencing tools, for instance, now offers students opportunities to evaluate, summarize, and communicate critical information about a case situation or problem. Recent developments on the WWW have made available cheap, fast, and broad opportunities for preservice teacher case reflection as well as potential access to expert teachers and mentors. Using the web, college instructors, therefore, might apprentice preservice teacher learning by modeling expert-like answers, providing feedback on student misconceptions, and offering key instructional help and task structuring. Electronic cases might also allow preservice teachers to jointly construct new knowledge with distant peers under the tutelage real-world practitioners (Riesbeck, 1996).

As Singletary and Anderson (1995) state, there are a number of emerging computer conferencing technologies to support beginning and inexperienced teachers with specialized training and consultation. Web-based conferencing (WBC) allows users to read, browse, and add to multiple discussions by using a web browser anywhere in the world. Hence, one does not need access to networks or systems at a particular university to participate in an electronic discussion. All that is needed is access to the WWW and conference clearance from the conference moderator. Another benefit of WBC is that discussions occur asynchronously, permitting the user to read, browse, or add to them at his or her convenience.
Most research on the use of collaborative educational technologies in higher education fails to provide extensive theoretical grounding (Koschmann, 1994). Moreover, faculty and public school teachers sorely lack important information about the effects of various tools and how to embed them in their classes. As a result, some researchers turned to sociocultural theory (Vygotsky, 1986) to evaluate and understand electronic learning environments. Though sociocultural theory continues to evolve (Wertsch, 1985), few studies focus on how sociocultural variables impact adult learning and problem solving (Forman & McPhail, 1993). One sociocultural concern in electronic learning environments is what forms of learning assistance (e.g., scaffolding, see Collins, Brown, & Newman, 1989; Teles, 1993) are evident in electronic computer conferences. Another variable of interest relates to how meaning is negotiated and common knowledge acquired (Rogoff, 1993) are evident in electronic computer conferences. A third crucial sociocultural issue is how experts or practitioners cognitively apprentice novice learners in developing skill through authentic learning experiences or exposure to cultural practices (Lave, 1991).

Research Questions
The following research questions were examined:

Dialogue
- What topics spur discussion? How does peer responsiveness affect the depth of dialogue? How is intersubjectivity displayed?

Requests for help/Learning assistance
- How do students ask for and receive help? What types of advice and learning assistance (i.e., questioning, feedback) do peers, cooperating teachers, and instructors provide in this web-based conference?

Scaffolding and apprenticeship
- What might be the indicators or signals of effective mentoring on the web? How might apprenticeship and emerging expertise be captured electronically?

Attitudes
- What are the students’ attitudes toward using computer conferencing within their early field experience? Will they prefer heavy or weak scaffolded discussion?

Teaching philosophy
- Will using conferencing tools foster new expectations of teaching and learning?

Research Methods
Subjects and Intervention
During the academic year of 1996-1997, 146 undergraduate educational psychology students were randomly assigned to two different electronic conferencing groups, one group was heavily scaffolded and the other was not. When in a strong scaffolding conference, students received more task structuring, instructor guidance and feedback, moderator queries, and cooperative teacher recommendations. When in a weak scaffolding conference, students received feedback from their peers, and, when they requested it, help from the instructor. Each student was asked to generate two problematic teaching cases based on his or her observations in the field, as well as provide plausible case resolutions based on readings and lectures. Students were also asked to give feedback to at least four peers on their cases and summarize the electronic discussion generated by his or her respective case as well as at least one peer’s case. After three weeks the students who received heavy scaffolding were assigned to another conference where they received weak scaffolding. Along the same lines, the students who received weak scaffolding during the first three weeks, were assigned to a conference where they received strong scaffolding. Such counterbalanced research design was important to control for the effects of system familiarity and utility.

Conferencing Technology
The WBC tool used here is called Conferencing on the Web (COW). COW is organized into three basic levels. At the base level is the conference level. While this is typically a single class, the four conferences reported later on in this paper each consisted of students from five different sections of undergraduate educational psychology. Conferences can be public (i.e., needing only a COW account) or private (i.e., needing permission of the conference moderator or “fair witness” to view). At the second level of COW, each conference is organized into topics (e.g., lecture-based questions or issues). Topics are typically listed at the bottom of the conference main page. At the third level of COW are conversations between students and instructors in response to the material presented in class. Most electronic conferencing actually occurs at the conversation level wherein new messages are posted below older messages. Anyone permitted to join a COW conference can start conversations or reply to conversations here.

Data and Instruments
All of COW case discussions and conferencing activities were saved and archived for in-depth analysis. Aggregate conference posting data was printed out after the conferences ended. In addition, a sample of 60 case discussion threads were analyzed for dialogue content, case quality, and forms of mentoring. Exemplary instances of individual commenting were noted. Finally, after the conferences ended, three of the five course sections took a five minute survey about their attitudes toward the conferencing activity.

Quantitative Analysis
As indicated, the WBC system automatically provided extensive empirical data regarding system usage. This information included: (1) the number of people who
accessed the system and who actively contributed; (2) the overall number of messages and length of message posted to COW; (3) the number and length of responses in the HS and WS conditions; and (4) the average length of a case, case threads, and case summaries.

**Qualitative Analysis**

Qualitative data were combined with the above quantitative data to build a chain of evidence about the collaborative formats and interaction patterns that facilitate student learning and reflection on the web. Student electronic transcript conversations were coded for discourse type, case components, case summary components, question type, and the forms of learning assistance and mentoring (Tharp & Gallimore, 1988). After the semester ended, a stratified random sample of 35 HS and 25 WS cases or electronic discussion topic threads representing a wide range of discussion and response depth were chosen for content analysis (e.g., Bonk, Hansen, Grabner, Lazar, & Mirabelli, in press; Henri, 1992). Two of the sixty threads were found to be repetitions or extensions of other cases and were removed from the analysis.

Besides recording the components of a typical case and case summary, the content analysis scheme chosen recorded the following forms of electronic discourse: (1) social acknowledgments; (2) unsupported claims and opinions; (3) justified comments; (4) questions and dialogue extension prompts raised; and (5) mentor scaffolding. From these data, we attempted to determine the types of conferencing structures and instructional scaffolding that promoted more extensive dialogue and debate. The key variables of interest here were the depth of dialogue, references to classroom resources, instances of intersubjectivity, and general peer responsiveness.

**Discussion of Results**

There were a myriad of interesting findings in this study of asynchronous web-based conferencing. First of all, with 1,549 (229 cases and 1,320 replies to them) student case-based postings, it can be argued that students were heavily involved in electronic writing during this six week period. Writing was a way for students to clarify their thinking about field observations and the text material. The electronic traffic registered indicated that the system functioned as planned; while all case conversations were logged and stored for later analysis, the user friendly COW system did not interfere with student case discussions. In over 1,500 postings, students were sharing stories and were apprenticed into teacher education by expert mentors and peers. COW training was so easy, in fact, that immediately after their training students were observed writing new cases as well as firing off responses to the cases of their peers. Since the computer laboratory could accommodate 25-30 students for training, there were times the COW conferencing took on a synchronous flavor.

Other positive results included the fact that groups involved in teacher education (i.e., students, instructors, and cooperating teachers) were communicating with each other through an electronic conferencing tool that was fresh and exciting. In this electronic conferencing system, students were sharing problems and events, asking for help, offering advice, and sharing related stories and events in their lives. To consistently receive five or six responses to a teaching related problem or dilemma one observes in the field is remarkable. In effect, students were conversing about their real problems that they may soon have to face and receive timely and candid feedback. The electronic conference was also a place for extensive social acknowledgment and support. Hence, despite survey data to the contrary, the initial goal of the teacher education program was met with some success—students were not so isolated from their peers and teachers when observing in the field.

Though case quality scores were not related to the depth of electronic discussion, students were reflecting on their field observations in an electronic “shared space” (Schrage, 1990). Instead of case quality or length, case description and topic appears to draw students and mentors into an electronic discussion. Naturally, currently “hot” topics were major draws for such case-based dialogue. Another enticement was that students were not afraid to request help in solving or addressing their dilemmas. Even with all these requests, mentors seldom replied to student questions and concerns with direct instruction. In effect, teachers electronically scaffolded or apprenticed learning without giving away answers. In summary, then, most cases encouraged responses by having interesting contexts and problems, student solicitations for help, and general receptivity to feedback.

Despite these positive findings, there were a myriad of concerns as well. First of all, a twenty percent reduction in the number of mentor and student postings during the second three week period may indicate a drop in interest in sharing field experience information with one’s peers and teachers. Perhaps the novelty of COW may have wore off. This decline in participation may also reflect a decrease in time for such activities late in the semester. At the same time, the latter three week cases and discussion threads were longer than the first three weeks, indicating that, while the sheer volume of postings decreased over time, students became more thoughtful and elaborate in their responding.

Another interesting finding across all conferences and conditions, was that case threads averaged between five to seven postings. Such a consistent average could reflect the number of users in these conferences, the time allotted, message scrolling frustrations, or a feeling that a half dozen responses was sufficient. More research may be needed here to sort this out.

It was also difficult to explain why students generated more cases when in the HS condition, while creating cases
of significantly higher quality in the WS condition. Perhaps
students in HS took advantage of mentor feedback and
submitted a myriad of problems for which they expected
advice, while the WS condition fostered a more laid back
atmosphere and complete case submissions. More analyses
are clearly needed here.

A less surprising finding, though also disappointing,
was that few student electronic responses to these cases
were grounded or justified in course material. While
students documented 229 real-life cases of the classroom
teacher and introduced a wealth of intriguing topics for
discussion, they, for the most part, failed to generate and
evaluate cases that were grounded in educational psychology
theory and concepts. And while students were
observed opening their textbook more during the second
three week conference, such direct course linkages were,
nevertheless, scarce. Not only were direct links to text and
class resources extremely limited, few student responses
were controversial in nature. Too many simplistic and
naive ideas and remarks were responded to with an “I
agree” from a peer. Though students tended to ignore some
of the case structure, one possible recommendation for
fostering critical thought is to force students to back up
each point made with a concept and page reference from
their textbook. In effect, students need to be more explicit
about their connections. Equally important, there is also a
need to foster more disagreements and counterassertions
such as through role assignment (e.g., watchdog, pessimist,
debater, warrior, idea squelcher, and devil’s advocate) or
electronic debates.

There were also a few problems involving both
preservice and inservice teachers in the same study. Despite
conference moderator assurances to the contrary, some
students were extremely concerned that their comments
would be accessed by the teachers they were observing. In
fact, since students were observing in most local schools,
we were limited in the cooperating teachers we could
include in this project. Expert teacher feedback, therefore,
became difficult to arrange for and more limited than
originally intended.

While students found COW to be an easy conferencing
tool to use, many of them looked at this as an additional
task burden of their class, not as an opportunity to interact
with their peers. The mechanical nature of the case creation
assignment limited opportunities for spontaneous learning
and risk taking. While off-task behaviors were virtually nil
and students were unaware of the volume of written text
they were producing (as in the original study), they did not
seem to be having fun writing. Students, wanting grades
and points, were task, not mastery, driven. As a result, there
was no real sense of learning community felt here. Perhaps
the three week time period for each set of conferences was
too restrictive. Often times mentors would provide
feedback and scaffolding at the end of the three week
period and students would not realize that there were
additional comments to read. Not surprisingly, many
students did not appreciate the mentoring.

Contributing to the lack of an electronic learning
community was that many comments from mentors were of
an authoritarian or vertical nature, not collegial. Of course,
it is a difficult situation for mentors to simultaneously
suggest various course connections and real-world ex-
amples, while trying not to act as purveyors of knowledge.
Moreover, with one to two postings from mentors per case,
the term “heavy scaffolding” may be a misnomer. Perhaps,
in the future, such “modest” scaffolding might be compared
to more extensive scaffolding.

Conclusions

In an earlier study, delayed collaboration and real-time
case fostered completely different social interaction and
dialogue patterns. Notably, asynchronous cases were more
productive in terms of student engagement in the learning
process and overall responsiveness. Students in the delayed
mode challenged and encouraged each other to think more
deeply about educational issues and problems. The real-
time focus, on the other hand, was on content generation,
not on extended peer interaction and dialogue.

In this follow-up study, students once again appeared
task focused. Perhaps student and teacher interviews in the
upcoming third study will help us build electronic supports
that foster more intrinsic learning opportunities and
electronic cognitive apprenticeships, thereby helping
advance research in computer-mediated communication
from a sociocultural perspective. We concur with Owston
(1997, p. 33) who notes that, “No doubt further research and
development on the application of the Web to teaching and
learning is needed.” Based on the initial work here, the
WWW may soon become used in a myriad of preservice
learning activities. As a result of this research, we are
beginning to understand how preservice teachers remote
from the university setting can communicate with their
instructors, peers, and cooperating teachers regardless of
distance or time.

Telecommunications: Preservice Applications — 1097
TEACHERNET: ON-LINE K-12 CLASSROOMS NOW READY FOR ON-LINE STUDENT TEACHERS

Jean M. Casey
California State University

Since 1989, hundreds of student teachers have participated in the TeacherNet telecommunications project. Many have formed a cadre of technology using educators that still communicate and support one another through the beginning years of teaching. No longer isolated in the classroom, they now have the information resources of the Internet and the community support of peers to rely on during their teaching. It is hoped that this support will help reduce the teacher retention problem.

The major benefits to telecommunications during student teaching have been found to be the following:
1. Increased reflectivity - Student teachers reported increased time to reflect on what they were learning, including teaching approaches and decision making. Use of e-mail writing helped foster probing to promote deep understanding of teaching, to engage in a written conversation about experiences associated with their making meaning of teaching.
2. Increased feeling of rapport and support from university supervisor, access to other supervisors and university personnel.
3. Increased team support, decreased feelings of isolation. Perhaps one of the most notable outcomes of the e-mail approach is the immediacy with which students can establish contact with the university supervisor or their peers or master teacher. No longer do they have to call for an appointment or wait until the next seminar class to address concerns, questions, or ideas.
4. Increased self-esteem due to mastering technology and receiving positive support through e-mail messages, increased pride from the professional documents they could create at home.
5. Increased knowledge and use of information access and retrieval as well as various types of technology, such as multi-media. Great enthusiasm on finding wonderful classrooms resources on the Internet by themselves.
6. Increased use of the computer at home for personal and professional work and in the classroom when teaching.

Today and Tomorrow
One of the problems of the initial studies was the expense and management of providing students with loaner computers. Also, the early communication networks posed access problems.

Fortunately now in 1997, many more student have their own computers at home. In order to have students ready for TeacherNet as soon as they begin student teaching, this semester I have required them to get a free university account during my methods course prior to student teaching. 90 students have been on-line and communicating lesson plans with me all semester, on their own or university computers (no loaners required). This new cadre of students will come to student teaching as knowledgeable computer users.

Finally, this Fall some of the elementary school field sites we use will have telecommunication in the classrooms. This will allow us to close the loop and have methods students working with K-12 students and teachers and university professors on-line.

Expanding classroom contact to global sites where classrooms can be working on collaborative projects of interest to students in cooperating countries around the world is the other element we will put in place in Fall 98.

Change in the Classrooms
The university reading methods students have been trained to use the Internet in finding teaching resources; they have been using e-mail for communications with university professors and peer teachers; and now they are working with K-8 students in the classrooms. They serve as a model of the classroom teacher as they demonstrate to the K-8 students how to use e-mail, how to communicate with global penpals and how to find information on the Internet.

The student teachers working in schools that have just been wired for the Internet are an important resource, coming to the classroom with on-line skills, these new teachers lead the way by working side by side with other teachers and helping them acquire the necessary skills for information evaluation and retrieval to use in their classrooms and to model for their students. The embracing of
technology in every school classroom has been a very slow process; schools were resistant to any innovation that massively changed the existing structure of schooling. At first computers were only accepted into the schools in lab settings. However, as the information society has exploded in the outside world and realization has occurred that one hour a week in a computer lab does not prepare students effectively for the technology they will need in the workplace, schools have slowly begun to place computers, moving one to six networked stations into the classroom. The national goal is to have all classrooms wired by the year 2000 and with only a couple years remaining to accomplish this goal, suddenly school districts are implementing this idea and wiring up the classrooms. However, that is only the first step. There are large numbers of classroom teachers who still are not comfortable using the computer for themselves, let alone supporting and facilitating computer use for their students. Districts often save money by excluding teacher technology training packages, and knowledgeable technology teachers are still a great need in our schools.

The university provides a partial solution by making sure that all new teachers come to the schools knowledgeable about on-line communications and Internet resources. It is vital that they understand and convey to their students not only where to locate information, but then the harder task of evaluating the value of the many resources that exist and using the most pertinent and accurate information in the classroom.

Summary

At California State University, Long Beach, we have harnessed the Internet as a step toward easing the anxiety of student teachers and reducing the numbers who drop out of the profession in their early years. TeacherNet allows student teachers to keep in touch both with their colleagues and professors, giving them quick access to ideas for the classroom as well as to emotional support via e-mail that lets them know they are not alone in running into instructional classroom management problems.

With elementary classrooms nationwide getting wired for the Internet, the program has taken off and provides numerous benefits to everyone concerned. A supervising professor can observe a student teacher giving a lesson and rather than attempting a quick debriefing before rushing off to the next observation can reflect on the lesson later in the day and communicate by e-mail during evening hours. Student teachers can prepare lesson plans in advance and send them off for review and comment by both the master teacher and the university supervisor before delivering them.

Research shows our graduates are computer-using educators in their classrooms. The Teacher Education program at California State University Long Beach, is one of the largest in the state with 60 members and ties to almost 50 school districts in Southern California.

But as important, student teachers communicate with one another, creating a peer support network. They can ask each other about what might work in the classroom — when, for example, someone is stumped about explaining pulleys while three students goof off in the corner — as well as find out they aren't the first student teachers to harbor thoughts about chucking a career still-born.

The days are gone when a student teacher has to wait for an appointment or meeting of colleagues to address concerns. "Technology is not the be-all and end-all," Casey says. "But it is a useful tool... we are in the infancy of something that can really change our educational world." And that means the student teachers will remain as teachers, too.

This year was the beginning of the final and most exciting step yet for TeacherNet, we now are not just linking pre-service teachers and university supervisors but we have expanded the web to include in-service teachers and most important the entire K-8 elementary population that will now have classroom access to the Internet for global communications and information resources. In order to assure that the technology is used wisely and effectively all these partners need to be communicating with one another and spreading the wealth of information among all the educational institutions from home to university with the one major goal of educating the child to be an effective adult in the information age. Three year old Katie Casey wrote her first letter to Santa Claus on the Internet, she was pictured in a Washington Post story, as she composed the letter. When she is ready to enter the classroom door will the teachers be there who are trained and ready to continue Katie's education by supporting her on-line knowledge?

That is our challenge and together we need to make it happen.

Current NCATE/ISTE standards (ISTE, 1997) require that students have a working knowledge of telecommunications and its use in the classroom. The Task Force on Technology and Teacher Education has recommended to the National Council for Accreditation of Teacher Education (NCATE) that technology be emphasized as central to teacher preparation in the 2000 NCATE accreditation standards. Future teachers learn from what they observe during their field or internship experiences in the P-12 schools (NCATE, 1997). They must see technology modeled by college methods instructors as well as by P-12 teachers during their practica experiences.

The State of Illinois and NCATE standards both recommend more field based training such as Professional Development Schools for preservice teachers. Increased field placement is difficult given the 1300 elementary education students enrolled at Illinois State University. This research explores the possibility of whether an electronic connection utilizing Telementoring can provide an enhancement to the current initial field experience. It also looks at whether an electronic collaborative environment can provide an opportunity for students to put the theory and research from a Language Arts Methods class into practice during field experience and student teaching.

Telementoring is the mentoring of a group of novices through telecommunications by an individual or group of practitioners (Wighton, 1993). In this research, it refers to the mentoring of preservice teachers over the Internet by an individual teacher or group of current teachers.

Much of the research that has been done with Computer Mediation Communications (CMC) has taken place on a text-based environment such as a listserv or newsgroup or through the use of e-mail (Dobson, 1997; Tannehill & LaMaster, 1996; & Weiss, 1997). Tannehill & LaMaster (1996) present a summary of the research findings on the benefits of mentoring using e-mail as a supplement to classroom communications and as a facilitator of collaborative opportunities. They further discuss the research in teacher education as a way to maintain communications between teachers and university faculty and to support student teachers.

Video connections between schools and universities for collaboration are beginning to be reported. Two-way interactive video was used in Texas (Cifuentes, Sivo, & Reynolds, 1997) to provide a virtual field-based experience for preservice teachers. Inservice and preservice teachers collaborated to develop materials that supported thematic units. Both groups generally found the interactive videoconferencing partnerships to be rewarding with some reservations. At the current time videoconferencing either requires expensive equipment or requires extensive bandwidth over the Web. NetWorkPlace adds an inexpensive visual component that avoids the limitations imposed by video formats.

This research adds a visual component to a newsgroup type discussion structure to increase the ease of use. NetWorkPlace provides a visual metaphor of a building as a place for preservice teachers and mentor teachers to meet and discuss theoretical and practical educational issues. The location for this research is Floor 5 of the building (http://gallen.ncsa.uiuc.edu:5152/html/floor5/lobby/index.html). Each floor provides an informal discussion area located by the Water Cooler, three threaded discussion areas and three chat rooms designated as Conference Rooms, an Office with a database of participant information, and a Library for resource files. NetWorkPlace was developed at the National Center for SuperComputing Applications (NCSA) in Urbana and is being tested as a visual environment. Other collaborative environments are currently being researched by NCSA and may be used in future research.

Methodology

Participants

During Fall Semester 1997, inservice and preservice teachers used an on-line collaborative environment for mentoring activities. All participating mentoring teachers teach in one of four district elementary schools or teach language arts at the junior high school. The inservice teachers were enrolled in a Language Arts and Technology
graduate class taught by the researcher. The tuition for all teachers was being paid by a Goals 2000 grant. The class was being offered after school in one of the district computer labs. All teachers were required to apply to the district to be selected for the class. All teachers had e-mail addresses and direct connections to the Internet in their classrooms. All schools had LCD Panels available for teacher use. Video output cards had been purchased for all classrooms but were not installed during the semester. These teachers are serving as mentor teachers for preservice teachers enrolled in a section of C&I 256 Teaching Language Arts in the Elementary School, also taught by the researcher. Seventy-four percent of the preservice teachers in the study had e-mail addresses prior to class. The remaining 26 percent obtained e-mail addresses as a class requirement. All participating teachers had e-mail address at the beginning of the project.

Data
An initial questionnaire was administered to both groups to determine their level of experience with technology including the World Wide Web. A five point Likert scale was used to rate experience ranging from 1 (have taught) to 5 (have never used). Table 1 shows the number of participants in each category for World Wide Web experience. A question about the effectiveness of NetWorkPlace was included on the posttest questionnaire administered to both groups.

<table>

<td>0 48</td>
<td>22 26</td>
</tr>
<tr>
<td>Inservice teachers</td>
<td>6 31</td>
<td>26 19</td>
</tr>
</tbody>
</table>

Data were collected through process journals from both preservice and inservice teachers. Data were also collected from interactions on NetWorkPlace and from interviews from a sampling of both groups.

Procedure
Preservice teachers and inservice teachers were provided training on beginning and advanced e-mail skills and World Wide Web search engines as part of their classes. NetWorkPlace was demonstrated and participants were initially given class time to post or respond to messages. Preservice teachers were required to post a question related to a class topic that they had chosen to research. They could also post additional questions that arose during the semester. Mentoring teachers were to respond to questions from the preservice teachers and post further questions to invoke problem solving and theory application by the preservice teachers. Both groups were given some class time during the semester to post and respond to questions.

Results and Discussion
A discussion from NetWorkPlace is presented first as a sample of the questions and responses posted in the collaborative discussion environment. Data from the posttest questionnaires and qualitative data from teacher and preservice teacher journals is presented. This is a preliminary report of research conducted Fall Semester 1997.

The most discussed NetWorkPlace topic was classroom management. From the researcher's past experience with preliminary field experiences, this is one of the most difficult to teach in the university classroom and may be one of the most beneficial topics to receive input from actual teachers. Two preservice teachers asked teachers what types of management techniques that they use in their classrooms. Responses were posted by a Learning Disabilities teacher, a fifth grade teacher, two primary teachers, a junior high teacher, and a gifted teacher. An example of responses that reflected conflicting methodology and provided a basis for classroom discussion follows.

This statement is from a gifted teacher:

My philosophy of classroom management is that my primary goal is to help my students develop self-discipline and a sense of responsibility for their actions and their learning, to behave in acceptable ways because they want to, not because they have to. I emphasize that we are a community of learners working together in our classroom. Students are encouraged and sometimes assigned to work together on classroom projects and problem-solving activities.

"Put-downs" are not allowed. Students may disagree with each other and the teacher, but must do it in a polite way. If I have a student acting in an unacceptable way, often just a look or a light touch will produce a change for the better in the behavior. If not, I say something such as "You seem to be having a problem. Can you handle it or do you need my help?" Usually they choose to handle it themselves. I never give rewards for good behavior but occasionally will remind students of such things as "The reason we are able to take field trips is that you behave appropriately and learn things on our trips."

A pair of primary teachers advocated a different approach:

We believe that classroom management is an ongoing process. You constantly re-evaluate the mechanics of your students and room. We move the classroom around frequently to enhance student learning. Group activities are established depending on the age group and the needs of students. Positive
required to learn an environment still reported by other telecommunications researchers (Powers, 1997).

Both groups made suggestions to improve the effectiveness of the collaborative environment. The most suggestions related to building virtual community between individual or small groups. Nine preservice teacher suggestions related to community building as did six inservice teacher responses. Sample suggestions from preservice teachers include the following: "Assign one or two teachers to a student so that all questions are answered." "More prior knowledge about teachers would be helpful. Maybe set up a meeting to 'get to know' each other." Sample responses from teachers included the following: "I would have liked to try communicating back and forth with the same student so a relationship could be started." "I would have liked to have been able to have a more sustained dialog with a student or students rather than just posting a reply or a question to the group in general."

On the posttest, participants were asked to rate the usefulness of NetWorkPlace. Table 2 shows the results.

### Implications for Future Study

While there were many positive comments and suggestions about the use of NetWorkPlace, preservice and inservice teachers rated its usefulness only as 2.53 and 2.41 respectively on a five point Likert scale. The following factors should be considered in designing future research on telementoring of preservice teachers.

During this study, all participants were required to participate in the collaboration as part of their class assignments. Other collaborative researchers report alternate methods for selection of teacher mentors. Norton and Sprague (1997) used an application process to select inservice teachers to mentor undergraduates enrolled in an introductory educational technology class. Johnson (1997) recruited mentoring teachers for an undergraduate reading methods class from an educational listserv. Future research is needed to determine how to maximize the different selection methods most effectively.

Ideas for motivating teachers to participate need to be further researched. Several possibilities were suggested by the current study. Inservice teachers participating in this study reported time to search the Web as a major limitation for the integration of Internet into the elementary classroom. Preservice teachers could search Internet for websites for paired inservice teachers to use in classroom units. Inservice
teachers could have a separate conference room on NetWorkPlace to network with teachers from other districts to share resources and ideas. One inservice teacher suggested college credit as a motivation for recruiting mentoring teachers.

The discussion group format needs community building between participating individuals or groups to make it more effective. Possible suggestions for building community include pairing individuals or creating small groups which include both preservice and inservice individuals. More research needs to be done on the effect of including desktop videoconferencing or an actual face-to-face meeting.

The researcher will use a collaborative environment Spring Semester 1998 between preservice teachers and inservice teachers who volunteer to participate. Fall Semester 1998 it will again be possible to link graduate classes and an undergraduate class taught by the researcher to continue this research.

References

Donald Schon (Schon, 1983) in his seminal book on professionals as reflective practitioners described professional practice as a reflective conversation with an uncertain situation, taking stances, experimenting, and learning from the back-talk of the situation. Beginners in a field need opportunities to practice this reflective conversation and to make sense of the back-talk. Professional preparation programs address this need by having novices learn from field experience or through exposure to various representations of realistic experience, such as simulations, problem-based learning, or cases. The key to learning, however, is not in the exposure, but in the “reflective conversation” and the meaning that the student draws from the experience.

**Introduction**

Believing in the importance of learning from field experience and valuing the development of reflective practitioners has led the College of Education (COE), University of Missouri-Columbia to reform its undergraduate teacher education program. A fundamental learning process of the new program is (1) for students to experience teaching through observation or practice in schools and (2) to articulate the meaning they derive from the experience (a first level of reflection), (3) for faculty and experienced teachers to provide feedback and counsel so as to shape and enhance the “meanings” (a second level of reflection), and (4) for the body of experiences and “meanings” to grow and evolve through the undergraduate program and continue as professional development in the early years of teaching (a possible third level of reflection). A goal of the reformed teacher education program was to implement this learning process across the entire curriculum of teacher preparation and not just as a culminating student teaching experience or as a few aiding or observation opportunities. This goal required new forms of support for teaching and learning.

Concurrent with the curriculum redesign was an effort to use technology in the service of the new program implementation and in the development of technology using teachers. A technology infrastructure (Laffey, Musser, & Wedman, 1998) was designed and implemented that includes an emphasis on developing competency with technology for students, powerbook computers for all faculty and students, and substantial enhancements to network services. A significant component of the technology infrastructure was the design of an interactive shared journal system (ISJS) to facilitate the reflective learning process from field experience (Laffey & Musser, 1996). In addition to supporting the learning process enumerated above ISJS afforded students and faculty the opportunity to communicate with multi-media representations of experience, communicate both asynchronously and synchronously (via chat), and have access to a community knowledge-base of experiences from anywhere they could establish an internet connection.

**Interactive Shared Journal System (ISJS)**

ISJS was designed, developed, and implemented to support the representation and sharing services of the new reflective learning process from field experience. ISJS is implemented on a Macintosh client and Silicon Graphics Indy servers. The clients and servers communicate over the internet using TCP/IP connections. Anyone who has access to the internet via a direct connection or a SLIP or PPP connection is able to participate; thus students can connect from any home or school location in Missouri and beyond. In addition, the software supports the creation and editing of journal entries off-line for later upload when a connection is available. A custom server was created for connecting and maintaining a login to the journal system. The server provides communication between the client and an Oracle database. ISJS is a flexible system for the development and support of learning communities, but in the context of the undergraduate teacher development program it can best be understood as enabling three key processes: access to Internet-based resources, capturing experiences, and sharing experiences. These processes are undertaken in the context of a community made up of four roles:
administrators, who are responsible for the system;
mentors, who are responsible for instruction and modeling;
students, who are responsible for articulation of experiences; and
guests, who have limited access to public information.

ISJS includes facility for:
- creating multi-media journal entries that can link to other entries or web sites,
- appending notes and comments to a journal entry,
- determining access and privacy levels,
- a flexible teaming structure
- faculty-created tasks (assignments) that can be distributed into student journals and then monitored for progress,
- user profiles to support access and sharing,
- system-based email, and
- real-time chat.

Logging into ISJS requires an id and password to connect to the intranet of information and communication services. Figure 1 shows the menu of tools available within ISJS. Moving from right to left in the figure users have access to a set of internet-based communications tools: email, a browser, chat, and a news group.

The My Journal button opens a list of journal entries. There are four types of stationery for journal entries. The first is a personal entry that is used to represent an experience or reflection. The second is an append. An append is personal journal entry that is attached to another person’s journal entry. For example, a mentor or other user might be reading a journal entry from a student. The reader can click the append button that allows for a new entry to be created and attaches it to the open entry. A third type of entry is a source task. Mentors create journal entries and use a toggle switch to turn the entry into a source task. Source tasks are assignments and can be distributed to students and then monitored for progress. The fourth type of entry is a task, which is what the student receives from the mentor. The sections of the task created by the mentor cannot be modified by the student. The student can, however, insert his or her response to the assignment and indicate level of progress. When entries are created or updated the author can set access privileges to be private, public or by group membership. Figure 2 shows an example list of the public documents for one user. Documents can also be arranged in folders created to represent various groupings of members for access and sharing.

You are connected to the University of Missouri College of Education journal system server. This server was established to support teachers learning from each other using performance support technologies. The development of the journal system software, and this journal system site, is supported by the Institute for Instructional Development at the University of Missouri. Thank you for using this system.

If you have any questions, you can contact the software development team at ctie@tie.missouri.edu.

Figure 1. Tools window provides access to shared services.
A user can create a journal entry with the New button on the list window or directly from the File menu. A standard entry has several elements: a title, keywords, access privileges, an author, a body, and it may have appends. A source task has a distribution list, and a task has a progress status. A key design goal of ISJS was to enable mentors and students to express themselves with as much representation power as possible in order to facilitate articulation and communication. To this end we have created a journal entry as a set of media and link objects. Figure 3 shows a journal entry about a discussion of software design. This one entry includes text fields, a link to a web page, a link to another journal entry, a sound object, and an image.

In addition entries can include links to other journal entries and attached binary files (e.g., an Excel spreadsheet or video clip). A key design goal of ISJS has been to make the construction of a multi-media, multi-object journal document easy and straightforward, even for a fairly novice user. The media objects can be imported into an entry through cut and paste or, if they reside as a file, in computer storage. Objects can also be acquired on the fly by selecting an open web page or journal entry, or by using a media control panel for capturing sound through a microphone, a video still from a camera, or an image from a scanner. The object rich journal entry form can facilitate the student as they capture their experience and as they represent it. For example, a student asked to visit a fourth grade class and evaluate the reading level of a child could record the child reading a passage via the microphone and then comment on their diagnosis. Fellow students or the instructor could not only discuss the thoroughness of the diagnostic report, but by listening to the audio clip could also give feedback on accuracy, as well as leave appends that extend the diagnosis.

**Lessons Learned during the Pilot Year**

The first cohort of students (freshmen in 1996/97) received powerbooks at the end of the Fall semester. They began to use their powerbooks and the ISJS in the Winter semester. As one might expect the first semester of implementation proved to have many technical challenges both for the program and for individual users. Much progress, however, was made and the usage of ISJS during this period demonstrated some of the potential benefits and highlighted some of the key challenges still to be overcome. Table 1 illustrates that some faculty began to appropriate ISJS into their instruction and some faculty were reluctant. Faculty High was included to represent a faculty member who made a distinct effort to implement ISJS in an extensive way. Faculty Low was included to represent a faculty member who chose not to use ISJS in any substantive way. Faculty 1, 2 & 3 represent faculty randomly selected from among the total faculty to illustrate typical use. The numbers represent journal entries from January 1997 to November 1997. The table shows the total number of journal entries.
Hello all. First, some interesting links for you...

- http://babylon.coe.missouri.edu/design
  Be sure to check this web page, the class site, for more information regarding activity theory and its application to the design of educational computing systems.

- Coaching vs. Assistance, and Implications for Design
  This is an interesting journal that touches on some aspects of the design of software for learners. Check it out!

And an audio note regarding the graph below...

Figure 3. Journal entry showing text, sound, images and links
and the number of those entries that were appends. Student entries were taken by randomly selecting 3 students from each teachers group (total number of students in group averaged 10 to 12 members) and then averaged their counts to represent a typical student user.

Table 1 shows that use varied substantially among faculty members and their students. Faculty High used the system extensively as a means for students to capture their field experiences and create a feedback loop from faculty to student. Having 254 appends out of a total of 263 shows that most of this faculty’s use of ISJS was to respond to student entries. The typical student for this faculty member created 60 entries of which 47% were appends to other students’ journals. A high rate of appends indicates that the faculty had students interacting amongst themselves rather than simply creating a teacher to student channel of communication. On the other extreme is Faculty Low for whom several of the entries probably represent those made during training or practice sessions. Correspondingly his students did not use ISJS. Several faculty who chose not to use ISJS in any substantial way did have their students write about their field experiences, only they used word processors to create entries, print them out, and hand them in.

Even faculty who used ISJS extensively only used it in its most simple form. Few journal entries contain media or link objects, few faculty have used tasks to create and distribute assignments, and few faculty have used chat sessions to enhance communication among students. It is easy to project that faculty high and faculty 1 and 2 will progress toward these more advanced features of the system, but it is hard to predict whether additional support or other incentives will move faculty low and 3 toward significant use of ISJS. We do expect though, that as the total curriculum and higher numbers of faculty use ISJS in ever more advanced ways, that all faculty will adopt ISJS as a part of their teaching repertoire. In fairness to the reluctant users, ISJS and the network infrastructure needed much improvement to make them more robust and reliable. Progress has been made in these areas, but some faculty remember very well a few failed attempts. It is also true that problems still persist and will always be part of a complex intranet environment and some faculty and students are more comfortable than others with a level of risk or in their ability to troubleshoot a problem.

Some faculty have begun to develop innovative teaching approaches based on use of ISJS. Several faculty have been developing the concept of a virtual school, wherein the teacher education students create virtual students and describe their experiences and reactions to events via journal entries. A science educator has begun to use ISJS to connect his students with students in high schools who are undertaking project based learning as part of an NSF grant. The high school students use ISJS to report about their projects. The college students review the journals of the high school students and take on various roles of observer, mentor or teaching assistant and use ISJS as a vehicle for communicating with the high school teacher and students.

Questionnaires were given to students in several of the teams at midterms and at the end of the year to learn about their perceptions of ISJS use. For many students there has been quite a learning curve to use the Powerbooks, ISJS, and other technology of their freshmen year. They have suffered failures and have overcome numerous technical or user error challenges. In particular there has been a persistent problem for many students in using ISJS via a dial-up mode. This problem has significantly limited the value and flexibility of ISJS. Most students make journal entries only when required. Some students do, however, cite making entries about significant life events and discussions from class sessions. Reference to using more features and using ISJS for more varied purposes increased form the beginning to end of semester. One student stated, “Honestly, at the beginning I did my entries for the grade and for the class points. However, as time passed I wanted to share my exciting experiences with other students. I also wanted to read about the other students’ observations.”

Conclusions

The usage data and student reports suggest that, while there have been many barriers to usage, ISJS is supporting the reflective learning process and many faculty and students are increasing their usage and capacity with ISJS. Clearly faculty and students will need more and better support, and ISJS and the network services will need to become more robust and reliable. As faculty and students begin to appropriate and innovate with ISJS its potential for facilitating the reflective learning process will be tested and developed. Faculty and students, however, have already begun to appreciate the communication processes facilitated by ISJS, and are coming to see the value of having the “reflective conversations” of learning to become a teacher articulated and shared as a community memory.

A recent observer of changes in our society brought on by technology (Shenk, 1997) has observed that “Information, once rare and cherished like caviar, is now plentiful and taken for granted like potatoes” (p. 32). Yet while powerful new technology now makes information within easy grasp of many, it has yet to influence in any real fashion youngsters in poor, urban areas. This project attempted to meet that need and link prospective teachers with urban youngsters using an advanced distance learning system involving high speed two-way teleconferencing designed for distance education activities.

Related Projects
Various other telementoring projects exist ranging from e-mail based question and answer systems to multi-party real-time desktop video conferencing. In the Electronic Emissary Project, for example, subject matter and pedagogical experts are matched with students and teachers who are studying similar topics (Harris, 1997). One Electronic Emissary project involved fifth grade students from Amarillo, Texas and a researcher from AT&T Bell Laboratories. During the telementoring, the researcher answered questions about sailing and celestial navigation, and suggested experiments for the students to aid in comprehension of subject matter. Similarly, in a Department of Education funded Four Directions Project, remotely situated schools serving Native American children collaborate with Native American volunteers from a wide variety of expertise and interests (Four Directions, 1997). Not only do students engage in question-answer scenarios, but they also come in contact with Native American role models. Like the Four Directions Project, the Telementoring Young Women in Science, Engineering, and Computing project encourages young women to pursue careers in science, engineering, and computing by providing support and communication from female professionals (Meade, 1997). Mentors provide advice and support on courses and careers in science and related fields, as well as opportunities for young women to discuss relationships between their classes and the experts’ fields.

Unlike the e-mail dependent telementoring projects, the Global Schoolhouse Project focuses on desktop video conferencing to support its goals of teaching research skills and fostering relationships between scientists and students (Global SchoolNet Foundation, 1997). In one example of their project, scientists from the Jet Propulsion Laboratory have the opportunity to share pictures and information about on-going projects such as their Galileo spacecraft and Hubble telescope. Finally, the largest telementoring project of its kind, the Collaborative Visualization (CoVis) project, uses a wide range of collaboration and communications tools to help students in their study of atmospheric and environmental sciences (CoVis Project, 1997). The inquiry-based activities use desktop video conferencing, shared software, Internet, and visualization software to provide project-oriented activities which “resemble the authentic practice of science.”

Nature of Study
The participants in this study were prospective teachers in the College of Education at Old Dominion University in Norfolk, Virginia and elementary students in an urban public school some ten miles from the university. The computer system, formally known as Interactive Remote Instructional (IRI) system, was developed as part of a grant from the National Science Foundation to Old Dominion University. IRI is a Unix-based system consisting of two classrooms of ten computers each 20 miles apart in Norfolk and Virginia Beach, Virginia and an additional mini-classroom in the elementary school. Each ‘desk’ consists of a Sparc 5 workstation, a microphone, speaker, video camera, and a video board. All participants, therefore, in any computer event interacted in a terrestrial-connected, 10-Mbps environment in which they could see and hear one another and dynamically share electronic resources. This project linked 20 prospective teachers with two classrooms of elementary-age children in a distance tutoring arrangement designed to test the range of instructional possibilities using a new array of distance learning tools.

Hardware and Software
The participants in this study used the distance multicast protocols and IRI software developed at Old Dominion University. All computers were connected with ATM links provided by Cox Fibernet, a cable TV service provider. A typical student desktop included a monitor
with a resolution of 1152 x 900 pixels capable of showing four windows simultaneously, which could consist of, for example, a window showing the teacher or student, a window showing a text screen with the lesson objectives, one showing a browser on the Web, and another displaying a whiteboard for mutual problem solving. The teacher’s desktop was more elaborate because this machine contained the above hardware plus an overhead camera for displays and an additional video board for connecting an NTSC signal displaying a VCR or other images. The instructor’s computer also contained the software (IRI Version 1.1) designed to manage communication and carry out a multidimensional instructional dialogue. In a typical full-class exchange, teachers would send students their own image and three other related images designed to enrich the experience. Whenever students asked a question, their cameras and microphones reversed the communications flow, and all participants could then see and hear them as well.

Shared Tools

Both teachers and students received the same screen images, and they also shared control over select tools. Students, for example, could send back to teachers a document or an electronic drawing they produced. Additionally, teachers and students could view the same browser session while exploring a useful Internet site, and either one could control subsequent links. Similarly, students and teachers could work collaboratively at the whiteboard passing back and forth the control and the marking function. Lesson outlines, classroom handouts, or content-related background reports could flow readily among participants; even mutually-constructed reports generated by students and teachers within the session could be saved for later use in something known as WebBooks. All electronic documents, downloaded Web material, or even teacher/student transcripts could be saved as files that became part of a student’s WebBook. The WebBook collection was then made accessible to participants over the Internet from any location.

Project Activities

This project took place over one semester of 1997 and was 14 weeks in duration. To begin the project, the prospective teachers were required to participate in a presentation to be “broadcast” to groups of children in the school. The purpose of this presentation was to acclimate both the prospective teachers and the children to the capabilities of the IRI system and have them view the computer-delivery mechanism as a bona fide means of delivery of educational content. The prospective teachers were then required to work in pairs, tutoring a pair of fourth grade students in a content area the classroom teacher chose. Since the classroom teachers were involved in the planning of events, they most often asked the prospective teachers to help children find on-line resources using the shared Internet browser that was part of the system to locate information related to classroom study topics. The end goal of these activities in the teachers’ views was a report developed by the children.

Participants

The participants in this project included twenty prospective teachers enrolled in a required course in instructional technology and fifty-seven students in the third and fourth graders of the elementary school. The prospective teachers were required to engage the students in periodic whole-class exchanges so that all parties could become comfortable in their new electronic environment. The children involved were thirty-seven fourth and fifth grade students from an urban elementary school. The school draws from a portion of the city of Norfolk, Virginia marked by subsidized housing and high rates of unemployment. The youngsters who participated in the study were encouraged to become empowered and take advantage of the two-way capabilities of the system. The ultimate task of the prospective teachers, however, was to serve as a virtual tutor to the youngsters, helping them with their studies and exploiting the considerable power of educational technology.

Preparation of Participating Prospective Teachers

The prospective teachers who served as the tutors in this project were enrolled in a course offered by the Department of Curriculum and Instruction emphasizing educational technology. They exhibited an enormous range of backgrounds in the use of computer, including some students who described themselves as total novices and some who described themselves as highly-skilled daily users of computers. This group of future teachers were administered the Computer Attitudes Scale (1993), and the range of their composite scores, however, were very similar to those found in other research. Their mean of means score was 3.45 with a standard deviation of 1.2, again similar to other such populations.

Because the operation of the IRI system required knowledge of its interface, the prospective teachers had to be taught its use; this training required two 1-hour training session. Because they worked in pairs, they were able to help each other in becoming comfortable operating the interface.

Gathering Pre-Experimental Data

In an effort to assess the attitudes of the participants prior to the beginning of the project, both the preservice teachers and the children were asked to respond in writing to their perceptions of the idea of having a tutor appear over a computer system. Substantial details were given to what
the computers were and how the system worked. However, the explanation was purposely painted without bias and with no suggestion as to how the system should be used. Some categorized responses from the children are given below.

General acceptance
"What a cool idea."
"If I had a virtual tutor, it would be really neat."
"I would love to have a virtual tutor. Everyday I would pull out my homework, and my virtual tutor would do it for me."

Slightly qualified acceptance
"I would like maybe love to have a virtual tutor."

Specific Sub-Domain Acceptance
"It would be nice to have help when ever I want and on day I want the neatest thing I ever had. It could help me with my spelling for exampl."

Family Benefit
"It would really help me out and it would be cool. I would really enjoy it, and my mom would too."

Perceiving the bigger picture
If I had a virtual tutor, it would be cool because, you would be allowed to say home. So you could do your work at home."
"Having that kind of technology would not only be helpful for me, but for people around the world."

Perceiving problems
"I wouldn’t want to have one because I think it would be cheating. You should be listening in class so you know what to do. I think you should do your homework on your own because I think when you do it you gain knowledge and to work independently."

Advantages over traditional instruction
"When a kid logs on to a virtual tutor the kid wouldn’t be afraid to ask questions that would make him or her embarrassed in class."
"A virtual tutor would not say you should always pay extra attention in class. A virtual tutor would not interrupt you while you were talking and would not say you should rewrite that."
"Maybe you could find it on the Web."

Rejection:
"I probably wouldn’t ever use it because most of the time I don’t need help with stuff."

Reactions from Prospective Teachers
The prospective teachers also demonstrated a considerable range of responses to the idea. Some of their reactions are given as well.

General Acceptance
"Cool idea!"
"I think it is a great idea."

"I think the idea of using a computer to teach students on the opposite side of the globe is great."
"Learning at a distance is still learning."
"I think it is great that they have computer lab time in school because kids will know how to use the computer at a young age. I know some kids that know more about computers than I do."

Special Applications
"The idea of having remote teaching is very exciting to me. Even though there are problems to be worked out such as young children knowing ‘video teleconferencing etiquette.’ The possibilities are incredible. Locally it would allow gifted children to challenge their intellect by hooking them up with a college student tutor who has better knowledge of a subject matter such as a foreign language."

Technological Restraints
"This is a very interesting and fascinating idea, but what are the implications in reality? There is no air conditioning in many classrooms of some public schools, not to mention electrical outlets."

Classroom Control
"I am skeptical as to how well this idea will work. First, I wonder about the discipline problems. Sometimes the student does not always want to learn and with the teacher or tutor not physically there it puts the tutor/teacher at the students’ mercy. It removes the authority from the teacher and places the students and teacher on the same level. . . The cold touch of a keyboard should never replace a live human teacher."

Findings
The actual tutoring sessions were conducted with little problem in terms of hardware operation and software stability; the IRI system has been refined over the past two years. The prospective teachers did not have noticeable difficulty operating the system, but some were much more at ease in this role than others. Some remarked that the tutoring would, in fact, be easier to conduct in person in which the warmth of human exchange takes place more naturally. More information needs to be gathered regarding this issue.

It also soon became apparent that issues of management at the remote site were interfering with the tutoring sessions; fortunately, university interns were working in this school setting who could spend time supervising the participating youngsters. Final data collection is still in progress.

Need for Additional Empirical Data
This project attempted to shed light on the potential future of virtual tutoring, and it points to the need for additional empirical data to answer questions such as those that follow. Does the interactivity of the IRI system give economically deprived youngsters an added sense of self-
efficacy and self-esteem in the use of technology over time? Does IRI-based tutoring contribute to the meaningful learning of youngsters within traditional curricular areas? How realistic is electronic tutoring given the absence of human proximity and face to face contact without the availability of on-site tutors? To what extent should youngsters be allowed to control electronic dialogue? To what range of new pedagogical practices should teacher education students be exposed and what technological skills should they be required to master? What new research paradigms will best inform the profession about learning and learner/teacher relationships in an electronically rich, distance-connected environment? What does limited experience with these distance learning systems tell us about the possibility of alternative “early and continuous” field experiences? These initial attempts to make the best use of technology will help define the human and technical elements of effective technology-based learning in coming years.

Conclusion

Distance education systems such as the one described in this project are becoming more common, at least in more modest versions, and their potential to impact education is enormous. An important finding of this study is that participating children’s expectations in many ways are shaped by their view of its potential, and young people are becoming more regular users of telecommunication technology with each passing day. The problems for students and teachers of the future is not whether to use computers for learning but how to navigate and assimilate growing quantities of information. A recent Time magazine (Wuff, 1997) put it this way: “All kids, not just ones from families that can afford a home computer, should grow up with a mouse in their hand. As a learning tool, computers make kids adventurers and avid learners, taking them beyond the traditional walls of the schoolhouse” (p. 31). Both future teachers and children of tomorrow may well find the prospect of a virtual tutor a comforting idea and a natural part of their learning world.

GETTING ELEMENTARY EDUCATORS CAUGHT UP IN THE WEB

Nancy A. Tate
Washburn University

For the past four years I have conducted a one-week summer computer camp for fifth through seventh grade students which has been a fun and effective learning experience for the attendees. Invariably, I receive comments from elementary and middle school teachers regarding the possibility of holding a camp for teachers or allowing teachers to register for the camp. Based on comments such as these, as well as comments from my own children’s elementary school teachers, I began to perceive the need to develop a hands-on learning experience for public school teachers. This learning experience would be designed to familiarize them with the resources available on the World Wide Web so that they could use the Web as a tool to enhance their teaching.

In particular, I believe teachers need to become aware of the myriad of curricular sites targeted for elementary education developed by educators for educators. They need to know about the opportunities available for collaborative learning projects and on-line classes. In addition, they need to become aware of how easy it would be for them to develop their own web lessons using web authoring tools.

I approached a fellow colleague with this idea, and, together, we developed a proposal for providing a hands-on World Wide Web training opportunity for a local elementary school. This proposal was presented to the elementary school principal in the spring of 1997, and the training was scheduled as an in-service session which would be held in late August prior to the beginning of the fall, 1997 school year.

Preparation

My colleague and I requested the name of an on-site contact person from the elementary school so that we could funnel requests for information back and forth from the school. One of our first requests of the contact was for teachers to submit a list of units they would be covering early in the fall semester of the new academic year. We requested this information last spring so that appropriate materials could be developed prior to the beginning of the upcoming school year. By focusing on topics for which the teachers were already preparing lesson plans, we hoped to demonstrate that the World Wide Web could be used as a tool to immediately enhance the curriculum which was being taught rather than an additional subject to be added to their already full load.

Our on-site contact person provided the following list of curriculum units in late May:

Fourth Grade
Celebrations

Fifth Grade
Environment/Conservation
Native Americans/N. American Prehistory
Six Trait Writing

Sixth Grade
Volcanoes
South America
Mexico

We did not receive unit information from the K-3 teachers. Our contact explained that the late elementary grades would probably have wiring to connect to the Internet in their individual classrooms by the fall semester and the school would prefer to concentrate on these grades. Based on the information obtained, we were ready to begin gathering together our web-based curriculum resources.

In preparation for this training, I subscribed to a K-12 World Wide Web Educators’ listserv (WWWEDU-listproc@ready.epb.org). This mailing list was invaluable in obtaining suggestions for web-based curriculum resources which K-12 educators had reviewed and evaluated. I saved these postings to a mail folder and in the months that followed, I visited many of the suggested sites and bookmarked those that were appropriate for K-6 educators. I made certain that at least two curriculum resources sites were identified for every unit suggested by the teachers the previous spring. In addition, since the specialty teachers and administrators were also attending this training, curricular resource sites for art, physical education, music, special education, counseling, and elementary educational administration were included. These “specialty” sites proved to be the most challenging to locate. We employed
several advanced search techniques to locate relevant, appropriate curriculum sites for these educators to visit.

Because this was to be a hands-on lab experience, we reserved a computing lab at Washburn University for this training. The university lab was chosen for the following reasons:

1. The lab contained powerful microcomputers which were connected to the Internet by means of a T1 connection. This ensured the participants would be able to browse the Web relatively quickly and not become frustrated waiting for web pages to load.

2. The university lab contained a sufficient number of microcomputers so that the participants would be able to work in pairs rather than being forced to work in groups of three or four.

3. The elementary school had been targeted to receive a new computer lab during the summer; however, there was no guarantee that the lab would be ready by the training date.

4. We were familiar with the university lab and had ready access to it while preparing for this in-service.

5. The university lab was configured similarly to the way the elementary school lab was to be configured.

After much discussion, my colleague and I decided to provide a written reference manual for the teachers to take away with them. Past experience had taught us that hands-on lab activities, while easy to complete with the instructor’s guidance, become much more difficult for learners once they leave the classroom environment. By providing step-by-step written instructions for the lab activities completed during the in-service, teachers would be able to recreate this lab experience when they returned to their elementary school.

The goals of this teacher in-service training were three-fold. First, we wanted to provide background information—what the World Wide Web is, how it works, and some general searching techniques. Second, we wanted to increase the teachers’ awareness of the multitude of curriculum resources already available on the Internet for K-6 educators. Third, we wanted the teachers to create a simple web-based activity using a web authoring tool. In order to accomplish these goals it was necessary to streamline the process by which the teachers would access web sites. We determined that the most efficient way to streamline web site visitation was to design a home page which contained links to various categories of web sites to visit. Because the URL address links were included in these web pages, the teachers would not be required to type in the individual locations. They would simply need to scroll down the web page, read the description of the link, then point and click to access the site. By eliminating the typing time and the data entry errors which are commonly made when entering URLs, the teachers would be able to spend more time exploring and less time typing. This proved to be a very effective method of allowing teachers to quickly “Surf the Net” and it reinforced the concept of hyperlinks.

We created the in-service home page using Netscape Navigator Gold Version 3.01. This version of Netscape contains a web authoring program—Netscape Editor. Because all of the curriculum sites to visit had been bookmarked in Netscape Navigator, it was a simple process to copy the links from the Bookmark file into the web page as it was being created in Netscape Editor. Once our home page was built, it was stored on a floppy disk along with all the associated web page files and graphics. Every teacher received a copy of this disk. During the in-service training, the teachers were able to open the home page file in the Netscape browser from their floppy disk drive and they were off and running.

Because of the limited amount of time available for the teachers to learn to develop web pages themselves, we decided to guide the teachers as a group through the creation of a web unit. I designed and created this web activity before the training was held. After reviewing the list of units submitted by the teachers, I selected the Nutrition unit to be the subject of my web-based activity. I searched for appropriate kid-oriented sites to become links in my web activity and bookmarked them. I then utilized Netscape Editor to create a web activity that would require students to read and follow directions given on the web page. Internet resources were embedded within the web activity to provide assistance to the students in completing their assignment. By utilizing only text and Internet links (no graphic images), a simple but effective project was developed which the teachers could easily complete in the limited time available to them. We incorporated a printout of the finished product into the written reference manual so that the teachers would be able to refer to the booklet as they created the web page.

As with all seminars, this seminar was planned for a particular day, with no possibility of postponement due to “technical difficulties.” The major portion of this training session was dependent upon the availability of Internet resources. To prepare for the possibility of a disruption in web access, we saved all critical web sites on the floppy disks which were provided for the teachers. If the Internet connection was not available on that day, we would still be able to utilize the browser software to open these web sites locally.

Implementation

The teachers who were involved in the training varied widely in their knowledge of the World Wide Web. Some teachers knew how to access the Web and had even incorporated some web activities into their curricula. Others had limited exposure to technology and were quite apprehensive about exploring this brand new tool. No attempt was made to group the teachers by their level of expertise. On the day of the training, teachers were grouped

1116 — Technology and Teacher Education Annual — 1998
at the computers, two to a computer, according to grade level. In addition, the early elementary grade levels (K-1) were placed adjacent to each other as were the intermediate elementary grade levels (2-3) and the late elementary grade levels (4-6). This arrangement allowed for increased interaction among the grade level instructors who had similar curricular interests. As the day progressed, it was interesting to note how the groups of teachers began sharing information among themselves. Because of their close proximity, first grade teachers could see what the kindergarten teachers were viewing on the screen and vice versa. This led to exchanges of web site URLs and peer instruction regarding how to navigate around at different web sites.

My colleague and I designed the following schedule of activities for the in-service:

8:30-9:30 What Is This Thing Called the World Wide Web?

During this activity the teachers were introduced to the basic concepts of web pages and links as well as to how uniform resource locators (URLs) represent address locations on the World Wide Web. We discussed the purpose of the home page as well as the underlying HTML code which is used to generate web pages. We then introduced the teachers to Netscape Navigator and explained fundamental navigation activities such as clicking on links, using the navigation buttons, and setting bookmarks.

9:30-10:30 What's Out There for Educators?

At this time teachers learned how to use the home page we created which contained links to the various curriculum sites we had identified. They learned to use commands such as File I Open File in Browser and were reminded to set bookmarks at sites which they found interesting and which they might wish to revisit later. During this session, we began to see the beginnings of collaboration among the various teachers as they discovered and shared with their cohorts sites which might be useful in their own classrooms. Because we had intentionally included curriculum resources which directly related to the curriculum units they had submitted the previous spring, they were able to find relevant sites very quickly without having to learn how to ferret them out using search engines.

10:45-11:30 What Have Other K-6 Teachers and Elementary Schools Done?

We had created another linked web page which contained a list of exemplary elementary school web sites and good examples of web activities which elementary school teachers have created for their classrooms. Teachers visited these links to discover how other K-6 educators were currently using the web in their schools. Many of the elementary school links listed were using their web sites to communicate with parents and students as well as to provide web resources and technical assistance for their teachers. The web activities developed by other elementary educators gave our teachers some indication of how their counterparts were using the web as a means of enhancing learning opportunities for their students.

1:00-1:45 Internet Search Strategies

In order for teachers to utilize the web effectively in their classrooms, they needed to learn how to develop effective searching strategies so they could locate relevant and beneficial web sites to use as curricular resources to enhance students' learning experiences. We discussed the importance of determining the type of information they wanted to find (lesson plans, scavenger hunts, web activities, etc.) as well as the target audience (other teachers, students, themselves). In addition, we emphasized the need to create descriptive search strings. We then led the teachers through a series of searches where the increasingly descriptive search strings narrowed in on fewer and fewer "hits" and created a manageable number of sites to visit.

1:45-3:00 Let's Build a Web Lesson TOGETHER

The teachers were ready now to begin building their own web activity. As previously stated, I had chosen the nutrition unit to be the web lesson we would design. We walked through the entire process as a group, beginning with determining the type of information (web activity) and the audience (students). We then brainstormed a list of descriptive phrases which we could use to search for appropriate resources for their elementary students to visit as they worked through this web activity. We conducted a few of the searches, but in the interest of time, I gave them the URLs I had previously located for the web activity. The teachers accessed these locations and bookmarked each of them for use in our web activity. This gave us the opportunity to review the "anatomy of a URL" which had been discussed much earlier in the day. Once all of the sites were visited and bookmarked, we were ready to develop our web activity.

The teachers were directed to examine the printout in their reference manual which showed how our finished web activity would appear when we had completed our task. By reviewing the finished product, the teachers were able to envision how students would access our bookmarked sites as reference materials when working through this web assignment. We discussed the fact that the only difference between using a word processor and Netscape Editor to create this activity was the ability to insert links and graphics. We briefly talked about how many of the newest versions of popular word processors such as Word and WordPerfect have incorporated this web page design capability into their products.

At that point, we were ready to begin. Together we walked through the process of activating the Bookmark file (Window I Bookmarks) so that we could use it to copy our links into the web page we were creating with the Right-
We then opened the Netscape Editor (File | New | Blank Document) and immediately named our lesson (File | Save As). The teachers were then able to type in the text of the activity as printed in the written manual. When all of the typists reached the point where they needed to insert a link, we walked through the following process together the first time:

1. Activate the Bookmark window
2. Highlight the appropriate bookmark to copy
3. Right-click the mouse and choose Copy
4. Activate the Netscape Editor window
5. Position the cursor at the point to include the link
6. Click on the Link button on the button bar.
7. Complete the link dialog box making certain that the actual URL is copied using the Right-click Paste option into the location entry box.

When the entire lesson was completed in Netscape Editor, the teachers saved the file (File | Save), closed Netscape Editor (File | Close), and accessed their newly created web activity (File | Open File in Browser) to check their work.

3:15-4:00 How Could You Use the World Wide Web In Your Classroom?

The final activity of the day required the teachers to work together by grade level to synthesize what they had learned during this in-service and to brainstorm ideas as to how they might be able to utilize the World Wide Web to enhance their students’ classroom learning experience. Several of the suggestions shared by the teachers appear below.

1. Students could access several of the excellent Civil War sites on the Web to locate information for research projects they complete during the school year.
2. Teachers could search for existing lesson plans at the curriculum resource sites they had visited.
3. Students could access Native American Indian tribal sites to learn about the history and culture of various Indian tribes they would be studying.
4. Teachers could download activities such as coloring pages and crossword puzzles already available on the Web to use in their classrooms.
5. Students in the early elementary grades could use interactive Web sites dealing with colors and shapes to assist them in learning these concepts.
6. Teachers could find information on the Web regarding Johnny Appleseed which they could incorporate into their lesson on this historical figure.
7. Teachers could use the “Problem of the Day” site to introduce mathematics concepts each day.
8. Teachers who would be teaching the nutrition unit had already decided to use the Nutrition Web Activity developed during the in-service. They also indicated they wanted to add some graphics to the page to enhance it visually.

Feedback from the Teachers

The response from the teachers was very positive. I have included a few of their comments:

“You made the class fun and interesting, and you were so kind and helpful.”

“Thank you for a very valuable, informative workshop!”

“You taught us useful skills on the Internet.”

“You made the class very relaxing and enjoyable!”

“Had you read our outcomes? The curriculum resources we visited fit so nicely with our grade level outcomes.”

“I have been to meetings before where you are shown how to develop web activities; but actually doing it myself, I understand what is going on.”

Those teachers who had previously been exposed to the Internet commented that they had learned more than they expected. The teachers who had very limited exposure were astonished at the resources that were available on the World Wide Web. Most, if not all, of the educators left the session eager to explore in more detail the curricular web sites they had visited or wanted to visit and to incorporate this technology into their curriculum.

Critical Success Factors

The success of this in-service seminar was based on the following critical factors:

1. The establishment of an on-site contact person increased communication between the school and the presenters so more relevant training content could be included in the training session.
2. The grouping of teachers by grade and placing them adjacent to teachers of similar grade levels (K-1, 2-3, 4-6) led to sharing of web resource information since the groups had similar curricular interests.
3. The use of HTML pages as the major technique for facilitating technology transfer was central to the success of this training.
4. The creation of lab activities which were challenging in concept yet were relatively simple to implement sustained the interest of all participants.
5. The availability of an appropriate lab facility was essential. Powerful microcomputers, high-speed access, and a sufficient number of computers to allow a hands-on experience created an effective learning environment.
By designing an innovative training session which consisted of easy-to-accomplish, hands-on tasks which were relevant to classroom teachers my colleague and I were successful in getting elementary educators caught up in the web.

Acknowledgments

I would like to thank my colleague in this endeavor, my husband and fellow web educator, Michael Tate.

A STUDY OF THE INTERNET RESEARCH ACTIVITIES OF PRESERVICE TEACHERS

Raymond S. Pastore
Bloomsburg University

The Internet provides students with information which is dynamic, interactive, and diverse in nature. With the enormous growth of the Internet, more teachers are encouraging students to use the Internet as a resource for classroom activities. The notion of Internet as a research tool for students is beginning to emerge. In an email survey, Starr & Mithei (1996) found that professors were just beginning to use the Internet for student research. As with the introduction of any new technology, the use of the Internet as a research tool may pose more questions than answers. This paper will address several questions related to the resources given to students to conduct Internet research and identify areas for future research.

Role of the Teacher

The role of the teacher in providing Internet assignments can range from information provider to problem presenter. The goal of the teacher should be to create an environment in which students think, explore, and construct meaning (Nicaise & Barnes, 1996). Students should spend less time looking for information and more time synthesizing, analyzing, and reflecting. Students should develop "digital literacy" (Pool, 1997), the ability to understand, evaluate, and integrate information in multiple formats.

Meaningful Internet research should take advantage of the interactive and dynamic nature of the Internet. Students should be able to utilize information which is not easily attainable from other sources.

Teachers who give assignments in which students are required to gather information from the Internet are faced with many questions:
1. Should students be directed to specific web sites for research or should they be given the freedom to explore their own sources of information?
2. Can students identify valid sources of information (Duncan, 1996) and separate "junk" information (Nigohosian, 1996) from reliable sources?
3. Will students conduct more research if they are given web sites or if they are allowed to explore on their own?
4. Does the level of research affect students' willingness to conduct research?

Internet in the Teacher Education Program

Fueyo & Koorland (1997) propose the idea of enhancing teacher professionalism by the integration of research in the teacher preparation program. One way of accomplishing this is through the implementation of Internet research in courses throughout the teacher education curriculum.

Although more students are using the Internet on their own, assignments which require students to conduct basic Internet research may stimulate them to use Internet as a resource in future classes. Farenga & Joyce (1996) describe a model in which short-term Internet training was sufficient to change education students' behavior regarding use of the Internet.

Levels of Internet Research

Barron & Ivers (1996) identify three levels of Internet research: basic, advanced, and original. Basic Internet research refers to retrieving information from a single resource. Advanced Internet research involves high-order thinking skills and requires the student to analyze and synthesize information. Original Internet research is investigative in nature whereby students may conduct survey and experimental research. This study addresses the first two levels of Internet research: basic and advanced.

Purpose of the Study

The purpose of this study was to determine the relationship between levels of Internet research and number of Internet resources given to students and their effect on the number of web site resources used by students during Internet research.

The following questions were asked:
1. Should students be given web site resources to conduct Internet research?
2. Is there a relationship between the number of web sites given to students and the number of web sites used by students during Internet research?
3. Will students use more web site resources in conducting basic Internet research or advanced Internet research?
Procedures

Subjects were approximately 250 students enrolled in an introductory course titled “Field Studies One.” This is a one-credit course required for elementary and secondary education majors and is usually the first education course taken in their program. As a part of course requirements, students were given two questions which required them to conduct Internet research. Question one was at the basic research level in which students were required to retrieve 5 sources of information from the Internet. Question two was at the advanced research level in which students were required to retrieve and synthesize Internet information in response to an analytical question. For each question, students were required to support their answer with a bibliography of web sites. Students were not required to utilize a minimum or maximum number of web sites in formulating their answers.

The subjects were randomly assigned to one of three groups according to the web site resources given to them: 1) Group One was not given any web sites to use as a resource. 2) Group Two was given one web site for each question to use as a resource. 3) Group Three was given five web sites for each question to use as a resource.

Each web site given to groups two and three provided sufficient information to answer the question without further exploration. The content of questions was different for each of the three groups to prevent students from sharing the given web site resources between groups. However, the research level of each question (basic for question one and advanced for question two) was consistent from group to group.

Research Design

This study employed a 3 x 2 factorial design (Borg & Gall, 1989). The independent variables were (1) degree of information given to students (no web sites, one web site, five web sites) and (2) level of research (basic and advanced).

The three types of information given to students were crossed with the two levels of research. The dependent variable was the number of web sites students reported for each question (question one & question two).

A two-factor analysis of variance (ANOVA) will be conducted to determine whether the mean differences between the number of resources are statistically significant.

Conclusions

Results will be reported in the final presentation of the paper.

Conclusions will address the following questions:

- What is the relationship between the levels of Internet research (basic and advanced) and the number of web sites used by students during Internet research?
- What are the implications for teachers who give students web site resources to conduct Internet research?

Telecommunications: Preservice Applications — 1121
GUIDING STUDENTS IN WEB-BASED RESEARCH PROJECTS

Roy Tamashiro
Webster University

Students (and their instructors as well) are often surprised and disappointed to discover that using the World Wide Web for research assignments does not automatically enable them to do faster research or write better papers. In fact many high school, undergraduate and graduate students are overwhelmed by a research assignment involving the web. When they cannot manage the volume of information, instructors see a variety of problems, from poorly-focused topics and reports that lack coherence and organization, to assignments with inappropriate referencing or even plagiarized materials.

Numerous publications that guide students in doing research on the web (e.g., Branscomb, 1997; Calishain, 1996; Campbell, 1995; Harris, 1996; Maloy, 1996) try to address these problems. Some guides are available on-line (e.g., Cummings, 1997; Rodrigues, 1997; University of Tulsa, 1997). However, the wide variety of research assignments in the various academic disciplines makes it difficult to provide universal guidelines for students. The instructor is in a more strategic position to address the problems. The instructors’ structuring of assignments will most likely enable students to conduct their web-based research more efficiently, and to produce work that is more focused and pertinent, more up-to-date, and less likely to have been plagiarized. Strategies for doing this are described in this paper.

Research papers, projects and assignments refer to any class assignments that involve library materials that can now be accessed via the Internet and the web. They include reviews, position papers, theses, assessments or other studies (interviews, questionnaires, surveys, case studies), annotated bibliographies, and other papers, reports or assignments that involve traditional or electronic library material. Assignments like these are made in classes in the arts and humanities, in the social sciences, in the natural and applied sciences, in business and management, and in professional development courses in many fields. Instructors at all levels from the elementary grades to graduate and professional schools make these assignments.

Infrastructure

Web-based assignments require institutional infrastructure that includes considerations of equipment and software, as well as library support facilities and staff to assist instructors and students. School networks linked to the web and other community or home access to the Internet are necessary. Access to appropriate research and academic databases, available by institutional or individual subscriptions, must be in place. Software tools including web browsers, word processors, image editing software, and presentation or multimedia authoring software are necessary for students to conduct their research on the web, to organize their material, and to submit, present or publish their reports. Assignments involving collaboration also require e-mail or conferencing capabilities.

Students and instructors must have the knowledge and ability to use these tools to work productively on their papers, projects and assignments. The training or orientation to these tools may be provided in several ways such as workshops or mini-courses; personal assistance in libraries or in labs; telephone or e-mail consultation or help-line; online tutorials and references. Schools must commit to and provide adequate staffing, facilities and other material support for the workshops, for the library and lab assistance, for the help desks or for the on-line programming and design.

Instructors may either expect students to know how to use the software tools as a prerequisite to the class or activity, or they may ask students who do not have prior experience to learn the skills concurrently with completing the assignment. Instructors themselves should be familiar with the tools, preferably, before making the assignments. However it is possible for instructors (with some risk tolerance and flexibility) to be learning to use the tools along with students doing the assignment.

Reliability of the technologies is an important consideration for the institution, the instructor and the student. It is the school’s responsibility to provide consistent access on the school’s network, and to ensure that their ISPs and database vendors are also reliable in their service. Instructors may provide students with contingencies, precautions and alternatives in dealing with technology reliability issues. For example, instructors may place class web pages on multiple (mirror) servers, or provide links to different servers that provide access to particular data bases. Students need to be aware of these reliability issues and be flexible.
They should be aware, for example, that the instructor may not accept their excuse that the DNS was down 24 hours before the project was due when they just started to work on the assignment.

**Strategies and Resources**

Strategies for guiding students in doing research on the web are grouped into six areas: (1) selecting and focusing the topic, (2) organization and timeline aids, (3) strategies for searching the web, (4) strategies for collecting and organizing the materials, (5) minimizing plagiarism, and (6) options for publishing students’ work.

1. **Selecting and Focusing the Topic**

   The selection and focus of the topic may be the most critical factor leading to the success of a research paper or project. The definition of the research topic, the degree of specificity and scope of the topic can determine the quality and quantity of the sources to be found. The instructor’s assignment objective defines how the topics will be selected, and how narrow or broad the topic will be. Given that, instructors should strive for the most specific research topic as is reasonable. The volume of material available on the web makes it possible to find answers to very specific questions. In an American History class, for example, a topic such as the Truman Presidency should be narrowed, first to a situation like the 1948 election, then to specific issues and questions such as: “What were the polling strategies the media used in the 1948 Presidential election?” “Compare the campaign strategies Truman and Dewey used in the 1948,” “What were the expenses and sources of funding for the 1948 Presidential campaign?,” “What media did Dewey and Truman use in the 1948 campaign?” or “What were the most influential themes in Dewey’s and Truman’s campaign speeches in the 1948 Election?”

   Whether students choose their own research topics or are assigned the topics, the topics should be narrowly focused. It may be helpful to require that the topics be declared in the form of a question. If the assignment is a term project, have the students submit their research questions early in the term. This enables the instructor to provide students with feedback and suggestions on the workability of topic. The feedback and suggestions returned may be alternative phrasing of the topic question, suggestions for different perspectives in the study (e.g., seeking the pros and cons of a controversial topic), and suggestions and alternative questions for further narrowing the focus of the topic.

   Instructor feedback can be supplemented with student-to-student collaboration in defining the topic. One format is to place students in groups of 3-4. In these groups, the student tells the others his or her proposed topic and what feedback the instructor gave. The group members provide additional suggestions on the selection and phrasing of the research question. Each student then decides on revisions and resubmits the proposed research topic to the instructor.

   The topic selection process can be further facilitated by the instructor providing a worksheet or form in which the requirements and steps are listed, and space is provided for including topic proposed, instructor feedback, peer suggestions, and revised topic.

2. **Organization and Timeline aids**

   When the instructor provides organizational structure for the assignment, students are more likely to fully understand the assignment objectives and are more likely to achieve the objectives. Organizational structure refers to (a) the elements required in the research report or assignment, and (b) the process for doing the assignment.

   Instructors should strive to be as clear as possible about what they are seeking in the research report. This should be made explicit to students. For example, an instructor might convey to students that the project should contain the following elements: A personal and academic rationale why the topic is a compelling one; historical background on how the topic has been addressed past and present; the kind of charts, maps, photos, tables, or other graphics that would be relevant for the report; a personal synthesis; and recommendations. Instructors may also prescribe that students follow a particular outline for the reports. Students find that it is helpful when instructors provide guidelines for the maximum, minimum or expected lengths for each section. The length of each section may be given as the number of words or page length for written reports, or the number of screens for each section in a presentation.

   Students are aided when the instructor understands the process by which the assignment is done and communicates this to students. This process may be linear-sequential, or looping, or a combination of both. For example, a linear-sequential process may be: (1) brainstorm possible topics, (2) select the most interesting and workable, (3) focus the topic and define the question, (4) conduct the literature search, (5) retrieve the documents, (6) select relevant data, (7) assemble material into the outline, (8) write the report, (9) revise and edit the report, and (10) submit the report. A looping process might involve repeated searches, weekly revisions of the research topics, and an evolving annotated bibliography.

   In either process, the instructor should consider requiring students to submit their work in progress throughout the period. Check points and due dates for various steps in the process ensure that students are proceeding appropriately, and the instructor can correct problems before the student submits the final report. For example, due dates can be set for the intended research topic, for a printout of the search parameters, and for working reference lists.
3. Strategies for Searching the Web

Instructors can refer students to the numerous guides which provide instructions on how to do research on the web. (See References below.) These guides provide helpful strategies and resources for conducting searches. In addition to these guides, instructors should provide instructions, guidelines and resources which are particular to the discipline or topic, to the particular relevant data bases, and to the objectives of the assignment.

Instructors should define which databases are appropriate for the assignment. For example, an instructor for a course on child psychology might require that students only use PsycFirst (1997) or Ovid Mental Health Collection (1997) for their searches. There are several advantages to restricting students to using only discipline-based databases: Students are less likely to be overwhelmed or distracted by the volume of resources. Students become more familiar with the literature of the particular academic discipline. They get to relevant and appropriate material more quickly. They can be more certain about the credibility of the sources.

If instructors provide web pages or resource lists for their courses, direct links to the prescribed databases may be included. These links enable students to select and access the appropriate data bases with less chance of misdirection or errors typing URLs.

In addition to directing students to discipline-based databases, it is important to provide guidelines on entering search parameters in those databases. This information may be available on-line in the particular database, or it may be one of the services provided by the school’s library or computer resource center, or it may be explained in publications on Internet research. The instructor should point students to the resource that will provide the necessary guidelines for entering search parameters. If such a resource is not available, the instructor should prepare a brief list of suggestions and instructions that will assist students in making their search efficient. For example, instructions for searching the journals in education in a “Contemporary Educational Issues” course were given as follows:

1. Access the ERIC databases through FirstSearch Data-
bases on the Eden-Webster Library web site (http://
library.websteruniv.edu/database.html#e). Enter your
student ID number when prompted.
2. On the Search Screen, click on the button labeled
“Advanced Search.”
3. Enter your topics in the “Search For” field. In the
“Search Type” field, click in the box marked “Subject.”
Limit your search to recent years, such as 1992-1997. In
the “Division” field, select the CJE (Current Index to
Journals in Education). In the “Language” field, select
English. Click on the “Start Search” button.
4. From the list of articles, click on the underlined title to
view the full abstract and bibliographical information
for each article. You can Print or Save (to a disk) this
information by choosing these commands from your
computer’s file menu.
5. On the Results screen, you may also click on the
checkbox marked “Tag Record” for each article you
want to save or print. When you have marked all the
articles you want, click on the button marked “Show All
Tags.” You can then print, save or e-mail (to yourself)
the entire list of articles with abstracts.

Research assignments may also involve library catalogs,
databases to popular periodicals, newspapers, other news
media (e.g. television, syndicated wire services), maps or
graphics. Some assignments may also involve searching the
web or newsgroups using web search engines. If so,
instructors should customize instructions for these sources
as appropriate for the assignment.

4. Strategies for Collecting and Organizing the
Materials

Instructors can provide specific suggestions to students
to make collecting and organizing material from web
sources efficient. A worksheet of instructions or an in-class
demonstration may be sufficient. For example, the follow-
ing instructions provide such guidance:
1) Open both the word processor and the web browser.
2) Highlight the text you want, and use the copy function in
web browser.
3) Paste this text into the word processor document.
4) Copy the URL from the browser’s location window and
paste it into word processor document.
5) After the search, edit and reformat the report.

To further assist the student in the organization,
instructors can provide students with a template of the
prescribed outline. Students paste the material they are
collecting from the web search into appropriate sections of
this template, thus saving them time deciding where the
material will go.

If the final form of the research assignment is a presenta-
tion or hypermedia stack, then the presentation software or
the cards of a hypermedia stack could replace the word
processor in the instructions to students. The instructor may
also provide students with a template for the presentation or
the hypermedia stack.

5. Minimizing Plagiarism

Instructors are understandably concerned about research
on the web increasing the opportunity for plagiarism. While
there may not be any surefire means to prevent or detect
plagiarized work, instructors can take steps to minimize its
occurring for their assignment. The following suggestions
may be appropriate for a variety of web-based research
assignments:
• Require citation of all sources. Have students include all URLs, and announce that instructors will verify these URLs.

• Require fresh sources. In many research projects, instructors could require materials to be those that were posted in the current semester or term, or in the last several months. This ensures that another student’s report from a previous semester is not likely to be submitted without additional current research.

• Require analytical links between textbook and current resources from the web based materials. For example, ask students to relate how a current event found in a web search relates to a case described in the textbook.

• Require personal links. Ask students to include personal experiences that can be related to the research. This may be included in giving a personal rationale for the topic, in providing a personal experience anecdote, and in synthesizing the material or in making recommendations for oneself about actions steps involving the topic.

6. Options for Publishing Students’ Work.

The emerging technologies enable students to submit, present and publish their work in new ways. In addition to research reports submitted on the traditional term paper formats, other electronic formats may be used. The same report may be submitted on a floppy disk, or via e-mail. The report can be distributed easily to other students or instructors. The report may be done on media other than a word processor, such as on presentation software, on a hypermedia stack, or on a web page authoring tool. These formats make it possible for the student to present the research report to the class or other group, or post the report on the web, on a CD-ROM or even record it on a videotape for playback on a VCR.

These new opportunities for students to show their project to others besides their instructors, increases the potential meaningfulness of the paper or project. Instructors should use these avenues for students to share their research results with others as a way to increase the value and meaning of each student’s work.

Discussion

If an instructor has not previously used the guidelines and suggestions outlined in this paper, it may be unrealistic to expect one to be able to implement them all right away. Each guideline and suggestion has underlying pedagogical assumptions that instructors may or may not agree with. Instructors must think through the implications of the change on their own pedagogy or teaching style. It takes time and several rounds of revision to get things to work for each assignment. In fact, instructors who have used written research guidelines for their assignments continue to frequently revise both the assignments and the written guide sheets. Nevertheless instructors who wish to assist their students in improving their web-based research are likely to find the suggested direction invaluable for their students.

Frustration, Frustration, FRUSTRATION . . . . . Students are not unlike their teachers when confronted with the use of technological innovations such as the World Wide Web. For many, this new instructional tool produces an inability to cope with the confusion presented by inappropriate web site design. Novice web site authors, who may have very little knowledge in the area of instructional design, are exacerbating the frustration. In most cases, without even knowing. . . . they have created a NIGHTMARE for the innocent student. Have some forgotten that providing students with a positive, experience based instructional design ought to be the essential foundation for all learning experiences? There should not be significant differences in the development of sound instruction, just because the instructor is trying to integrate the use of technology into the learning processes.

The emergence and use of web sites for the immediate access and dissemination of information provided by instructors has become a phenomenon for the 21st century high school and college classroom. One of the most obvious observations of this rush to the web is the naive use of hypertext linking (Schoon, 1997, p. 4). According to Sano (1996) “Unfortunately, many web sites today appear as if they were hurried onto the net, disregarding user’s needs, requirements, and preferences” (p. 13). How many web site authors know what hypertext linking is or what linkage models are, as well as their appropriateness for use with specific instructional applications? Increasing numbers of educators are examining how the World Wide Web can help in the classroom (Dyrli & Kinnaman, 1995), but are the results of those studies reaching instructors who are taking on the responsibilities for the authoring of web sites?

Two years ago, Doty (1995) stated that lesson plans, projects, and resource kits are being developed and (Ryan, 1995; Sanchez, 1995) affirmed that interesting sites for student access are being identified. With all of the development and identification that has been undertaken in the past several years, one would think the frustrations of students must be non-existent in our classrooms and computer labs. Unfortunately, that may not be the case in most institutions. As the nation’s schools move toward adopting a more technological approach, the future of instruction may be based on how quickly the schools can be wired for those multiple trips down the information super highways to the interactive world of the Web Site of Knowledge. Where are the checks and balances? Who is evaluating the competence of the designer when using this new instructional tool?

Could it be that some instructors are blindly creating web sites with those “navigational nightmares” their students have been identifying in recent studies?

This paper will address several issues that students have identified in two independent studies conducted at a midwestern university when using the world wide web in instruction. The high incidence of frustration reported by these students may provide insights into the necessity for proper instructional design and modeling. Findings of both studies indicate the need for greater commitment from educators in utilizing appropriate design principles for both informational and instructional web sites.

The Studies
A total of 314 students participated in these studies. The majority of the students were juniors having various content specializations. The participants were represented by 171 males and 143 females. The sample from the Weber (1996) study was comprised of two sections of teacher education students. The Schoon (1997) study consisted of students in two sections taking courses in the business department. The studies used various quantitative and qualitative research methods to analyze the data.

Each of the studies had been designed to help researchers understand what barriers students encounter as they are introduced to Netscape navigation and the use of the World Wide Web from an instructional perspective. Duchastel (1990) suggested that hypertext usage could be categorized into three broad forms: cultural, educational, and informational. “These forms constitute a continuum on which the
elements vary in the degree of explicit goal directiveness” (p. 224). Users at the information end of the continuum are looking for information that they need to answer a question they have. This type of discrete information is called closed-task information. A closed-task is one in which there is only a single factual answer to a question (Marchionini, 1989). Although the two studies identified being used in an instructional setting, the web site assignments were designed using the hypertext category which by definition was informational not educational.

Data Collection
The 1996 study used five questionnaires to collect data. One instrument Mid-Term Course Analysis (MTCA) collected data mid-term and one Barriers Identification Survey (BIS) was administered end-term to provide a comparative evaluation. The 1997 study used one questionnaire and one participant activity sheet that was completed after the student concluded the WWW navigational activity with a randomly assigned hypertext linkage pattern e.g.: (a) linear (with side steps); (b) star (extended); (c) hierarchy; and (d) arbitrary.

Findings
Content analysis of the MTCA and BIS open-ended questions from the 1996 study provided 13 categories of barriers which were identified by participants and determined as either internal or external. The following statements are representative of the comments made by students who completed a WWW search activity:

Internal Netscape Barriers
- I got very frustrated because I felt like I was wasting my time spending hours finding answers
- I was frustrated with the way Netscape was presented to us
- We weren’t given enough background
- Time was a factor when using Netscape. In order to find one piece of important information, it took a couple of hours. This was not possible for me. Netscape was not useful
- Becoming overwhelmed with the amount of info available!
- This program is so confusing... I never knew how to go from here to anywhere!
- I was frustrated because it is so hard to relate the information I found to actually doing something. It is very subjective. The information can guide students, but the Internet cannot teach
- Sure, ‘surfing’ is easy, but searching is a different story. I also needed long blocks of time to get something substantial, like 3+ hours, but I never spent that long at a terminal
- It is intimidating. I feel like they said, (they being the instructors on using this equipment) ‘Hey kid, here’s how you click a mouse. Now go find the most obscure info in the world!
- It has been difficult motivating myself to want to use this system. I believe that information found on the Internet is available in books, as well, and as a result, most research I have done has not included the Internet (Netscape), because the ‘old-fashioned’ way is much more comfortable to me.

External Netscape Barriers
- The most frustrating part of using the Net was the ‘Professional Inquiry’ project!! We had very little knowledge or experience using it and because of that fact it took me 2 days (eight hours) of time-consuming frustration trying to find the answers! What was the point of the project? We could have learned faster methods of exploring the Net by working in groups within class!
- The in class sessions were terrible. The lab instructor didn’t know how to teach and in fact, didn’t teach us anything. I learned how to do this myself.
- Although there were many similarities as well as apparent differences identified by the students, there was a statistically significant difference reported between male and female students and the use of Netscape. Female students reported having more difficulty than male students.

Findings from the 1997 study were based primarily on the data collected from the WWW search activity where the participants were randomly assigned to navigate one of the four web sites designed using one of the four hypertext linkage patterns. Of the 261 participants, 66 were assigned to the linear site (25.3%), 65 to the star site (24.9%), 66 to the hierarchy site (25.3%), and 64 to the arbitrary site (24.5%). Over 77% of the students in the study rated themselves as being somewhat inexperienced or less. Only one female rated herself as being very experienced with using the web over the past two semesters.

In order to help distinguish the barriers students encountered during the web site navigation, a final path steps was computed for each incidence. The final path steps are the number of steps taken by a web user from the home page directly to the location of the desired information (target page). The final path step numbers for three of the four web sites constructed for use in this study were equivalent to the number of steps in the optimal path. This is due to the fact that for the linear, star, and hierarchy web sites, there was only one possible path for a user to navigate to find the desired information. The hierarchy site has three steps in the optimal path. The star site had four steps in the optimal path. The linear site had eight steps in the optimal path. Only the arbitrary site offered web users more than one path to the desired information (target page). The minimal number of steps for any of the optimal paths for this site was six.
Because there was only one possible path for a user to navigate to the target page in the linear, star, and hierarchy web sites, the overall mean number of final steps for both genders for these sites was equivalent to the optimal number of steps for these sites (see Table 2). Only the arbitrary web site varied in the number of final steps. The overall mean number of steps for the arbitrary site was 6.80 (SD = .80). It took females fewer steps than males to arrive at the target page on the arbitrary site. The 29 females assigned to the arbitrary site had a mean number of final steps of 6.76 (SD = .79) while the 35 males assigned to the site had a mean of 6.83 (SD = .82). However, females had on average more restarts and revisits than males did.

Restarts were also computed for analysis. A restart occurs when a user goes back to the homepage either through revisits (backing up) or by pressing the home key in the World Wide Web browser. The home key in the browser used for this study was turned off. Therefore, in this study, a restart could only occur through revisits. Overall, the most restarts occurred within the arbitrary web site. The least number of restarts occurred in the hierarchy web site. Both male and female participants assigned to the linear and hierarchy web sites averaged less than one restart. Both male and female participants assigned to the star and arbitrary web sites averaged close to one restart. Females assigned to the arbitrary web site averaged close to two restarts. On average, females had more restarts than males in all of the four web sites in this study.

Revisits were also determined as important to the collection of the data. A revisit occurs when a user goes to an HTML document that he or she has already visited. Whether the participant uses the forward or backward button to revisit an HTML document is not important, only that they have revisited a document. Overall, the most revisits occurred within the arbitrary web site (M = 24.20). The least number of revisits occurred in the hierarchy web site (M = 1.67). Males had, on average, more revisits in the hierarchy web site. Females had, on average, more revisits than males in three of the four web sites in this study. Overall, the most revisits occurred within the arbitrary web site (M = 24.20). The least number of revisits occurred in the hierarchy web site (M = 1.67). Males had, on average, more revisits in the hierarchy web site. Females had, on average, more revisits than males in three of the four web sites in this study.

Figure 2. Revisits by Gender and by Type of Site.

Analysis of the data showed that:
- linear, star, and hierarchy hypertext linking patterns are all more efficient for finding closed-task information than an arbitrary hypertext linking pattern. The star and hierarchy hypertext linking patterns are also more efficient than the linear hypertext linking pattern,
- there were no significant differences between experienced and inexperienced World Wide Web users in their efficiency in finding closed-task information within web sites constructed using different hypertext linking patterns, and
- there is a significant difference between males and females in their efficiency in finding closed-task information within the arbitrary web site. Males, as evidenced by a lower NAE value, had an easier time of navigating this type of web site than did females. There is no significant difference between males and females in their efficiency in finding closed-task information within the linear, star, or hierarchy web sites.

Conclusions

These studies were conducted to provide a foundational investigation of use of the world wide web in an instruc-
tional setting. The samples in these studies, although limited in number, recognized the barriers that inhibit to some degree the students' efficiency relative to the learning processes. Students told the researchers of their frustrations repeatedly. If frustration would have been identified by the number of revisits and restarts the students encountered, then the data collection findings may indicate why there ought to be concern for the appropriate designing of web sites for instructional purposes. As the community of educators moves into the technological classroom, instructional designing for the improvement or enhancement of the learning processes must be strongly considered as top priority, rather than rushing to the Internet to produce frustration, frustration, frustration.

DEVELOPING AND DELIVERING INSTRUCTIONAL TECHNOLOGY FOR IN-SERVICE TEACHERS

Abbie Brown
Walden University

Although its official title is Development and Delivery Utilizing Technology, the students and I wound up referring to the course as “geek boot-camp.” (The term “geek” is one that I and other students in Indiana University’s Department of Instructional Systems Technology use with great pride; it signifies to us a level of technological mastery and computing skill.) The residency portion of the course was indeed a “boot-camp” setting: up early each day, learning new skills, and putting those skills to use negotiating a series of obstacles. There was laughter, there were tears...there was... The results however seem worth the effort.

Course Description

The course Development and Delivery Utilizing Technology is part of Walden University’s new Educational Change and Technology Innovation (ECTI) master of science program. Walden’s ECTI program is intended for in-service professionals, the majority of whom work within a k-12 environment. Development and Delivery Utilizing Technology was offered for the first time this past year in the summer of 1997. The students consisted of seventeen individuals from various parts of the United States; they included nine classroom teachers, two library and media-resource specialists, and two district technology coordinators working in k-12 public and private school settings. Of the three students not placed in k-12 settings, two worked in post-secondary settings; and one worked as a corporate trainer. All students had at least three years of professional, in-service experience (the majority had ten or more years of experience). The range of students’ technological expertise and comfort level was extreme: some were experienced multi-media producers; some were technology “newbies” with little more than basic competence in using e-mail software. All were bright, highly motivated individuals capable of the independent study required by Walden’s distance-education format.

The course includes an introduction to instructional design theories, principles, and processes as well as the opportunity to work with advanced, computer-based technologies including HTML, multimedia-authoring tools, and desktop-publishing software. During the course, students were assisted in the development of personal guidelines intended to assist the decision-making processes that accompany the production, utilization, and evaluation of computer-based and other state-of-the-art technologies for purposes of instruction.

Students worked in groups to produce support materials for a larger content unit (for example: a mini-lesson on planet distances to accompany a larger unit on astronomy for 8th graders; or a multi-media presentation on the Globe Theater to accompany a larger unit on Shakespeare’s Othello for high school juniors). This support material included a World Wide Web site; a desktop-published paper reference; and a multimedia-authored, stand-alone program. Evaluation was based on the quality of the projects and their accompanying documentation, including usability testing results and “bug reports.” Personal journals were kept by each student and submitted at the end of the residency.

Development and Delivery Utilizing Technology is part of Walden’s summer quarter, running from early June to the end of August. Although students and the instructor were in contact via e-mail (and in some cases telephone) during the entire quarter, the bulk of the work was accomplished during the two-week residency period. Students were required to attend the residency portion of the course, making use of the computing facilities on Indiana University’s Bloomington campus (and staying in IU’s dorms, further adding to the “boot-camp” feeling). During the three weeks prior to arrival at the IU campus, students were given the course assignments via Walden’s web site and e-mail messages from the course instructor. Prior to arrival for the residency, all students were directed to form groups (with no more than three other students) and to decide on the subject matter for their project.

Using e-mail and telephone to negotiate groups and project subject matter before the residency solved a number of problems. With only two-weeks of “face-time” to accomplish three sophisticated technology projects, students needed as much advance preparation as possible in order to
make best use of their time together. By knowing who their team-mates were and what their subject matter was in advance, the students were able to focus on the technological problems during the residency (they were also able to bring appropriate materials with them from home). The problem encountered with this approach was that the instructor had to carefully monitor the process of team formation and subject choice in order to avoid misunderstanding or inappropriate interpretations of the assignment — although this is true of almost any course, it seems particularly difficult in a distance-learning, asynchronous environment.

The course was developed and delivered using a problem-based-learning (PBL) approach. Students were encouraged to solve the problems of developing the web site, desktop published documentation, and multimedia-authored program by sharing their expertise and by participation in instructor-led formal presentations and informal mini-lessons. During the residency, students typically spent four hours in a traditional classroom setting learning about various technology and design-process issues. The rest of their time was spent in small groups working in the computer laboratories or in counsel with the instructor or an instructional assistant.

The problems associated with group work naturally include dealing with personalities that may not naturally "mesh" with each other. This can be a particularly difficult obstacle when all group members are highly competent and autonomous within their professional setting. A considerable amount of class time early on in the residency was devoted to group-work processes and suggested procedures. While it was helpful to outline strategies that tend to work well for groups, it was perhaps inevitable that the group process would break down for everyone at some point or another during the residency — problems existed, but (with one exception) proved themselves to be only minor stumbling blocks along the path to completing the projects. Learning to work in groups seems to be an important part of creating technology-based instruction; the intricacy of the work and the amount of person-power needed to create a successful technology-based presentation currently demands a combined effort. Therefore, although the process has its painful moments, the group-based, PBL approach seems to be the most appropriate choice in the delivery of this type of course.

Course Content

Choosing content for the Development and Delivery Utilizing Technology was difficult. The question that posed itself at the outset was, "What skills does a person need to have in order to be considered a competent user of instructional technology?" The decision was to include three broad areas of technology-based production skills: Internet-based communication, stand-alone, personal computer application development, and the development of sophisticated print material. This decision was made based on the instructor's personal teaching experience, not on formal research.

Upon course completion, students were expected to have a working knowledge of HTML development, paper-based design, interface design (with particular emphasis on navigational elements and standard conventions), as well as the standard conventions and concepts currently used in digital media design (e.g., image resolution, bit depth, file type...etc.).

The concepts and protocols of instructional design were the focus of Development and Delivery Utilizing Technology. Students learned and put into practice some of the standard procedures associated with instructional design, including rapid prototyping, implementation of the ADDIE model, usability testing, and formative evaluation. This proved to be one of the most satisfying elements of the course for most students. The concepts are not new ones for experienced educators, but their articulation in terms of instructional design seem to serve as a conceptual bridge between traditional classroom practice and the development of technology-based instruction.

Software and Hardware Considerations

The software and hardware used to complete the projects was chosen with some consideration as to what was considered "industry standard" and what might be most available in K-12 and post-secondary educational settings (Macintosh and PC platforms, using Photoshop, HyperStudio, and Pagemaker — web pages were created with word-processing software, not HTML editors). The goal of the course is not to accomplish technical competency with any one software package, but to understand the underlying concepts of instructional design and multimedia development in order to be able to apply these concepts to any software package. Although students ultimately agreed that this was a sensible approach to their learning, there was some initial concern about using unfamiliar software — a series of mini-lessons on the navigational elements of the various software packages used proved helpful in getting people comfortable enough with the software to allow them to focus on more general concepts.

Conclusion

Few people actually enjoy boot-camp while they are going through it, but it often serves as a transitional experience that gives an individual greater skill and greater confidence. This seems to have been the case for Development and Delivery Utilizing Technology. Observation from the instructor's point of view suggests that the course itself was challenging and stressful for the majority of learners. However, the course reviews were consistently supportive of the approach — students reported a strong sense of satisfaction and increased confidence in their
instructional design skills and technological understanding. Correspondence from the students to the instructor that continue to this day suggest that these in-service professionals are making active use of the skills acquired in Development and Delivery Utilizing Technology, provided that they are in settings that support advanced technologies.

Abbie Brown is a faculty member of Walden University's Educational Change and Technology Innovation program, Associate Instructor/Coordinator of Indiana University's Teacher Education Laboratory, and a doctoral student in Indiana University's department of Instructional Systems Technology. The articles in this year’s Telecommunications Systems and Services section document the continued spread of the Internet into teacher education programs throughout the world. These writings explore the formation of a variety of electronic educational communities and propose innovative methods for integrating online resources into teacher education. Zimmerman and Greene begin the section with a paper that chronicles a five-year program at Appalachian State University. They describe the project in which they have developed an electronic community that links preservice teachers with university faculty and cooperating teachers. This report chronicles the events giving stimulus to the experience, summarizes pertinent findings, and offers insight into the challenges and rewards of such an effort. Pagnucci, Macauley, Winner-White, and Mauriello explore how the growing use of technology for teaching writing promotes increased teacher collaboration. In particular, the authors focus on four types of technology-based collaborations and provide concrete examples by relating their own personal stories of teaching with technology.

Zhao, Worthington, and Ingram describe a program that equipped student teaching interns at Michigan State University with laptop computers for use in their assigned classrooms. The article documents the experiences of these interns as they developed their own sense of what it means to teach with technology, what it means to be a teaching intern in the context of technology use, and what it means to troubleshoot problems with technology. Davis provides a look at how Telematics, a European term for information and communication technologies, is being integrated into the educational system in the UK and several other countries in Europe. She discusses her work on telematics and teacher training and describes the T3 (Telematics for Teacher Training) project which focuses the preservice training of student teachers, the continuing professional development of inservice teachers, as well as the training of teacher educators and library staff working with teachers.

Kanji Akahori of the Tokyo Institute of Technology describes the effectiveness of integrating the Internet into education in Japan. Akahori also points out some of the problems that Japan is facing as it begins to utilize newer forms of communication technology and discusses the research that is investigating the effectiveness of these technological resources and the impact they are having on schools and the school reform movement. In the next article, Madhumita and Akahori propose a functional model of a computer-based instructional system. The authors describe their work on the design and development of new curriculum that uses a Web-based system for collaborative learning and emphasizes problem-based learning.

Clarke recounts the story of the Education Network of Ontario, a province-wide Intranet, that has grown to over 50,000 registered educators, nearly half of the eligible teachers, administrators, teacher trainees and elected education officials in Ontario. McIntyre and Hollon, of the University of Wisconsin - Eau Claire, describe the Virtual Learning Technology Community, a collaborative professional development model that supports K-12 students, K-12 teachers, university faculty, preservice teachers, and instructional technology staff developers at local service agencies as they learn to use technology as a tool for enhancing learning. The vision of the VLTC is to provide assistance to additional PK-12 schools seeking support for improving the use of technology to help students develop competence in (a) finding and evaluating information and ideas, (b) using available learning tools, and (c) communicating effectively. Maney, Brooks and Perry discuss three statewide technology initiatives that aim to infuse technology into K-12 education and set the stage for cultural transformation of teaching and learning in Ohio. This paper describes how one successful project has developed a K-16 telecommunity to encourage the adoption of education technology.
Breuleux, Laferrière and Bracewell describe a research initiative to design and document technology-supported integrated learning communities for the extended professional development of teachers facing the new Canadian requirements for distributed knowledge of technology. Powers and Dutt-Doner ask the question, "Can an electronic communication system hold discussion as effectively as regular classroom communication?" This paper uses the traditional communication model of source, receiver, message, channel, noise and feedback to demonstrate how an instructor can plan effective electronic communication.

Hrabe, Adamy, Milman, Washington and Howard recount how instructors of seven university educational technology courses at the University of Virginia created a Web-based discussion group for their students to engage in online discussions about issues related to the use of technology in education. This article describes a qualitative analysis of the online discourse as it developed and the participants’ reflections on the experience. Sivan documents his work with the Lamda Community project in Israel and argues that "knowledge sharing" - the previously argued essence of any "virtual community" - does not fully capture the dynamics of large-scale virtual communities. Instead, he proposes the concept of "knowledge infrastructure" as a more appropriate term to describe the reason why more people use, and will use, virtual communities.

Manchee's article describes a Web site evaluation project used with fourth grade students. The project was designed to teach critical thinking and research skills valuable in using the World Wide Web and was also used to help train teachers who contributed to the final product. Bronack and Kilbane write about CaseNET, a World Wide Web-based learning environment where teachers utilize the latest technologies to form communities of professionals who hone their decision-making skills via encounters with "slice-of-life" cases. This paper presents an evaluation of the practical implications of this technologically-enhanced learning environment, where both inservice and preservice teachers are actively engaged in decision-making, communication, reflection, and analysis of teaching situations. Galloway's paper targets the training of educators new to the Internet and outlines Web applications for teaching. A variety of Internet uses are discussed including the application of Internet tools in traditional classroom courses. The author provides specific suggestions for teachers who want to incorporate the Internet in their teaching.

Dowling, Sanjur and Maciocha present an overview of a museum Web site created by the National Museum of American Art that supports project-based integration of art and technology in K-12 education. Parmley, Hutchinson, and Parmley chronicle the development of a Web site and educational resources for Hovenweep National Monument in Cortez, Colorado. The partners in this project describe how they addressed the needs of electronic Park visitors applied them to the development of an educational Web site that incorporates classroom learning activities and teacher professional development. Davis, Selinger, Soetaert, van Belle and Robin discuss the development of Web Sites, comparing and contrasting approaches to placing educational material online. Overviews of several Web sites are presented that illustrate plans for development as well as issues relating to an international collaboration that aims to create communities of teachers and learners.

Next, Galloway gives his views on designing Web-based courses and presents a model for teachers who want to provide instruction and course delivery on the Internet. This model starts with the beginner level of basic e-mail and Web browsing and progresses to the highest level, becoming independent distance educators. In their paper, Tu, Babione, and Chen focus on the use and design of online survey, enrollment, and examination technology. An online service system designed for students to enroll electronically at the Teachers College, Emporia State University in Kansas is used to demonstrate the basic techniques and concepts for this new area of Web application.

The next two papers deal with the growing use of electronic mail. In the first, Wilkinson and Buboltz point out that most researchers have focused on the potential advantages gained through the use of technology and have ignored potential risks or disadvantages. In this paper, they highlight some of the potential risks of using this communication medium. In the second paper, Soper, Wilkinson, and Von Bergen discuss how e-mail may be abused as a communication technique. In this paper, the authors discuss the prevalence of e-mail, who tends to misuse it and why, and present some recommendations to counter misuse.

Altun continues the investigation of electronic communication in his article that describes an ethnographic microanalysis that focuses on the discourse and how interaction management strategies function in two different chat rooms: Internet Relay Chat and 3-D Virtual chat rooms. Knee and Cafolla discuss how to bring interactivity to the Web. They present an overview of Java, the object-oriented programming language that has taken the Internet by storm and maintain that with the use of Java, the Internet no longer need remain a static communication vehicle.

Gunter and Gunter describe the Federal Communications Commission’s E-Rate Discount Program, that will provide $2.25 billion a year in telecommunication discounts to K-12 schools and public libraries in the United States. The paper provides a summary of the major components of the E-Rate discount program and issues two challenges to administrators so that maximum benefits of the E-Rate program may be realized in classrooms throughout America. Finally, Knaak, Lüssem, Spalka, and Sünderkamp of the University of Bonn, conclude the section with a reminder that the Internet is not without its
problems as they write about the issue of computer security in schools. They suggest that protection of a local school network with access to the Internet requires the formulation, implementation and frequent analysis of a school-wide security policy. They argue that in order for such a policy to be effective, teachers need to be involved in the development and the constant enforcement and that computer security should be an integral part of teacher training. Collectively, these twenty-seven papers help tell the story of how telecommunication technology has become part of our jobs as teachers and they can surely assist us as both developers and consumers of electronic information.

A FIVE-YEAR CHRONICLE: USING TECHNOLOGY IN A TEACHER EDUCATION PROGRAM

Sara Olin Zimmerman  
Appalachian State University

Melanie W. Greene  
Appalachian State University

At the beginning of this decade a network of electronic mail systems connected most universities throughout the United States and several foreign countries. Colleges of education had begun linkages with public schools to support the student teaching process. Telecommunication tools for collaboration promised benefits for university faculty, student teachers, and cooperating teachers. The Curry School of Education at the University of Virginia was a premier example of an electronic academic village. Their first experimentation with electronic mail began in 1984 as a result of a joint study with IBM Academic Information Systems and the Curry School of Education. Implications and recommendations from this project have since impacted universities and public schools internationally (Bull, Harris, Lloyd, & Short, 1989).

Appalachian State University (ASU) is one example of an electronic community founded on the piloting results of studies similar to that conducted by Bull and his colleagues at the University of Virginia. In the past few years our research group has reported widely on building a technology-rich community of learners. We have found that our electronic community provides clear advantages for both public schools and our teacher education programs. For the first time we have linked preservice teachers with university faculty and cooperating teachers.

This historical account chronicles the uses of technology in the field experiences of our teacher education program. The purpose of this chronicle is twofold. First, the implementation of this program needed to be reviewed so that others may learn from the process of creating such an electronic community. Second, technology must be carefully integrated and used within teacher preparation programs.

Concurrent Impetus for Change

Throughout the last decade teacher preparation has undergone a “quiet revolution” in response to radical social and economic transformation (Darling-Hammond, 1996). Being apprised of this information, ASU reviewed practices and compared them with state and national licensing standards and ultimately with what students learned and what they could do as a result of their experiences in school. From this information, a university cohort of faculty began to grapple with field experiences as a logical place to begin major changes needed in the teacher education program. Central to the commitment was the desire to thoughtfully transform the teacher education program into a community of inquirers who come together to examine the aims of education and the nature of teaching and learning for achieving worthy educational goals. Technology surfaced as a natural tool for transformation.

Preservice teacher training programs have acknowledged the emerging contributions of educational psychology and technology. A combination of philosophy and technological innovations is critical information in understanding the potential to reinvent a teacher preparation program. Neither a community of learners nor technologies can effortlessly transform education. A combination of both is necessary to create a powerful opportunity to change the structure of public school education and teacher preparation.

Theoretical Framework

The Reich College of Education (RCOE) at ASU has become a participant in this “quiet revolution” with the goal of reinventing itself in terms of mission and work. Teaching is currently defined as a dynamic, goal-oriented social activity which reflects a commitment to both the value of cultural diversity and to the identification and solution of social problems. Learning is seen as an active process of acquiring, assessing, and producing knowledge in an environment of care and respect for others. New forms of learning and teaching can be acquired through experimentation and the exploration of new technologies.

The framework of social constructivism serves as the research base for college reform. Vygotsky’s socio-cultural approach affords us the support to guide the process of transformation. Two key implications for ASU were drawn from the literature on social constructivism. First, it is
imperative that we assess the space and interactions where assistance from others occurs as preservice teachers enter the field. Second, hands-on experiences, which can only occur externally or socially, must be perceived as scaffolding in the gradual internalization and the ultimate development of an expert teacher. Both require social interactions or a community of practice (Lave & Wenger, 1990). The concept of interdependence of context, people, and process are integral to the development of teachers (Rogoff, 1994).

**Model Clinical Teaching Program**

The story of this technological force and the projects developed from it, which brought about change in the RCOE, began in 1992 with a small project called the Model Clinical Teaching Program. The goal of this program was to apply "several technological innovations and procedures that could revolutionize the way in which interaction took place between the university and the schools, professors and teachers, and professors and student teachers" (Blanton, 1992). To develop a basis for a new college model of teaching and teacher preparation, particularly for methods courses and field experiences, the RCOE surveyed and interviewed teachers in the region for guidance. The results of these surveys pointed out the need for increased communication between teachers in the school system, methods professors at the university, and preservice teachers attending college classes and field experiences.

A pilot section of one field experience served as a setting that encouraged preservice teachers to discuss, analyze, evaluate, and interpret their experiences in the schools with professors and teachers. A "Thoughtful Community of Teaching, Learning, and Technology" was created to build a partnership between the public schools and the university in the preparation of preservice teachers. E-mail was employed to link these three groups together for improved communication and increased understanding of expectations in the clinical setting. Funding was obtained from AT&T, Bell South, and the university to utilize an Integrated Systems Digital Network, permitting full video, audio, and data transmission over telephone lines. Public schools in this partnership were equipped with a technology room containing 8 to 20 microcomputers and a multimedia terminal. All participants were trained in the use of e-mail and videoconferencing. Participants were cohorts of preservice teachers in their senior elementary education field experience (Blanton, 1992).

Once the equipment was in the schools, another pilot project was initiated. These preservice teachers were "teaching fellows." This group of students was on full scholarship for high academic achievement and their commitment to the field of education. They were college sophomores and juniors and were mandated to complete one year of tutoring students in the public schools. These participants were required to write e-mail entries at least once a week to their professor who was supervising their experience. Entries were responded to on a daily basis by their professor and careful records of all e-mail transactions were kept for later analysis (Zimmerman & Blanton, 1993).

**Year Long Block-Elementary Education**

From the two pilot studies it was obvious that increased communication could occur with the use of e-mail and videoconferencing. After additional research and study of our own college practices, five concerns came to light in our field experiences. First, university supervisors, cooperating teachers, and interns were having difficulty communicating and understanding the expectations of clinical experiences. Second, the supervisory process did not seem to facilitate interns’ application of formal concepts to the real world of teaching or the construction of meaning from the everyday practice of teaching. Third, interns seemed to reject formal knowledge acquired at the university early in their teaching experience. Fourth, university faculty and cooperating teachers did not share a common body of knowledge and language. And last, the structure of clinical teaching experiences prohibited the social construction of knowledge (Blanton, Thompson, & Zimmerman, 1993). Given these concerns, a cohort of faculty began to examine current practice and from this it became evident that our traditional field experiences needed restructuring.

In the fall semester of the 1993-94 academic year, 16 students and five faculty members launched an experimental yearlong training project. Each of the four participating schools had a computer lab and was connected to the university's local network. Students were required initially to send two messages per week via e-mail. Listservs were set up for all subject areas for preservice teachers, cooperating teachers, and for university faculty to participate in topical discussions and information sharing. Data in the form of e-mail were collected over the course of the semester and archived for analysis. All participants received training in telecommunications. Faculty members taught courses in content methodology curriculum and media and learning. During the first semester students were engaged in these courses for ten weeks and then were assigned to five-week internships in nearby partnership schools. Preservice teachers intermittently returned to campus for seminars, which focused on issues such as classroom management, mainstreaming, strategies, and technology. During the second semester of student teaching students attended periodic seminars and workshops. Videoconferences were also held between and among faculty, preservice teachers, and cooperating teachers. University methods professors continued to communicate with students throughout the year primarily through telecommunications.

At this point, it was obvious that pilot projects using technology to increase communication were promising and that the concept of a yearlong experience in one setting with the same support personnel was advantageous. During the third year of this experimental project, faculty began an...
in-depth look at the interactions within the partnership. Notes conferencing was utilized for specific topics in university methods classes. E-mail was designated for the discussion of concepts, issues, and reflections related to communication skills, social studies, math, and classroom management during the internship and student teaching. Listserv entries were analyzed for discussion of critical concepts taught in the methods courses. These discussions were also examined to determine declarative, procedural, and conditional levels of knowledge. Connections between concepts and application in the classroom were also noted (Greene & Zimmerman, 1996).

Faculty began training preservice teachers as active consumers of the Internet and then followed the effects of Internet use into the regular classroom during the 1994-95 school year (Zimmerman & Zimmerman, 1996). The training enhanced lesson and unit planning and provided a medium for researching specific topics within the state mandated curriculum.

This same year, the North Carolina State Education Department created technology competencies for all preservice teachers. We started analyzing the year long block group of preservice teachers to measure their technological competence in comparison with state guidelines. This was completed through questionnaires and self report (Zimmerman & Zimmerman, 1996). Deficient competencies were then targeted for remediation.

**Summary of Findings**

Initially e-mail discussions were unstructured and substantiated previous studies which had found that student teachers used technology more for exchange of social and emotional support than exchange of ideas (Thomas, Clift, & Sugimoto, 1996). In an early investigation, e-mail discussions were categorized into responses to class assignments, socio-emotional exchanges, housekeeping queries and bulletins, and spontaneous sustained exchanges of ideas (Schlagel, Trathen, & Blanton, 1996).

Findings indicated that e-mail facilitated the creation of active social context in which professional conversation led to professional growth.

To encourage more focused discussions via telecommunication, use of listservs were guided by faculty in the following academic year. Critical teaching concepts were targeted for development. Those included were: Instructional Goals, Learner Characteristics, Curriculum, Classroom Management, Allocation of Time, Instructional Strategies, Instructional Materials, Grouping Practices, Lesson Presentation, and Assessment. A strong knowledge base for the declarative and procedural levels of instructional strategies was evidenced by journal entries. The concept of classroom management was clearly a concern in their preservice development as teachers. The need to develop and link declarative and procedural with conditional knowledge exists in preservice teacher training programs. Reflections and dialogue provided ongoing opportunities for these concepts to be discussed and examined. An electronic community not only eliminated the isolation of teachers; it also created a forum for problem solving (Greene & Zimmerman, 1996).

During the first two years, cooperating teacher's participation was extremely limited. Individual training and encouragement was given by faculty to increase participation. Limited time and desire for personal contacts were cited as reasons for their reluctance. Currently, this participation has increased but is still inconsistent and less interactive.

New and emerging technologies continued to be incorporated, as they became available. In addition to listservs, notes conferencing, web authoring, World Wide Web boards, video-conferencing, and Internet searches were incorporated into the preservice training. When surveyed, the majority of the graduates of this program have noted that e-mail and word processing are the two major technological skills they obtained. The preservice teachers did not feel competent in other areas of technology. When a similar survey was given to the cooperating teachers in this program, teachers listed many more areas of technology in which they were competent. The attitudes of these preservice teachers were positive toward technology. The hindrances, however, were listed as limited funds, equipment, and time (Zimmerman & Zimmerman, 1996).

**Implications**

University professors have archived a wealth of information in the form of e-mail discussions, preservice teacher portfolios, professional publications, and faculty anecdotal notes. We have learned over the past five years that with careful preparation and facilitation, telecommunication tools are well suited for constituting social arrangements that enable students to jointly construct knowledge about teaching. This application provides rich opportunities for students engaged in internships and student teaching to discuss how they are making sense of everyday classroom experiences. Discourse of this kind becomes a tool for reflection and the creation and restructuring of knowledge about teaching. Further research aimed at demonstrating the effects of these applications on teacher preparation programs is needed.

An ongoing struggle in our college is to increase participation by cooperating teachers in this program. There may be little incentive for expert teachers to publicly reflect about teaching on a listserv. As Bull and colleagues wrote, "Benefits must also accrue to users from the public schools if use of the network is to flourish” (1989). He elaborates on potential instructional benefits for teachers in the public schools. Somehow our communication of these benefits has fallen short of effecting the cooperating teachers in this program.
Increased use of technology must be infused into our methods courses. The value of technology needs to be continually addressed. We found that classroom teachers were using more technology in their classrooms than our newly trained preservice teachers. This may be due to the fact that preservice teachers have less experience in education in general and do not have the necessary skills to adequately integrate the use of technology into their teaching at an early stage. More research is necessary to identify the reasons behind this phenomenon (Zimmerman & Zimmerman, 1996).

To summarize, with easy access to a network and a true social and instructional community for support, we have created an environment for teachers, students and university faculty to grow and explore. Factors essential for success – such as support, leadership, and funds – have been included in our plan. The application of technology has not replaced the special teacher-student relationship, but has helped redefine and strengthen it. Increased participation in this project is warranted and further research must be carefully planned for the future.

**Current Participation**

Where are we today? We have established an electronic community. We have connected our university with local public schools and other universities, creating a network where teachers, students, and university faculty can become full participants in shared pedagogical dialogue and activities. In this community of learners, we have multi-level, multi-skill membership. Experienced educators collaborate with new teachers, enabling their induction into teaching in a non-threatening atmosphere. Dialogue among participants creates a community where all members learn as they participate in practice. Throughout courses, the university faculty structures telecommunications activities to help students connect abstract university classroom knowledge to their public school experiences. Assistance in the application of technologies is also a common practice in this program. We believe that a key role for university faculty in these partnerships is to help public school teachers and preservice teachers learn to use telecommunications and other technologies by using them together. It is through participation in shared activity that learning best occurs (Zimmerman, Greene, Schlagal, Trathen, & Blanton, 1997).

When our new RCOE model for teaching and learning was implemented this year, our technological innovations were right on target. Faculty had started a serious transformation that reflected the current knowledge base on teaching and learning. With the aid of technology, we had started to use community collaboration as an asset in creating a quality learning experience. The disparity that exists between theory and practice was minimized. The goal of preparing teachers in this type of partnership can link state-of-the-art preparation and induction for teachers (Darling-Hammond, 1994). Here a collective knowledge base will be the norm for our graduates who can learn by doing and ultimately develop a strong repertoire for understandings about practice.

Traditionally, teaching is lonely work. Collaboratively taught courses are the rare exception, not the rule. Teacher's draining schedules leave them little time for meeting with colleagues to discuss new ideas or pedagogies. Worse, departments are often fueled by a fierce spirit of competitiveness and protectionism. And professional conferences, where there are some opportunities to talk with colleagues, are too short for establishing truly meaningful teacher communities.

The World Wide Web, however, offers a new way to bring teachers together. Even with our doors closed, the Internet can take us in and out of each other's classrooms. It is these new possibilities for teacher collaboration which we would like to focus on in this article.

Like many institutions, for the last few years Indiana University of Pennsylvania (IUP) has been integrating information technologies into its educational efforts. In particular, a handful of IUP English teachers have begun using new technologies to teach writing: technologies like electronic mail, desktop publishing, and Web page publishing. These technologies offer many benefits to developing student writers. They give students new tools to use, new ways to work and think, and new audiences to reach.

Yet perhaps more importantly, as individual teachers have worked to bring new technologies into their classrooms, they have found themselves forming new teaching partnerships. These collaborations usually start out the same way, with requests for help: “How do I get e-mail accounts for my students?” “How do you put up a Web page on the campus system?” “Have you got a set of directions for scanning images?” Mastering technology requires us to learn from each other, since few teachers can figure out all the potentials of an educational technology alone. Thus, one dimension of technology collaboration is teachers working for mutual assistance.

Trading technical information is, though, usually just the beginning. At IUP, composition teachers who work with technology frequently also make these sorts of statements: “Have you seen the Web pages my students wrote?” “Look at this magazine my class produced.” “Let me forward you this paper review a student e-mailed me.” Most teachers love to show off their students’ work, and the new technologies at our disposal make such showcasing quick and easy, thereby providing another avenue for collaboration.

In addition, using new technologies seems to consistently bring us into each other’s classes. Again, such collaborations start simply: “I’m showing my class how to write Web pages on Thursday. Can you give me a hand?” “If you help me with the e-mail workshop, I’ll show your class how to do the PowerPoint presentations.” Since the difficulties of teaching with technology are well known, experienced technology teachers are much more willing to lend a hand because they know the favor will be needed in return. Again and again, both at IUP and elsewhere, we have seen teachers who use technology regularly working together, something quite rare for most other teachers.

Finally, new technologies encourage us to link our classrooms. At IUP, our students regularly read the Web pages written by students in other class sections. The students also converse over e-mail, trading comments on rough drafts of papers. Students hold meetings in chat rooms and MOOS. And one of our most exciting new projects is connecting our students in Western Pennsylvania with writing students in other states.

Technology can be the catalyst for a broad range of teacher collaborations. Those collaborations have multiple dimensions, from simple question answering to active co teaching. In the following sections, we offer four different stories of collaborative teacher work sparked by technology. In a variety of ways, the stories reflect the common
threads we’ve outlined above. They also provide some descriptive accounts of the nature of collaborating with technology. It is our hope that these stories will help other teachers learn to view technology as not simply a new pedagogical tool, but as a means for ending their solitude.

Gian’s Story

“My printer just died and I have to get this proposal in the mail by two o’clock. Can you help me?”

“Sure,” I said, “let me see the disk.”

When you teach with technology, you get these kinds of requests a lot. People learn to come to you for help, and if you’re successful, they keep coming back. When I first came to IUP, most of my early technology work for the English department was acting as a trouble-shooter. People would ask me how to convert files, fix printers, and solve network problems. As I gradually met other people who were technically savvy, these help sessions began to work both ways. I am grateful to more than one colleague who were technically savvy, these help sessions began to work both ways. I am grateful to more than one colleague who

Still, without the Web, most of my collaborations would probably have remained at this level, as problem solving and the occasional gripe session about troublesome software upgrades. But then one day I attended a workshop about creating Web pages. The woman in charge of the workshop, a computer science professor, did a nice job explaining the basics of HTML Web programming, and after a couple of hours I had a home page with my office hours and a few cartoon images.

Before long, I found myself teaching my students how to put their writing online, and after that I was being asked to give guest workshops for other teachers’ classes. The Web thrills English teachers because it offers such a cheap and simple way to publish our students’ writing. A partnership with William Macauley led to the development of a technology-based first-year college writing course that included e-mail, desktop publishing, and Web work for students. Later developments involved sharing drafts via e-mail and critiquing students’ papers online. I learned more manageable Web page authoring techniques from Tammy Winner-White and high-level coding skills from Nick Mauriello.

In the past few semesters, I have begun to write, publish, and present with these and other colleagues about the theory and practice of teaching with technology. A current effort I am involved in is linking a group of technical writing teachers with a class of technical writing students for a series of Web-based documentation projects. Of course, I still get asked how to unjam a computer printer from time to time, but these days that tends to be just the beginning.

Bill’s Story

“You know you can change your e-mail name, Bill,” Nick Mauriello said. There’s some kind of weird tech-lovers’ club that forces its members to say things like that. The address Nick was referring to was on 500 business cards I had just purchased.

“Really?” I thought back to the professor who had tried to modify my login.com file and had accidentally locked me out of my e-mail account for several weeks. I also thought about the fellow graduate student who came to my house and helped clean up my hard drive after I told him about the error messages I kept getting from my Web browser.

“Yeah, it’s really simple. Just type in ‘make me’ and then I’ll show you what to do from there,” Nick said.

“Macauley” is a much nicer e-mail address than “TGZD.”

I have been learning a lot about technology since I came to IUP in 1994. I have taught in computerized composition classrooms since 1991, and that brought about collaborations with many teachers who were curious about technology and with tutors who were willing to help me. In fact, ever since I became interested in using technology in my teaching, I have been helped by people who knew what they were doing already, or at least knew more than me.

“If you want your students to do Web pages, you could use Tripod,” Tammy Winner-White said. I had been telling her of my frustrations trying to teach students to write HTML code.

“What’s Tripod?” I asked.

Tammy walked me through the acquisition of a Tripod account and helped me start my first page. Eight months and three completed Web pages later, I now have several sections of first-year writing students using Tripod to easily make great Web pages.

One of the best examples of collaboration via the Web is the work I have been doing with Gian Pagnucci. We started teaching collaboratively over a year ago. My dissatisfaction with my teaching and his technological know-how were a perfect match. Gian’s knowledge and expertise with the Web was contagious, and out of our collaboration has come, directly and indirectly, 19 individual publications, 11 presentations, five editorships, and seven different workshops.

Other teachers are now even beginning to identify me as a member of the tech-lovers’ club. Not only have I shared my new knowledge of technology with fellow colleagues, but I have also taken my work off-campus to several local organizations. Along with all the sharing of expertise which takes place when learning about technology, I believe there
is also a sharing of excitement over the possibilities for teaching in these new virtual worlds. That excitement tends to be pretty infectious.

Tammy’s Story

“So what’s this workshop about?” I asked Nick Mauriello.

“I’m doing a workshop for faculty on how to make Web pages.”

“How many people will be there?” I asked.

“There are 23 signed up so far.”

“I bet you could use some help.”

In the four years that I have been teaching English at the college level, I have experienced many different levels of teacher-to-teacher collaboration. One such example of this dynamic interaction occurred during the fall of 1996. I was a beginning Ph.D. student at IUP, and upon my arrival I made it clear to the program director that I was interested in the ways written communication could be expressed in electronic forms. I also kept bringing up technology issues in the graduate courses I was taking. During the fifth week of the semester, another Ph.D. student, Nick Mauriello, was asked to give two workshops, one for students and another for faculty, on how to build a Web page using the IUP’s VAX system. I had a feeling that it would be hard for Nick to manage this task alone given that all of the workshop participants were new to the VAX and to HTML code, so I offered to help. These two workshops perhaps proved to Nick and I that two heads, and two pairs of hands, are better than one when teaching students and faculty how to write HTML code on a Friday afternoon (especially technophobic faculty members). Because we were both able to collaborate to solve minor and major problems that day, the workshop was a success—and the first of many to follow.

After that workshop, one of the faculty members who had attended asked Nick and me to act as facilitators for his summer course titled “Technology and Literacy.” Once again I found myself volunteering to help another teacher use technology in the classroom to facilitate a writing process. Although I was in a class of my peers, I found that I was constantly roaming the room to put out “technology fires” so that the teacher of the course could focus on the material he wanted to discuss. On more than one occasion, the teacher of the course consulted with Nick and me on the best way to approach class activities which introduced the Web, chat rooms, and MOOs. During the second summer session, another faculty member, Gian Pagnucci, asked me to come to his undergraduate class on a day when his students were building Web pages. It seemed that the class was happy to have more than one person available to help address individual questions about doing HTML authoring.

It was also at this time that Gian and I started to explore the best ways to teach Web page authoring in English classes.

More recently, two weeks into the Fall, 1997, semester at IUP, I was given an unexpected opportunity to teach two sections of college writing in a networked computer lab. Since I wasn’t appointed to teach these courses until after the semester had begun, I had to rush to put together a course syllabus and materials. But I found that Nick, who was also teaching two sections of writing courses, was more than willing to help me design my course even though I only had six hours to prepare before I was to start teaching. Nick invited me over to his house and we discussed the ways he was using the Web, e-mail, and chat rooms in his classes. Nick suggested that I adopt his course outline, and join him as a participant in the College Writing Peer Response Project, a project he had designed for students to publish their writing on the Web and solicit peer reviews from a national audience. Without Nick’s help, I could not have walked into this class (already two weeks behind) and given my students the full benefits of writing in a networked lab. A willingness by teachers to share ideas, talents, and materials with each other has been, for me, the key to promoting electronic literacy.

Nick’s Story

“Oh, do you mind?”

I was talking to the director of our graduate program when a flyer on his desk caught my attention. The flyer was advertising a departmental forum on using technology within the Rhetoric and Linguistics Doctoral Program at IUP. A quick glance told me that the use of e-mail, Web sites, and PowerPoint were on the agenda, nothing too surprising. What did surprise me was seeing my name listed as one of the session’s facilitators!

“What’s this?” I asked.

“Oh, do you mind?” was the reply. Well, of course I didn’t, and together with Tammy Winner-White, we initiated yet another 25 academics into the cyberclub.

To some, “do you mind?” may seem brazen or offensive, but not to me. As an instructor who pushes technical literacy, I have positioned myself into a unique corner of the institution. Along with other “techno-colleagues,” William Macauley, Gian Pagnucci, and Tammy Winner-White, I have become accustomed to the “do you mind?” syndrome, and have come to interpret it as “Can you help me here?” Technology can be frightening, especially to many academics who feel institutional pressures to bring technology into their classrooms, but don’t know where to turn for help. The natural source for this help should be one’s colleagues who are already successfully using the technology.
I taught in traditional classrooms the first five years of my career. I planned my lessons at home, graded papers alone, and very rarely consulted with colleagues about my pedagogy. I never knew what my colleagues taught behind their classroom doors and they knew just as little about what I did. I came to believe that this was the proper structure for higher education, and worse, I accepted it.

Fortunately, though, technology has changed that. I now regularly give workshops on Web page creation to faculty and students. I have helped out in the classrooms of my colleagues, especially my "techno-colleagues," Gian Pagnucci, William Macauley, and Tammy Winner-White. Gian and I even put together a proposal for an IUP Center dedicated to the Advancement of Web-Based Teaching and Technical Literacy. And one of my most exciting initiatives has been designing, building, and administrating the College Writing Peer Response Project. This Web site is used to post student papers and solicit critical revision comments from outside readers. I created the site as a way to link my students at IUP with the students of fellow teachers in Alaska, Minnesota, and Kansas. Since the site was first created, we've received over 1200 responses.

The social dimensions inherent in using technology in the classroom have ended for me the loneliness of teaching. I now collaborate with colleagues both on and off campus. As our friendships have bonded, we have been able to push each other professionally. Together, we present at conferences and publish articles. We have managed to open the doors to each other's classroom and in doing so we have built a community of scholars that gives us pride.

**Academic Collaborative Exchange (ACE)**

Because all four of us believe so strongly in the benefits of technology-fostered collaboration, we have begun developing a Web site called the Academic Collaborative Exchange (ACE). Our idea is to create a space where teachers can find resources to facilitate collaborations, technological and otherwise. The site will describe collaborative projects on which ACE participants are currently working, provide lists of names of teachers interested in doing collaborative work, and highlight scholarship on the subject of collaboration. We also hope to eventually hold an annual collaborative conference where people can come together to work on tackling key issues of teaching with technology. For more information, please visit our ACE Web site at:

WHAT STUDENT TEACHING MEANS TO ME: THE INTRODUCTION OF PORTABLE COMPUTERS INTO A TEACHER PREPARATION PROGRAM

Yong Zhao
Michigan State Univ.

Valerie L. Worthington
Michigan State Univ.

Tamika L. Ingram
Michigan State Univ.

The technological changes taking place in society have implications that reverberate throughout entire social systems. In education, for instance, institutions of higher learning and other organizations that represent academia struggle with devising optimal methods for implementing technology meaningfully, just as do teacher preparation programs and practicing and preservice teachers. Indeed, as more and more parents clamor for meaningful educational technology experiences for their children in the classroom, those who research the work teachers do and those who prepare them to do this work must also devise ways to support teachers as they incorporate the use of technology into this work. Programs such as the Apple Classrooms of Tomorrow (ACOT, 1997) are designed to address these issues, but the work is far from complete.

Indeed, the incorporation of technology into education is not a smooth, linear enterprise, but rather is characterized by fits and starts as individuals come to terms with what technology and teaching with technology truly mean to them. It is likely that most every teacher and preservice teacher today has some sense that technology is becoming an integral part of what it means to be a teacher—especially a newly-minted teacher—even those who have not had many or any direct encounters with technology. Even teachers who are complete technology novices have likely developed expectations and assumptions about the meaning of technology use in the context of the classroom. But what happens when a novice teacher is faced with technology in the context of her classroom for the first time? How, if at all, does she find it necessary to adjust her beliefs and assumptions in interaction with the technology? How does the use of the technology in the classroom context interact with her beliefs about the nature of teaching in general? Further, what impact does the use of the technology have on her perception of the way to carry out the duties of her teaching?

The Laptop Programs: A Site for Studying What It Means to Teach with Technology

A program in the college of education at a large, midwestern university offers ways to think about examining some of these questions as it simultaneously attempts to structure the teacher education experiences of its students with respect to technology. In keeping with the university’s commitment to helping prepare its teacher education students to work in technologically sophisticated classrooms, the program distributed laptop computers to two groups of roughly 90 preservice undergraduate teaching interns each, for use in the public schools in which they were student teaching. The laptops were equipped with e-mail and web capabilities, as well as word processing and spreadsheet applications. Orientation sessions early in the semester provided an opportunity for the researchers both to distribute the laptops to the interns and to collect baseline data about the interns’ demographics, computer experiences, and expectations about using the laptops in their internships.

The orientation of one group of interns was heavily influenced by the assumption that the interns should use the laptops to improve communication among themselves, their cooperating teachers (CTs) in the classroom, and the field instructors (FIs) who served as liaisons between them and the university while they were in the classroom. Modes of communication have long been at issue for these triads, and the project leaders believed that the communications capabilities of the laptops could help the involved parties maintain better lines of communication among themselves. Thus, the orientation for this group of interns was focused toward this end. For instance, during the orientation, teaching interns learned how to send e-mail, specifically e-mail attachments, the idea being that they could share lesson plan ideas and examples with their CTs even when they were away from the classroom. The orientation also encouraged intern-CT co-planning by highlighting the features of a word processing application that enables users...
to add comments to drafts and distinguish their own comments from those of other users. Further, this program's emphasis on communication also manifested itself in the fact that in many cases, the intern's CT also attended the orientation, pairing up with the intern so that they could both become acquainted with the laptop and its capacities to support their communication and sharing.

The orientation of the other group of interns was markedly less focused. These interns also experienced an orientation that introduced them to salient applications and features of the laptop, but while the first group’s orientation focused specifically on communication needs, the second group’s orientation was designed to help students think broadly about using the laptop in their internship experiences. In other words, the second group of interns basically had carte blanche to use the laptops as they saw fit to help them with their internship duties.

Further, whereas in the first group the program was designed so that all of the CTs, FIs, and interns would share the laptop among themselves and possibly with other triads based in the same school, in the second group each secondary intern received his or her own laptop and was not directed to share it with anyone else. At the same time, however, several groups of the elementary interns were assigned only one laptop, and they were not given specific instructions regarding the expectations of their sharing practices. (It will be interesting to compare the sharing practices of the first group to the sharing practices of the elementary interns.)

Thus, a comparison of the ways these different groups of interns chose to use the computers to support their teaching once they actually had them could help us begin to understand the processes by which novice computer-using teachers coordinate their initial understandings of teaching with technology in their actual experiences in doing so.

The different instructions for each group provide a contrast between more typical, directive teacher education programs and an approach that allows interns to be more exploratory and creative by deciding for themselves how they would like to use the technology to support their teaching. Thus, in addition to the baseline survey data, the researchers have begun collecting data by observing the interns engaged in an "authentic" task. Namely, the researchers are assisting interns in one-on-one troubleshooting sessions as interns discover and try to address minor or major laptop malfunctions that are hindering their use of the technology for teaching. Through conversations with the interns around these specific computer problems, the researchers are beginning to uncover their more general experiences with the laptops in the context of their teaching. It is the belief of the researchers that such a study is relevant to teacher preparation programs seeking to turn out technologically-capable teachers and the public schools seeking to hire them, because the findings could illuminate the strengths and weaknesses of both a prescriptive and an open-ended mode of preparing future teachers to teach with technology.

Preliminary results of these conversations indicate that within the first group, interns in some schools are indeed using the laptops to enhance their communication and co-planning with CTs and FIs, e-mailing attachments and using the word processing applications in ways very similar to those modeled in the orientation. However, interns in other schools are not using the laptops much at all, and when they are, their CTs are decidedly "out of the loop," either demonstrating reluctance to use the laptop or not having any awareness that they are still involved in the laptop program. It appears that interns who are actively using the laptops have been placed in schools that themselves are equipped with ample technology. In addition, the CTs in these schools have their own personal computers at home. Interns seem to be less active with their laptops in schools that are not as well equipped with technology.

In the other group, a similar situation has occurred. Much of the interns' usage of the laptops for teaching or education-related purposes is strongly influenced by the CT. Just as in the first group, interns that have been placed in technologically equipped schools are expected to utilize the technology by their CT. Other interns who have been paired with CTs who are not accustomed to using technology are being discouraged from using it. During a conversation with an intern, it was revealed that one CT preferred calling interns to using electronic mail to discuss lesson plans or general classroom issues. There hasn't been any evidence yet that revealed an intern encouraging his or her CT to incorporate technology into the teaching practices. However, there has been an instance in which the CT was dismayed by the intern's lack of computer skills and strongly encouraged this intern to become more knowledgeable in this area.

A Site for Studying the Experience of Being an Intern

The laptop program at this university also enables researchers to better understand the experience of being an intern in the context of technology use. Students coming into the internship program and taking responsibility for the laptops not only had to care for the actual equipment, but also had to begin to make sense of how to use it meaningfully. For the interns, this meant developing a sense both of their duties as interns and of their duties as interns who teach with technology. We wondered about the impact of students' interaction with the technology on their generalized assumptions about teaching. Would these assumptions change and incorporate beliefs about teaching with technology? How did the interns reconcile their own experiences and beliefs about technology with their beliefs about the expectations and demands of being a teaching intern?
As both individual "consumers" of technology for teaching and representatives of technology use for a larger culture of teaching, these interns are having to synthesize the different messages they are receiving about technology use and develop their own understanding of what teaching with technology—and in the process, what being an intern—is all about. First of all, much rhetoric indicates that teachers need to use technology because it is a "magic bullet" that can solve many educational problems, despite the fact that the realities of using technology in the classroom are much more complex. As an example of this rhetoric, President Clinton has promised to connect all schools in the United States to the Internet by the year 2000. Second of all, the teacher educators who provided the interns with the laptops have certain expectations about what meaningful uses of technology in the classroom might look like. These expectations are grounded in educational and learning theory, but they are expectations nonetheless, and they are brought to bear on the interns' beliefs and ways of making sense of their experiences. And finally, the interns themselves have brought to the table their own beliefs about teaching with technology and about what being a good teacher entails, not to mention experience of the realities of classroom teaching that may not mesh with either the rhetoric they have heard or the expectations of those who educate them.

Following Vygotsky (1978), in this culture of teaching, these interns must internalize all of these messages about what it means to teach well and to teach well with technology and eventually shape their own understanding of these concepts. Again, conversations with interns can help us access the thought processes of these interns, who are striving to make sense of teaching with technology as they simultaneously struggle to develop an understanding of teaching in general. Preliminary findings indicate that some interns are discovering the ease of completing tasks such as computing grades with a spreadsheet and gathering information to include in a lesson plan by downloading sample lesson plans from the Internet. Other interns are searching the Web in hopes of finding interesting sites that contain information that they can include in their lesson plan. They want to provide the students with an interesting and informative lesson when they teach. This essentially means that the students are becoming aware of the many responsibilities associated with being a teacher and are utilizing technology to simplify this job. At the same time, the interns are taking advantage of the broad range of information that is available on the World Wide Web in order to provide students with a good lesson simultaneously realizing the importance of student engagement.

**A Site for Studying the Experience of Troubleshooting Technology Problems**

An added complication for these teaching interns involves their physical distance from the supportive community of the university. Before they entered the internship phase of their education, many interns lived or at least spent an appreciable amount of time on campus, where they were surrounded by support for their technology use. A computer store and center, computer lab monitors, and hotline services all helped these interns feel that their technology use was supported and encouraged. As a result, it is likely that few of them had to solve many technical problems on their own; a distributed cognition model (e.g., Hutchins & Klausen, in press) indicates that everything the interns needed to know in order to use technology was spread throughout the system of the university. Despite the fact that they themselves may not have known how to troubleshoot their computer problems, the university setting was responsive to their needs in the form of the support previously mentioned.

In contrast, the internship year takes students out of the university context and places them "in the field," where they spend most of their time teaching and working with their CT in the classroom setting, away from the university. With the physical distance from the university, the interns are in a position of having to relearn how to get the help they need to carry out their day-to-day activities using the computer. The programs that issued the laptops do provide support in the form of hotline hours, handouts of relevant information, and periodic visits from program assistants who can help with troubleshooting at designated times. However, the structure of this support is significantly different from that provided in the university setting; given the distribution of the interns over a variety of schools and school districts, there is only so much continuous support that can be offered to interns who are experiencing "technical difficulties."

Thus, we have been investigating the hypothesis that the interns must become more resourceful and restructure their understanding of the laptop in this less supportive setting. Not only does the laptop become a tool for helping interns teach, but it also becomes an exercise in creative problem solving, forcing interns to rely on each other and their own ingenuity more than would be expected in the supportive university setting. We are interested in these possibilities to the extent that dialogue with other interns and CTS about these specific technological problems could help to spark the kinds of conversations we as teacher educators would like to see occurring among student interns. We hope to see discussions on topics more specifically related to how to be a good teacher or how to teach well with technology. Further, we are interested in the extent to which the technology resources of the school become incorporated into the interns’ coping strategies.

**Summary**

In this paper we have described an attempt to integrate technology into a teacher education program and a set of issues that are worthy of serious investigation. Based on
preliminary data, we have made some suggestions and hypotheses. These suggestions and hypotheses, while by no means conclusive, can serve to frame future studies on technology integration.

The Commission of the European Union clearly recognises strategic benefits of extending 'advanced distance learning techniques into schools and colleges' within the Bangerman report. Information and communication technologies (Telematics), one of the 10 key application areas, was noted to provide more efficient, more available education and training better able to meet needs (Bates, 1995). Indeed the central tenet of the European policy toward the information society is that European citizens will have the opportunity to become skilled and highly educated irrespective of location. In Europe, each individual's education is established during compulsory schooling under the guidance of the teacher. Teacher training is therefore high on the priorities of the European Commission. One action has been to fund three Telematics projects that focus on telematics and teacher training within the Telematics Application Programme. This paper is part of the work of the T3 (Telematics for Teacher Training) project which is coordinated from Exeter by the author.

The European Commission used the term Telematics because the term Informatics had been used instead of Information Technology in some European countries. The addition of telecommunications resulted in a change of the term to Telematics. Today it is just as acceptable to use the phrase Information and Communication Technologies (ICT), but as this paper describes much work carried out within the Telematics for Teacher Training project, the term Telematics will be used throughout.

Teacher educators are one body of people who can significantly change education in Europe because their effect is multiplied twice: they educate teachers who educate students who are the future citizens of Europe. Training of teacher trainers escalates this to a cubing of the action (Training$^3$). Teacher educators who model good practice with telecommunications and information technology with their students and for their own professional development will permit their students to take it on board for themselves. This is the principle behind the T3 project. In each country, we have a partner teacher training institution that contributes to establishment and sharing of good practice, and together, we hope to encourage the growth of communities of practice. T3 partners include eight teacher training organisations located across the European Union: Utrecht University (The Netherlands), Dublin City University (Ireland), IUFM Grenoble (France), The University of Gent (Belgium), Instituto Tecnologico Didattiche Genoa (Italy), the University of Minho (Portugal) and the University of Oulu (Finland). The coordinating partner is the University of Exeter (United Kingdom).

The T3 Project focuses on the establishment of communities of teachers in four discipline areas:

1. mathematics
2. science
3. languages
4. technology

It is embedding telematics within courses for teachers, both preservice training for student teachers and continuing professional development for practising teachers. There are also strands specifically for teacher educators and library staff working with teachers. Best practice is being established in a distributed and growing network of higher education institutions and partner schools that will welcome opportunities to assist in the growth of community through discussion and demonstration.

The development of practice within each discipline is led by a university in a different European country: the UK, Italy, The Netherlands, and Finland respectively. The French partner teacher education institution also enhances the translations of language and tests the transferability of the courses. We are developing approaches to teacher education which model best practice with telematics, in order to provide an ongoing context for the use of telematics in education.

The T3 project consortium decided that, as the Telematics applications need to be accessible to teacher educators, to disregard satellite and broad-band techniques, except for dissemination purposes. However, it should be noted that the use of satellite telecommunications for
courses has been demonstrated and other Telematics Application Programme projects are working on its feasibility for a variety of purposes. T3 uses two complementary channels of telecommunications:
1. Internet applications including WWW, E-mail and computer conferencing, and
2. ISDN applications, particularly, point-to-point enhanced video conferencing.

Previous Research
The use of communications and information technology in education is not new and T3 draws upon work developed over the last fifteen years around the world. Veen, Collis, de Vries, and Vogelgang (1994) review a range of communication and information technology projects within and across European countries. The majority describe the collaborative use of electronic mail between schools nationally and internationally. A few provide case studies in teacher education, including some of our early work in Exeter. Osorio (1995) describes a needs analysis performed during an international conference in Europe before the arrival of multimedia telematics. Veen, et al. (1994) attempt to draw out the lessons from these projects to provide a basis for teachers new to the use of electronic communications in education and to policy makers.

There have been significant projects in the Far East and Australasia. Similarly there have been major projects in states such as Florida and Virginia. Ruopp, Gal, Drayton, and Pfister (1993) describe a long term project called LabNet which attempts to develop a community of practice among teachers for supporting each other’s professional development across the USA. Companies such as AT&T have become involved in the development of services under the guidance of experts such as Margaret Riel. Attempts have also been made to quantify the benefits of such electronic information and communication services. For example, Riel (1994) provides evidence related to development of the skills that employers wish to see in their new recruits and Davis (1994) provides a cost benefit analysis for ISDN in teacher education.

Others within the T3 consortium have worked in this area for some considerable time developing Telematics networks for education and researching the needs and pedagogy for Telematics in education. Notable are the University of Oulu which uses video conferencing for remote teaching in Finland, ITD which provides curriculum development and inservice training through a number of projects in Italy, Project MINERVA which developed Telematics in Portugal, and the NITEC network which supports teachers in schools across Ireland (described by McKenna in Veen et al., 1994).

The Association for Teacher Education in Europe has also been active in this area. Bob Moon led a research seminar for ATEE’s Working Group 6 ‘New Technologies and teacher education’ on this topic in Bruges in July 1996 complimented with a draft paper and literature review (Moon, 1996). The European Commission’s Multimedia Report (1996) provides a view of the actions for multimedia and telecommunications in education and training across Europe and has been used to inform more recent policy.

The high hopes for the deployment of Telematics to enhance harmonisation across European culture and to improve European education and training provide the context for this paper and the T3 project’s work. It is also useful to note that the need for improved forms of teacher training and a major ‘updating’ of the teaching force are widely recognised by policy makers and those in industry and commerce. The next section describes what we have been able to develop before considering some successes and stresses.

The Development of Telecommunications within European Teacher Education
Our Telematics for Teacher Training project is in the final of its three years in 1998. By September 1997, we had already put telematics into the courses of over 2,000 student or practising teachers. Two examples of courses illustrate the wide variation in approaches and content.

Courses and Resources for Science Teachers
The development for science has been spread across several partners. The early lead was given to Dublin City University (DCU) where Michael Cotter complemented his co-ordination of Ireland’s collaboration in the GLOBE project with T3. The GLOBE project, which is centered in the USA, focuses on measurement of climate by each participating school around the world, with a Web Site disseminating information from both schools and satellites in many forms, including weather maps (http://globe.fsl.noaa.gov/). DCU’s approach was to provide a two day course for practising teachers to get them started in using the Internet links to GLOBE and in skills for making scientific measurements. Michael’s report (Cotter, Davis, & McShea, 1995) showed that this first approach was not replicable across Europe for several reasons, not least that the focus on detailed daily scientific measurements was difficult to fit into the school timetable and access to the Internet was problematic.

The T3 consortium learned from this experience to take a wider variety of strategies which teacher educators could adapt to their purposes and from which to select resources.

Telecommunications: Systems and Services — 1149
1. **Euroturtle.** This is an internationally valuable website that has been developed to act as a model of good practice and to support environmental education by Roger Poland, a teacher and research student in England. The European turtle is an animal under major threat on Greek beaches in the Mediterranean, even greater threat than the related populations which nest on beaches in Florida. The website provides detailed scientific information about turtles and their habits and information about environmental risks. There are materials and teaching activities for both primary and secondary students, including a multimedia simulation about the laying and hatching of turtle eggs and an identification kit. Students' work is displayed and the website continues to be evaluated and to grow in a suitably organic fashion.

2. **Exeter's Preservice Course with Biology Students**
   Teachers. Linda Baggott has placed many of the materials that she uses in her course for postgraduate students online. The Exeter model of teaching is on the project's T3Centrum website, along with model lesson plans, student work and discussion forums are in preparation. Linda uses these materials to extend her teaching and reduce the face-to-face taught elements. As Exeter students only study in the university for the first of their three terms, this online material and mode of communication is expected to be valuable. Linda also uses video conferencing (the other telecommunications channel used by T3) for supervision 'visits' with her students when they are on teaching practice in certain schools with this telecommunications facility and for liaison with teacher mentors in that school.

3. **Environmental Education Course**
   T3’s Italian partners are constructing a course which will enable student teachers in multi-disciplinary groups to develop appropriate strategies for teaching environmental education. It is derived from an approach used for groups of teachers across Italy in the Media project (Briano, Midoro, & Trentin, 1977). The course will be led by Vittorio Meddera from Genoa, mainly using the Internet to provide the course materials, discussion groups and collaborative work. Starting in early 1998, the pilot will be delivered to groups of student teachers and their local supervising tutors in three countries. Thus the student will not only learn how to deploy telematics within the teaching of environmental education, but they will have the process modeled for them.

**Courses for Teacher Educators**

   The T3 project has included many approaches to training the trainers. This eclectic style is one that the Telematics Centre first noted when researching professional and organisational development of the use of Information Technology within initial teacher training in 1992, during project INTENT (Davis, Kirkman, Tearle, Taylor, & Wright, 1996). Three of these approaches have been developed to act as a model of good practice and to support environmental education by Roger Poland, a teacher and research student in England. The European turtle is an animal under major threat on Greek beaches in the Mediterranean, even greater threat than the related populations which nest on beaches in Florida. The website provides detailed scientific information about turtles and their habits and information about environmental risks. There are materials and teaching activities for both primary and secondary students, including a multimedia simulation about the laying and hatching of turtle eggs and an identification kit. Students’ work is displayed and the website continues to be evaluated and to grow in a suitably organic fashion.

1. **Collaborative Professional Development.** The T3 project participants are, in the main, teacher educators who are undertaking significant action research and developing themselves professionally as they develop courses for others. This is a collaborative learning process as well as a collaborative working process. An early form of our professional development was sharing of our approaches to the deployment of Telematics using a 'needs analysis' structured interview over video conference. Six scenarios were illustrated within the interview process (Davis, McShea, H., McShea J., Osorio, Still, & Wright, 1997). Significant learning also occurs during meetings, writing reports and commenting on other peoples' work. Most significant are probably the online discussion groups which our Utrecht colleagues, who lead the formative evaluation, have designed as 'a virtual workshop' (Lam, Taconis, & Veen, 1997).

2. **Online Service to Teachers in Schools**
   The Telematics Centre within the University of Exeter School of Education has created a new form of inservice training to teachers directly in their schools using video conference telecommunications. The services are being provided in England and partners indicated that they could find the approach useful in the T3 multimedia needs analysis (Davis, 1997). The technology is used in a point-to-point link from the university to a school and in addition to the voice and video of participants, they share resources on video tape and disk, and put documents, slides and objects under the document camera. The video channel is also used to show live footage of demonstrations or work on the traditional board. Teachers can have an intense one-to-one tuition with a teacher educator in Exeter, or small groups of students can be linked to an expert who extends the curriculum and provides a model for new approaches to the curriculum and to teaching. For example, practising artists are one form of this 'expert in non residence' service.

3. **A Modular Course for Advanced Students**
   Several of the T3 universities have masters level courses for practising teachers and a common approach is modular. We are currently redesigning a new set of three modules to take full benefit from the flexibility offered by telematics. The first course, *Teaching effectively using...*
The Successes and the Stresses

This paper will now consider the international collaboration uncovering the successes and the stresses. The courses described above show ways in which strategies and resources can be transferred across institutional and national boundaries. Already we are being asked by others can they join in and do the same? The answer is of course national boundaries. Already we are being asked by others resources can be transferred across institutional and courses described above show ways in which strategies and uncovering the successes and the stresses. The modeling of good practice.

Telematics applications are built upon the process of online discussions. Phone and E-mail will be widely deployed for individual contact. All the tutors will share a discussion forum of their own. Tutors will be encouraged to support variations in the course in order to adapt to the needs of the individual teachers and groups, particularly in relation to the discussion of examples of ICT applications and their contexts, including assessment. A second course 'Learning effectively using ICT' is planned for summer 1998.

The Successes and the Stresses

This paper will now consider the international collaboration uncovering the successes and the stresses. The courses described above show ways in which strategies and resources can be transferred across institutional and national boundaries. Already we are being asked by others can they join in and do the same? The answer is of course yes, you can share too, but actually none of us are the same. Telematics applications are built upon the process of teacher education. None of us have simply applied a T3 like a coat of paint to our courses. To ensure that telecommunications are deployed effectively, the process must involve reflecting on the act of communication within a course, its resources and organisation and changing them to deploy ICT effectively for teaching and learning, including the modeling of good practice.

The majority of T3 courses encourage action research and reflective practice, thus enhancing the quality of teaching and learning. For example, courses for student teachers in Exeter are structured by the Exeter model of reflective practice. Another University cannot simply take Exeter's material and strategies, but it can learn from its approach, just as Exeter can learn from partners' experience and experiments.

The design of the Environmental Education course and the advanced courses described above have been significantly influenced by the trial of a course for student teachers of Technology which was created by our Finnish colleagues and taught over three countries in summer 1997. The Control Technology Course can be visited at http://edtech.oulu.fi/t3/courses/wp13/english/ Interestingly the course was not a universally enjoyable experience, especially noted by Exeter students who were unfamiliar with both telematics and control technology. McShea and Givens (submitted) discuss how this was related to both the technology and the approach. Students had difficulties with the interfaces, which although friendly on the WWW, their central learning task involved both the transfer and integration of files across formats, computer systems and countries, plus control of a model train using programming commands, occasionally with delayed and misleading feedback. Even an expert could have been confused when working at this level. Many of the Exeter student teachers were also telematic and control technology novices. Although they found the tasks uncomfortably challenging, on reflection they commented on how much they had learned and recognised the extraordinary challenges that learners can face and still learn!

In addition to these technological stresses, we find that the approaches and philosophy of teacher education varies with the institution and the country. Philosophies of education and approaches to research and development in teacher education with IT do vary widely, as described by Jerry Willis in his keynote paper to the ITTE Memorial conference for Brent Robinson (Willis, 1997). He notes that the more traditional empirical approach is complemented today with more qualitative and contextualised views from critical theorists and constructivists. We suspect that our 'constructivist' approach in Exeter (Dunne & Harvard, 1993) is not shared by all of our partners and this may prove the most challenging issue of all.

Further Developments in 1998

I am hoping that our consortium of teacher educators across Europe will understand and continue to respect each others' approaches and philosophies during this last year. Our move to retain telematics within teacher training courses without direct support from the European Commission will undoubtedly cause stress. Should you wish to join and spread this community of practice, please visit the T3Centrum and see where your context and philosophical approach can fit to our mutual benefit.

Later this year we will abstract a core curriculum in telematics for teacher training for Europe and we plan to turn this into a policy document to help ourselves and our colleagues around the world to agree with their policy makers on the importance of strategic planning for teacher training and its wider value to the employers and the community.
Acknowledgements

Telematics for Teacher Training (T3) is supported by DG XIII_C of the European Commission under the auspices of the Telematics Programme. Sponsoring partners include ICL, Olivetti, UK Open University, Dutch Telecom, Telecom Finland, Videra Oy, CET Portugal, Parque National da Peneda-Geres.

Effectiveness and Some Problems of the Internet Utilization to Education from Overview of School Practice Research in Japan

Kanji Akahori  
Tokyo Institute of Technology

The 100-school networking project began in 1993, sponsored by MITI (Ministry of International Trade and Industry) and Ministry of Education, and directly supported and managed by IPA (Information-technology Promotion Agency) and CEC (Center for Educational Computing) and CII (Center for Information Infrastructure). One hundred schools were selected from 1,543 schools applicants. The features of this project can be summarized as follows: (1) one server computer per school, (2) supported by government organization or quasi government organization, (3) supported by local volunteer groups including company engineers, and (4) a voluntary activity plan proposed by each school. This organization is shown in Figure 1.

Many activities were developed by the 100 schools who worked with other schools. These included:

1) Collaborative learning in environmental education such as an acid rain project in which 40 schools participated. The pH of rain was measured at 40 schools and the data were shared by all schools.

2) Report making by enlisting the aid of experts in social studies, in which volunteers answered students’ questions.

3) Weather study by connecting to the weather bureau and having students compare weather charts with pictures produced by weather satellites.

4) Cross-cultural education by connecting to overseas schools. This included real time video exchange using CU-SeeMe with a foreign high school and using surveys of topics share information with overseas Japanese schools.

The graph in Figure 2 shows an example of a hamburger price survey in social studies conducted by overseas schools. Children learn economics and social factors by exploring the price of food in different parts of the world.

5) Moral education is addressed using a worldwide questionnaire survey, in which students engage in fruitful discussion about the peace problem based on questionnaire responses about a nuclear experiment conducted by the French government. A portion of the questionnaire is shown in Figure 3. Web-based questionnaires were very effective and more than 2,000 respondents answered from all over the world.

6) Problem based learning by connecting other schools to a specialist. In one example, a chemical experiment was conducted with input from a professor of chemistry.
7) Special education for handicapped children was accomplished by developing Web pages. Teachers were interested in this opportunity to open children's minds by delivering their works to the worldwide Internet community.

**Consideration of Educational Effectiveness based on Project Research**

The impact of the project on schools is summarized below.

**Connection of School to Real World**

The most significant impact was the change of knowledge resources from a limited school space to expanded information resources worldwide. School resources are mainly teachers and textbooks, and by connecting schools to the real world, the resources expanded widely by including a great deal of information produced by various organizations and professions. Students could gain new knowledge, and the amount of knowledge changed from fixed to dynamic and alive. School textbooks are released by those in authority and are seldom revised. In contrast, Web pages are produced not only by experts but also novices and are often updated.

Table 1 shows a comparison of resources between school and real world.

**Introducing Wide Area Collaborative Learning**

In the information age, individual learning was the important concept in school education, but in Internet utilization, collaborative learning was recognized as important. Participants in the exchange project among Japanese and foreign schools reported that through collaborative learning, students exchange different ideas and different ways of thinking. By exchanging ideas and
opinions about common topics, they can share different ideas and thinking and also find commonality. This works well for promoting cross-cultural understanding.

**Change from Memory-based Teaching to Problem-based Learning**

A student centered learning style was realized by accessing information in the real world for problem solving. In order to solve problems, students search and retrieve information related to the problems. It is quite different from memory-based teaching. Also, students return to read textbooks for further understanding of the topic. This means that students can link the problem to the fundamental knowledge contained in the textbook. Students make their own knowledge structure depending on the problem, and it works well in solving other problems.

**Change of Teachers’ Role**

By introducing the Internet to schools, especially for problem solving, the role of the teacher changes from knowledge transmitter to facilitator for assisting students in the problem solving process. However, in order to play the role of facilitator, not only students, but teacher themselves, are required to act as problem solvers.

**Change of Communicating Skills and Computer Literacy**

There are remarkable differences in communication skills between old media communication, such as face-to-face or telephone, and electronic media communication via the Internet through such resources as e-mail, BBS or the World Wide Web. Old media communication style requires talking and listening skills, whereas electronic media communication style requires writing and reading skills. Also in the old media style, information is stored in the human memory and is easily removed, such as when it is forgotten. On the other hand, with electronic media, information is stored on a computer disk and cannot be deleted unless one intends for it to be removed. In the old media style, communication was possible only with a small number of people. Conversely, with electronic media, communication with large numbers of people can take place, such as using a world wide mailing list. Therefore, communication skills based on writing and reading will be more important in network age. Practical research demonstrates that students make progress in reading and writing skills through Internet communication, so it is necessary to promote students’ electronic media skills as part of their education.

Table 2 shows a comparison of communication skills between old media and electronic media.

**Problems and Discussion**

**Establishment of Social Rules and Manners**

Various educators have pointed out the importance of establishing social manners for privacy protection and maintaining interpersonal communication. Many teachers have tried to establish social manners through students’ volunteer activities.

**Filtering Harmful Information**

This problem has been pointed out by many educators and researchers. Technically, it is possible to avoid accessing harmful information. Some researchers, including this author, assert the necessity of network awareness education.

**Linkage to School Curriculum**

At present, the Internet has been used mainly for promoting computer literacy in Japan. The Internet will be used not only in computer education but also in all subjects. In order to realize this goal, it is important to connect Internet usage to school curriculum, and development of lesson plans together with Internet usage activities and development of useful materials.

**Reducing Computer Teachers’ Load on Network Maintenance**

In Japan, few classroom teachers manage and maintain computer environments as volunteer activities. It is necessary to reduce teachers’ loads, for example, reducing teaching time introducing a computer coordinator system where computer specialists are employed.

**Enrichment of School Learning Environment**

Resources will shift from book-based to electronic media-based. In the future, it will be important to enrich the learning environment in such ways as setting up Internet terminals in school libraries, and adding intranets within schools.

**Introducing a New Evaluation Method**

The Internet is especially useful in problem solving, and in order to evaluate students’ problem-solving skills, new evaluation methods, such as portfolio assessment, will be required.

**Self-establishment by Communicating to the Real World**

Globalization will spread widely and rapidly in the network age. The Internet will be used in schools more and
more as a communication tool with other countries because this use promotes cross-cultural understanding. It also helps us better understand ourselves and our culture by observing from outside. Self-understanding will lead to self-establishment. How to realize self-establishment through Internet communication in a networked society is an important and challenging educational issue.

A COMPUTER-BASED INSTRUCTIONAL SYSTEM ON PROBLEM-BASED LEARNING (PBL) FOR FACULTY TRAINING

Madhumita Kanji Akahori
Tokyo Institute of Technology

Faculty who use a problem-based learning (PBL) curriculum need to alter their traditional teaching methods of lectures, discussions and asking students to memorize materials for tests. In PBL, a faculty member acts more as a facilitator than a disseminator of information. The faculty's role is to encourage student participation, provide appropriate information to keep students on track, avoid negative feedback, and assume the role of fellow learner. As this role will be foreign to many faculty members, they may have trouble breaking out of their past habits. Therefore, the faculty needs training to develop facilitator skills or they may be unsuccessful in PBL.

In relation to this discussion, the main focus of this paper is on the design and development of a computer-based instructional system for PBL. This system provides online training to faculty for implementation of PBL in order to develop students' metacognitive skills, reflective thinking, decision-making and problem-solving strategies through integration of knowledge and information. The system, as designed, provides guidelines for effective instructional design with appropriate examples for the benefit of the faculty. The present system provides practice in framing problems for PBL.

One of the effective uses of such an instructional system is to support work on a task undertaken collaboratively by a number of dispersed teachers and students where students include trainee teachers. Using this system, the teacher can monitor the progress of an individual learner at any time. The role of the computer is to form mixed-ability student groups based on their prior knowledge and entry test performance, to provide strategies for problem-solving, keep track of all the information collected by the user at different times, and to help organize information for ease of concept mapping, decision-making, and finally, problem-solving. Based on the learner's progress, teachers can provide suggestions and guidance to the students in the form of tutorials and feedback sessions. Students, on the other hand, can hold discussions and seek clarification from each other about any information or ideas. The computer helps in the assessment of performance of each student by manipulating the information obtained from peer review and teachers' judgment. The system is under construction using the HTML programming language and a database designed in Microsoft Access. This system will be implemented using the Internet and interactions will be carried out using 'ActiveX' and 'NetMeeting' software. Regarding future directions, this paper discusses the potential of the present instructional system towards the development of a WWW-based PBL system.

The Functional Model

Based on the background research and design of the present system (Madhumita, Fujitani & Akahori, 1997), a functional model has been envisaged. The functional model of the instructional system (Figure 1) consists mainly of two parts, the Teacher Module and the Student Module. Further, the Student Module is divided into two parts, one for Individual Learning and the other for Collaborative Learning. The teacher is able to access all the input information from the Student Module at any time. The individual learner can access relevant information from the Teacher module when the teacher puts the information on the student's site and also the students can access information from a common collaborative learning area.

Online training is provided to the faculty in different aspects of instructional design, especially for PBL. Similarly learners are given instruction on group dynamics, self-assessment, concept mapping etc. Group formation can be automatically done by the system or it may be done by the teacher.

Evaluation of entry tests are provided by the system based on the preset criterion. The faculty is provided with a list of cognitive strategies to choose from but then they are also allowed to make additions in the database of cognitive strategies. Explanation of each cognitive strategy is given by the system, based on our previous research (Madhumita & Akahori, 1997). The other databases of problem statements, available resources, concept maps, etc., will be created for future reference.
The database of entry test evaluation, performance assessment, etc., will be used only for a particular problem at hand. The teacher provides the course profile and student provides the student profile, respectively. If the student opts for the course after going through the course profile, objectives and introductory session, then only his/her profile information is entered in the database.

**Work in Progress**

Based on the functional model, we have made progress towards the development of the instructional system. In the Teacher Module, the faculty can get guidance and help on different pedagogical aspects such as: What are learning objectives? How to formulate learning objectives? What is an entry test? What are the different features of good multiple-choice items? What is problem-based learning? In this way, faculty receive online training while implementing a course by using the present system. A screen for the Entry Test in the Teacher Module is shown in Figure 2. While developing the entry test, the teacher can learn more about multiple-choice items or the entry test by clicking the appropriate link.

Similarly, in the Student Module, students/student teachers not only get information on the subject matter but they also learn such issues as concept mapping, self-assessment, peer assessment, and group dynamics provided by the system. Students receive guidance and information provided by the teacher through introductory sessions, tutorials, available resources, feedback, etc. Figure 3 shows a typical Available Resources screen for a course on Instructional Design.

**Expected Outcomes**

When it is implemented, the computer-based instructional system will have the following features:

- Faculty will be able to design and deliver PBL curriculum and will be able to play the role of facilitator in the problem solving process.
- Concept maps produced by the learners with the systems help will be the basic source of learner self-reflection and for assisting students/trainee teachers with understanding and misconceptions in order provide appropriate feedback.
Students/trainee teachers will be able to develop, revise and maintain their own personal plans for learning, where the students control the scope and sequences of their learning.

- Students/trainee teachers will be able to collaborate on getting, organizing, presenting, and critiquing the information for problem solving.
- The information collected during problem-based learning will build up databases to be used by other students. In this way, the students/trainee teachers will get multiple viewpoints on complex problems.

In brief, this system will help groups of people who work together, such as teachers and students, design and carry out learning goals which are meaningful to them.

Future Directions

We plan to implement the instructional system for the training of graduate students of educational technology in PBL. The present system will be especially useful for the inservice faculty who have little or no experience in a PBL curriculum. An instructional system that is content independent can be made content dependent and can be used for different subject matter areas. As we plan to implement the system through the World Wide Web, we plan to design a tool for asynchronous conferencing among a distributed learner population as a vehicle for training and implementation of PBL in a distributed learning environment. Then the system can be used for teacher education to provide the trainees a first hand experience of PBL when the teachers and the learners are physically at a distance from each other.

Sooner or later in the PBL curriculum, faculty from different disciplines will find themselves teaching together. If this is practiced then it will add another dimension to the present system as a computer-supported instructional system for team teaching for collaborative learning.

THE EDUCATION NETWORK OF ONTARIO: IMPLEMENTATION STORIES

Terry Clarke
Education Network of Ontario

The initial stage of the Education Network of Ontario (ENO) was a UNIX-based, cross-platform, TCP/IP protocol distributed network application which provided bilingual (English and French) electronic mail, moderated conferencing (facilitated newsgroups), and database and Internet access across Ontario. It started with just 18 members in 1993 and has grown to register more than 50,000 teachers, administrators and trustees, nearly half of the 126,000 K-12 personnel of the province. The project has migrated to Web-based conferencing, electronic mail, document publishing and classroom projects. With this growth, we have learned a great deal about how educators use this suite of services. Presently, we are coaching over 4000 students engaged in teacher-devised classroom projects. Their personal and project work is published online for their families and communities to view.

Financial Support/Management
The Education Network of Ontario is financially supported by the Ontario Ministries of Education and Training and Economic Development and Trade. The organization is housed at the Ontario Teachers' Federation, the professional organization of the 126,000 teachers of the province. The funding has grown from $200,000 to over $3,000,000 per year as more teachers, administrators and students use the services.

There is a very small central management staff of six with a trained field staff of approximately 30 who lead projects, moderate conferences and train colleagues in their home environments in either English or French. In the coming months, there will be a continuing emphasis on training teachers, administrators and students throughout the province. Moderated conferences, the private professional environment, and universal access continue to differentiate ENO's service from other Internet Service Providers or bulletin boards.

Technological Partnerships
The vast majority of the budget is allocated to infrastructure development and maintenance. Many of our more successful partnerships arise from investigation and implementation of new services and equipment. This allows ENO to do more technical development, implement better solutions, assess unique pieces of equipment, or acquire in-kind licenses or services.

For instance, AT&T Canada is working with ENO to create the most cost-efficient '800 service' which allows members to access ENO using long distance lines without enormous costs. In doing this, we are using software-based switching and blocking to bar local users from abusing 'free' long distance lines. We are progressing to using this service to build in automatic redundancy should one of our 'hubs' fail. We are also working with US Robotics and installing digital technology using innovative 'rack-mount' modems with built in routers and management tools.

We have signed an agreement and are working on Internet videoconferencing with White Pine, the company developing the videoconferencing software, CUSeeMe. A software and implementation solution by ENO is being compensated with a large licensing agreement. Because we are such a large system using the UNIX Operating System, SCO OSE (Open Server Enterprise) 5.0, we have been able to negotiate timely 'fixes' for problems that arise with new versions of the software.

Technical Issues
The network has a base structure of 34 'hubs,' each of which consists of a Pentium Pro server with (depending on the population served) 4 to 40 modems on a high-speed IP Wide Area Network which covers the province. The connecting links are 56 kilobits per second or higher to our backbone infrastructure which is connected to the Internet. The operating system is SCO OSE 5.0. The mail, conferencing, and web access all use off-the-shelf protocols and software to maintain the open systems standards and avoid ongoing software and upgrade fees. The major proprietary piece is the authentication server since few other networks are authenticating over 50,000 members to selective services depending on whether they are students.
or adults, and the activities to which they are subscribed with transparent, province-wide access.

Users can dial from anywhere in the province free of charge and establish standard PPP connections enabling graphical display with a standard browser such as Netscape Navigator or Microsoft Internet Explorer. Members may also establish a text-based connection using Lynx if they do not have a graphics-capable machine or wish higher speed access to documents without graphics.

Of course, members can access the system from the Web site and be authenticated to the Intranet or private conferences through the authentication server. This allows the project to present services to a much larger number of members than would be possible through dial-up access alone.

Statistics and Effects

During a typical month, more than thirty percent of these teachers, administrators, trustees, technical and support staff, education faculty, their students, and Ministry of Education officials participate. The network logs over 4,000 participants a day and over 35,000 hours a month of connect time. A typical moderated conference, an Intranet newsgroup, generates several thousand searchable messages within a few weeks. To handle this volume of access and activity in such a large geographic area, we have modified the software from a simple bulletin board application to an integrated, Web-based suite of tools for telecommunications on a system of instantly updated servers throughout the province. However, the objectives remain those of a tightly knit education community: equality of access, pedagogic integrity and classroom-based action research.

Almost since the beginning of the project, women have participated at a level of 30% or higher. In fact the number of women in the group of those who access once a week or more is higher than that average. This reflects other projects which have investigated gender and participation in professional Internet activities.

Reasons for Success

A major factor in the system's success has been the freedom enjoyed by all participants and a supportive government grant structure. The ability of educators to use the facilities at any time of day, from both sophisticated and more modest machines, from school or from home, in either official language makes the process relevant for both classroom activities and lesson discussion and preparation.

Educators share a personalized environment of professional conferences selected from a list created by them and moderated and maintained by colleagues who receive a small honorarium or modest time relief. As well as the assistance and encouragement they receive from the online moderators, there is an active program of orientation and training about telecommunications from early navigation of electronic mail and the conferencing system to document retrieval from Internet sites and educational servers.

ENO's focus on creating and implementing creative classroom projects using connectivity among students and teachers around common activities continues to provide impetus to teacher participation. Personal student access codes have been a great success for the 4,000 students who have participated thus far. ENO has created a 'support' Web structure with traditional frequently asked questions and modem and browser settings. It is also embedding scripts with the ability to query the server for information and repair problems.

Activities

The major activity of the teachers continues to focus on the moderated conferences that are used to discuss and solve such global issues as local versus standardized evaluation, reporting to parents, community work/learn programs, and general subject-based or level-based curriculum issues. A second established use occurs whenever a new provincial license for software is purchased. A conference is opened in which the technical support team from the vendor can discuss issues of use and technical implementation with teachers throughout the province.

Smaller groups of teachers voluntarily initiate a series of professional activities such as writing primary school curriculum units themed on two-dimensional measurement with a central fictional character called 'Flat Stanley.' After the provincial collaboration, they then mount the curriculum units on personal home pages with pointers from ENO's home page. Those who create the material then update and maintain it.

Educators are creating a centralized resource of activities for teachers and administrators of northern schools who have no outside student recess for as long as six weeks in mid-winter. Others create a file of model parent letters and report cards for middle school students during a period of education reform. The network has a forum for school administrators in which teachers who wish to be administrators are mentored concerning effective career paths. Teachers, education faculty and students work on computer literacy curriculum units, plan professional development conferences, and hold meetings of subject-specific committee executives. One school of over 2000 students uses the system for its internal electronic mail, information distribution and meeting mechanism. Another district's school custodians are working on practical identification and warning about workplace issues and hazards.

Currently, we are developing on an online course about telecommunications in which templates for classroom activities are discussed, implemented in specific classrooms and improved for the system as a whole. Our largest project to date is an online environment to assist the National Marsville Program, a project based on intermediate-level students creating a living environment for the pioneer astronauts and settlers of Mars. Students are uploading their
air, water and food supply system drawings to their team’s Web pages. They access mentors’ comments from Spar Aerospace and the Canadian Space Agency. They communicate with one another to prepare for the final ‘link-up’ day. Using the online environment prior to the main event enhances classroom learning activities.

Summary

Because ENO’s funding is limited, we continuously seek support from individual grants and strive to use resources outside of our small staff complement to accomplish tasks. For instance, senior secondary student journalists are engaged in reading the text of conferences to create and package ‘stories’ of the development of our WWW site. We are sharing points of high-speed access with other public sector agencies and ministries. Special educational projects purchase conference ‘space’ and moderation. We are instrumental in providing Ontario student access to the federal program, SchoolNet and look forward to greater integration with a more regionalized SchoolNet Web site in the future.

As we stabilize our network and work toward nearly universal direct dial-up and school access, we look forward to fulfilling our potential as a ubiquitous background tool for elementary and secondary education in Ontario. Our implementation focus concerns student projects and environment and our organizational focus is on financial sustainability. Our technical focus is aimed at increased access, speed and reliability through continuous experimentation with new modem, server and transmission equipment and technologies.

Terry Clarke is Assistant Director of the Education Network of Ontario, 1260 Bay Street, Toronto, ON, Canada, M5R 2B5. E-mail: terrclar@enoreo.on.ca URL: http://www.enoreo.on.ca
AN EFFECTIVE MODEL FOR CREATING VIRTUAL LEARNING TECHNOLOGY COMMUNITIES

Susan R. McIntyre
University of Wisconsin
- Eau Claire

Robert E. Holton
University of Wisconsin
- Eau Claire

The "Support Service Crisis," termed such by the American Association of Higher Education, is a national crisis for services and support for the use of instructional and information technologies (IIT) in all educational settings. Although the larger goal is for all students, faculty, and staff to become self-sufficient with respect to using technology and be able to help each learn about technology, the immediate need is for support to develop a critical mass of technology and information-literate individuals who can function as core support for others.

Colleges and universities support themselves as well as their students and local industries by providing opportunities for their students to become technology assistants and training students to function in support roles. While such measures provide short term relief, long term support remains sporadic and provides uneven quality of service. State and local initiatives continue to grow in direct response to the need to provide for the development and implementation of online access for education institutions, faculty training, and PK-12 teacher training to include IIT.

In Wisconsin, for example, the state legislature, the University of Wisconsin System, and numerous business communities have combined resources to provide direct staff development for PK-16 educators, and have provided competitive funds to support regional and local projects to develop self-supporting staff development models. Similarly, K-12 institutions are coping by implementing their own staff development programs and relying on services provided by regional and local agencies. Many school districts have embraced the International Society for Technology in Education (ISTE) standards as guidelines for instructional technology staff development while at the same time many teacher education programs have incorporated them into preservice curriculum.

The need for support services is recognized as a continual and growing problem. Yet, the problem is not only one of meeting critical needs but is also a problem of making best use of available resources. Lack of coordination of efforts across agencies and poor communication between/among the various service providers results in duplication of efforts, under-use of technological resources, and fragmented progress toward larger goals. Fragmentation and duplication are too expensive to ignore in a time of limited resources.

The Virtual Learning Technology Community (VLTC) directly addresses the problems of fragmentation and duplication of efforts. Through a grant from the University of Wisconsin Extension PK-12 Initiative, we are establishing a regional consortium that ties together preservice teachers, K-12 educators, regional support staff, and University teacher educators. In particular, the VLTC provides communication networking, hardware, software, and training site resource sharing, and collaborative access to expertise among universities, K-12 schools, and support agencies (e.g., CESA, Cooperative Education Service Agency) in north central Wisconsin. It will become a self-sustaining community of learners who are constantly challenged by change, change that is driven in large part by technology.

The VLTC community members share a need for knowledge (an understanding of the nature and structure of using technology in teaching and strategies that work), skills (how to use the technology appropriately), and dispositions (a willingness to use and experiment with new technologies and pedagogies) surrounding the infusion and adoption of IIT. Further, the VLTC provides multiple opportunities to develop deep knowledge about regional strategies for the implementation and dissemination of the knowledge, skills and dispositions related to IIT. Increased awareness of emerging and effective strategies, resources, and expertise (both technological and pedagogical) will affect the K-12 environment as well as the university environment in synergistic ways. Developing new strategies for extending knowledge to others (thus increasing the overall base of knowledge and awareness of existing strategies) is central to the key notion of the VLTC; that is,
that a virtual community can share existing and dwindling resources while curtailing fragmentation and duplication.

**Structure of the VLTC**

The VLTC can be viewed as a network of conceptual, social, technological, and physical sites in the Chippewa Valley of Wisconsin. Each site can be viewed as a node in a neural or knowledge representation network. The nodes represent particular centers of expertise and knowledge such as university system centers and projects, cooperative educational service agencies (CESA), and K-12 districts. Each offers experience and expertise that can be shared with other nodes and offers opportunities for building new connections. Links among nodes are the communications pathways. Both the nodes and links need articulation and support if the community is to emerge as a living, growing model. Figure 1 below illustrates the conceptual structure of the VLTC.

**Establishing the VLTC**

Developing the VLTC is a three-year process. Our goal is to connect and support ongoing “pockets of excellence” by enhancing their ability to grow and share expertise. Then, we will gradually add new staff development projects and sites that draw on the pockets of excellence to extend everyone’s existing knowledge and skill base. The process of establishing the VLTC is described in detail below.

**Phase I: Establishing the Virtual Learning Technologies Community**

The VLTC project requires a coordinator with time and resources to foster communication among core institutions, find suitable training sites and key personnel for the VLTC team, establish a communications process among participants, coordinate identification of model learning technology projects among participating institutions, and coordinate the selection of projects being supported. Key teachers at the K-12 and university levels, student interns from the university and some K-12 students will serve as the advisory council to the VLTC Coordinator. This advisory council will meet at least two times per year over the three-year period of the project to review the activities of the VLTC relative to the mission and vision, examine emerging needs, and develop ideas for meeting new needs and providing for dissemination of information regarding the VLTC activities.

**Phase II: Establishing Links between the VLTC and Regional Institutions**

The emphasis in phase II will be to build links between the VLTC and area institutions. By identifying model projects in PK-12 institutions, CESA, and UW institutions, establishing support, training, and materials needed to enhance the model projects, and finding collaborative mechanisms to meet identified needs, the VLTC will effectively generate a regional network. Support for new or extended projects will be enhanced through opportunities for advanced graduate study by VLTC teachers. UW system institutions will provide additional support for VLTC projects by developing cadres of university students in teacher education programs interested in working in VLTC schools. The participating university students will supply some technical expertise, learn new ways of integrating technology into teaching, and assist VLTC teachers as they develop new projects. To increase the quality and timeliness of the communication between/among the advisory committee and the VLTC participants, a telecommunication network using a client system such as the First Class network software will be established.
Phase III: Strengthening Links among Regional PK-12 Schools

Phase III will extend and strengthen the social context supporting the risks and growth associated with changing teaching and learning paradigms. Through a variety of mechanisms, VLTC participants will share their developing knowledge of current regional projects, establish communications, and publicize ongoing efforts. We will also conduct mini-conferences in which VLTC members spend focused time working together to extend their existing projects. Additional opportunities for sharing new knowledge include the Northwest Education Association annual meeting, the annual Technology Fair sponsored by CESA 10, professional conferences such as Wisconsin Council of Teachers of English, Wisconsin Society of Science Teachers, Wisconsin Elementary and Middle Science Teachers, and Wisconsin Math Council. These avenues are of particular importance because they encourage participants to think about technology as a tool for learning subject matter rather than just learning about technology.

Phase IV: Supporting New Projects Impacting Students In VLTC Schools

The VLTC will coordinate activities in which participants identify opportunities to continue to work together to develop new and spin-off projects that expand the impact on learners (e.g., parents of students in the K-12 schools, faculty instructors for student teachers and graduate students in the K-12 schools). The VLTC will provide communications links between the participants for sharing of ongoing projects, find ways to meet new training needs, and support efforts to generate new resources.

Evaluating the Success of the VLTC

Key outcomes of the VLTC include: (a) the development of a self-sustaining community focused on state of the art use of instructional and information technologies; (b) increasing student and teacher ability to make effective and efficient use of technology; (c) increasing the overall quality of student learning; and (d) increased communication, increased relationships between/among the constituents of the VLTC and better access to new and existing initiatives for the entire set of participants.

Formative evaluation will be accomplished through questions posted to the electronic network and through small-group interviews. Artifacts drawn from school projects will provide further evidence of teachers' readiness to implement technology-rich curriculum and teaching strategies. Student growth will be monitored in a similar fashion. We will administer a modified version of the technology survey to track growth in students' basic knowledge and skills. Since a key element of learning is the ability to locate, evaluate, and effectively use information, we will gather samples of student work that require demonstration of those abilities and support the artifacts with participating teachers' evaluations of student growth.

Further evidence will be gathered by conducting student interviews at participating schools. Finally, the advisory team will meet at least two times per year over the three-year period of the project to review the activities of the VLTC relative to the mission and vision, and examine emerging needs.

Evaluating the outcomes of the VLTC on teachers' and students' knowledge and learning skills is an essential process guiding the evolution of the VLTC. Central to the mission of UW-Eau Claire is faculty/student research and collaborative activities. Therefore, preservice teachers (undergraduate students) will work directly with VLTC faculty and staff in carrying out assessment activities. In particular, the VLTC faculty, staff and students will track changes in teachers' perceptions of their own knowledge and skills using a pre-post survey of teacher's technologies skills and readiness to implement ISTE recommendations. The survey is currently in use in the School of Education at UW-Eau Claire.

Summary

Efforts such as the VLTC are essential if support for IIT is to grow. Understanding the processes of developing models that make creative and efficient use of resources provides valuable insights needed for extending the VLTC approach to other arenas. The VLTC is replicable in most environments because it uses existing technology and human resources to address contextualized needs. It doesn't require technology experts, or large capital expenses. It is adaptable because it draws on local expertise and shares ideas and knowledge within a learning community and therefore provides participants with multiple entry points, regardless of grade levels and/or levels of expertise.

USING TELECOMMUNITY TO DEVELOP A K-16 APPROACH TO EDUCATION TECHNOLOGY ADOPTION

J. Kevin Maney
Miami University, Ohio

Douglas M. Brooks
Miami University, Ohio

Bruce E. Perry
Miami University, Ohio

In the state of Ohio, three current state technology initiatives, SchoolNet, SchoolNet Plus, and Telecommunity have been funded. Combined, these three projects have dramatic implications for each other. The goal of SchoolNet is to provide network capacity for every K-12 classroom. The goal of SchoolNet Plus is to provide one computer workstation for every five students in grades K-4 while the goal of Ohio’s Telecommunity initiative is to increase collaboration among schools and service providers to enrich the public school curriculum. The three programs represent a $700,000,000 commitment by the state and service providers to infuse technology into K-12 education and set the stage for cultural transformation of teaching and learning in Ohio. Moreover, if these initiatives are to enjoy widespread adoption throughout the state, it is critical that schools of education and K-12 schools collaborate to develop a K-16 approach to pre- and inservice teacher education in the area of educational technology. The Technology in Education Adoption Model (TEAM) recognizes the importance of this approach to professional development and this paper describes how one successful Ohio SchoolNet prototype, Partners in Learning, located in Oxford, Ohio, has developed a K-16 telecommunity to encourage the adoption of educational technology.

Restructured Learning

In 1990, Partners in Learning was organized by Dr. Douglas Brooks of Miami University, as a community-wide collaborative leadership team that included the Talawanda Local School District, Tri-Village Local School District, Miami University, the Oxford Chamber of Commerce, and communications companies, Warner Cable and GTE. The vision of Partners in Learning embraces the national goals of education, Ohio’s vision for school renewal, and advances a “break-the-mold system” for high performance teaching and learning in extended learning communities. The goal has been to design and implement a prototype of a “near and distanced learning community” that would guide Ohio schools, communities, and universities into the 21st century. This prototype learning community features the application of integrated technologies to: (1) enhance learning systems design; (2) develop an extended learning community; and (3) enable full human resource development through life-long learning.

Partners In Learning/SchoolNet has been operational for 18 months and is now the first and best example in Ohio of how a telecommunity can stimulate and support a K-16 approach to educational technology adoption. Two hundred-eighty teachers and administrators in 15 buildings across two school districts and Miami University are in the early developmental stages of “near” and “distanced learning.” Project teachers have “near distance” learning capacity using FirstClass telecommunications software as well as Internet access. Data collected during the first 18 months of use has provided critical insight on the natural maturity of near and distanced learning in classrooms. This data has been collected using questionnaires, journals, online surveys, and measures of use information retained by the network system software.

Results of Telecommunity Development

Infrastructure

The project infrastructure has performed with great reliability. Teachers and administrators have reported that reliable SchoolNet system operation has stimulated teacher access and use. Two category-five wires and two coaxial cables were installed in each classroom close to the teacher’s workstation, conveniently located for easy access.

Access

The number and frequency of teacher and administrator logons have grown steadily over the 18 months of the project. The goal of the access phase of the project was to reduce to a minimum the number of mouse clicks and keystrokes necessary to access FirstClass telecommunications software or the Internet. Launchers were configured for all teachers’ computer desktops to enable quick and easy access to telecommunications and other software.
classrooms where the Launcher was not used, teacher use of telecommunications tended to decrease until the Launcher was reinstalled or activated. Morning logons to FirstClass were also stimulated by the presence of building and district news bulletins posted to its conferences by administrators and building secretaries. In addition, teachers who reported difficulty accessing the FirstClass telecommunications server were (and are) immediately provided with mentoring from another teacher and/or help from building technology support personnel which includes high school students organized into a “Tech Squad.”

**Professional Development**

The professional development plan has been guided by a "Teacher Leader model" that emphasizes voluntary, personalized, and developmentally sensitive training and curriculum development. Teachers are encouraged to participate, but not required to do so. Two consecutive two-week summer “Playshops” have attracted over 60% of the project’s 280 teachers who participated in team building and online simulations conducted over the FirstClass telecommunications network. High school students were hired to provide technical support during the summer “Playshops” and remain part of the “Tech Squad” during the academic year. The Tech Squad sets up and makes minor repairs on computers, solves problems through a “Help Desk” on FirstClass, documents teacher competence gains, and helps identify emerging technology needs. In fact, this systemic use of students to provide technical support has proven to be critical to the success of the project. The results of this past summer’s telecommunity training have been spontaneous online mentoring, resource sharing, and content access from Miami University.

Telecommunity has also permitted dramatic advances in preservice teacher development. University and preservice teachers now have telecommunity support which has changed the structure of university mentoring during student teaching and dramatically extended the learning community available to preservice teachers. For example, in the computer module of EDT 343, Media and Technology For Teaching, all students are required to use Conferencing on the Web (COW) to ask SchoolNet teachers about teaching strategies related to using technology. Since COW is Web-based, students have had online conversations with teachers as far away as northwest Ohio, providing students with resources which otherwise would not be available to them. Whenever possible, student teachers are placed in technology-rich SchoolNet classrooms with the objective of further developing their ability to integrate technology into curriculum and instruction, skills which were introduced to them in the computer module of EDT 343. Using SchoolNet resources, telecommunities have developed between university supervisors, mentor teachers, and student teachers to enhance communications between all parties and advance student teachers’ learning experiences and opportunities. Student teachers and their supervisors are also given regular opportunities to develop their teaching with technology skills on a per-request basis and to develop a Web presence by learning HTML and Web site design skills. As a result, students have learned new technologies like HyperStudio and developed personal home pages, online professional portfolios, and Web pages to support the respective classes they teach.

**Curriculum Development**

Talawanda City Schools and Tri-Village Local Schools are also collaborating districts in Ohio’s Schools On The Move project. The goal of this project is to design a technology-supported curriculum that improves fourth and eighth grade proficiency test scores. These two districts, along with Miami University, were selected because their intact SchoolNet infrastructure could produce information on the impact of telecommunity-supported curriculum development. Unlike other participating schools, a Web site (at http://www2.eap.muohio.edu/SoM/) was developed by Dr. Kevin Maney of Miami University for constructing Lesson Labs that can be authored, edited, and shared across districts and teachers. Results to date suggest that more frequent, timely, and cost effective communications are occurring between project participants than in other areas of the state where the SchoolNet infrastructure has not been installed.

Summer SchoolNet “Playshops” have also been designed to provide authentic opportunities to improve current instructional activities and to extend curriculum design into more advanced technology-rich activities. Consistent with ACOT research (Sandholtz, Ringstaff, & Dwyer, 1997), teachers have sought first to improve their current practices and then pursue more advanced applications and activities that employ available technologies. Moreover, a curriculum bank developed in the “Playshops” is stored online and teachers have reported accessing this resource for ideas on how to integrate technology into their instruction. Perhaps most exciting is that these same teachers can use the “Chat” or simple e-mail features of FirstClass to contact the author of the curriculum idea for clarification and suggestions. In contrast, the chance of a classroom teacher contacting the author of a textbook is almost nonexistent. As teachers use these SchoolNet-based resources and engage in professional development opportunities to enhance their teaching with technology skills, they also become better able to mentor preservice teachers, both in person and online, who are learning to do the same in university environments. This is the component of teacher education programs that is usually missing, but which is critical to training preservice teachers to use technology as tools for learning (OTA, 1995).

Telecommunications: Systems and Services — 1167
Transformative Realities

Transformative outcomes in the *Partners in Learning* SchoolNet project have proven to be developmental. In both Talawanda and Tri-Village Schools, the intermediate level building emerged as the district leader in the full application of telecommunity and the following developmental stages have been identified in the process.

Installation and Access Equity Stage

This stage is characterized by computer availability and total faculty access to the FirstClass telecommunications server via their computer desktops. Teacher Leaders were predictably the first group to be interested and motivated to master access skills whereas non-users elected not to attend professional development opportunities or to contact building technical support to help them develop the skills needed (four key strokes) to access the network. The main reason cited by non-users for not using FirstClass as a communications tool was that not all of the district's personnel used their computers. System-wide strategies to move teachers and administrators past this stage included checking for connectivity problems, buying a full complement of computers for all teachers in all buildings, standardizing and minimizing the routine needed to access FirstClass, problem-solving with building-level teachers and student technical support, and checks of system logons to identify non-adopters.

Play and Interpersonal Use Stage

This stage is characterized by teachers and administrators who were comfortable with each other exchanging non-substantive e-mail and using the FirstClass “Chat” feature to converse online about non-substantive matters. Others reported using Internet e-mail to contact relatives, especially children at college. In contrast, non-users tended not to play even when they understood that they could access the system and were seemingly cognizant that the network had “Play Potential.” The common reason cited for not “Playing” was that they did not have time to do so.

System-wide strategies to move teachers and administrators past this stage included invitations to work with trusted, but more advanced, colleagues after school or on weekends, to take summer Playshops, or have a Tech Squad student privately mentor them.

Building and District Information Stage

This stage is characterized by the building administrator endorsing and using telecommunity as a management system. Adopter administrators actively modeled the use of the network and invited office staff and Teacher Leaders to imagine and implement FirstClass as a building communication and management tool. In contrast, non-user administrators did not actively model the system and they tended to rely on conventional communication systems like announcements, faculty meetings, newsletters, daily bulletins, and classroom visits. While FirstClass conference environ-ments emerged in the developmentally advanced buildings, the conference environment and file accumulation within conferences remained minimal or nonexistent in the buildings of non-adopting administrators. System-wide strategies to move administrators and teachers past this stage included creating online building conferences, suggesting to office staff and administrators how FirstClass telecommunications software could facilitate office tasks, training individual secretaries on ClarisWorks to create daily bulletins and newsletters, and regularly reporting on advanced applications in other buildings.

Individual and Team Instructional Stage

This stage is characterized by individual teachers or small teams of teachers at the same grade level or content area combining energies and technology skills to improve or develop instructional activities. Non-user teachers chose not to team with adopters, elected not to participate in immersion or individual training sessions, and were not drawn to self-directed, discovery, or simulation-type professional development sessions. The main system-wide strategy used to move administrators and teachers past this stage was the two summer “Playshops” organized so teachers could work in teams within their own buildings and classrooms. Data from teachers’ daily journals and an exit survey suggested that the design of the Playshops complemented self-directed and discovery learning styles and created advanced Teacher Leaders for colleague mentoring in technology use. Teachers who did not enjoy these approaches to learning received whole group, professionally led, hands-on skill training that targeted specific computer applications. The combination of these two approaches appears to have significantly advanced the overall skills of the project’s teachers and consequently increased their capacity to serve as resources for preservice and student teachers.

Projects and Initiatives Management Stage

This stage is characterized by the use of SchoolNet resources and the conference feature of FirstClass to manage projects, grants, and initiatives that emerged as the school year unfolded. Grants managed in this fashion appeared to flourish whereas non-user teachers and administrators who continued to rely on frequent committee meetings showed limited productivity. Moreover, while FirstClass conference folders were often created for projects, if the project director did not utilize the network infrastructure and software features, the project participants were not inclined to do so either. System-wide strategies to move administrators and teachers past this stage included e-mail reminders on the effectiveness of FirstClass, meetings with project directors to encourage its adoption, and designing functional project desktops on FirstClass. These efforts, however, were mostly to no avail.
Interorganizational Communications Stage

This stage is characterized by communications between pairs of teachers or administrators between the Talawanda and Tri-Village school districts. Adopting building administrators and teachers have been capable of using the FirstClass network at this level but it remains the most undeveloped of the stages with the fewest examples of productive outcomes. One reason for this is that many teachers and administrators were very sensitive to online remarks made early in the partnership. While the connection between with Miami University and the two school districts is maturing at an advanced rate, interdistrict collaboration is almost nonexistent to date. Speculation that face-to-face contact is a prerequisite for extended network collaboration remains supported.

Conclusion

The Partners In Learning'SchoolNet Prototype in the Talawanda City Schools, Tri-Village Local Schools, and Miami University is positioned to advance and offer developmental insight on teacher and administrator network, telecommunity, and curriculum development as well as education technology adoption. Outcomes to date suggest that near and distanced telecommunities, properly installed and professionally developed, can have a transformative impact on the culture of teaching and learning and serve as a critical component of a K-16 approach to the adoption of education technology.

Networked Learning Communities in Teacher Education

Alain Breuleux  
McGill University  
Thérèse Laferrière  
Laval University  
Robert Bracewell  
McGill University

Faculties in schools of education are challenged to prepare educators for a changing world. The world of learning is changing and there are numerous possible scenarios for the future of education. In Canada, a growing number of educators are proactive in the face of a networked world. SchoolNet (http://www.schoolnet.ca) and its educational partners have been instrumental in articulating the possibilities that lie ahead. Learning and learning systems may also move in a number of possible directions.

SchoolNet’s Vision of learners (SchoolNet, 1996) presents key aspects of the preferred future of education and this vision can be assessed in terms of some of the following major alternatives:

Business as Usual. We continue going as we are, relying on our existing assumptions, structures and labour-intensive ways of teaching and learning. Attempts continue to integrate technology into existing structures. Resources are limited and in many places decline, affecting learning quality and public confidence. Competition among schools and school systems intensifies. Is this approach serving individuals and society well at the present time? Can we provide quality learning services with the resources available? Are we missing opportunities to make creative use of the new technologies?

The Funnel. The range of employment opportunities narrows as technology and global competitiveness limit the job market to low-level service skills needing little education and high-level technical and managerial skills based on post-secondary certification. For most of the population, a rewarding job is a scarce resource with few winners and many losers. What happens to the link between learning and career? What kind of learning is needed for those outside the job funnel? Can learning enlarge the funnel? Do we need new definitions of work and job?

Competing Systems. There is growing political conflict and economic competition for clients and funding; between the present education establishment and the virtual learning system of communications and information technologies in which teachers and institutions are of minor importance. Is such a conflict inevitable, built into the nature of competing philosophies? Is it helpful or dangerous?

In contrast, our preferred vision, as expressed in SchoolNet’s Vision of learners, is one in which the need for all to learn is embraced and translated into a converging, vigorous action-research program. In this program, the new requirements for knowledge of technology is a key driver and a key enabler.

Cultivating the Need to Learn

The individual’s need to learn must be met in considerable and meaningful ways. The necessity to improve our pedagogies is there, and part of the pressure is coming from young learners who are “growing up digital” (Tapscott, 1997). Moreover, too many children leave high school with a lesser desire to learn than when they entered. This is unacceptable for any nation wanting to evolve as a democracy, be part of the new global economy, and have its quality of life benefit from technological developments.

Higher expectations for all is also a reality in the realm of education worldwide (see UNESCO, 1996; OECD, 1997). Countries which foresee an economy where half of all new jobs created will require a university degree, must move away from associating high school schooling with social selection. Though it is voiced that without a high school diploma, individuals’ futures will be greatly reduced, educational systems are slow to transform themselves in such ways as to offer more engaging learning activities and provide more flexible learning. As educational systems decentralize — a major worldwide trend — there are educators and communities who understand that the education of all children (and adolescents) is now both a moral and an economic imperative. However, classroom interaction is very timidly looked at as the essential core that could make the difference if adequately transformed. Our main research assumption, as we foster networked communities in our work as educators of educators, is that it is the interaction between the learner and knowledge, scaffolded by the teacher, that is the most critical one.

School and classroom organizations have been modeled to serve an industrial era that now belongs to the past. The hidden curriculum has been to prepare obedient, conformist, and competitive individuals, and classroom interaction has successfully been directed to these ends. Today’s technology, educational research and social expectations now call, and support, the move of educators and communities whose purpose for schooling children is...
to foster their intellectual capacities and creativity in many diverse ways and at higher levels, and who are willing to monitor, and temper, their own need for control to the benefit of learners' acquisition of autonomy and capacity for collaboration.

The New Requirements for Knowledge of Technology in Education: A Key Driver and a Key Enabler
In the context of our schools, the need for professional development is realized by teachers most directly in relation to information and communication technologies. The goal of integrating these technologies is at the same time creating a requirement for new knowledge, as well as creating new opportunities for cultivating knowledge. More and more educators understand that current requirements for technology in schools are markedly distinct from earlier attempts to import computers into the classroom by fostering specialists and leaders who form a minority of highly knowledgeable individuals. Today, the achievement of a better distribution of the knowledge is a growing imperative. One identified means to achieve this coverage is the initiation of learning communities formed mainly (but not exclusively) of teachers and student-teachers. This need for a more collectively oriented approach to knowledge is illustrated in Figure 1 on the vertical axis. This dimension complements the "Type of Participant" dimension in Mergendoller, Jonhston, Rockman, and Willis, (1994).

Figure 1 also illustrates another dimension that characterizes the new requirement for knowledge of technology: the need to use technology within a transformative vision of learning, to support with technology the new learning that could barely take place before, for example, the advent of networked computers. This tension between reproduction and transformation, illustrated in Figure 1, on the horizontal axis, corresponds to the contrast between a "focus within," to adjust the current system, and a "leap out" from the boundaries of our existing systems (Banathy, 1994).

An important aspect of the conversations we are having within our professional development activities is to qualify the major components represented in Figure 1:

- Ownership of knowledge: in what ways can we characterize the relationship to knowledge in our different settings; what does a collective ownership mean with regard to knowledge of technology; through what processes can experts in the school setting (including students) become better able to share their knowledge?

- Vision of learning and technology: what are the characteristics of profound uses of technology; what is exemplary use of technology in support of learning; what types of transformations do we expect to see as a result of exemplary use of technology?

- How can we characterize different communities in terms of the four quadrants in the figure (A, B, C, and D); and how can we characterize professional development in terms of movements across the quadrants (e.g., from A to C, and from C to D)?

Figure 1. Dimensions of TeleLearning Professional Development.

Schools Of Education's Response
In response to the growing needs for learning and the changing worlds of education, our schools of education are working on a converging, vigorous action-research program, based around the TeleLearning Professional Development School (TL•PDS). We present three key goals of our TL•PDS (with associated practices and findings for each goal):

- making the discourse on learning and the knowledge about learning more public to sustain a knowledge-based society;
- developing new knowledge of how telelearning technologies can support sustainable communities of learners;
- extending opportunities for the professional development of educators through Web-extended institutes and practica.

To act responsibly in the face of the uncertainties mentioned above means asking ourselves what kind of learning environments should be designed for children and adults to learn and grow. As educators of educators, we know, for instance, that we need to immerse future educators in powerful learning experiences that lead to the development of generative, adaptive, and robust knowledge. These learning experiences need to be embedded in rich, authentic contexts such as intensive practica, face-to-face encounters and seminars. The cultivation of knowledge is best achieved through a process of conversations and reflection.

One promising response from schools of education in recent years has been the articulation of closer collaboration between universities and schools through "professional development schools" (PDSs). The PDS model, as
implemented at numerous sites, has been well formulated in
the recent Draft Standards of the National Council for the
Accreditation of Teacher Education (NCATE, 1997a). We
are expanding the PDS model into the TeleLearning PDS
described below.

The Tele Learning Network of Centres of Excellence,
their connected associated schools. It is a research activity
a multi-site network of Faculties of Education (Laval,
McGill, Oise/UT, and University of British Columbia) with
their connected associated schools. It is a research activity
of the TeleLearning Network of Centres of Excellence,
funded in September 1995 through the Social Science
Research Council of Canada. As faculty members of McGill
University and Laval University, we are contributing to
building new models of professional development and
teacher education that are required today to address the new
needs for technology knowledge and use of technology of
practicing and graduating school teachers.

Establishing communities of learners around the
teaching professional and student-teachers supported by
networked computers is one major component of the new
model we are designing. As we implement this model,
within each learning community, high school learners,
student-teachers, school-based and university-based
teachers are interacting in increasingly differentiated ways.
As in other communities of learners (Brown, 1997), we base
our design on agency, reflection, collaboration, and culture.

Within our research network, the design of such
communities is seen as critical. At each setting, this
community, based in a school or group of schools, sharing a
vision of school learning and teaching, establishes for itself
goals as well as instruments to acquire and share the
knowledge required for the achievement of their goals. In
this context, we are facing a larger and more and more
differentiated number of learners (the entire school staff, the
parents, the students, etc.), and we need to consider
effective learning mechanisms to handle this demand. We
have to establish a community of learners that will be able,
to the largest extent possible, to handle its own learning
needs and to build capacity for the school to adapt and
grow.

The TL PDS is a construct anchored in two major
realities: the physical PDS (professional development
schools where there is substantial use of technology for
teaching and learning) and the virtual PDW (professional
development webs constructed at each site, using various
telelearning tools (such as the WWW and online discussion
forums), linked to one another, and which support and
reflect the activities occurring in the PDSs). Two official
languages are spoken in the TL PDS, English and French.

To establish networked learning communities in
teacher education that help shape emerging practices is a
work of design fostered and documented through our
research activities. It is, in the words of Banathy (1994), a
"future-creating disciplined inquiry."

The Telelearning Professional Development Web
The task of helping student-teachers learn new
pedagogies for instructional purposes in a rapidly changing
social context is supported by Virtual U. Built on ten years
of research (Harasim, 1997), Virtual U is a Web site with
authorized access, a powerful conferencing system, internal
search engine, learner workbenches, and more. This
telelearning environment currently supports teachers'
collaborative reflective practice (pre-active, interactive, and
post-active phases) and knowledge-building, thus address-
ing complex questions and perplexing dilemmas inherent
daily practice. Online discussions about curriculum and
pedagogy (PDW) merge with face-to-face conversations
(PDS) to contribute to the learning experience of the
student-teachers who participate in the program.

The anonymity of the student-teachers, teachers, and
teacher educators is protected, and the sites opened to
others who want to explore the benefits, on a voluntary
basis, of the resources of this learning place. Ways of
fostering and managing these virtual communities of
practice are progressively uncovered.

Making Public the Discourse and Knowledge of
Learning
A first important objective of our TL PDS is to make
the discourse on learning and the knowledge about
learning more public. The need for greater awareness of
learning, and of ways of knowing and talking about
learning, is another requirement of a sustainable knowl-
edge-based society. The American Psychological
Association’s Learner-centered psychological principles
(1995) have been found instrumental in this respect. In
order to build our knowledge society, we need to allow
more people to talk in more sophisticated ways about
learning.

The TL PDS uses telelearning tools in order to achieve
this objective. Local Web sites are found informative by
student-teachers and educators. Student-teachers, cooperat-
ing teachers, and teacher educators participate in online
discussion forums. The discourse that is created in this
context is useful in achieving resolution on key challenges
that educators face in their practice. The discourse also has
interesting additional properties: because it is online and
written, there is the creation of a social text that is
inspectable. This text, in turn, becomes the object of
sharing and shaping of knowledge about learning.

To illustrate, there are, this semester, at Laval Univer-
sity, over 15 discussion forums related to four student-
teacher cohorts (15 students – cohort, 3 cooperative
teachers, and 3 university-based teachers). Three student-
teachers are involved daily in a high school which is
implementing a program, PROTIC (Programme PRO

1172 — Technology and Teacher Education Annual — 1998
Technologies de l'Information et des Communications), now involving 62 children, all receiving laptop computers, which foster project-based learning. Twelve other student-teachers visit the school once a week. Others are "virtually" connected through either their discussion forums and/or the Web site.

**Topics and Learning Scenarios.** In this PDW, the education of reflective teachers for elementary and secondary schools, ones who will understand the use of telelearning technologies for high-level learning tasks is the problem at hand. Subtasks are identified, and gravitate around the three moments of the teaching act (pre-action, inter-action, and post-action). Planning, implementation, and evaluation tasks have their own components, and these are more often than not left to the initiative of each individual or team.

The discussions have centered around the following scenarios and learning issues:

- **Participant observation.** Student-teachers 1) observe classroom interaction and/or participate in the ongoing learning activity; 2) present a descriptive statement and comments on a particular element of the observed educational situation within a VGroup (Virtual U); 3) construct, later in the semester, reflective statements using one another's first-hand journal excerpts.

- **Deliberative role learning.** Student-teachers acquire knowledge in changing social expectations and explore the evolving roles of teachers and learners in telelearning environments. As their personal values, learning styles and habits are at times confronted by newly emerging pedagogical practices, some value conflict resolution must be found, and face-to-face meetings are most instrumental in this respect. Online discussions contribute to the uncovering of new possibilities for learning and teaching.

- **Professional development planning.** Student-teachers are using a VGroup to plan for future professional development that will unfold during their induction years in the teaching profession. Plans include ways to learn to integrate telelearning technologies, and to stay connected to the professional development Web.

- **Collaborative reflective practice.** Teachers share their understanding of specific learning situations, and find ways to improve future action. At first, patterns of connection reflect local activities and research preoccupations. As common understanding and opportunities for collaboration grow, more cooperation, coordination, and integration occur. These patterns parallel Banathy's four phases (1991).

**Knowing How to Support Sustainable Communities of Learners**

The TL-PDS is developing new knowledge of how telelearning technologies can support sustainable communities of learners. Knowledge grows out of the interactions taking place in this virtual community, and of reflective practice. Because each site is developing its own Web site (Tact, Csile, Studio A, McGill TK), each offers a unique and context-based perspective on the integration of ICTs (Information and Communication Technologies) in learning environments. The building of interactive capacities within and across sites is seen as highly relevant by the teacher educators and researchers. They aim at assisting preservice and inservice teachers while gaining knowledge and skills of a practical or intellectual nature which they are called upon to master, in order to accomplish the tasks and functions expected of them now or in the not too distant future.

Our willingness to use telelearning technologies in such ways as to contribute to the creation of functional and collaborative communities of practice has led to the following practices:

- at the process level, patterns of connection (between high school learners, student-teachers, teachers, and teacher educators) were examined, using principles of discourse analysis, and used to guide further steps in the design of the TL-PDS;
- at the content level, bi-polar themes have been identified, including public-private, school-work learning and tradition-innovation. Student-teachers' concerns for classroom management issues are crossed by these different tensions.

Preliminary examination of our data reveals important patterns of conceptual change triggered by participating in a networked community: changes concerning the conception of the learner, of the teacher, and of the modes of interacting with knowledge objects. Another important finding concerns the high inter-dependency between these changes: certain re-conceptualizations of the teacher's work are possible only from a re-conceptualization of the role of the learner, and of the relationships between the learner and various knowledge objects. For example, building groups of active learners supported by potent technologies create powerful opportunities for teachers to participate in professional communities.

Our experiences also inform us of the important role of the online discussion facilitator. One major aspect of this role is to help participants negotiate their transitions between physical and virtual worlds. In order to maximize the level and quality of participation, it now seems useful to use "transitional objects:" symbolic objects that can be present or even produced in face-to-face situations and then digitized, with opportunities for further manipulation and sharing in the virtual group. For example, the concept maps produced in a seminar meeting using physical transparencies and markers, discussed during the meeting, can be posted on the seminar Web space for further reference. The concept map then becomes a symbolic object that helps participants relate their work from the physical onto the virtual.
To facilitate participation in virtual groups, two other important conditions have been identified: the clarity and centrality of expectations to participate, and the specification of complementary roles and responsibilities. For teachers and students to participate in online discussions, these discussions must be set as an integral part of meaningful learning activities. It must be clear that all are expected to participate, and that participation is fully valued. Situations where the online discussion is an add-on do not generate productive work. Similarly, the complementary roles and responsibilities allow individuals to focus on a certain layer of conversation, while keeping the whole discussion in mind. By including responsibilities to report from other discussions, different sub-groups can maintain a coherent picture of a conversation that would not be manageable otherwise (for instance, in the case of forums reaching 600 kilobytes over a four-week period).

**Resources and Assistance.** The TACT Web site (with its electronic materials and links to materials on other Web sites), collaborative spaces such as V-Groups, Web-CSILE databases, CD-ROMs, videotapes, conceptual maps and representations provide computer-supported collaborative learning environments to student-teachers and teachers. E-mail and the exchange of files remain basic ways of communication, but our collaboration is increasingly supported by V-Groups (Virtual U). Once a statement or a question has been written, students are eager for a response. Ways of managing the increased expectations for social interaction must be found.

Simulations as such are not used per se, but evocative examples are. More experienced participants help less experienced ones. Sometimes, a student has learned something only a few months, weeks, hours, or minutes earlier, and is asked to guide a newcomer in a particular task. Coaching on the part of the instructor is key, including technical assistance at times. It must be stressed that the use of telelearning technologies acts as a catalyst for the transformation of the role of the traditional teacher. Modeling is key, and entails the roles of teacher facilitator, coach, mentor, guide, mediator, project manager, and director of learning (for additional information on teacher beliefs and practices with these technologies see: [http://www.education.mcgill.ca/fedwww/cils/Telelearning/Telelearn.html](http://www.education.mcgill.ca/fedwww/cils/Telelearning/Telelearn.html))

The sharing and shaping of experiences in ways facilitated by the increased information, communication, and collaboration powers of new technologies are becoming more and more obvious. Collaborative teaching is in sight. The main focus is on the knowledge teachers use in the process of implementing information and communication technologies in their teaching.

**Web-Extended Professional Development for Educators**

The third main goal of the TLPDS is to provide extended professional development opportunities to educators (including practicing teachers, student-teachers, and teacher educators) through establishing regular learning activities, Web-extended institutes and practices.

Our design of TLPDS, and the discussions taking place within and between each site, reveals the challenge of sustainability in establishing learning communities in teacher education. We treat this challenge in terms of requirements to embed activities that survive single teacher-development events and that will become part of the school and/or university ethos. Examples of such activities are e-mail discussions, team work on curriculum innovation with technology, lunch-time project sharing, and various celebrations.

Another example of the ways in which it is possible to provide extended professional development for educators is our current design of TeleLearning Institutes. The first of these Institutes is planned to occur with the McGill Faculty of Education in August 1998. The essential components of the Institute are the objectives, the theme, and the process we are designing to ensure that the Institute is coherent with established long-term relationships. The objectives of the Institute are to allow participants to:

- learn to use ICT in support of student-learning;
- create resources that will be useful in teaching and learning current curricula;
- plan the school Web site and prepare continuous work to maintain it;
- establish and deepen collaborative working and learning relationships with colleagues both online and face-to-face;
- discover ways of using technology to collect, interpret, and share portfolios of student learning.

The theme of the Institute is "The Web site as a strategic project for the school." Around this theme, participants will work on the establishment of learning resources and student-centered projects on the school Web. In order to ensure that the Institute is coherent with established and long-term relationships, we are inviting teams of teachers and administrators from our PDSs to join teams of student-teachers and faculty members. Members of teams at the Institute will work together to share information and to connect their resources.

School-based teams of teachers (possibly with school administrators) will be working during the Institute on the initial design of their school home page, or on improving the existing design. They will identify specific accountability measures to evaluate the success of their Web design (for example, in terms of the capacity of students to achieve higher learning goals). Each school team will be matched with a team from the Faculty of Education composed of one...
Institute, telelearning faculty members will offer support to the different professional roles within a team. During the learning in this context also, through peer coaching across faculty member and two to three student-teachers who will want to meet regularly to develop new knowledge and technology in the classroom" is offered to schools where a example, a site-based McGill course on "Integrating within on-going practices at the school and the Faculty. For the Institute will ensure that the Institute is embedded previous conversations. Activities prior to and following the school becomes a continuation of relationships and discussion forums. As such, the work of student-teachers in the school becomes a continuation of relationships and previous conversations. Activities prior to and following the Institute will ensure that the Institute is embedded within on-going practices at the school and the Faculty. For example, a site-based McGill course on “Integrating technology in the classroom” is offered to schools where a group of teachers (in some cases with students and parents) wants to meet regularly to develop new knowledge and skills in this area. We foresee PDWs becoming another key activity, in addition to courses, seminars, and practica, for universities’ professional schools.

Conclusion
The social and cognitive circumstances that seem to be required for successful networked learning communities in teacher education - as those mentioned above - are still at an early stage of conceptualization. Networked learning and teaching is indeed a whole new practice, one likely to gain greater relevance while the demand for education keeps increasing as we move in the Knowledge Age. The initiatives described in this paper are part of our "local" endeavor to design a "teacher education culture that promotes curriculum experimentation, collaborative learning, faculty development, and better linkages to P-12 schools" (NCATE, 1997b). Our approach is to start with a critical mass of participants, and then to celebrate and publicize success (Mergendoller, Johnston, Rockman, & Willis, 1994).

REPLACING THE TIN CAN: CREATING AN EFFECTIVE ELECTRONIC COMMUNICATION ENVIRONMENT

Susan M. Powers
Indiana State University

Karen M. Dutt-Doner
University of New England

communicate 1. to impart, transmit; 2. to make known, tell; 3. to be connected; 4. to hold converse; impart ideas or information - Scribner Dictionary, 1977

It is easy to remember fondly the days when we would hold a tin can to our ear which was connected by a string to another tin can and a friend. We would struggle to hear our friend through the piece of yarn. The goal was more the act of putting the device together and less the actual communication itself. The same held true for the childhood game of operator, when one person started a message and the message was whispered from ear to ear to ear, around a circle until the final person said the altered message out loud. Everyone would laugh to hear how the message had changed during the communication process.

However, the simplicity of that type of communication does not work in the classroom. The purpose of communication in the classroom is to impart knowledge and information and to receive feedback. A garbled message will not work when students and faculty are depending upon clear, cogent communication. This need is particularly true in the realm of teacher education when not only is communication necessary for the learning process, but as a modeling process of effective classroom communication that preservice teachers will use in the field.

To accomplish that mission, a large number of texts have been created to help faculty and teacher alike create a scaffold where communication thrives for all persons. Friedrich, Galvin and Book (1976) break down the communication process into a system of communication where the student and the teacher have specific roles. Gavriel Salomon (1981) examines the richness and reciprocal interactions inherent in classroom communication. Hurt, Scott and McCroskey (1978) return to the classic communication model of source, receiver, channel, message and feedback and relate this specifically to classroom communication and how each piece plays out in the classroom environment. Finally, Cazden (1988) provides specific analysis tools and exercises to enable the teacher to understand the type of communication interactions which take place in the classroom and the variety of roles that are played by the individuals. The books mentioned here are just a taste of what sources are available regarding the facilitation and understanding of the classroom communication process. That process is far more complex than the string and tin can or the ring of friends whispering in each other’s ears.

Classroom Communication in the Electronic Age

In an odd way, however, the tin can has returned to our communication system in the way of computer e-mail (i.e., two pieces of metal connected by fiber wire). At the same time, the circle of friends whispering to each other has returned as the electronic discussion group, where a message is passed to everyone. The analogy may seem stretched, but in many ways, the new electronic communication tools may have more in common with these old games than with traditional classroom communication. The charge is to find ways to make the communication more like, and possibly better, than effective classroom communication.

The statement above demonstrates that childhood games are similar to electronic communication tools. The question then arises, how are these forms of communication alike? They would seem remarkably dissimilar in their complexity and expense. However, just like the two people joined only by metal and string, e-mail messages are devoid of nonverbal communication and inflection. The hope is that the person at the other end understood what you were really trying to say. Likewise, the circle playing "operator" is much like the electronic discussion group where an original message is sent, and each person involved receives a slightly different message. The original sender is not able to relay the context of the message to every person and the final outcome or interpretation of that message may in no way resemble the original.

This paper and these authors will not begin to assume that all communication that takes place in a classroom
setting is effective. The face-to-face communication can also be charged with misunderstanding and false communication. However, classroom communication has the value-added benefit of immediacy and the possibility of immediate feedback (Hurt et al., 1978) for the purposes of clarification and consensus of understanding. Models such as these provide teachers with methods to ensure that the “noise” which disrupts communication is eliminated. Therefore, can these same models be applied to the development of an effective communication model for electronic discussion?

**Building a Foundation for Electronic Communication**

Creating a firm foundation for successful electronic communication must start prior to the models, i.e., before the source sends the message. First, the consideration must be made on whether the technology should be used. The mere ability to use electronic communication tools does not translate into an instructional need for the tool. For instance, perhaps a class meets several times a week and engages in active discussion during the class period and students are readily able to have all topics and questions covered during scheduled class periods. It could be argued that the use of electronic discussion in this instance would possible take away from and not complement the rich discussions already taking place. However, if there are students who are not comfortable speaking aloud in front of their peers, or class time does not permit discussion of new issues indirectly related to course topics, or even if students have experiences (such as in previous early field experiences) that they would like to share immediately instead of waiting for class time, an electronic discussion forum would appear to be a useful tool. When an instructional or student need is fulfilled by a tool, students will not feel a need to use it just to make the instructor happy or just for a grade, and more meaningful communication can take place.

If there appears to be an instructional and student need for electronic communication, the next step would be to determine which type of tool would be used. This step could be equated with selecting a channel for communication and messages. Again the student needs must take precedence in the selection. As an instructor, I may have become interested in the concept of conferencing on the web. However, a tool such as this will require students to have access to a certain level of software and computer in order to have class communication that is not frustrating because of the mechanics. Alternatively, perhaps communication with the entire class is not necessary, and only e-mail links to the instructor need to be established to encourage students to seek information and mentoring from the instructor. By matching the tool to the needs and resources of the students, a foundation is being built that will help support effective communication.

The next step is also entangled with the previous steps and relates to message creation. The specific types of electronic communication that will be sent must be determined and established. Will the electronic discussion be dedicated only to certain topics that are either integral to the course or, at the other extreme, will students be allowed to determine what topics will be discussed collectively. Perhaps students in the class have little time to develop social relationships with classmates, or are unable to do so in a distance environment. Therefore, it might be appropriate to allow students to use an electronic discussion group to form those important bonds with peers. On the other hand, it might also be equally important that students don’t want to waste valuable time with trivial information and all communication must be professional in nature.

**Implementing the Electronic Discussion**

With the above decisions made, the foundation for an effective, electronic class discussion has been set. Now all that remains is the implementation. Implementation may seem to be a simple task, but once again, it is necessary to do some preparation in order to assure effectiveness. The environment itself needs to be built. As much as effective classroom discourse is managed and planned (Cazden, 1988), so too must the electronic classroom be managed. Many of these steps might appear to affect the message development. Their real purpose though is to eliminate the noise that disrupts the receiver from fully understanding, or even receiving, the source’s message.

**Training the Participants**

There are many things that all the participants must learn in order to eliminate noise and hold effective communication. First, can all participants use the electronic tools that have been selected? For example, do all students have an active e-mail account and know how to send and read their e-mail? If web conferencing is being used, do students know how to input their information in a web form? Also, if a listserv is being used, does the faculty member have the knowledge to moderate the list? To ensure that everyone has the same basic level of psychomotor skills, it might be necessary to provide class time to learn these skills, or workshop time to do the same.

When you consider classroom discussion, there exists a certain degree of etiquette and a code of conduct. Students have learned not to interrupt the instructor. Students will usually raise a hand before speaking, or at least look to see if someone else is about to speak. For the most part, students and instructor alike are respectful of each other and allow each other to complete thoughts without interruption. These standards of behavior are not something that must be taught at the beginning of the class; instead, those skills have been learned over the years as students travel through a variety of educational levels.
It would absurd to assume students will enter an electronic communication environment and be able to achieve the same skill level they have obtained in face-to-face communication. In the first place, electronic discussion gives the user a certain level of anonymity that empowers individuals to say things they may not have said before. This empowerment may be to the betterment of the class as students who may not speak in a classroom environment now are willing to discuss issues and communicate with others electronically (Powers & Mitchell, 1997; Powers & Dutt, 1997; Johnson, 1997). However, the anonymity can also permit individuals to say things they would not ordinarily say to another person if they were sitting in a classroom together which might be to the detriment of the class environment.

Developing Guidelines

There are other skills to be learned to help eliminate noise. The written, textual base of words do not necessarily carry the same meaning as the spoken word. In other words, I may say something harsh in a classroom discussion to provoke debate. However, through the use of my body language, facial expression and tonality, I can soften the words enough that they will in fact provoke debate and not insult. Through the text of electronic communication, I am not able to convey all those communication tools that are outside of the words. I would therefore need to find different words and phrases that will accomplish the same mission and purpose and not offend or insult.

For basic Internet usage, there is reference source of online etiquette principles called "netiquette." These are core rules of acceptable behavior for online interactions, such as Virginia Shea’s Core Rules of Netiquette (1997). These rules cover issues such as saying electronically only what you would say to someone face-to-face, ethics, sharing expertise with others, and forgiveness. Groups take netiquette guidelines such as these and adapt them to their specific needs. For example, Augsburg College (Mateer, 1996) has posted a list of guidelines with which they hope to guide their constituents. These guidelines also deal with issues of respect, educate users about how inflections in voice can change meaning and the related problem of not having that inflection present, and how the mere typing of text (e.g., all capital letters come across like shouting) can change meaning. By compiling these guidelines, Augsburg College is hoping to influence its community of electronic discussion.

The same process of "guideline creation" or adaptation of netiquette principles can take place at the classroom level. As mentioned previously, classroom communication generally takes a certain shape based on the years of experience the participants have in classroom discussion. Even when an instructor wants to change classroom discussion, students must be informed of the "new rules." For example, if an instructor wants students to jump in with comments at any point during a lecture, the students will probably need to be informed that it would be considered acceptable behavior. Therefore, we should expect electronic communication, which is undoubtedly new to many of the participants, to need the same level of permission and information.

Before the first electronic discussion takes place, the instructor needs to develop guidelines and criteria that are specific to that class. These guidelines would incorporate many of the decisions made previously in the process, such as whether social conversations are appropriate or if all communication must be professional in nature. The guidelines can include provisions for who can participate in the discussion; for example, will the instructor take the lead role in answering questions or initiating communication, or will all participants be considered equal. The guidelines can be even more basic and cover issues such as whether or not aliases will be allowed by individuals or must a student's identity always be obvious; whether or not signature lines can include items of a personal nature (scripture or sayings); preferences for responses to messages (should original message be included and to what degree); whether spelling and grammar is important in messages. Finally, the repercussions for violating the class policy must be codified.

Generally speaking, students are informed at the front end as to what the penalties will be if they, for instance, miss class or fail to complete assignments on time. If the electronic communication is truly a part of the classroom communication structure, the same information and repercussions must be made available to students for that part of the class. The instructor must decide up front whether students who abuse the electronic communication system will lose those privileges, and how that will impact their performance in the class. At one end of the spectrum, there might be no impact on final class outcomes, at the other end of the spectrum a student may not be able to successfully complete the class without the electronic communication. An instructor must decide whether there will be a series of warnings, or if there might be offenses severe enough to warrant immediate removal. Opinions and options will vary on this issue. However, the consideration must be made that our students are being prepared for participation in the world at large. It is far preferable that students make these types of errors within the confines of our educational system where we can work with the students and help their understanding, than to have them make these same mistakes in electronic communications that may be worldwide. Our education of students should extend beyond content and should include the tools for transmittal of content.

It could be argued that these principles and guidelines could be achieved through modeling by the instructor who would pay special attention not violate her own guidelines.
However, the instructor is not a peer and students will not be privy to all of the communications that take place, as in the case of private electronic communication. The modeling will help support the guidelines and give the students examples, but the overarching classroom electronic communication principles will provide a scaffold for students as they develop their communications.

Faculty Role

As one additional way to eliminate noise, faculty must also consider their level and type of participation in the electronic communication process. As with many teaching decisions, the purpose for implementing a teaching strategy must be considered when deciding the role s/he wants to play. For example, an instructor could choose to use an electronic discussion group to address specific topics related to course content; or, the instructor could decide to use an electronic discussion group to discuss issues related to the course that may or may not be addressed in class. In this last example, students would drive the message design by posting issues that have interest to them. In all of these scenarios, just like with regular class discussions, the instructor must decide his/her level of participation in the discussion. Confusion about faculty roles will create noise or disruption for the student as s/he struggles to determine the role as student. In any case, whether the instructor participates in the electronic discussion on a regular basis or chooses to step aside, the instructor must find a way to communicate to the students that s/he is reading the ongoing discussion. In this way, students still feel a responsibility to participate in the electronic discussion and know that the instructor cares about the ensuing discussion.

Specific Thoughts for Teacher Education

Recent teacher education reform movements including the National Board for Professional Teaching Standards (NBPTS), National Council for the Accreditation of Teacher Education (NCATE), and the Interstate New Teacher Assessment and Support Consortium (INTASC) acknowledge the need for beginning and experienced teachers to demonstrate competence in the use of technology as well as effective communication skills. Integrating electronic communication into teacher preparation courses not only provides students with exposure to technology-related communication, but also provides students with an opportunity to practice effective communication skills in new contexts. In addition, it seems that professors of education are always concerned with the over abundance of content to cover during class time, especially now as field experiences become such a critical component of many teacher preparation programs. Electronic discussion can provide instructors with opportunities to use other forums for communicating with students and provide students with other forums for communicating with each other. As a tool, it provides a vehicle for students to share ideas, discuss topics, ask questions that would otherwise take up class time. It is also an effective way to open communication lines while students are out in the field.

Conclusion

Returning to the definition provided by Scribner on communication, we see that to communicate means to impart or transmit, to make known or tell, to be connected, and to impart ideas or information. All of these aspects, molded together along with the deliberative design of the communication system will create an effective electronic communication environment for classroom discussion. In a condensed form, the instructor must:

1. determine the instructional need that would indicate whether or not electronic communication tools should be used;
2. determine exactly which tools would be used to implement an electronic communication system, again dependent on the student and instructional needs;
3. determine what forms of electronic communication will take place;
4. train all participants on the various uses of the technology;
5. create guidelines or principles related to the use of the electronic communication;
6. provide training and information on the proper, ethical use of the communication tools; and,
7. determine faculty role of management and facilitation.

Effective electronic communication can take place without all these decisions being made and this advanced planning. Some classes of students contain the capacity and critical mass to be able to approach these tasks without problems. However, the risk and outcome of unsuccessful electronic communication may be too great and may prove to be too heavy a burden on the class as a whole or the individual participants. By carefully planning this discourse, much as other parts of a class are planned, a beneficial environment can be more assured.

How can fledgling teachers and administrators begin to develop the habits of professional collegiality and collaboration when the "closed door" mentality, symbol of the traditional K-12 classroom isolation, is also alive and well in schools of education?

At the University of Virginia's Curry School of Education, we have been exploring ways of cracking open those doors by facilitating communication among education students through an innovative project, Curry CONNECT. Curry CONNECT is a Web-based discussion group that links preservice teachers with graduate inservice teachers and apprenticing administrators.

In this paper, we will report on what we're learning from this project. Using content, survey, and interview data collected from the discussion postings and student feedback, we will present a qualitative analysis examining the nature of the participant discourse as it evolved over the semester. In particular, we will consider the following questions: Does the evolving discourse reflect the growth of a shared community of understanding among the participants? How does the motivation for participation affect the discourse and the development of a sense of a collaborative community?

**Perspectives**

**Curry CONNECT - Rationale**

One important result of the practice of university teacher education students working in isolation is the lack of opportunity for them to interact with each other about important concepts and issues. Student-to-student interaction usually occurs within a classroom through cooperative projects or discussion but rarely goes beyond the classroom. Preservice teacher education students have little time to communicate with one another or with experienced teachers when they observe or student teach in K-12 classrooms. Seldom, if ever, do they have the opportunity to exchange ideas with administrators. Yet we accept as the basis for much of what we teach today in education that real learning takes place in a social context. From Dewey (1916) and Vygotsky (1978), we have developed learning theory which is predicated on the idea that knowledge is socially constructed. As learners, we are actively engaged in the production of shared "communal understandings" which help us to derive meaning from everyday messy, puzzling experience. Through encounters with multiple perspectives, we acquire mature and mutual understandings about the nature of reality (Sugar & Bonk, 1995). By providing future educators of all stripes with a common social context in which to discuss ideas and build meaning, we can facilitate their learning. We believe that technology has the capacity to bring together such diverse groups of students in different classes with varying degrees of experience to exchange ideas and knowledge.

**Curry CONNECT - Design**

The instructors of seven educational technology courses (four undergraduate classes, three graduate classes) created a Web-based discussion group, Curry CONNECT, for their students to engage in online discussions about issues related to the use of technology in education. The underlying purpose of the Curry CONNECT project, however, was to build a virtual "community" in which preservice teachers, inservice teachers and interning administrators could develop the understanding that they are part of a larger educational community which can provide them with support, challenge, and an enriched social context for learning. An electronic link among the classes was selected as the best method for creating this perception (Bonk, Appleman, & Hay, 1996).

Students accessed the Curry CONNECT Website to discuss common readings about educational technology designated by the instructors. The Website is available at the following URL: http://curry.edschool.virginia.edu/go/connect. After an initial "practice" discussion in which
students could post and respond to any idea, we held three discussions based on common readings.

**Methods**

**Participants**

The classes were comprised of the following students:

- *Introduction to Educational Technology* (Undergraduate, four sections—primarily preservice elementary and secondary teacher education students)
- *Instructional Computing* (Graduate, one section—primarily graduate teacher education students, most of whom were experienced teachers)
- *Educational Software Applications* (Graduate, one section—a diverse group of students from the entire university)
- *Problems in School Business: Computer Applications* (Graduate, one section—experienced teachers and administrative interns working on graduate degrees in school administration)

These students offered a breadth of classroom experience to the discussion group, ranging from those who had only observed in classrooms to those who had taught for many years. It also included a contingent of students from other schools of the university who were not interested in becoming teachers. Mostly undergraduates, these students represented the important constituencies of future parents, business leaders, and other professionals for the education students in the group.

**Data Collection and Analysis**

Curry CONNECT consisted of the participating classes (approximately 140 students total) and seven instructors. Participants were identified by their “roles” within this educational community: Preservice teachers, experienced teachers, administrators, those characterized as community members (non-education students), and Instructors.

In addition to follow-up surveys provided to the entire population of students, we selected two students from each class, who had posted to the discussion group, to follow during the course of the semester. These students, or “posters,” were interviewed following each discussion to gain insight into their views on the nature of the discussion, what they learned from the experience, and how they felt about the other participants in the discussion. “Non-posters” from each group were to be selected and interviewed at the end of the semester course to determine reasons why they chose not to participate. Finally, instructors from two of the courses were interviewed.

The results of the surveys, the interviews, and a discourse analysis on all of the posted students’ responses were examined qualitatively with particular emphasis on the following questions:

1. Does the motivation for participation affect the quality of discourse and the development of a sense of participating in learning community?
2. Is there evidence that the evolving discourse reflects a sense of community (shared communal understanding) among the participants?

**Preliminary Results and Discussion**

Interviews and postings were analyzed and content analysis was performed. The following categories were determined to be important indicators that respondents were describing a sense of participating in a shared community:

- Motivation for participation which is primarily internal
- Awareness of the social context of the discussion group and perception of other participants as peer members
- The ability to acknowledge and appreciate multiple perspectives

**Discussion One** “The Computer Delusion” (Oppenheimer, 1997) provided the topic for discussion. A link was available from the Curry CONNECT site to an online version of the article at: http://www.theatlantic.com/issues/97jul/computer.htm.

This was a relatively straightforward discussion arising from a single reading. Responses provided a lively back and forth debate surrounding the issues raised in the article with participants about evenly split either for or against the author’s position. The following are excerpts from the discussion:

> We all agree our children will need more computer skills in the future and we probably all agree that we need to spend more money on education in general, so why not use capitalism’s competitive nature to solve all of our problems. Let the public sector spend more on the traditional programs and let the private provide the rest. (Experienced teacher’s posting)

> ... your argument of private vs. public spending sounds great on the surface, but what about the long-term effects? Won’t this cause great disparity among schools? The richer schools will get richer and the poor school districts will remain poor. We will create a greater disparity among schools than what we presently have. Is this fair to all students? I don’t think school choice is the answer to this dilemma either. It is our obligation as a free society to provide an equal education to all of our youth. (Administrator’s response)

**Discussion Two** The general topic was Censorship and Copyright Issues. Links were provided to several sites that provided information and articles on these issues at: http://curry.edschool.virginia.EDU/go/connect/discussions/
The format was somewhat less structured since students were required to look up a number of resources and links in order to develop their own understanding of the issues.

Although the format was more problematic for some students, participation was high and multiple perspectives were evident in the series of postings. The following example demonstrates one discussion strand that arose about “censorship” on the Web:

...Part of the skill required to make the Internet experience into a meaningful learning experience for the student, teacher or parent is found in gaining the ability to discern. Access to the Internet-and all it has to offer-is growing exponentially. I don’t believe that we could or should exercise control over users’ exposure... (Preservice teacher’s posting)

I’m not sure that I agree-though in theory I think your ideas are marvelous, I can see a lot of adolescents not grasping the deeply rooted concept. Education about the craziness that exists on the net should certainly be addressed, but I’m not sure that would keep an eager adolescent from learning too much too quickly. (Experienced teacher’s response)

I met a man once who was very disconcerted by television sets. He did not give the normal speech about TV being trash or a waste of time or not educational. He saw televisions as a very disturbing invasion of privacy. He said, “Yesterday when I came home from work a strange man I had never seen before was talking to my daughter in the living room.”...I think the fact that TV and computers allow millions of strangers into our lives is indeed quite disturbing. I do not believe that the net should be censored but I do not believe that it has much of a place in schools...Internet access in schools is like having tax-funded strip dancers in off limits classrooms. (Community member’s comments)

Motivation for Participation

We asked participants what initially motivated them to participate. Interest in the topic was given as the primary reason by most participants as indicated below:

I think that the impetus behind my posting in that particular circumstance was based upon the article itself. I was so enraged by the opinions put forth in the article. (Experienced teacher)

I think that I read the article, and I thought it was interesting, so I wanted to comment on it. (Preservice teacher)

I’ve always heard things about censorship on the web, and I wanted to look into it. When I did I went to a lot of the sites, and I was really surprised with what I found. I think I gave some examples in what I wrote-the things that really shocked me. (Preservice teacher)

Of equal importance to respondents was finding out what other people thought:

I think I was interested in seeing if other people saw things the same way I did. (Preservice teacher)

I was curious to see what other people posted. (Experienced teacher)

Although most students noted that there were course expectations or requirements for their participation in the discussion group, only one mentioned this as the sole motivation for involvement.

I liked the topic, but the only reason that I posted was because it was part of an assignment. (Community member)

Instructors cited the importance of responding to their own students’ posts as their main motivation for posting to the discussion group. One wrote “...it’s very difficult for people when they post something and don’t get a response at all. It’s one of the worst feelings in the world to not get a response from anybody. You start to wonder whether you had anything worthwhile to say or what folks’ reactions are to your message.”

With one exception (“I did not want to see the responses people might have given to my particular response.”), all of the student participants reported that, indeed, they were motivated to return to the discussion on several occasions after they had posted in order to find out what others may have responded to them.

I wanted to see if people had responded to what I had written. And it was new to me-the whole newsgroup thing, so I just wanted to see how it worked. So I looked at some people’s comments. Not just who had responded to me, but some people that I knew-I wanted to know what they thought of it. (Experienced teacher)

I returned [several times] to see if there was reaction to my posting. (Administrator)

Internal/External Motivation

All students taking part in Curry CONNECT discussion groups were presented with some form of extrinsic motivation for participating. Reading the common resources and posting to the discussion group was required, suggested, or encouraged by the course requirements in all of the classes. It was, therefore, a matter of interest to examine the effect of these requirements on student motivation.

Two classes were given the option of either posting to the discussion group or submitting a reading reaction paper...
to their instructor. In the third class, students were "strongly encouraged" to post although there was no mandatory requirement that they do so. In the fourth class, while again there was no mandatory requirement for posting, two extra credit points were awarded to students who joined in an online discussion.

An analysis of the interview data suggests that for the non-education students, required participation became the chief motivating factor in their involvement; whereas for those students engaged in education and anticipating a career in the field, interest in the discussion topics and themes was cited as more important or equally important. Except for one student, all respondents were motivated to return to view the discussions thereafter more than once.

Awareness of Social Context

We were curious about the participants' perceptions of the other members of the CONNECT group. As one instructor interviewed put it:

...obviously the literature shows that when you have familiarity with people, you know the person, that there is more of a chance that you would talk to them again, and the same on the Internet. It opens the chance to talk to a whole bunch of different people, but given the choice of talking with somebody you know and somebody you don’t know, you’re more likely to talk to somebody you know-unless somebody you don’t know really says something controversial and you just absolutely have to respond to them.

All respondents were clear that they felt the Web discussion was a significantly different experience than a face-to-face encounter.

Some students clearly didn’t feel that they were involved in a “discussion:”

I didn’t really feel like I was participating in a discussion. I thought I was just putting on a comment to see how other people would respond to it. (Preservice teacher)

I did not get the feeling that I was participating in a real discussion. I consider a discussion more than just a written response to somebody else’s thoughts. (Community member)

Several, however, did indicate that they felt there was a conversation taking place and especially approved of the asynchronous nature of the format:

But yes, I think I thought I was participating in a discussion. That it was there. Those that were interested in a topic could read, react and that type of thing...It was very convenient in that you could do it on your own schedule and time. (Administrator)

At least three students we talked with appeared to find both liberation and the ability to reflect in this form of discussion.

I thought it was pretty close to what you have in class. Except you do have the time to actually think - ...I think I wrote in things that I wouldn’t have said in person. (Preservice teacher)

...although there will be certain tones and moods when you can note from the reading. Writing is a physical manifestation of spiritual thought and there’s a transformation that occurs from the thought to the paper. I guess that what I’m trying to point out is that when we read someone else’s writing we read it in their voice. That’s why you get a sense of a person’s mindset. That’s why it is a viable level of communication-discussion groups. We’re touching one another. (Experienced teacher)

It’s more than just words on a screen. It’s really communicating. Writing is thinking. Sometimes I don’t know what I think until I write it down. (Experienced teacher)

Acknowledgement of Multiple Perspectives

One of the most crucial themes to our investigation into the nature of how a community builds relationships and constructs meaning arises out of the apprehension of the multiple perspectives which can only present themselves in a social context. There was evidence from our respondents that such a process was beginning to take place.

I have to admit I was surprised. You get so insular sometimes-as we all do all the time in education in general-and you forget that there’s a whole world out there that doesn’t read the same books, use the same jargon, share the same ideas. (Experienced teacher)

I think a lot of people felt the way I did-they just felt more comfortable writing it than would just raising their hand and saying it. I think you got a lot of different opinions. I didn’t expect a lot of different opinions. (Preservice teacher)
It helped to give me some insight to their ideas and views which a lot of the time were different from mine. (Preservice teacher)

By reading the responses of other people, I was exposed to different views and opinions than my own. Word choices and tones conveyed in the postings helped me see where the students were coming from. (Community member)

Future Research
We will continue to investigate the extent to which our results indicate that the Curry CONNECT discussion group succeeds in its mission of creating a “shared community of understanding” among education students and make adjustments to its use as necessary. As in the real world, we will need to be sensitive to finding ways to involve community members more thoroughly in our mutual meaning making.

FROM "KNOWLEDGE SHARING" TO "KNOWLEDGE INFRASTRUCTURE:" LESSONS FROM A VIRTUAL PROFESSIONAL COMMUNITY OF 250 ISRAELI EDUCATORS WHO USED 18,000 WEB PAGES

Yesha Y. Sivan
Tel Aviv University

The Lamda Community project was created to "use the Internet to support science and technology education" as part of the Israeli national program "Tomorrow 98" or in its Hebrew name, "MAHAR 98" to "advance science and technology education in Israel. (For an extended discussion about the project see Sivan, 1997; Sivan, In Press). The following paragraphs describe the project's 1994-1997 history.

- In the first year, 1994, we conducted a general overview of network technologies, and their potential educational use both in Israel and in the world. This initial examination revealed what we then called "a messy situation." It appeared that beyond the usual challenges of "large scale changes in K-12 education," educational research and practice lacked a clear understanding regarding the role of networks in such a change.
- In the second year, 1995, the first 50 members joined in and an initial 100-page Web site was created.
- In the third year, 1996, we started the actual development. By the end of the year we had about 150 members who used 5000 static Web pages, and about 5000 dynamic pages (mostly in the discussion centers). Among other things, the Lamda site included a dual e-mail/Web discussion center; weekly news; automatic front page and support for project-based learning; and various content centers in the area of science and technology education.
- In the fourth year, 1997, we started to realize the true nature of professional development over networks. 1997 became the year of realization. After two years of operation with about 18,000 Web pages that serve 250 members, we began examining our initial ideas about using the Web to support professional development. (See Figure 1).

Perspective Theoretical Framework: A Call for New CMC Understandings

Since the 1970s, the term Computer Mediated-Communication (CMC) has been used in education (Harasim, 1989; Rice, 1992). Concepts like remote learning, copyright, lurking, MUDing (Multi User Dungeon), and other CMC lingo have appeared in the literature. While Rice (1992) says "there is little theoretical or empirical research in this area" he, with others, published a few hundred papers about CMC.

Such pre-1995 research dealt mostly with text-based systems that were used by computer users. The "text-ness" and the "computer-ness" of CMC have changed dramatically with the emergence of the Internet. As of 1996, even novice users can use CMC with relatively easy-to-use Graphical User Interfaces (GUIs).

Three factors led to the demise of "text-ness" and "computer-ness" of CMC. These include the development of Point to Point Protocol (PPP), the World Wide Web (WWW), and an improved cost/speed ratio of modems. The combination of these three factors created the initial boom of the Internet, a boom that has changed the field of CMC. Let me therefore humbly argue that the value of pre-1995 research mostly stemmed from suggesting concepts and issues. Yet now we must take a fresh look at the relations between these concepts and the real world. CMC terms like, remote learning, copyright, lurking take on a different meaning when millions of users are involved.

Lamda Community was designed to examine the new meaning of CMC. Lamda Community was not a classic experiment; it was designed to be a self-evolving experiment in the tradition of action research. The community is designed to foster an iterative interactive process among the members, the material on the Lamda Community site, and the technological systems supporting the community. The research questions of the project...
revolve around the nature of professional virtual communities. More specifically, we were looking at user-network interaction, site design, authoring of CMC content, the building of sub-communities, and project-based learning.

Methods

Three kinds of data were collected: use data; online reflection; and focus groups. They are described next.

Figure 2. Hourly summary of use in June 1996.

1. **Use data** - The Web allows real-time capturing of data of members' behavior. Since all members must logon to the site we are able to know who used which service. For example (see Figure 2), we can see a decline in use around 8:00pm (possibly due to family time). The numeric data allows us to analyze patterns of use (e.g., novice vs. expert use of the site; the appeal of various services, etc.). Further cross analysis (e.g., kind of member vs. kind of service) allows us to fine tune and adjust the services.

2. **Online reflection** - beyond the quantitative data that we get from the system there is also the automatic capturing of discussions. The main forum for discussion is called the "Discusatorium." The Discusatorium combines both the capturing of the data (into Web pages) and the links to members via e-mail. The qualitative data is stored for future reference and study.

3. **Focus groups** - each month we gather with members to explore the state of the community. Valuable data and ideas are generated in these meetings. The meeting are logged and transcribed for further study.

**Results: From "Knowledge Sharing" to "Knowledge Infrastructure"**

**Phase 1: The End "Knowledge Sharing"**

When we started the project, we, like many other Internet veterans, advocated the idea of virtual communities (e.g., members will start discussion groups; members will share information with each other; when asked, members will contribute their knowledge). This "free flow of knowledge" idea was well phrased in the concept of "virtual communities." The pre-1996 CMC literature reports, and often praises this notion of sharing and collaboration.

In the first years, based on early observations, we thought that our Lamda was indeed a virtual community. Few members started some discussions; few contributed papers to the library; few even answered questions. Later we realized that these signs were misleading. Apparently the few members who acted as members of virtual communities were themselves "good old Internet advocates" who believed in the idea of knowledge sharing. They were especially active in Internet issues (e.g., where is a good site for biology, how to use Netscape, how to read Hebrew on the net).

In 1997, while these good old "Internet advocates" were still using the Lamda community, they became a minority. Within the 250 members, the Internet advocates' activity was felt but it was no longer in the center. Members seemed to want something else.

**Phase 2: The Rise of a Knowledge Infrastructure**

So what do members of the Lamda community do after all? Our preliminary research shows that members basically do three things (which we have termed as using a "Knowledge Infrastructure"):  

1. **Use professional services that the community offers**

   These include a links database (each entry includes a 5 line description in Hebrew followed by a picture); a search center where members get help with searching, including a human search assistant; and use of content databases.

2. **Participate in a small group discussion concerning a particular topic**

   For example, one experimental school called Cramim, where all the teachers are connected to the net, joined in and opened its own discussion group. They use the "Cramim-all" list to exchange various messages. They used the list for professional work and seemed comfortable doing it. Another list called K6, which deals with computers in the K6 area, is also very active.

3. **Contribute to and benefit from the entire community**

   Few, especially those who are advocates of the old Internet tradition, still contribute to the community in the tradition of a virtual community. Most simply enjoy the action passively.

Telecommunications: Systems and Services — 1187
Supporting Evidence

We have not yet completed a full analysis of our data. Our claim regarding “the rise of knowledge infrastructure” stems mostly from anecdotal evidence supported by some theoretical base from the literature of knowledge management.

Consider the following quotes taken from the online reflection made by members of the community:

• “...in this age we can not continue to contribute and survive with out getting information and help. Who can go to 300 workshops a year to get some info? I foresee in the very near future that most of the workshops will be done via the net.”

• “...during the last 2 years, the community have succeeded to build a group of 250 members, create a wide infrastructure in various subjects (math, science, computers in school, biology and more) ... What was especially unique is the ability of members to build their own centers by creating mini libraries or moderating conferences.”

• “... the great potential of the community is to allow teachers to develop themselves without the limitations of time and space ... The ability to get high quality info is critical to my work as a teacher.”

• “... it is somewhat difficult to fully describe the sense of the community that I feel. The links with the team members [staff people], the reading of news, cool sites, hi-tech corner, getting feedback from members about my work etc. [became part of my professional life].”

Equipped with the prism of a “knowledge infrastructure,” one can see how the members use the community to find, seek, and publish knowledge. The literature of knowledge management (which is now emerging at a rapid pace) involves “technologies for knowledge management” (Davenport, 1998); “new technical processes and tools” (Leonard-Barton, 1995); and “rethinking structure [with technology],” in the case of the Swedish based Skandia (Edvinsson, 1997).

To some extent these authors and others link the managing of knowledge with a technological infrastructure. We, at the Lamda community, came to the same conclusion - albeit from the practical side - from observing what people did within the community.

Implications

Much of what is true for a group of 10-20 people who use the Web (“knowledge sharing”) is simply the opposite when it comes to large-scale communities. In this project (with its 250 members, 18,000 Web pages), I believe we named a lasting motivation (“knowledge infrastructure”) for teachers to use a particular community.

In more general terms, CMC systems for education seem to be positioned to become a critical factor in creating a sustainable improvement in education. We must be careful not to treat the Internet like we have treated all other technologies. Decades of misuse and underuse of technology in education are in the way of using the Internet. Indepth analysis and treatment like the one we have undertaken within the Lamda community will hopefully allow education to make the best of this new social technology.

In the process of creating an electronic reference resource, a customized directory, students gained many useful skills. Students learned about Web searching, about search engines, and Web directories. They learned how to evaluate Web sites; they developed criteria for rating the sites, and after rating the sites, they categorized them. They titled their directory Where We Went on the World Wide Web. It gave them ready access to information about sites that they decided worked best for their assignments and extracurricular interests.

While searching the Web, students access a vast amount of information of varying quality and need to know how to evaluate it. For example, one of the fourth grade assignments is to do a report on birds. Each student is assigned a different bird to research. Being only generally familiar with basic usage of the Web, students as a class come into the lab with the assignment to see if they can find information on their bird. Our browser default is set to Yahooligans (http://www.yahooligans.com). Students start their inquiries there and then are allowed to use other search engines and directories. Some find useful information, but most discover firsthand just why it is valuable to have research skills and an effective strategy to be successful.

Perhaps, students researching cardinals will bring up information about the baseball team. Another student might find sites produced by a university, a commercial organization and another elementary student respectively. They will need to know how to differentiate between the different types of sites and validity of the information found. As Kinnaman (1997) has said:

The beauty of the Internet is that it holds the potential for each of us to be the captain of our own ship on the sea of information. If we learn how to organize and apply information, access to it will certainly yield knowledge, and through experience, even wisdom.

More than ever before, we need to teach our children the art of critical analysis, so that they can detect and avoid the dangerous assumptions that threaten to sink their ships and drown them in irrelevant and misleading information. (p. 72)

This project was designed to help students and staff learn to navigate the vast sea of information on the Web. After learning about selection criteria and seeing examples of other directories for comparison and evaluation, a customized directory will be created and used as a reference source. It will be added to by students and staff and updated on an ongoing basis.

The Project

The first lesson of the project is an explanation of search engines and Web directories. We access a Web site that contains much information useful in searching and includes a slide show, that explains the difference between search engines and directories (Schrock, 1997). Several good examples of directories are shown. While on the Web, we review how to access the various engines and directories.

A site called K.I.D.S.-Kids Identifying and Discovering Sites is accessed (K.I.D.S., 1997). This site contains reviews of sites by K-12 students. Some of the reviews that are provided on this site are discussed, as are their site selection criteria. Next, students are asked to think about what criteria would be most helpful to them.

When presenting to the staff, we explore a site that contains a bibliography of sites concerned with evaluation of Internet resources (Auer, 1997). At least one site is examined and discussed to identify evaluation criteria (King, 1997). After exploring information about selection criteria and evaluation of sites, a checklist of criteria is produced to be used as a starting point to select criteria that will be used in evaluating sites for their own directory. Below are some possible criteria the checklist might include:

- easily accessible
- accurate information
- provides links
- appropriate links
- significant awards
- appropriate for audience
- appropriate reading level
• accurate spelling and grammar
• well written
• includes bibliography
• content rich site
• useful for curriculum
• valuable information
• current information
• unbiased
• well designed
• interactive
• easily navigated
• provides text alternatives
• easy to read
• well organized
• tables and charts are readable
• helper applications identified
• title is appropriate
• no fee or name necessary to use site
• author can be contacted
• copyright date listed
• last update listed
• author recognized expert, educational or government institution or reputable corporate body

Next, students design a standard form to use to record their evaluation of sites. The form should include spaces for the date, reviewer’s name, site title, URL, rating and comments. An area including criteria with check boxes will be the basis for the rating. The more criteria met, the higher the rating. Students decide on the criteria to be included.

The forms make up the pages of their directory. The forms will be inserted into a binder in the appropriate category. Perhaps some forms may be included in more than one category. Several directories are examined to provide examples of how their directory might be organized. Graphic pages to head each category are created in various software programs.

Conclusion
Throughout the year as students and staff research on the Web, they keep track of useful sites by using the form they developed and adding the forms to their directory which is kept in the computer lab. They have access to this book to help them in their research and to find out about other sites students and staff have found to be interesting and valuable. They produce a reference source, a directory, tailored to our curriculum and their interests.

CASENET: TEACHING DECISIONS VIA A WEB-BASED LEARNING ENVIRONMENT

Stephen C. Bronack
University of Virginia

Clare R. Kilbane
University of Virginia

In the recent National Council for Accreditation of Teacher Education (NCATE) report Technology and the New Professional Teacher: Preparing for the 21st Century Classroom, NCATE president Art Wise comments: As technology moves from the periphery to the center in P-12 schools, it should also move from the periphery to the center in teacher candidate preparation. We must all work together to help ensure that tomorrow's teachers are prepared for the challenges of teaching in the 21st century. (pg. 2)

The Office of Technology Assessment (1995) suggested that the successful utilization of technology in classrooms resides primarily in the hands of teachers, and that the training of these teachers is vital for its success. State and federal licensure agencies advocate standards for the integration and assessment of technology and teacher education. Such advocacy from policy- and decision-makers at all levels of the American educational system certainly may be advantageous to teacher educators, but only when one understands that the true educative value of current technologies such as the World Wide Web lies more in their use as a social medium for enabling effective decision-making, than as another productivity tool. Historically, most of the emphasis on technology within teacher preparation has historically been skills- and competency-based (OTA, 1995), with little context or foundation for its use in the act or profession of teaching.

Cases and Teaching Decisions

Generally speaking, classroom teachers make approximately 60 teaching decisions per hour (Jackson, 1968; Hunt, 1971). Each decision requires the teacher to possess dynamic skills of analysis and a keen sense of situation. Classroom teachers are engaged constantly in an environment where success requires fast, contextually-relevant decisions. The dynamic nature of “thinking as a teacher” is a professional attribute which demands flexibility, analysis, and perspective. Kennedy (1990) suggests that the approach historically taken to prepare teachers for making such decisions has consisted of a two-pronged approach: first, the development of a codified, theory-laden knowledge base, and second the development of useful decision-making skills for situation-based reasoning and analysis. Unfortunately, feasibility issues have generally dictated that these decision-making strategies be conveyed via a more formalized setting-one that lacks connection to any real context-resulting in what some refer to as “inert” knowledge (Risko, 1991). As Bruner (1996) states: “The challenge is always to situate our knowledge in the living context that poses the ‘presenting problem,’” (pg. 44). The use of cases may offset such concerns by offering a method of preparing teachers that most closely approximates the real-life environment of rigorous decision-making opportunities that classrooms afford.

A case is a situation-based narrative that requires an analysis of context and an understanding of the idiosyncrasies associated with real-world practicalities, presented to prompt a suggested action or implementation. The case study approach—though not an entirely new concept (Merseth, 1991)—has recently gained prominence in teacher preparation (Herbert, White & McNergney, 1992; McNergney, Herbert & Ford, 1993). Case-methods provide avenues through which the creation of a knowledge base and of an environment for contextual reasoning can be fostered. A case-study method challenges students to examine theories they have learned or are learning and to apply these theories to situations they may encounter in the future. Application of this method in preservice teacher preparation has been shown to bridge the gap between theory and practice (Sudzina & Kilbane, 1992). Although it is impossible for a case to address completely the complexity in teachers' lives, case methods may provide realistic environments through which various decision-making tactics can be applied and investigated (McNergney et al., 1994).

One of the advantages of using teaching cases-specifically, using teaching cases as opportunities for analysis and contemplation—is the ease with which a case fosters problem-solving and decision-making skills (Merseth, 1996). These skills include the ability to analyze situations and the corresponding multiple perspectives of those cases.
involved. A teaching case can assist the teacher to “think as a teacher would think” given the parameters of the case situation. Cases influence problem-solving and decision-making skills through the provision of vicarious situations through which educators can gain multiple perspectives and develop skills of analyzing situations from the viewpoints of those involved. Cases provide an excellent arena for the testing of ideas against given conditions—conditions generally agreed upon as critical attributes of the given situation as depicted in the case scenario. Finally, cases used as opportunities for analysis and contemplation encourage the use of technical skills and critical knowledge which are unique to the professional educator. In these ways, the teaching case can assist the student to more ably “think as a professional” given the parameters of the case situation.

**CaseNET: Web-based Learning through Cases**

CaseNET is a Web-based learning environment where teachers utilize the latest technologies to form communities of professionals who hone their decision-making skills via “slice-of-life” cases (see http://casenet.edschool.virginia.edu, for instructions on receiving a guest username and password). Students involved with CaseNET physically meet during regularly scheduled times at a designated site. Each site is staffed with an instructor, or team of instructors, who use case methodology to guide the students’ participation. The online component of CaseNET is comprised of the cases, discussion groups, journals and reference materials. The value of CaseNET lies in the successful integration of teacher development, the Web, and case methodology.

The characteristics of Web-based technology lend an element of realism to the use of case-study methods in teacher education that is otherwise unattainable in print materials. For one, the Web allows for a highly interactive environment-enabling more meaningful transactions among people than any other technology before. Teachers can work together through the WEB, unhindered by space and time boundaries. The Web provides a true multimedia experience—displaying information in combinations of text, video, and sound. This has been an important factor in the successful combination of case-study methods and Web-based technologies. The Web provides an environment through which multimedia cases—those combining various media to provide a richer representation of the situation at hand—are more easily provided. Multimedia cases have high face validity (Herbert & McNergney, 1995). The situations portrayed in the cases are realistic and close approximations of real-life. Therefore, the combination results in an environment which is more accessible and truer to real-life than any other medium through which real-life approximations may be offered.

CaseNET matches the inherent characteristics of certain types of communication tools with learning activities deemed useful for teacher development. Instructors are using technology with an understanding of what it is that students need to do to continue developing as professional educators and also with a clearer conception of what role they, as instructors, play in such an environment. For example, teamwork is an integral component of the CaseNET experience, since decisions in schools are rarely made in isolation. Participants are encouraged to cooperate within teams and to compare analyses across teams in search of solutions to real-life educational problems. In reaction to one of the cases, one teacher commented:

The teachers in this case didn’t always agree on ideas and ways of carrying out projects. This case showed me that teachers must work together and compromise on projects like this and let the students make many decisions in order for it to be successful.

Teachers are encouraged also to forge relationships with participants from other CaseNET sites and to use these relationships as further stimulus for continued reflection concerning case issues. Another student suggested that CaseNET “helped me in self evaluation, self-awareness, and in peer interaction. I find in conferring with other teachers regarding a student or issue, I am much more aware of the perspectives, side issues, etc.” In large part, both student and instructor are actively engaged in sharing, questioning, and directly experiencing the consequences of making teaching decisions.

We believe that masterful teachers reflect on life in classrooms. Reflection encourages teachers to think like professionals (Kleinfeld, 1992) through an increased power to reason (Sprinthall & Thies-Sprinthall, 1983). Problem-solving in this capacity is a direct result of teachers thinking about teaching as a composite activity-involving issues, perspectives, and possible courses of action—and making decisions based upon the best perceived consequences (McNergney et al., 1994). What emerges from this view of reflective problem-solving is the five-step process for analyzing cases around which CaseNET is centered. The steps in this process include: perceiving issues, problems, dilemmas, and opportunities; recognizing values and perspectives that drive actions; applying appropriate knowledge; suggesting an action one might take; and examining the possible consequences (McNergney & Medley, 1984; McNergney et al., 1993).

**Issues.** Cases are grounded in core issues and relevant facts. These issues are identifiable and provide the foundation for the interpretation of that particular situation. Issues may take the form of problems, dilemmas, or opportunities. Problems are issues that one may conceivably solve. Dilemmas are unique problems that have no apparent solution and, therefore, require some type of coping mechanism. Opportunities are simply occasions for improving on a situation which already appears to be
working well, as is. The value of identifying the salient issues contained within a case is perhaps best captured in the following student statement:

While students in other courses were making bulletin boards, we were dealing with real-life situations, ones that we will encounter in the field. This course helped me to realize the many problems that occur in schools and ways to handle those problems.

Teachers make decisions largely based upon the issues they perceive as timely and important. However, what constitutes “timely” and “important” depends upon situation and context. Therefore, merely identifying categories of issues is insufficient. What is necessary is a recognition of the types of skills necessary to distinguish important from relatively inconsequential. CaseNET provides an environment for honing such skills. As one student stated: “This course presented me with many new issues and helped me develop skills for how to deal with them.”

**Perspectives.** One reason for variability of what may be perceived as salient issues within each case is the fact that various perspectives play a key role in deciding which issues rise to the forefront and which ones are left, for the time being, unattended. One’s perspective is often heavily informed by the beliefs one holds about students, about teaching, and about the essential qualities of the content at hand. Teachers make decisions largely based on the interactions of these beliefs. For this reason, an essential component of the case analysis process is an identification of the perspectives and values held by each stakeholder with the case. In multimedia teaching cases, these stakeholders are often students, parents, principals, and other teachers.

Cases provide exposure to various school settings and to the myriad perspectives which are naturally associated with each situation. In so doing, students gain the ability to generate a mental image of each participant’s vantage point which the student may use to develop a more robust plan for action. CaseNET participants can draw on the critical perspectives of experts, as well as the professional knowledge of their peers through web-based discourse and repositories of information. These activities are deemed important to teacher development, and most if not all are absent from the more formal, decontextualized approaches of preparing teachers. As one student commented, “To see how people reacted to the situations in the case gives us a running knowledge of how things could happen and what we could do to change it.”

**Knowledge.** Knowledge is the component that distinguishes teachers as a community of professionals who know things that others do not. This professional knowledge is informed by practice, theory, and research that teachers may draw from and bring to bear upon the problems represented in each case. Such knowledge provides the foundation and support for the actions one may suggest as appropriate for addressing these problems. Knowledge resides in multiple sources. Printed materials, previous experience and theoretical pieces may be valuable resources for making informed decisions. The current that runs throughout each is the fact that knowledge is valuable when it is shared among like-minded peers. Solving cases in teams provides an environment where such peers may benefit from the knowledge held by each individual. Bruner (1997) suggests that: “There are things known by each individual ...more still is known by the group or is discoverable by discussion within the group; and much more still is stored somewhere else-in the ‘culture’...” (pg. 52). We agree. For this reason, CaseNET provides several avenues through which participants can communicate and share professional knowledge- through discussion groups, journals, videoconferencing, and other social technologies.

**Action and Consequences.** At some point, teachers are required to do something in their classrooms. The five-step process for case analysis suggests that, after considering the issues, perspectives, and appropriate knowledge, one might suggest a projected teaching action. In other words, if you were this teacher in this situation, what might you do? It is important to understand that, in most situations, there does not exist one “right” action. Instead, it is quite possible that there may be many defensible courses of action that one would possibly choose to address the issues embedded in a particular case. Such an understanding frees the teacher to begin considering varying courses of action she might take, given the situation presented in the case. Pragmatic teachers consider the likely consequences of their projected actions. This consideration combines both the projected positive and negative repercussions of chosen actions. As teachers become more experienced as professional decision-makers, they become more aware of the fact that not all actions turn out well, and not all decisions have the intended results. It is critical, therefore, for developing teachers to constantly remain aware of the potential consequences of their actions in real-life teaching situations.

**Conclusion.**

The elements of the five-step process described above should not suggest that each situation may be addressed in such a linear fashion. Indeed, context often dictates that one begin at one end and progress in the opposite direction, or even begin in the middle and jump around. The journey from one end of the decision-making process to the other is rarely a direct one, and effective utilization of the process with teaching cases must reflect this as well. We only suggest that, in order to foster a more meaningful system of making teaching decisions, both in-service and preservice teachers take into account each of the five factors delineated in the process. CaseNET is intended as an environment in which developing teachers may learn to “play the
game,” within the relatively safe confines of a case-study before making decisions in actual real-life situations. As one student recognized: “Everything we did in the course we will take with us to our future classrooms.” Another student offers the following:

The most valuable part of the course is the interaction with preservice and other inservice teachers. Our class discussions and on-line chats provided the most stimulating experiences. And it is such an eye-opener for preservice teachers and equally educational for inservice teachers to “see” the different ways each of us views a classroom situation. This course certainly offers a wealth of information on the subjects of teacher thinking and expert and novice differences.

A recent report sponsored by the Office of Educational Research and Improvement (OERI) suggests that the use of technology in schools may be a catalyst for the change that is occurring through a concerted focus upon the professionalization of teachers (SRI International, 1996). What we offer with CaseNET is an environment where this professionalization, fostered by case analysis and interactive technologies, is displayed in the quality of the decisions participating teachers make.

It might be said that education of the past attempted to create students as possessors of information. Today's education must create students as expert communicators and problem solvers. The availability and accessibility of information requires less memorization and more technical skill.

The best, most immediate opportunity to significantly expand our educational horizons lies in the development of the Internet as an education delivery and management tool. Much like the research from the late 70s and early 80s that sought to explore the benefits and justify the use of computers across the curriculum, a great deal of writing now outlines advantages of using the Internet throughout education (Ryder & Hughes, 1997). Such issues as how teachers can begin to use the Internet and setup custom World Wide Web pages for use in teaching are commonly found.

As discussed in Talley (1997), an interactive Web site is included in Pepperdine University's transition to a "virtual university" (p. 69) environment. Positive and negative aspects of learning in a school without walls are described and it is reported that the progression toward cyberspace seems imminent and inevitable. The infusion of e-mail, the Web, Internet-based education (IBE), and all types of telecommunications into virtually every aspect of teaching and learning is an immediate responsibility for us all. The issues are clearly "how," rather than "if"-how to implement, integrate, and utilize, rather than whether or not it is relevant or worth our attention.

Educators Use the Internet

E-mail is one of the more basic and widespread uses of the Internet yet and provides very important communication opportunities for teachers and students. Karayan (1997) examined student perceptions in electronic (e-mail) discussion groups. Although, students resisted the dependence on technology, they were more likely to participate positively in electronic discussions exhibiting more desirable behaviors. Likewise, there was a corresponding beneficial impact on class performance.

The latest buzzword, fad, or preoccupation in cyberspace is the World Wide Web, and for good reason. Not only can virtually any institution, school or educator have their own Web site, very often it is the student who is first to have and develop their own Web page. However, as outlined in Mandell (1997), the Internet offers much more than simply the World Wide Web (Information Systems: Compuserve, GEnie, Delphi, America Online, Prodigy, DIALOG, BRS/After Dark, Dow Jones News/Retrieval, Microsoft Network, CNN and more). These databases, service and retrieval systems offer what amounts to an "online knowledge bank" (p. 281) of information access to companies, organizations and individuals. However, in addition to academic networks (BITNET, USENET), most teachers are likely to be most interested in the direct interaction with students provided by e-mail and the Web.

Although "it appears that the Internet will form the foundation...of the 'information superhighway' that will eventually connect all schools, businesses, and homes" (Newby, Stepich, Lehman, & Russell, 1996, p. 133), it is not without its problems. As recently as two years ago, the Internet for teachers was described as being very rough around the edges. They do acknowledge that developments in user-friendly software for accessing the Internet which would simplify use.

Newby et al. (1996) also describe and support the use of e-mail and bulletin boards for students. This would allow students to communicate with each other and instructors both locally and across long distances. The communication can include everything from sharing information to transferring attached files. A full writing network can be established on the Internet where students share their written work with students at other schools, other classes, and even other countries. Also described are experimental projects where students link to other schools to share data and projects with other students and to conduct general research by accessing on-line database services to read or download information. The sharing of information by students can be extended to using the Internet to interface with local colleges to create a local area network for accessing K-12 student projects at the university and getting technical assistance from college professors and technicians (Gipper, 1997).

The Internet represents an opportunity to break away from being "limited to those potential participants who could meet in a single place at a pre-specified time."
(Burgstahler, 1997, p.61). Education in classrooms without walls (as described earlier) can now include traditional course components such as text and lessons (lectures, handouts, etc. stored on a Web site) and class discussions on e-mail (required contributions by student participants).

Other applications of traditional experiences suggested by Burgstahler (1997) include:

- a) student or teacher demonstrations (digitized video and audio distribution over the Web);
- b) guest speakers (anyone anytime via teleconferencing or e-mail contributions);
- c) library research (a dedicated course Web site, Web search engines, information databases);
- d) student assignments (when assigned via course Web site or email, and submitted via FTP or e-mail attachments, feedback and sharing among others is made easy);
- e) field experiences for preservice teachers (site visits with location local to student participant, student submits report via e-mail); and
- f) examinations (distributed via e-mail).

Other ideas include the creation and use of private “chat” rooms where students over long distances can meet for simultaneous group interaction. Also, more developed Web sites can allow students to take exams interactively over the Internet, online instead of via e-mail. Likewise, field experiences might also be conducted remotely with live video transmissions across the Web without the need to actually visit a classroom in person.

**Problems for Educators**

As the past 25 years of computer technology in education has demonstrated, there is virtually no end to real and potential problems inhibiting or preventing adoption and integration. Expense, training, education and of course experience are all limitations.

Newby et al. (1996) outlined a number of problems including the nature of the Internet as unregulated and unprotected for safe, productive and effective use by students. Education and teachers can become technologically dependent leaving the complete system subject to functional breakdown or failure. The lack of education and experience contributes to the very real potential for unproductive, superficial and impotent use of the quickly changing Internet.

Alexander, Crowley, Lundin, Mudry, Palmer, and Rabkin (1997) specifically addressed the issues of training for instructors. This author would suggest the more elaborate and global issue of computer education rather than the simpler or more ritualized notion of mere training. Other problems discussed include teachers’ need for extra preparation, extra flexibility, and their fear of loss of authority.

Not the least problem for teaching over the Internet involves the security of examinations. Of course a test can be distributed on e-mail or even posted on a Web site for students to access. As discussed earlier, interactive Web sites can administer tests on-line. But, confidentiality and dishonesty among student participants is still a problem. Bicanich, Slivinski, Hardwicke, and Kapes (1997) elaborate some issues for offering tests over the Internet. Most issues (e.g., cost) seem beyond the means of the average classroom. Nevertheless, important insights are discussed in detail. For example, test security may be handled by providing the test instrument(s) at specific times with passwords required and with the access of each participant recorded and traceable. This method probably verified the particular student computer or terminal involved but still may not have ensured the student-user’s identity. Thus, the problem continues.

**Suggestions for Educators**

Potentially the most important suggestion for teachers can be found in Davies (1997). From students’ journal writing to PowerPoint presentations, Davies emphasizes the need for advance planning. Teachers should have a clearly defined goal and planned approach when arranging students’ interaction with the Internet. For example, with just a little bit of advance research, teachers can target a small number of sites for virtually any topic to enhance the day’s lesson or to provide outside work for students as homework, projects or research.

Web sites often have useful links which connect to other sites with links which in turn link to more sites to continually provide an opportunity to explore an almost endless series of resources. There are a number of key Web sites which provide search mechanisms designed to find information on virtually any topic. These tools and other searching techniques can provide teachers with the means for advanced planning or may become the students’ tools in the learning activity itself.

Teachers can easily prepare their own relatively simple Web pages for information delivery and other professional activities. Such pages can be organized around courses, instructional units or topic areas to include special links to any desired sites right on the “home” page. Teachers’ Web pages can solicit information directly from the student and pass it back to the teacher. Students can view graphics, animation and even real-time video over the Internet all as fundamental components of or added embellishments to instruction.

HTML (hypertext mark-up language) is easy to learn and simple to use in constructing personal Web pages, at least at basic levels. However, new software programs, as mentioned above (Newby et al., 1996), provide easy to use authoring tools for designing Web pages in a WYSIWYG (what-you-see-is-what-you-get) format. Advancements in authoring tools will quickly make creating high-quality Web pages within virtually anyone’s grasp.

A MUSEUM WEBSITE THAT SUPPORTS PROJECT-BASED INTEGRATION OF ART AND TECHNOLOGY IN K-12 EDUCATION

Sherwood Dowling
National Museum of American Art, Smithsonian Institution

Mónica Sanjur
National Museum of American Art, Smithsonian Institution

Daryle Maciocha
National Museum of American Art, Smithsonian Institution

The Community Discovered is a collaborative project sponsored by the U.S. Department of Education’s Technology Innovation Challenge Grant Program. These grants are awarded for the purpose of developing and refining technological applications with the potential to make significant contributions to school improvement. The Community Discovered is one of 19 projects awarded Challenge Grants in fiscal 1995. This Challenge Grant, awarded to Westside Community Schools in Omaha is a project that links art and technology with integrated constructivist curricula designed to transform the education of rural and urban disadvantaged students. The project features a collaboration between Nebraska public school districts and Nebraska museums. The Smithsonian’s National Museum of American Art (NMAA), the University of Nebraska at Omaha (UNO) and Prairie Visions are also principal partners in this effort. The Prairie Vision Consortium was established by the Nebraska Art Teachers Association and Nebraska Department of Education (NDE) with support from the Getty Center for Education in the Arts, and includes over 90 public and private school districts in Nebraska. The Community Discovered builds upon and extends the impact of the Art and Technology Integration Project (ATI), conducted by Westside, Grand Island, the National Museum of American Art, and the University of Nebraska at Omaha. The ATI project received a two year grant from the Nebraska Excellence in Education Council.

In addition to Westside Community Schools, currently participating Nebraska K-12 school districts include the School District of Grand Island, Lexington Public Schools, Winnebago Public Schools, and Omaha Public Schools. These participants represent a diversity of students including significant African American and Latino populations. Urban, suburban and rural communities that feed these school systems are comprised of families with a broad range of socioeconomic circumstances. Further information on The Community Discovered can be found online at: http://communitydisc.wst.esu3.k12.ne.us

Basic Concept and Goals

The Community Discovered is a five-year project designed to link the use of technology and the visual arts with other subject areas throughout the K-12 curriculum with special emphasis on service to rural and urban disadvantaged students. A principal outcome of the project will be the development of curriculum models of engaged student learning featuring activity-based use of museum source materials made available electronically. The National Museum of American Art and the Nebraska partner museums are supporting the project in several ways. Digital images of museum artworks are being made available via the Internet with information about each work and model curricula using the work. The National Museum of American Art, the Joslyn Art Museum (Omaha, NE), the Sheldon Memorial Art Gallery and Sculpture Garden (Lincoln, NE), and the Museum of Nebraska Art ( Kearney, NE) are currently participating. NMAA has also produced a CD-ROM to provide access to museum art and information for students and teachers with personal computers, but without Internet access. Each summer NMAA hosts a one week inservice workshop preparing participating educators to use the visual arts and technology, to apply the constructivist theory of teaching and learning, and to integrate art resources into content areas. Throughout the school year, educators develop curricular units integrating Internet-based resources engaging students in an active learning process. The 1997 summer workshop presented materials thematically. Subsequently, participants were encouraged to join special interest groups organized by the same themes. The Websites featured in the subject poster session were developed by NMAA in support of the special interest group participants.
Special Interest Groups as an Organizing Metaphor

The themes and their special interest groups served multiple purposes. Educators who have adopted a constructivist approach are accustomed to organizing student projects around themes. Similarly, museum exhibitions often are organized around a thematic perspective. For example, educators participating in the post office murals special interest group reported the following curricular activities:

- Grade 2 - use of post office murals as a primary source to see how artists depict weather. Student creation of a mural depicting the 1980 tornado in Grand Island, Nebraska;
- Grades 3 & 5 - use of post office murals as a primary source to explore the social construction of local communities;
- Grade 4 - use of post office murals as a primary source depicting Nebraska history;
- Grade 5 - use of post office murals as a primary source to see how artists depict natural cycles such as seasons, life cycles, carbon cycle, etc;
- Grade 6 - use of post office murals as a primary source to practice analysis of point of view;
- Grade 8 - explicit investigation of the post office mural project in the context of an American History unit on the New Deal. Use of murals as a primary source to practice interpretation of concepts expressed by the artist;
- Grade 9 - in the context of writing and speech, use of post office murals as a primary source to practice skills of analysis and persuasion; and
- Grade 10 - in a World History context, use of post office murals as a primary source to investigate how art (particularly government sponsored art) reflects national concerns. Many of the above units also involved small group student mural creation.

With the above curricular uses in mind, the National Museum of American Art created a set of World Wide Web pages featuring the museum’s collection of post office mural studies. As mentioned above, a number of educational telecomputing activities were supported. Examples include:

- Keypals - After looking at NMAA post office murals, students were asked to "read" the images. A post office mural was assigned to each student and keypals were located near the location of the mural. Students discussed the mural with their keypals, examining issues of content and context. Students compared the information obtained from their keypals with their original analysis.

- Simulation - Groups of students from different school were created. Roles of artist, funder, local patron, etc. were assigned. Using e-mail, students role-played their assigned perspective to collaborate on what would be depicted in a community mural.
- Electronic Publishing - a number of school Websites were created documenting post office related student activities.

Similar curricular integration and telecomputing activities were organized for other thematic areas. Web pages supporting the project’s special interest groups can be found in the Education section of NMAA’s Website at: http://www.nmaa.si.edu

LESSONS LEARNED FROM NATIONAL PARK SERVICE ELECTRONIC VISITORS: IMPLICATIONS FOR K-12 CLASSROOMS AND TEACHERS

John D. Parmley  
Kansas State University

Art Hutchinson  
Hovenweep National Monument

Scott C. Parmley  
Kansas State University

During the early 1990’s Art Hutchinson, in his role as Park Ranger and Coordinator of Education/School Services at Mesa Verde, was exploring possible applications of the early digital information and multimedia technologies. The goal at that time was to provide new experiences for Park visitors on-site as well as for students across the Four Corners region. Hutchinson quickly recognized the initial challenges and opportunities being made available through technology and explored various strategies designed to help meet the needs of adult visitors as well as the young people who make up what is being described as the “Nintendo Generation” (National Academy of Sciences and National Academy of Engineering, 1993).

At the same time, John Parmley was exploring applications of the same technologies to enhance student learning experiences in school settings. Having spent his childhood years in the Four Corners region and being familiar with the Ancestral Puebloan or Anasazi culture preserved within Mesa Verde National Park, Parmley approached the Park administration about possible common interests. The initial conversations which began during the early months of 1992 focused on ways to convert still images into digital formats and make those images available on diskettes. Later the focus expanded to include video clips and sound files which could be distributed on compact disks (CDs). These early conversations along with those that followed provided the foundation for a very active partnership.

Consideration of Park’s Needs and Opportunities

The majority of the Partnership’s early activities were related to school-based activities. Then, in 1995, Art Hutchinson moved from Mesa Verde to the Superintendent at the National Park Service’s Hovenweep National Monument and John Parmley returned to full-time faculty status after seven years service as chair of an academic department. During this same time period, several significant advancements were made in computer technology and the Internet. The time was right to focus on opportunities to use technology to enhance Park missions.

During the months leading up to the events of early 1995, the authors spent considerable time examining the impact of emerging technologies on Parks and related sites. The authors found themselves engulfed in concepts such as the Internet, cyberspace, bits and bytes, chat lines and a host of other relatively new “techno words.” They watched with care as Parks developed Web pages and acquired electronic visitors who were able to learn a host of facts about various Park Service locations.

During the summer months of 1995, Hovenweep and Kansas State University (KSU) decided to launch the development of a multi-page Web site to provide additional services to visitors. However, implementing this project was not without substantial problems.

The Expanded Hovenweep Web Site

While many features make Hovenweep an intriguing place to visit, many of these same features became significant “off ramps” from the information super highway. Hovenweep is 41 miles from the nearest town and 12 miles from a telephone line. Thus, it became quite difficult for Hovenweep’s staff of two Park Service employees to establish a World Wide Web presence beyond what was being developed centrally by the National Park Service staff. At this point, Kansas State University stepped forward and offered to provide space on an existing Web server as well as the technical expertise to develop and manage the site if Hovenweep would provide the content expertise. Suddenly, the barriers of location, staff time, and round-the-clock management disappeared and the Official Expanded Web Site for Hovenweep National Monument was
launched. This partnership arrangement not only provided special opportunities for Hovenweep, it also provided opportunities for faculty and students on the KSU campus an occasion to have meaningful involvement in a highly unusual activity.

The partners began by identifying and developing images for the Web Site. They subsequently used Adobe Photoshop 3.0 and 4.0 to manipulate images. Adobe PageMill 2.0 was used to develop the HTML programming.

Lessons Learned by the Partners

One of the first lessons learned by the partners related to design and subsequent functioning of elements within the Site. It seemed important to have the appearance of the Web Site reflect the look and feel of the cultural artifacts preserved within the Monument. Based on that assumption, specific graphics were identified or developed to help tell the Hovenweep story. The initial plan for the Site included the following features:

- historical information,
- discussion of the various villages within the Monument,
- the location of the Monument,
- other important visitor information items,
- a link to the National Park Service Web Site,
- a Guest Book designed to provide an opportunity for visitor feedback, and
- a center for links to other regional and/or related Web sites.

Specifically, the design for the Web Site not only addressed the subject or primary content of the Monument, but also, reflected that primary content through graphics and the use of such applications as black background to reflect the solitude and sandstone textures on appropriate buttons and images to represent the sandstone blocks used by the early Native Americans who built the villages now preserved within Hovenweep.

With the basic design features in place, the partners began making a number of technological and design modifications. These early modifications involved testing such emerging concepts as a short sound file (800K) from an interview with Superintendent Hutchinson. Other related modifications considered during that initial year included an automated slide show option for visitors with additional interests and modification of several features to increase the overall loading speed of the site. The partners concluded that all modifications needed to be tested on their home computers which accessed the Web Site through local Internet service providers. If an addition or modification uploaded in a reasonable amount of time through typical modems and over telephone lines, they anticipated it would generally load in an acceptable manner for electronic visitors. Thus, uploading speed for all features and the need for balance between inviting graphic design and acceptable uploading speed were additional important lessons.

From the very beginning, the partners believed there was a need to provide a personal touch and interact with electronic visitors. The partners also needed to know what attracted visitors to the Web Site, what features they liked, and what features they found troublesome. One of the initial approaches to meeting these needs became the Hovenweep Guest Book. Electronic visitors were encouraged to provide their name, home location, e-mail address, and submit comments and/or questions. These e-mail responses were then forwarded to Hovenweep and KSU. Responses from electronic visitors supported the partners attention to the basic design concerns previously addressed. One early visitor stated concern when the home page for the Hovenweep Site took longer than 30 seconds to load. Input from electronic visitors became and continues to be an important source of decision making data. The partners had learned another important lesson as they considered the various messages they received through the Web Site. Their electronic visitors welcomed the opportunity for personal interaction and involvement in the Web Site.

Summary of Data provided by Guest Book Registrants

Even though technical problems occurred which kept the Guest Book from functioning from early June through mid September 1997, the peak visitation period, the site has accumulated 87 usable registrations.

Visitor Input. From the information provided by Guest Book registrants, the authors have determined that 53 (61%) of the registrant names were male, 30 (34%) of the registrant names were female, and 4 (5%) of those visitors who registered did not provide a name or the name provided could not be identified specifically as male or female. The partners are concerned about the difference between male and female registrations. They are continuing to examine the Web Site and comments from electronic visitors to determine if certain features attract male visitors more than female visitors.

The partners recognize that the current rate of registration for the Web Site is approximately one registrant out of every 40 visitors (2.5%). Visitor recommendations are viewed as important representations of opinions held by the greater electronic visiting public. However, with what seem to be quite low registration rates, care is always exercised before such recommendations are implemented. At the same time, commitments to the need for visitor input and opportunities for personal interaction continue to be viewed as very important and efforts to remedy the problem with the Guest Book registration feature have corrected the problematic situation. This modification should provide a greater accumulation of valuable data during the 1998 peak visitation period if the visitor registration rate approximates that experienced during 1996 when the Web Site received an average of one registrant for every 14 visitors (7%). The
total visitation hits recorded at the time of this writing exceeds 3600.

Location of Visitors. The 87 Guest Book registrations reached the Hovenweep Web Site from the United States (82 or 94%), Canada (4 or 5%) and Sweden (1 or 1%). Visitors from the United States reached the Web Site from 26 states and the District of Columbia with multiple registrations from Alabama, Arizona, Colorado, California, Georgia, Illinois, Kansas, Massachusetts, Minnesota, Missouri, New Mexico, New York, Pennsylvania, Texas, Utah.

Comments from Visitors. In addition to demographic data, visitors are provided an opportunity to share unsolicited comments or experiences related to their experiences with the Web Site and their on-site experiences while visiting the Monument. They also have the opportunity to ask questions and seek additional information. Among the initial findings were: 70% indicated the information provided through the Web Site was helpful and 42% indicated they wanted additional information about Hovenweep. Twenty percent of the registrations provided supportive comments about the artistic design of the Web Site. Those electronic visitors who indicated they had visited the American Southwest and Hovenweep offered comments about the Web Site capturing some of the look and feel experienced by the on-site visitor.

With two years of experience in providing the Web Site, and 13 months of experience with data collection through the electronic Guest Book, Superintendent Hutchinson has concluded the Web Site saves considerable staff time which would have previously been devoted to writing response letters and has reduced some actual expenses associated with mailing packets of information in response to various traditional mail requests. Through this technology, Park Service staff are able to provide rapid responses to paper and electronic requests while continuing to have personal interactions. They are able to track trends in visitation plans since more visitors are accessing electronic sources of information and using e-mail links to request specific trip planning information. The Hovenweep staff has observed a number of visitors arriving at the Monument with copies of the Web pages which they have printed to help them prepare for their visit.

Application of Lessons from Hovenweep to K-12 Settings and Teacher Education

The partners have continued to analyze data provided by electronic visitors and have the following findings and conclusions which they believe have implications for development of K-12 classroom learning sites as well as teacher education and professional development sites.

Design Issues

The partners considered the design recommendations offered by Milburn and Warner (1997) as they designed the Official Expanded Web Site for Hovenweep. Among the design considerations offered by Milburn and Warner are the following:

- The Web is a landscape view while printed paper is a portrait view.
- People get tired of reading sooner and faster on a computer screen.
- You have restricted control over type and layout.
- The Web is a multimedia experience.
- The Web is a hypermedia experience.

The partners also considered the context issues of Hovenweep as they developed separate pages for the history of Hovenweep, discussion of the various villages within the Hovenweep, recommendations for traveling to Hovenweep, and other important visitor information items. Thus, the technical, artistic, and contextual design considerations were addressed as integrated elements rather than separate issues. The authors recommend developers of Web sites for classroom use or professional development purposes approach development activities in a similar manner.

Personal Interaction and Involvement with the Web Site

The partners continue to be heavily committed to the concept of visitor interaction and involvement in the Hovenweep Web Site. Their commitment is based on a desire to provide meaningful experiences as well as access to information. They suggest we consider strategies used by Park Service professionals as they serve their clientele by making the learning and/or recreational experience as enlightening and enjoyable as possible. It seems that one of their secrets to success has long been their ability to help the visitor understand and appreciate the resource base over which they have responsibility. This assistance in enhancing the breadth and depth of understanding is referred to as interpretation, a concept that should be examined by K-12 educators as well as those helping to prepare K-12 educators.

With a firm belief that significant learning opportunities and experiences can be provided through uses of technology, the partners examined the work of The National Academy of Sciences and The National Academy of Engineering (1995) in a collaborative work titled, Reinventing Schools: The Technology Is Now:

Reinventing Schools: The Technology Is Now:

Children have always been explorers, born with the ability to interact and learn about the world. But children today are growing up in a different world. Those between the ages of 3 and 18--and especially children entering school today--are being hailed as the "Nintendo Generation." They live in a world that is increasingly interactive, communications intensive, and knowledge based. They are standard bearers in the technological revolution, having
never known anything else. Because of their ease in and with the information age, society needs their active involvement and interaction.

The changes going on today create an opportunity and necessity for a transformation in the way our schools function and our children are taught. If we cannot teach our children how to play and work in this world, our children will remain at risk. Education must be based on a model that is appropriate for an information-driven society. We must prepare children for a future of unforeseeable and rapid change. (http://www.nap.edu/readingroom/books/techgap/navigate.cgi)

The initial design of the Hovenweep Web site as well as the partners' recommendations for classroom-based Web sites has been influenced by the works of such authors as Means, Blando, Olson, and Middleton (1993) and Knapp and Glenn (1996). Means, et al. (1993) offer important considerations for using technology in education as they conclude:

The primary motivation for using technologies in education is the belief that they will support superior forms of learning. For this reason, theory and research in learning provide an extremely important source of ideas. Advances in cognitive psychology have sharpened our understanding of the nature of skilled intellectual performance and provide a basis for designing environments conducive to learning. There is now a widespread agreement among educators and psychologists ... that advanced skills of comprehension, reasoning, composition, and experimentation are acquired not through the transmission of facts but through the learner's interaction with content. This constructivist view of learning, with its call for teaching basic skills within authentic contexts (hence more complex problems), for modeling expert thought processes, and for providing for collaboration and external supports to permit students to achieve intellectual accomplishments they could not do on their own, provides the wellspring of ideas for many of this decade’s curriculum and instruction reform efforts. (http://www.ed.gov/pubs/EdReformStudies/TechReforms)

Knapp and Glenn (1996) report on the experience of teachers teaching with technology who say they:
- Expect more from their students and expect their students to take more care in preparing their work
- Can present more complex material (more complex ideas)
- Believe students understand more difficult concepts (concepts requiring critical thinking)
- Can meet the needs of individual students better
- Can be more student-centered in their teaching
- Are more willing to experiment
- Feel more professional because, among other things, they spend less time dispensing information and more time helping students learn (p. 17)

Finally, the partners want the electronic visitor to have a feeling of involvement and ownership. The Hovenweep Web Site was intended to provide a variety of experiences rather than simply transmit information. Efforts to accomplish this goal led the partners to include a variety of multimedia, provide an opportunity for visitors to receive an “electronic visitor’s certificate” which uses cgi technology to insert the visitors name into the certificate graphic, and the recent addition of the “Hovenweep Visitor’s Scrapbook” which provides opportunities for individuals who have visited on-site to share their favorite photographs with the world of electronic visitors.

In a classroom setting such involvement and ownership may be accomplished by providing opportunities for students to make contributions to a Web site which supports an area of the curriculum or by providing opportunities for students to design and implement their own Web pages to capture their interpretation of an area of the curriculum. Regardless of the strategy utilized, anything less than meaningful involvement of students will tend to be received as using technology to facilitate traditional teacher-centered learning experiences.

The authors recommend K-12 educators and those involved in preparing classroom teachers consider the recommendations of Singh and Means (1995) as they make decisions about developing classroom-based Web pages and other possible uses of technology:

If our goal is really to provide students with a different kind of education—structured around the provision of challenging tasks that can prepare them for a technology-laden world—the most relevant uses of technology are as tools and communication channels. Giving students experiences in selecting appropriate technology tools and in applying technologies such as word processors, spreadsheets, hypermedia, and network search tools to their work supports the performance of complex, authentic tasks and provides experiences that prepare students for the world outside of school. (http://www.ed.gov/pubs/EdReformStudies/EdTech/)

The Internet is currently perceived as a place to disseminate good practice for education and to promote lifelong learning throughout the world. The Society for Information Technology and Teacher Education (SITE) has been in the forefront of these activities with a particular focus on the professional development of teachers.

In 1996, Davis (1996) noted the important role for teachers and teacher educators as participating designers of Superhighways for education and training. The Society for Information Technology and Teacher Education has long been involved in the design, development and use of telecommunications resources to promote teaching and learning. These resources are now being joined on the Internet by a series of new and related Web sites that have particular foci - such as:

- Virtual Telematics Research Centre for Teachers
- Language Teacher Education
- Evaluation and Research
- Courses of Teacher Training

These Internet Web sites offer both similar and contrasting approaches to disseminating useful information for teachers and students and should be of particular interest to the SITE membership and to those who host and contribute to Web sites around the world. Several teacher education sites will be introduced in this overview, including:

- InSITE, the Information Network of the Society for Technology and Teacher Education
- SITE's international section of InSITE
- T3Centrum for teacher training across Europe
- ITTE's planned Virtual Research Centre for teacher education.

**InSITE**

The evolution of InSITE, from an early text-based Internet resource for teacher educators interested in the use of information technology, to a comprehensive Web site, is described by Robin, Bull, Bull, & Willis (1995) and Boger-Mehal, Rosa, & Nonis (1996). Originally set up as the Teacher Education Internet Server, the TEIS, was a collaborative effort among the Society for Information Technology and Teacher Education, the University of Virginia, and the University of Houston and was originally accessible only via gopher and Telnet Internet resources. With the widespread growth of the World Wide Web, InSITE was transformed into a more accessible Web resource dedicated to exploring ways in which the Internet can be used both to benefit teacher education programs at colleges and universities around the world and to support K-12 staff development technology initiatives. The mission of InSITE is twofold:

1. to serve as an online resource or clearing house that offers both text-based and multimedia materials related to the integration of technology in teacher education, including staff development; and
2. to explore how educators from various content areas and at various locations can collaborate over the Internet to discuss important issues and develop innovative ways to utilize technology in the field of teacher education and staff development.

InSITE continues to evolve as the use of educational telecommunications technologies grows and teacher education programs seek new ways to integrate these technologies into their training.

**InSITE International**

InSITE International has been developed specifically as the international section of InSITE. It seeks to provide a collection of materials, online discussions and links to other teacher education services and resources outside North America. It's aim is also to promote international collaboration between teacher educators and the classes with which they work, both inside and outside the USA and encourage and support teachers, teacher educators, and administrators in the use of Information Technology to meet their needs.

**T3Centrum**

The T3 Centrum is also a Web site for teacher education. It has been created as a central resource to support the European project "Telematics for Teacher Training" (T3).
The project is creating courses for the training of teachers through information and communication technologies, so the T3Centrum aims to enhance collaboration, teacher education courses, and dissemination. Although the project ends in December, 1998, it is hoped that the collaboration and support will continue and spread across Europe and the world. Already the T3Centrum contains resources and courses for teachers of mathematics, science, language, and technology and for librarians working with teacher trainers.

Virtual Research Centre

One of the plans for expansion to support teacher education on the Internet is for a Virtual Research Centre on the Internet. In autumn 1997, the UK Association for Information Technology in Teacher Education held its third Research Conference, in memory of Brent Robinson in Cambridge. The Association has agreed that these presentations may be placed on the Web to create a forum and resource to promote research and evaluation of IT in education. This may be linked with the SITE monograph and resource to promote research and evaluation of IT in presentations may be placed on the Web to create a forum and resource to promote research and evaluation of IT in education. This may be linked with the SITE monograph edited by Waxman and Bright (1993), the two international journals in the field, the Journal of Information Technology for Teacher Education and the Journal of Technology and Teacher Education, as well as a proposed book.

In Europe, a very creative site has been developed by Ronald Soetaert and Guy van Belle for language teachers. The site uses Robinson Crusoe in its many forms to challenge teachers of many languages (Soetaert, Top, & van Belle, 1995). Ronald and Guy are now developing a major site for language teachers across Europe in conjunction with the Telematics for Teacher Training project's T3Centrum mentioned above.

Michelle Selinger has developed expertise and research into online learning by student teachers using First Class computer conferencing that was implemented by the UK Open University's course for students teachers (Selinger, 1996). Michelle is now implementing a First Class Computer Conference across the UK form her post in the University of Warwick where she leads a course preparing teachers of IT.

Summary

It is obvious that the Internet and the World Wide Web offer valuable resources for teacher education programs, preservice teachers, practising teachers, and indeed, anyone interested in gaining knowledge related to teaching and learning. The "World Wide" nature of the Web is also obvious as more and more countries are understanding and promoting the power of the Internet as an educational force. We are certain that newer and better methods for world wide collaboration and interaction will be developed, tried, and evaluated and that these methods will lead to the further enhancement of teacher education with information and communication technologies.

Acknowledgments

The T3Centrum is supported by the Telematics Applications Programme of the EC DGXIII_c.

Language Teachers OnLine project is supported by the EC DG XXII.

InSITE is supported by the University of Houston, the University of Virginia and Exeter University.

A MODEL OF INTERNET USAGE FOR COURSE DELIVERY

Gary M. Galloway
Indiana University Northwest

In the world of limited funding, where teachers' needs always seem beyond their resources, the Internet is being used to expand educational opportunity. The Internet is not specifically designed to meet the needs of teachers or of education. The Internet is a network of networks, and it is up to educators to create educational opportunity and bring the education to the Internet. Teachers are quickly realizing that the Internet is a tool with unlimited possibilities for supplementing managing and delivering whole courses.

To improve teacher training, the following model was developed to summarize and categorize teachers' levels of current and future Internet usage in teaching. Educators have embraced the use of technology in education to better "challenge the bright and more effectively engage the less able" (T.H.E. Journal, 1997, p. 8). People are gaining access to the Internet at a record pace. The Department of Education (National Center for Educational Statistics, 1996), ran a survey that showed over 50% of U.S. schools have access to the Internet. That figure rose 15% between 1994 and 1995, and the Clinton Administration has urged a national commitment to have all classrooms and libraries connected to the Internet by the year 2000 (Grabe & Grabe, 1998). This model of Internet usage will hopefully better prepare teacher educators to help inservice teachers learn to use the Internet to support their courses.

Three levels are determined by how the Internet is used educationally by teachers. Grabe & Grabe (1998) indicate that a theme of technology use in the classroom creates the need for students to have an active role in order to benefit from that technology. Traditionally, an active learner may manipulate information to help in building their own personal understanding of content, but for the Internet to be helpful, its use has to be structured and its presentation integrated for specific content. Simply exposing students to information does not ensure that learning will occur. At all three levels of Internet inclusion, the student is subject to an environment whose value to the course is completely determined by the teacher. And so, this process requires both active students and active teachers.

This three-level model is derived from the principles of two mutually exclusive instructional approaches: explicit and implicit teaching. These two instructional approaches account for the most common teaching practices (Mercer, Lane, Jordan, Allsopp, & Eisele, 1996). Level One Internet use includes an explicit approach exclusively and Levels Two and Three use an implicit approach. The transition from Level One to Level Three is based on the increase of student interaction with the Internet and course content. Both instructional approaches are "needed to address the needs of students in a diverse classroom" (Mercer & Mercer, 1998, p.142). It should be noted that Level One and Level Two are intended as supplementary to traditional course structures and not intended to provide a complete course. Level Three may include entire courses offered on the Internet. Everything from electronic mail between teachers and students to interactive Web pages for full course delivery and beyond is described in terms of this three-part model.

Level One

Level One use of the Internet focuses on supporting a traditional classroom setting in two areas: management and instruction. "Management" ranges from course support material (syllabi, reduction of paper copies, etc.). "Instruction" encompasses the direct interaction between content (from the teacher) and students. Typically, the management of a course is a tedious and cumbersome process. The mountain of paperwork each teacher is under continues to grow and takes away valuable instructional planning time. This process is also difficult for the student who follows this paper trail. One option for using the Internet for management is to create a course Web site that can automate much of the process. This site can contain almost anything that an instructor deems important to the course. The result is increased efficiency. The student can access information from anywhere and at anytime by simply getting online. This access allows the student to track changes or updates and better follow the flow of the course.

Level One involves explicit instruction where the teacher is more directly involved. The teacher will guide the student to the information on the Internet. Discovery by the student will be controlled by the teacher and by the

Telecommunications: Systems and Services — 1207

1212
structure of the content on the Internet. This requires that a teacher’s preparation include scouting the Internet to find information that relates specifically to the content. Davies (1997) has indicated that advance planning for Internet use is important.

There is no creating or shaping of the Internet at this level. The teacher simply maps an activity and makes use of the already existing Internet. Students are exposed to skills and concepts in a clear and direct fashion in order to promote mastery. The approach is one of explicit teaching where the teacher and the Internet serve as the providers of knowledge. This level of use does not require that the student have any knowledge of computers beyond that of a “point and click” ability because the teacher takes the student to the information.

The Internet is analogous to a library where the teacher takes the student into the library and directly to a book (Level One). The Internet also serves as a provider of knowledge because the content on the Internet is authored by someone other than the teacher. Just like reading a book, viewing the Internet leaves the viewer subject to structure and content choices of that author. If the teacher assumes the students have some Internet access, the teacher can create a list of specific Web addresses (URLs, or uniform resource locators) to visit and specific things for the student to do. This is much like a directed worksheet where the Internet is the medium. In the library analogy, this would involve identifying the call numbers for specific books and using these numbers to locate the books. Using the card catalog is a system that is a bit more complex and the activity of using the card catalog moves us beyond Level One use and into Level Two.

E-mail can be used for students to contact the teacher and other students in the same course or around the world. The introduction of electronic mail to this level marks a change in the type of interaction the student is having with the Internet, but when this interaction takes the form of communication at a non-instructional level, it remains a Level One use of the Internet.

**Level Two**

Teachers’ usage of the Internet reaches Level Two when they use the Internet in the actual delivery of instruction (as compared to merely supporting instruction with additional content). The teacher can use the Internet to deliver course activities (assignments, collaborations, etc.) to students that have traditionally been provided on paper or a chalk board. At Level Two, this is done with an implicit approach to instruction. This means that the teacher becomes a facilitator of knowledge and creates situations where students can discover the content and create their own meanings. This is to say that the learning is somewhat self-regulated and the teacher assistance is more indirect. Teachers can use the Internet in two ways to accomplish this. First, they can have students make use of Internet tools to explore content and second, teachers can create actual lessons on the Internet.

Teachers can provide assignments directing students to use a Web browser to explore specific Web sites and e-mail to learn course content. The browser is equipped with a “bookmark” tool which gives students the ability to keep track of relevant places as they move through the Internet. There are also search engines that improve one’s efficiency in moving from place to place on the Internet. Chat rooms are available for online collaborations with other students, the teacher, or possibly an expert in a certain content area.

Some students are likely to have difficulty using these tools at first. Teachers may begin by modeling the use of these tools for the students to observe. There is a good compromise between teacher modeling and a completely independent student usage. The teacher could create a simple Web page with specific instructions of tool use, URLs, or even links to existing Web sites. This is designed to improve the students’ ability to explore rather than teach content. The more the students use this technology, the more proficient they will become. All that is left is for the teachers to use their imagination in creating assignments and activities (i.e., searching for resources, collaborations, etc.).

Level Two e-mail usage finds students submitting assignments as attachments or directly in the message, receiving data and answering questions through the Internet. So, Level Two accounts for e-mail usage expanded to involve instructional issues beyond the simple forms of casual communication. Grabe & Grabe (1998, p. 14) provide a list of e-mail project categories from Harris (1995) to help structure instructional activities. They are listed and described here to help generate ideas for Level Two usage of the Internet:

- **Interpersonal Exchanges** - “talk” among individuals, between an individual and a group, and among groups. This can be a Level Two usage by making the “talk” questions about content.
- **Key Pals** - unstructured exchange among individuals or groups; e.g., exchanges to develop cultural awareness or language skills.
- **Global Classrooms** - study of a common topic and exchange of accounts of what has been learned; e.g., themes in fairy tales.
- **Electronic Appearances** - e-mail or chat interaction with a guest, perhaps after some preparation; e.g., local engineer responds to questions from students in a physics class.
- **Electronic Mentoring** - ongoing interaction between expert and student on a specific topic; e.g., college education majors offering middle school students advice on class projects.
• Impersonations - participants interacting "in character"; e.g., correspondence with graduate student impersonating Benjamin Franklin.
• Information Collections - working together to collect and compile information provided by participants.
• Information Exchanges - accumulation of information on some theme; e.g., recycling practices.
• Electronic Publishing - publication of documents based on submission by group members.
• Tele-Field trips - shared observations made during field trips.
• Pooled Data Analysis - data collection from multiple sites, combined for analysis; e.g., cost comparison of gasoline.
• Information Searches - problem solving based on clues and reference sources; e.g., identifying state landmarks or cities in response to a progression of clues.
• Electronic Process Writing - posting written work for critiques before revisions; e.g., composition students commenting on classmates' papers.
• Sequential Creations - working on sequential components of an expressive piece; e.g., adding a stanza to a poem.

The Internet is a tool that has no inherent or required mode of application. The role of this technology in education is the responsibility of the teacher. Teachers can provide entire lessons on Web pages. This can be done with descriptions of assignments, explanations, concepts, examples, and illustrations. This is where a teachers' Web design skills or Web support personnel become important factors in quality and feasibility of creating lessons on the Web.

The teacher needs to become familiar with the world of Web-page construction. It is fair to say that almost anything a teacher would like to include in a lesson is possible, and there are so many Web-page editors available today that the process can be fairly automated. In fact, lots of software that teachers may already use in preparing lessons provides the option of being saved in an HTML (hypertext markup language), Web-ready format. This means that many teachers may already have much of the ground work completed for learning to prepare their own Web pages. To make more intricate Web pages and take full advantage of the tools available, it can be as simple as choosing a Web-page composer and learning it. The Internet would be a good place to search for one because many are available as freeware or shareware. This would allow the beginner to download one for free or for a small registration fee.

Learning Web construction may be viewed as programming in hypermedia, usually with a very user-friendly word processor-style editor or a relatively simple authoring language, such as those found with Toolbook or HyperCard.

Level Three

This model has first accounted for increasing student interaction with the Internet and course content. The second focus has dealt with educational philosophy (explicit/implicit roles). Level Three is an extension of the same phenomenon where students are even more dependent on the Internet for course content. Level Three finds complete courses offered and received through the Internet where teachers and students interact with each other and the material exclusively via technology. Level Three involves a greater technical function of Internet tools for interactive lessons, online assessment, real-time collaboration, and more.

The length of a Web-based course (WBC) tends to take twice as long as a normal course. Generally speaking, the time for development planning takes longer as well. One must make many pedagogical decisions about the course. It seems that the most organized teacher (regarding lesson content) will be able to make the easiest transition to a complete WBC. One suggestion is that teachers develop one WBC lesson or unit at a time to make the transition more gradual. This model exemplifies the details of a gradual transition.

At this level, having some form of technical support can be a very crucial element in the success of a WBC. It is important to note that e-mail and e-mail attachments will, most likely, become an important part of your course. This will be for communication, assignments, projects, assessment, etc. Look at any branch of the course and e-mail may be seen as having a role. One problem to anticipate is the finicky nature of file conversion that is inherent in e-mail interaction. There are ways around most of the problems that might be encountered, and most of those are probably not too complicated. Consult your technical support department.

At this point, there are no requirements or essential features that must be included for a WBC. One should still consider issues of course quality, from the perspective of the student, when developing the course. One quality issue is whether or not something more than a mere tutorial is being developed. To ensure that this happens, it seems important to focus on the interactivity of the course. Discussions are a nice way to do this. Many use asynchronous discussions via e-mail, which has the advantage of convenience. Another way to do this is through online discussions (chat sessions) done in real-time. Scheduled and assigned by the teacher, he or she can then directly participate and thus help drive the discussion. Many teachers have said that this process was invaluable. It even gives teachers the opportunity to get to know the students. Verifying the identity of the student can be a concern. Is the person taking the test the same person as the one doing the homework or participating in the discussions? The chat
sessions help the teachers identify and learn the students better.

Another quality concern is whether or not the technology used in the WBC is of high or low technology? It seems fair to say that a teacher wants as many people as possible to have access to their course. That prerequisite dictates that the course should be developed closer to the low end of technology since many people are always playing “catch up.” This will surely be a point of constant debate and cause the WBC designer to continually work on revising the course.

Summary

From the teacher whose goal is to increase efficiency, to the teacher concerned with designing a Web-based course, the three-level model structures various types of instructional use. Recognizing that such an organizational system includes a large degree of overlap, all levels include teachers using the Internet to improve instruction. Teachers make use of the Internet incrementally through the use of this model by progressing through the three levels. It is suggested that if the ultimate goal is to develop a WBC (time permitting), that it be done in a modularized approach, one unit at a time.

To help instructors focus on planning a list of ten ideas/issues for the development of a WBC include (in no particular order):

- Identity of student & passwording
- Time - course planning, course length
- Online discussions
- Technical support
- Assignments & activities
- Content
- Student access
- Copyright issues
- Technology - hardware & software
- Testing and assessment

Understanding how and at what levels the Internet may be implemented into education is a first step that will better enable us to meet specifically identified goals and objectives. As teachers are trained in the use of telecommunications and the Internet, this model can direct their study from beginner level through becoming independent distance educators.

In a popular New Yorker cartoon, a dog sitting in front of a computer says to another dog: "On the Internet, no one knows you're a dog." It is true, no one will be recognized by race, nationality, gender, or disability while surfing on the net. The Holmes Group (1993) called attention to the importance of technologically rich field sites for students to practice their teaching. Pre-service teachers must see how technology is used in school settings and have opportunities to practice teaching using these technologies. The Internet provides rich information for teaching as well as current research on effective curriculum and teaching strategies. Students can participate in electronic discussion forums that give them the opportunity to provide critiques and to share URLs identified on the Web.

Romiszowski (1994) reports that e-mail is more interactive than most other computer-based products. Student teachers view posted messages from other students, post their own messages, and respond to messages from others. Student teachers communicate with other students and view personal home pages and are able to maintain communication with university supervisors. They also apply technology skills as they search for sources for teaching strategies and lesson plans. While many students complete projects at their assigned school site, others use personal Internet applications or services in libraries or other settings. Class information, announcements, and schedules are posted with relevant information regarding meetings or deadlines for projects. Direct links are provided for students to preview teaching materials on the net. As student teachers move through the semester, they work through Russell's (1996) six categories of technology: awareness, learning the process, understanding and application of the process, familiarity and confidence, adaptation to the contexts, and creative application to new contexts. With the use of the Internet, parents, students, and teachers from all over the world can respond, communicate, and exchange ideas, post questions for discussions, create project Web pages, and even conduct surveys, enrollment, and examinations online.

**Online Survey, Enrollment and Examination**

In teacher education, staff and faculty often need to conduct surveys, provide enrollment procedures, and give student examinations in one form or another. Prior to the advent of the Internet and the World Wide Web, survey questions, enrollment material, and examinations were usually printed on paper and then sent to students via postal mail or handed to them in person. The whole process is somewhat rigid, inconvenient and time consuming. With current Internet technology, conducting surveys and enrollment online has become feasible and desirable. Allowing students to take examinations online is also technically possible, although some difficulties remain in terms of automatic grading of essay-type questions. The grading can be entirely automatic for single-choice or multiple-choice problems and for some simple answers.

Technically, the design and implementation of these three applications on the Internet all have similar features. Each of the applications involves some form of data collection. The main difference lies only in data processing. Four phases are in order: problem design, Web page design, implementation, and testing. During the problem design phase, the types of questions to be conducted should be determined, whether to use single choice, multiple choice, short answer, or long text. During the Web page design phase, the appearance of the forms should be addressed. The forms to be filled out by the students should be user-friendly, well organized, and suitably sized. The implementation phase involves the actual writing of the Web pages including forms and computer scripts for processing the data to be collected from the Web. Testing, though tedious, is an important step before the Web pages are posted on the Internet. In the following, we present a project that involves the design and implementation of an enrollment system for student teachers to register online. This system is already in use by the Office of Professional Education Services at Emporia State University. The techniques for developing online survey and online examination systems are similar.
to those involved in this project and, therefore, will be omitted.

**An Online Enrollment System**

**Project Description**

The Teachers College at Emporia State University in Kansas is now utilizing Web technology for automating the application procedure for student teaching. In previous semesters, students completed a five-page application using a typewriter or word processor. Students now demonstrate their technology skills through an electronic application process. The program can be accessed through any Netscape or Microsoft Internet Explorer Web browser. By completing an “Intent to Student Teach” form that includes the social security number, students gain access to the Internet program. Students enter information such as the list of courses taken, the requested districts for placement, a letter of introduction, and other personal information needed to make the placement. This process gives students another opportunity to apply technology skills and at the same time automates the application process. Students can apply at any time and at any place where there is an Internet connection, whether that be a university lab, wired dorm, or home computer.

**Background Knowledge**

Before describing the enrollment system, we shall briefly explain the general concepts and some of the key terms that are important for understanding the process involved in this project. Refer to Buhle, et al. (1996) and Stanek (1996) for more details.

- **Client-Server Model**
  Web technology is based on the client-server model in which the client makes requests to the intended server for services and the server provides such services for the requesting client. In our case, the client simply refers to the browser used by the applicant to access the Web pages and/or to enter the data for registration, and the server refers to the program that serves the Web pages and/or accepts the submitted data.

- **Hyper Text Markup Language (HTML)**
  Based on a subset of the Standard Generalized Markup Language (SGML), HTML is a specific language used to create and access resources on the Web. It uses tags and commands to format a document. Tags are also used to indicate functionality and to define services.

- **Hyper Text Transfer Protocol (HTTP)**
  HTTP is a set of rules that govern the communication between a Web browser and a Web server. It is regarded as the official language of the Web. An HTTP server, or a Web server, refers to a program that serves Web pages on a computer.

- **Common Gateway Interface (CGI)**
  CGI is the interface between an HTTP server and the resources of the server’s host computer. A CGI script refers to a program written in some suitable computer language such as Perl, Rexx, C, or Java, that accepts data from the Web server, performs necessary processing, and sends output to the server which will then report the results back to the client. The simplest client-server model for a Web client requesting a Web page from an HTTP server is shown in Figure 1, where no CGI script is involved in the process.

![Figure 1. The basic Web client-server model.](image)

For an online enrollment system to work, this simple model is not enough since one or more CGI scripts are required. Figure 2 shows a more general model that involves the interaction among the Web browser, HTTP server, and CGI scripts. With this background knowledge in mind, the design considerations and implementation strategies of the online enrollment system will be presented.

![Figure 2. A more interactive Web client-server model.](image)

**Design Considerations**

In designing such a system, we had three main requirements to consider. First, the system should allow student teachers to use a Web browser to enter and submit application data and personal information from remote computers connected on the Internet. Second, in addition to this basic capability, which is required in any online enrollment system, it should also allow the applicants to update their information at any later time after registration. This latter capability is especially convenient and useful since it not only enhances flexibility but adds modifiability by the applicants, encouraging them to update their data at their earliest convenience. Third, the system should allow only eligible students to register and should minimize the involvement of staff or personnel for maintenance.

**Implementation Strategies**

Our implementation consists of following three parts: The HTML document, 2) an identification database, and 3)
CGI scripts. The HTML document is created using the Hyper Text Markup Language and is grouped into three folders. The first folder stores the identification Web pages. The second folder stores blank application forms which include the applicant's demographic information sheet, teaching assignment request data, academic activities/experience, and statement of introduction. These two folders are common for all applicants. The third folder is initially empty and will be used by one of the scripts to create individual subfolders, one for each applicant. The data submitted by the applicants are processed using CGI scripts written in Perl. Two different scripts are implemented: one for identifying the applicants and for creating individual folders, the other for storing and updating the submitted data. The identification database is used by the script to identify whether the applicant is eligible for enrollment or not. This database should be and is the only part that need be maintained by the authorized personnel for adding and removing entries.

Application Procedure

The application of this system is divided into two stages: identification and enrollment. During the identification stage, an applicant is asked to provide his/her name and a password which are then checked against the identification database by the first script to determine if the applicant is eligible for enrollment. This stage is crucial since the system is to be used only for student teachers. Once eligibility is successfully determined, this same script also creates a private folder consisting of HTML files for this specific applicant. The system then enters the enrollment stage and prompts the applicant with application forms, one by one, asking for more information. These forms are designed as separate pages so as not to overwhelm the applicant with input. In other words, the second form will be available only after the first form has been submitted, the third form will be available only after the 2nd form has been submitted, and so on. Whenever a form is submitted, the HTTP server invokes the second CGI script to process the submitted data. Since the system is designed to allow the applicant to update information at any later time, the data submitted by the applicant are automatically entered into the form fields of the Web pages in the private subfolder to make them available to the applicant the next time the same pages are revisited. It is important to note that the subfolder belonging to an applicant is accessible only to that particular applicant.

Conclusion

According to Andres (1993), there are an estimated 50,000 teachers worldwide using the Internet. In the US, Internet access for schools ranges from 44% in Mississippi to 92% in Vermont, while many states, such as Kansas, hover around the national average of 70% (Education Week, 1997). The numbers are increasing on a yearly basis as President Clinton proposes to have all schools connected to the Internet by the year 2000. The continued growth of educational technology use in U.S. schools has prompted interest in strengthening technology literacy in teacher preparation programs. This interest is spearheaded by the National Council for the Accreditation of Teacher Education technology standards for prospective teachers that were developed in collaboration with the International Society for Technology and Education (ISTE:1992, NCATE:1994).

The importance of technology in teacher education was strengthened in recent months by the release of the 1997 NCATE Task Force on Technology and Teacher Education report, "Technology and the New Professional Teacher: Preparing for the 21st Century Classroom." The task force concluded that teachers must teach beyond the textbooks through applications such as Web technology to prepare students for an information-based society (Cooper, 1997). Studies of effective technology in teacher education emphasize that teacher education students must have opportunities to acquire understanding, skill, and confidence as they learn these new technologies (Niederhauser, 1996) and conventional methods of lectures and discussions are not sufficient for learning skills needed to implement educational technology (Dell & Disdier, 1994). Cognitive capacity for learning is greater when students are able to apply new knowledge to teaching situations (Watkins & Marsick, 1995). Teacher education must find ways to apply new technologies to classroom settings (McKinnie & Clay, 1995). Teacher education programs can use Web technology in various ways, including automated procedures that make existing organizations more efficient. The Web can also be used to support information technologies that expand knowledge and understanding (Zuboff, 1988).

The next goal of our project is to develop an electronic data interchange system where information from files can be merged and faculty can approve applications through a form-based system rather than by manual approval. It is also our goal to allow present and past cooperating teachers and other student teachers across the state and nation to participate in the bulletin board component. If teacher preparation programs are to produce teachers who are capable of using new computer technologies, preservice programs must prepare them. Only through extensive preservice applications will teachers acquire the understandings, skills, and confidence they need to use technology in their classrooms and prepare their students for an information-based society.

E-MAIL: COMMUNICATION OF THE FUTURE?

Lamar Wilkinson
Louisiana Tech University

Walter C. Buboltz, Jr.
Louisiana Tech University

Technology has been infiltrating our lives for years, but today technology is an integral and often necessary part of our lives, and many people cannot seem to function without it. Technology presents us with many new opportunities, which have potential advantages and disadvantages for the world and societies that employ technology. As technology has become a more integral part of our lives, so does it bring about changes in the humans that use the technology and the interactions that occur between individuals. The use of technology to communicate has brought about many advances in human communications, such as more frequent contacts, quicker delivery, and multiple contacts. However, while there are many advantages to using multimedia messaging (e-mail, faxes, video and data exchange), what are the costs that come along with its use? Today, multimedia messaging is becoming a natural part of business, education and interpersonal relationships. This form of communication was not part of the natural repartee of individuals in the past, individuals focused on face-to-face interaction when dealing with each other. What is the impact of using electronic messaging to communicate?

As technology continues to influence our communication so does it affect our very lives. This article addresses issues related to one particular type of electronic messaging, namely e-mail. E-mail is the practice of sending information from one computer user directly to other computer users, allowing nearly instantaneous transmission of messages, to anyone or any number of people with personal computers connected to the Internet or mainframe computers. E-mail messages may be sent around the globe, to the person in the office across the hall, or to the desk next to the one sending the message. To use e-mail, all an individual basically needs is a computer and the ability to connect to the Internet. Once these two basic requirements are met the skills needed to use this new technology are extremely easy to learn and master. They can even be performed by many children. The ability to e-mail a vast amount of people around the world almost instantaneously is due to the development of the Internet.

The Internet was originally devised as a way of linking a few university and defense laboratories in the 1960s, but has grown into a global network, currently connecting between 30 and 40 million people. It is estimated that up to 160 million people will be connected by the year 2000 (Weil & Rosen, 1997). The Internet is currently an international network linking hundreds of smaller computer networks in North America, Europe and Asia. Through the use of the Internet, computer users can connect and communicate with a variety of computers and their services with little effort and expense. Three of the main services currently provided by the Internet are: remote login, allowing an individual to log onto remote computers; file transfer, moving or sending files from one computer to another; and electronic mail. The use of e-mail through the Internet appears to be one of the fastest growing forms of communication.

Currently, little research has focused on the impact of electronic messaging, especially e-mail on the lives of individuals. In the recent past, as little as five years ago, many would state that e-mail only impacts a small portion of the population and thus was not worthy of investigation. However, with the rapid increase in the use of technology, the growth of the Internet, computer accessibility and ease of use, this may no longer be the case. The impact of electronic messaging (e-mail) on the lives of individuals should be explored to help understand the positives as well as the negatives of e-mail use. This is quickly becoming evident as such mainstream institutions as Time magazine documented the explosive growth of e-mail. From 1994 to 1996, the number of e-mail messages has swollen from 776 billion to 2.6 trillion, and is expected to top 6.6 trillion by the year 2000 (Gwynne & Dickerson, 1997). Additionally, the N.Y. Times recently reported on the changing of parental roles as technology increasing infiltrates the family at an ever increasing rate (Wire Reports, N.Y. Times, 1997). Taking these trends into consideration it becomes obvious that e-mail is proliferating at an astonishing rate and that we can no longer ignore its impact on society, families and the individuals in that society.

E-mail has become a natural part of many individuals lives, with some considering it a blessing, while others crediting it with creating a great deal of problems (Gwynne & Dickerson, 1997; Young, 1996; Parks & Floyd, 1996).
Before we can discuss the problems inherent in using e-mail or relying on e-mail as the only form of communication, it is necessary to outline how e-mail is currently being used in the world and how it may be employed in the future. First, e-mail is being employed in all areas of society due to the speed, ease of use, lack of effort needed to seek the receiver of the message and the cost. E-mail is also one of the few forms of communication where a single message can easily be distributed to a multitude of recipients. E-mail may also be viewed as a more efficient form of communication, where individuals do not have to seek out the receiver of the message, just send it to their e-mail address. However, just sending an e-mail to an individual does not guarantee that the message was received or that the person will respond to the message.

Currently, e-mail appears to serve two primary purposes in the world and society. First, e-mail is being used as a form of communication that allows individuals, no matter where they are located, to communicate with each other on a regular basis at a low cost. Second, is the use of e-mail to advertise and sell goods and services to individuals. Due to the ever-changing nature of technology and society, how e-mail may be used in the future is difficult to tell, but several possibilities do seem to emerge. E-mail will continue to grow as a low cost communication form that will link not only people in one society, but will lead to the connection of multiple societies. This linkage of multiple societies may eventually lead to a blurring of the distinction between societies and individuals of the world. It is possible that through the use of e-mail and other technologies (language translators) a new world society could emerge through the linking of societies and individuals within those societies. E-mail will more likely continue to grow as a business tool, not only to operate a single company, but to link several companies, all for the purpose of becoming more efficient and containing costs. In the educational realm, e-mail may become the mainstay of disseminating information to students and the primary form of communication between faculty and students. Finally, e-mail and it’s various forms may replace the telephone as the primary mode of communication between people who are physically separated.

In the use of electronic mail as an instructional aid, e-mail may provide students with greater access to faculty and peers, with the Internet providing access to a wider array of educational resources for students and faculty. Additionally, faculty may provide notes and materials to students through e-mail, allowing students to access this information at any time, for as long as the information is needed. This is in contrast to having only the notes that a student may take, material handed out in class, office hours and class time with a faculty member. Trapp, Hammond and Bray (1996) note that electronic messaging and the Internet can be used to foster independent learning activities that cannot be undertaken in a traditional course. D’Souza (1991) conducted research that showed that students using e-mail as a communication aid scored significantly higher than students using a more traditional mode of class information and communication modes. Tella (1992) found that with the introduction of communication networks and e-mail into the classroom, learning became more autonomous, small group work increased, and teachers became co-learners with students. Finally, observational data concerning 700 undergraduate students’ e-mail messages, showed that less than 50% of the messages addressed work-related concerns. For the most part, the majority of the e-mail messages served a purely social function with roughly 25% of the messages containing intimate content (McCormick & McCormick, 1992).

Although there are many advantages to using e-mail several disadvantages are inherent in the use of this technology. First, e-mail is a new mass media form, in which messages can come from a wide variety of individuals and sources, with little or no centralized control (Rafaeli & LaRose, 1993). This new form of communication blurs the boundaries between interpersonal and mass communication, raising new and exciting opportunities and potential risks for the way individuals relate to one another in the world (Lea & Spears, 1995).

Two popular views have been posited about communication and relationships that develop through the use of electronic media, especially e-mail. One view portrays relationships that develop through the use of electronic media as shallow, impersonal, and often hostile, with only an illusion of a sense of community (Berry, 1993; Stoll, 1995). The other view posits that electronic-mediated communication reduces the obstacles of physical locality, creates new, but genuine, personal relationships and communities (Pool, 1983).

Early research focused on the differences between small groups who communicated either face-to-face (FiF) or through computer-mediated communication (CMC). Findings have consistently pointed to the social disadvantages of CMC, positing that highly developed, positive personal relationships should rarely occur through the use of electronic media (Parks & Floyd, 1996). Culnan and Markus (1987) state that the differences that are observed can most often be explained by observing that many social cues are not possible through the use of e-mail and other electronic media. E-mail does not allow the receiver to focus on or perceive the physical context and nonverbal cues, such as vocal quality and tone, body posture and facial expressions that may be important to interpreting the actual meaning of the message. Thus, CMC would appear to have less information richness than FtF (Kiesler, Siegal, & McGuire, 1984) which may lead to a great deal of miscommunication. This in turn may lead to difficulty in developing personally meaningful relationships through
the use of e-mail and other forms of electronic media. Walther, Anderson, and Park (1994) pointed out that CMC is able to carry many aural and visual cues (included in the text of a message), but that they are restricted by the form of communication. The important point is not that personal and relational information cannot be communicated with CMC (e-mail), but rather that it may take longer to do so.

As research has moved from the laboratory to the field, studies have consistently shown the interpersonal side of CMC (e-mail). Users of CMC have reported on a consistent basis that they develop and maintain relationships, socialize, and receive emotional support via e-mail (McCormick & McCormick, 1992). Further evidence for this development and maintenance of personal relationships can be found in the popular press and some scholarly reports (Bock, 1994; Wilkins, 1991).

Although research appears to be mixed or inconsistent at the current time, the authors feel that e-mail communication and other forms of electronic media with their inherent shortcomings may lead to a variety of problems. Before we leap into this new form of communication and give up the more traditional face to face communication, the impact of these new forms of communication on humans and their interactions need to be examined. First, to develop a meaningful relationship, several prerequisite basic communication skills are required. These include the ability to vocally communicate, decipher the emotional content of messages and perceive and interpret nonverbal behaviors and cues. If individuals grow and develop in an age and society that is dominated by e-mail and other forms of electronic communication, individuals may not have the opportunities to develop and practice the necessary prerequisite skills to develop positive meaningful relationships later in life. This may already have become the case in many families. Several popular press reports (i.e., Wire Reports, NY Times, 1997) noted that children of today are part of the “techno generation.” An ever-increasing number of children have their own phone line, access to e-mail, chat rooms and the Internet. It has been estimated that the number of households that have access to e-mail will double by the year 2000. This change in communication and the patterns of behavior associated with it has lead to long-accepted family rules being challenged or twisted in new directions (Wire Reports, NY Times, 1997).

E-mail changes the need to see or interact with others on a personal level, as communication through an electronic medium can happen more regularly and frequently, decreasing the need for personal interaction between individuals. Many medical and psychological experts agree that one of the potentially most disturbing trends with the technology of today (e-mail and Internet use) is that it is addictive (Wire Reports, NY Times, 1997; Young, 1996). The development of the addiction leads many people to spend hours interacting with technology and other individuals through the use of technology, and not interacting with families and friends on a personal level. Young (1996) reported a case of a 43-year-old homemaker who abused the Internet, resulting in significant impairment in her family life. The authors contend that relying primarily on e-mail and other forms of electronic media for communication may lead children and others to not develop and maintain the prerequisite social skills needed to establish and maintain long-lasting meaningful relationships with other individuals. Clearly, further research is needed into how e-mail and other forms of electronic media, as well as technology in general will impact the development of individuals in a society.

A second major concern deals with the use of e-mail in college campus communities. If we view the college experience as an extension of the socialization process that was started in childhood, and continued in secondary education, e-mail use may have some deleterious effects. If students primarily rely on e-mail to communicate with peers and faculty, instead of face-to-face communication, they may not practice or even develop the social skills necessary to establish and maintain long-lasting personal relationships. College is a time for students to take many of the skills that were learned and practiced under parental supervision and for the first time try them out in an environment totally independent from their parents and family. This may even become a bigger problem if children were raised in a technology-rich family environment and never developed socialization skills. These individuals entering college are suddenly thrust into an environment where those skills would be needed to develop relationships with roommates, peers and faculty members. For example, many students who attend college live in dormitories and need to be able to communicate face-to-face and develop relationships quickly with roommates, hall mates and others that reside in the dorm if they are to thrive in these new surroundings. Secondly, due to the amount of time that may be needed to eventually develop relationships through e-mail, students may not develop relationships quickly enough in this new environment to provide the social support needed to help with the adjustment to college life.

Another possible problem that may emerge due to the use of e-mail is that college students will still be tied to their family of origin at a level that does not allow them to initially test their independence and later to become fully independent. Instead of making decisions for themselves, e-mail would allow college students to communicate with family members on a daily basis, thus allowing the student to be dependent on the family for guiding or making decisions for the student. In short, e-mail may interfere with the process of individuation that occurs as children leave home and establish themselves in society and the world.
Finally, the third area that we would like to address is the use of e-mail in the classroom. Although, there are many advantages to using e-mail in the classroom, and some results have been promising, there may be some unwanted consequences that need to be considered. First, messages sent by a faculty member to a student may not be received, or if received, may not be read or acknowledged by the student. This may lead to a variety of difficulties in class management. For example, a faculty member may send a message on Monday requesting a student complete an assignment or reading for class on Wednesday. The student does not check e-mail message until Wednesday just before class and thus has no time to complete the assignment before class. Secondly, by decreasing the exposure time to faculty members, through the use of e-mail, we may be decreasing the time that students are exposed to appropriate professional role models. Thirdly, by using e-mail to communicate with students we may be inadvertently blocking or delaying the development of mentor relationships between faculty members and students that have been posited to be important for the development of competent professionals.

Clearly, we have not yet fully realized the potential advantages and disadvantages of technology, especially e-mail. In reviewing the literature it would appear that most researchers have focused on the potential advantages gained through the use of technology and have ignored potential risks or disadvantages. With the constant pressure to incorporate technology into the lives of individuals and classrooms, the authors hope that this article highlights some of the potential risks of using e-mail and technology and that it spurs empirical investigations of the impact, both positive and negative on individuals. Only through sound empirical investigations can we make accurate conclusions about the impact and usefulness of technology.

MISMANAGEMENT BY E-MAIL

Barlow Soper  Lamar V. Wilkinson  C. W. Von Bergen
Louisiana Tech University  Louisiana Tech University  Southeastern Oklahoma State University

In the past, workers have been upset with the abuse of "management by memorandum," a practice in which administrators shotgun employees with mindless drivel or critical edicts that frequently would be served better by personal interaction with relevant individuals or by not being disseminated at all. Next came the fax, little more than an electronically transmitted memo. Today, a modern wonder of technology, the ubiquitous personal computer, linked to a local area network and/or the Internet allows an extension of the drawbacks of management by memo beyond what could have been imagined only a decade ago.

Enter electronic mail or e-mail. E-mail is the practice of sending information from one computer user directly to others, allowing nearly instantaneous transmission of messages, as fast as a person can type, to anyone or any number of people with networked personal computers or mainframe terminals. E-mail may be sent around the globe or to the person in the next office across the hall or at the desk next to the one sending the message.

Empirical evidence of the effects of e-mail are still sparse. Some studies have addressed e-mail as a classroom teaching aid (Allen & Thompson, 1995; Latting, 1994; Rosen & Petty, 1995), while others have explored its use as a research tool (Anderson & Gansneder, 1995; Kittleson, 1995; Mehta & Sivadas, 1995). As is to be expected with such new technology, controlled exploration of the effects of e-mail is in its infancy (Hinds & Kiesler, 1995; Latane & L'Herrou, 1996). Studies of e-mail's influence on management style and employees' attitudes and performance are rare in the professional literature (see Allen, 1995; Markus, 1994; Thach & Woodman, 1994).

However, as the use of e-mail has become common, the popular press has been responsive. For example Time magazine documented the explosive growth of e-mail. From 1994 to 1996 the number of e-mail messages sent has swelled from 776 billion to 2.6 trillion, and is expected to top 6.6 trillion by the year 2000 (Gwynne & Dickerson, 1997). These are numbers so huge as to be meaningless to all but federal budget managers. Also, the same article and others (e.g., McNichol, 1997) noted that the effects of the trend to more and more e-mail is far from exclusively positive. A study of Fortune 500 firms (cited in McNichol, 1997) found that 71% of their employees feel overwhelmed by the sheer number of messages they receive every day.

Problems with E-mail Communication

Though e-mail is a genuine boon to some types of communication, especially those at a distance, even on a global scale, it is ripe for abuse. E-mail has been likened to water cooler conversation (Gwynne & Dickerson, 1997) that can be overheard by hundreds or even thousands of people, without the sender knowing how the message is actually perceived or the reactions it elicits.

An important saving grace of direct, face-to-face communication is that we are forced to speak in an environment that allows, indeed even forces us, to be aware of how our message affects others. Even the telephone provides voice pitch, tone, and volume cues, along with rate of speech to aid understanding. We tend to alter our communication based on many subtle, nonverbal cues we perceive in our listeners. With e-mail, these cues are absent for the sender and the receivers alike. When we are forced to evaluate messages without adequate cues (e.g., e-mail), we tend to do so in a negative fashion (Maslach, 1979; Marshall & Zimbardo, 1979). Such messages readily can foster ill will among those who read them.

For the bottom line, ask most entertainers or teachers whether they prefer to perform before a live audience or a camera and we see immediately why production companies go to great expense to equip studios with warm bodies and teachers prefer to teach real classes. The key is immediate and ongoing feedback, which is lacking with e-mail.

Also, in a society fraught with evidence of increasing personal isolation (e.g., a larger proportion of marriage-aged persons choosing to live alone and doing so longer), the computer makes it easier than ever to avoid personal contact. We find ourselves increasingly sequestered at our desks, behind closed doors or within individual cubicles hunching over the keyboard. This is especially true on the
job, as has been so aptly satirized by Scott Adams of "Dilbert" fame (Adams, 1996). Noting e-mail's major contribution to this bothersome trend, even some computer companies, like multi-billion dollar Computer Associates International (CAI), have banned e-mail at certain times of the day and Charles Wang, CEO of CAI, states that, "It worked wonderfully. People are walking the corridors again talking to other people" (quoted in Gwynne & Dickerson, 1997, p. 88).

Also, record numbers of Americans (at least 35% of adults, according to Hellmich, 1997) are significantly overweight and out of condition (Rather, 1997). Each successive report suggests the problem continues to worsen. The widespread pursuit of passive or sedentary activities play a part in this problem. Untold hours a day staring at a computer screen, only vicariously interacting with the environment and others, cannot help but contribute to the continuation of this unhealthy trend. In discussing health issues, Vice President Al Gore recommended that we get up, physically move around, and spend more time personally interacting with co-workers (Hellmich, 1997).

There are other risks of heavy, uninterrupted computer usage. Increasing awareness of repetitive stress injuries such as carpal tunnel syndrome, including lawsuits directed at computer manufacturers (DEC Pays, 1997), have highlighted possible consequences of over-reliance on computers for simple, routine tasks. Intra-office communication is one activity that might better be accomplished by other means.

E-mail also contributes to what has been labeled "artificial urgency" (Howard, 1997). Since it is possible to send information, requests, and demands instantaneously, there is a tendency to expect results in the same manner, not considering the processes and time that might be required to produce a meaningful reply. As Howard puts it, "I e-mailed you four minutes ago. Where's my response?"

Another problem using e-mail for managerial communication was identified by a recent court ruling. E-mail can violate open meeting laws (Cauchon, 1997). This is an ongoing concern for elected officials at state and local levels who are frequently carefully monitored by concerned citizens and action groups. In fact, Cauchon reported that a Maryland community college returned $25,000 in computer equipment to avoid the possibility of such legal entanglements. The problem seems to appear when group e-mail discussions are initiated, appearing to function like a meeting.

Finally, since e-mail can follow us around the globe, including to our homes and elsewhere, we may be on the verge of a dangerous possibility of completely blurring the division between work and other legitimate activities such as leisure, marriage, child rearing, and personal development (Juersivich, 1997; Sloan, 1997). Many workers are familiar with this scenario: "You have a computer at home, don't you? So, let's get you online there, too." This may be followed shortly by, "Be sure to take your laptop or notebook on vacation with you, in case an emergency comes up." And, if we go along with these intrusions into other legitimate life domains, but do not respond quickly enough, we might hear, "Don't you check your e-mail? You need to do so at least every hour." Most of us need timeout-sanctuary from the firm, our position, professional responsibilities, the boss, subordinates, and/or the board. We may ultimately wonder why we should take a vacation at all, if work follows us anywhere and everywhere.

Factors that Encourage Management by E-mail

Given societal and systemic contributors to the trend toward isolation and sedentary pursuits and attendant problems, all of which over reliance on e-mail compliment and enhance, what are some personal and other issues that cause organizational leaders to rely on this impersonal means of communication? The reasons, of course, are as varied as the persons who have become dependent on the addictive e-mail drug. However, we can scratch the surface.

First, because of the lack of personal contact, e-mail allows those with a facility with words, but a paucity of substantive ideas, to hide from immediate interactive processing with others. Problematic or challenging e-mail replies may be deleted without being read and considered, cognitively or emotionally. Hence, management by e-mail is ideal for those who lack viable ideas, support for those ideas, self-confidence, or the conviction of their decisions and actions. All the while, these administrators are busy doing something at their keyboard-laden desks. E-mail is great for those who confuse a flurry of activity with productivity or results.

Also, e-mail allows a relatively safe existence for the person who has been labeled a "virtual manager." This is one who is defined as a "conflict avoiding character... [He or she] hides behind e-mail and uses it as an instrument of aggression, creating not only ill will but vast inefficiencies as well" (Gwynne & Dickerson, 1997, p. 89). E-mail is "perfect for managers who would rather do anything other than walk down the hall" (Gilman, quoted in Gwynne & Dickerson, 1997, p. 89), or we might add, who would rather do anything other than talk with people.

Because edicts and directives can be disseminated as easily as they can be typed or cut-and-pasted from other documents, it is easy via e-mail to bombard employees, often all employees, using a single macro-generated keystroke, with a barrage of material. Much of this material may be of questionable use to anyone. Even more, it is especially tedious to wade through, day after day, for those whom the messages are irrelevant. There are accounts of employees getting 200-300 e-mails a day (Gwynne & Dickerson, 1997)!
Further, since messages can now be delivered as quickly and haphazardly as they are conceived, at least by a moderately efficient touch typist, the old system of checks and balances, where an angry or aggressive admonition or unfeeling criticism would be allowed to cool because time was required to generate a presentable copy and make the delivery, is now gone. People can lash out as emotions strike them. Often writers only know that they feel better having gotten something off their chests, without a clue as to how those receiving such messages may agonize over them, nulling them over and reading between the lines, all the while ingesting massive quantities of antacids or seeking therapy. Such organizational knee-jerk e-mails may be likened to what can happen in domestic quarrels when a loaded gun is available.

Despite its drawbacks, lightning quick means of information dissemination are godsend for some types of communication. For example, it is great for announcements and interacting with people halfway around the world. It can also be a wonderful way to leave important messages and can even be set up to provide a modicum of security of communication, in some cases. But it is a lame substitute for two-way interactions with persons/employees 10-50 or even a 100 feet apart. We need not only the checks and balances in our interactions that eye-to-eye contact affords, but most of us need the physical activity which accompanies it, along with the serendipitous generation of ideas that occurs with such interactions.

**How to Deal with Virtual Managers**

As with any problem, human ingenuity provides answers to dealing with the virtual manager, some more proactive than others. In fact, a recent computer magazine outlined some of the more harmful in great detail in an article colorfully entitled, "How to use technology to get ahead, torture your enemies, and destroy the competition...without getting caught" (Jerome & Taylor, 1997). However, we believe there are positive means to thwart the e-mail addict.

Number one is to challenge the e-mail manager with personal replies whenever possible. Sit in the virtual manager's office or waiting room and actually demonstrate how to interact in person. In a pinch, even repeated phone calls can eventually get the message across. Also, do not underestimate the power of direct feedback during one-on-one contacts when they do occur. Let the sender know if either the medium, the message, or both seemed inappropriate. Let the sender know what you understood to have been conveyed from your perspective, and how you felt when you read the e-mail.

For example, "you said in your e-mail that... and when I read it, I felt ..." It can be helpful to have a copy of the actual e-mail in hand. Senders, when confronted with off-the-cuff missives, have been known to admit that they acted inappropriately, or responded out of anger, or the e-mail should not have been directed toward you.

If you decide you must respond to inappropriate e-mails via the keyboard, it may help to do so with a reasoned and logical reply, and get as many others as possible to do the same. Also, it may not hurt to keep copies of all e-mails and your replies, then forward them to the administrator's supervisor, if inappropriate e-mails continue. In some situations, higher level managers are not early adopters of new technologies, hence they may have no idea of the equipment they have provided their workers is actually being used.

**How to Avoid Becoming a Virtual Manager**

"Workers have all this incredible communications technology at their disposal, but often what people really want is two minutes face-to-face with a boss or co-worker" (Darrah, cited in McNichol, 1997, p.6). Believe it, remember it, and do it! Think before pushing the send button. Would you want to receive the message being sent? Also, do not send copies to everyone you know or everyone in the work setting. Who has a genuine need to know? For whom is the message irrelevant or worse? Just as one can make an all inclusive list of e-mail addresses attached to a "hot-key," so can one create more specific listings, directories that might represent more appropriate groupings of receivers of some messages, but not others. Finally, consider shutting down the e-mail system at regularly scheduled intervals. Otherwise dealing with e-mail might not just interfere with work, it may actually become the work (McNichol, 1997).

**Conclusion**

We have mentioned e-mail addiction in passing in this paper. However, it has been found that people can become addicted to e-mail (Juersivich, 1997) in much the same manner they can become addicted to virtually anything else, from gambling and video games, to running, eating, smoking, drinking, or sex. At that point we are no longer just "wired" into the computer network, but are "chained" to it. As one self-proclaimed e-mail addict put it, "To me the ultimate tool would be to have an e-mail terminal implanted in my head" (Juersivich, 1997, p. 9D). In reply, we say to such managers and workers alike, get a life! Talk with people and enjoy the personal interactions, as you nurture yourselves and your relationships. You will probably find you are also helping your job evaluations and your careers.

Internet Relay Chat (IRC) is an electronic medium that combines orthographic form with real time, synchronous transmission in an unregulated global multi-user environment. The orthographic letters mediate the interaction in that users can only access the IRC session through reading and writing. They have no access to any visual representations at all.

The 3-D virtual chat environment is available to computer users for interaction. In addition to all the characteristics that IRC has, the 3-D virtual environment supports users with three-dimensional graphics that represent an individual through the use of an avatar in a virtual environment.

The 3-D virtual chat room can be considered a community of practice. A community of practice is defined by Eckert and McConnell-Ginet (1992) as “an aggregate of people who come together around mutual engagement in an endeavor. Ways of doing things, ways of talking, beliefs, values, power relations—in short, practices—emerge in the course of this mutual endeavor” (p. 464).

It was initially believed that the discourse in the chat room would be linear, and therefore, easy to analyze. However, after collecting the data, the very complex nature of the discourse pushed this assumption to another important realization. Instead of focusing on the non-linear conversation (which is the type of discourses in the chat rooms) from a linear (real-life, face-to-face [FTF] conversation) point of view, the scope of the investigation was changed in order to explore the nature of discourse in 3-D virtual chat room where the visual images accompany the conversation. This is in contrast to IRC discourse, which does not allow users to benefit from visual images.

Thus, the research questions for this study were:
1. What is the nature of the context of discourse in a 3-D virtual chat room?
2. Is the 3-D virtual chat room different from text-only (non-virtual) chat room interaction in regard to invitations of speech acts?

Literature Review

The social interactions have been studied for over 25 years in order to find the patterns, routines, and the convention-based behavior in interpersonal interactions. Discourse analysis on real life, face-to-face interaction has been used to define the nature of interaction in terms of regulation (Burgoon, Buller, & Woodall, 1995; Cohen, 1996), and management (Rintel & Pittam, 1997). However, the developments in computer technology have introduced another aspect of interaction that takes place in a computer-mediated environment: computer-mediated communication.

The studies about computer-mediated communication (CMC) date back about 15 years. Early studies of CMC asserted that text-only CMC systems filtered out most social-contextualization cues and therefore greatly limited the interaction management possible for this type of social and interpersonal communication (e.g., Kiesler, Seigel, & Mcguire, 1984). However, in the early nineties, several research studies criticized this view for not considering the possibility of interaction adaptation that is claimed to occur in time by the users (Reid, 1993, cited in Rintel & Pittam, 1997). Recent research has also investigated the possible effects of interaction management strategies used in an interactive CMC medium (Rintel & Pittam, 1997).

The studies about the challenge of producing more contextually appropriate speech refocus attention on an important aspect of language use: speech acts. In terms of this study, a speech act is defined as a functional unit in communication. According to Austin’s theory of speech acts (Austin, 1962), the functional units have three kinds of meaning: locutionary or propositional, illocutionary, and perlocutionary meaning. A more detailed summary of Austin’s theory of speech acts, including a brief historical overview, appears in Cohen (1996, Ch.12).

The locutionary meaning is the literal meaning of the utterance or written text itself. These statements refer to what can be called objective reality on to the explanations or the declaration of the obvious situation. For example, if one person tells you that “I like dancing,” the locutionary meaning would concern one of his/her favorite hobbies or activities.
The second kind of meaning is illocutionary, which implies the social function of the utterance or written text. In this case, you not only share that information, but also infer something from the statement within its own social context. The illocutionary meaning from the previous example, for instance, would be that he/she wants to go somewhere and dance.

The perlocutionary meaning is the reaction to the received stimulus in a given context. Thus, if the utterance leads to an action of taking the person to a place to dance, then the perlocutionary force of the utterance would be greater than if the request is ignored.

In real life conversational interactions, such speech acts function as determinant factors in sustaining interpersonal relationships. Invitation is one of the speech acts that initiate such an interpersonal relationship. Based on the functions of speech acts, the performance of an invitation sets up a sequentially possible next act as either acceptance or a rejection. Many researchers conducted studies to determine the patterns and the norms of real-life interpersonal communication as far as invitations are concerned (Wolfson, D’Amico-Reisner, & Huber, 1983). The patterns and the norms in non-face-to-face environments are yet to be investigated.

Rintel and Pittam (1997) investigated the interactions that develop interpersonal relationships within a socio-emotional context and the strategies employed by the users throughout the interaction process. In their study, the writers compared the CMC interactions that occurred in IRC with real-life, face-to-face communication interactions during the opening and closing phases. They concluded that interaction management in IRC was similar to that in casual group FTF interactions in terms of the general functions of the strategies used, but that the content, structure, and ordering of the strategies are considered to be subject to adaptation.

Rintel and Pittam (1997) also proposed a framework for interaction management on IRC based on their research findings. These proposals will be quoted from their research:

- **Stage 1:** Server announces presence of newly joined user to all channel participants
- **Stage 2:** Exchange of exploratory/initiatory linguistic tokens- repeat as necessary:
  a. "blind," traditional mass greeting token to all users or
  b. traditional token to individual users (followed by other phatic communication or the use of another strategy) or
  c. statements or questions (interaction may follow with or
  d. without overt phatic tokens)
- **Stage 3:** Textualized exchange of conventional nonverbal contact gestures of greeting (as appropriate to relationship)- may not occur.
- **Stage 4:** Transition signals for moving to the medial phase (pp. 527-528).

Although there is research showing the framework of IRC interaction management strategies and the comparison between real life FTF interaction and CMC, there is no research investigating the nature of the context of discourse in a 3-D virtual chat room and how 3-D virtual chat differs from text-only IRC chat. In this research, the focus is on opening sequences and on invitations as being particularly important to the establishment and maintenance of interaction, and therefore the interaction management. This research examines the extent to which these are similar to, or different from, IRC interactions, and proposes an explanatory framework for this type (3-D virtual chat) of interaction management.

**Methodology**

The data were collected at a virtual chat room called Active Worlds which is a 3-D virtual chat room that enables users to interact via, typed messages while representing them with 3-D avatars. The interaction between participants was initiated and maintained through typing similar to IRC chat, but participants could see each other via their avatars on the screen as they typed during the interaction; moreover, their typed speech appeared above the head of their avatars.

There are two ways to participate in conversations in Active Worlds; either as a “tourist,” or as a “citizen” (the terms used by the channel owners referring to members and non-members respectively). The “citizen” participants also see themselves as being “a community” in their homepage. As a community, they communicate and interact with each other based on a series of practices in an endeavor. In the course of this “mutual endeavor;” they establish their “ways of doing things, ways of talking, beliefs, values, and power relations.”

The data collected for this study consisted of five 50-minute logs (written discourse) that occurred at the Gate, which is the entrance to the 3-D virtual chat room. This place was selected because it is a location where everyone has to stop before entering a chat session. The Gate functions as a social gathering room where people initiate conversation, meet each other, and invite each other to other places within Active Worlds. This function of the Gate was the ideal location to look at this community of practice. Yet, there were some disadvantages, too. Since all users stop at the Gate, there was no stability with the users. At any time, a new person could join the conversation. Second, people were free to choose a nickname for themselves and could change their nicknames at any time. Thus, it was impossible to provide any personal information about the participants such as, how many people were in the study, how old they were, their gender, etc.

In the Active Worlds, programmers post statistical information about the daily use of the resource. For the previous three weeks, the peak times for the Gate were reported by the program developers to be weekends.
between 12:00 to 2:30 p.m. Therefore, it was decided to collect the data on three consecutive weekends between 1:00 to 1:50 p.m., to ensure a relatively large amount of observable interaction.

As a qualitative form of analysis was being undertaken, the transcripts were read several times independently, and the context of opening phases and invitations were examined for all interactions that took place. Content analysis was employed to code interactions during opening phases and invitations.

The primary set was to explore and compare the data and with the IRC interaction findings of Rintel and Pittam (1997). The aim, therefore, was not to make generalizations about interactions on virtual chat rooms but to show a range of possibilities that illustrate how text-only (IRC) and text-visual (virtual) rooms present similarities and differences shaping the norms and the patterns of the social interaction. Examples are presented here from the captured screens to illustrate the points being made with no spelling or grammar corrections, and are provided with line numbers as they appeared, along with the discourse and the log numbers. The nicknames were also changed to pseudo-names to ensure anonymity of the participants.

**Findings: Similarities and Differences**

The interaction management strategies found in the data have been categorized under a single general heading: opening phase and invitation. These phases will be discussed in terms of their similarities and differences to IRC; and, the functions they appear to serve will be discussed in terms of two subheadings interpersonal goals, how people introduce each other to draw attention; and, level of experience and acquaintance how experience plays a role in interactive communication.

**Opening Phase and Invitations**

**Interpersonal Goals.** Rintel and Pittam (1997) reported that in order to help create a good initial impression for the desired respondent, the choice of the nickname is crucial in a CMC environment. The choice of a nickname can refer to personal unity; moreover, it may make the other participant speculate about the user's identity. Such implications of nickname choice can be seen in the example below:

(Log 6)

85 "Ana": Is there anybody out there?  
86 "Spain": Hi all  
87 "Ana": You must be from Spain

Rintel and Pittam (1997) also report that some users hide all personal information, especially to present selectively gender-switched or even multiple identities. In this research data, however, no cue is reported to show the relationship between nickname choice and gender. Yet, it is noteworthy that CMC is an environment where virtual gender-swapping is particularly significant (Turkle, 1995).

Although it is impossible to find out whether the person in the chat room is gender-swapping, it is sometimes possible when users themselves choose to reveal this information, as shown below:

(Log 4)

138 Kataline: How come no one is talking today  
140 Suyev: Kataline III talk with you  
163 Kataline: are you male or female  
166 Suyev: male today  
171 Kataline: Just today?  
172 Suyev: Well I'm pretty sure all of the time

Since it is not possible to find out which of the statements is fictitious, it can only be speculated that gender seems to be a conscious personal choice to initiate conversation. Elsewhere, gender is pointed out to be a primary concern in initiating the conversation.

(Log 3)

5 child: Cat, I'm female  
8 Cat: Angel would you like to talk in metropolis  
15 child: Are there any guys in here who want to chat with a 13 y/o f?

In this conversation, 'child' is trying to draw Cat's attention to initiate conversation by imposing her gender first. Cat seems to be obvious of the illocutionary force (meaning) of this statement. Yet, s/he begins by including her age. She receives no response to chat from Cat. This may be due to the fact that she did not start with appropriate opening linguistic tokens.

(Log 6)

27 Roze: hiya  
28 Cindy: where r u from  
30 Roze: is from NH, USA  
31 Cindy: me too  
33 Cindy: r u a boy or a girl  
34 Roze: is 17-year-old single male  
36 Cindy: u r to young for me, I am 24  
37 Cindy: I am a single girl who is 24 I live in Atlanta

Although the discourse, here, seems to be contextually appropriate, the desired result was not achieved possibly due to the fact that age seems to be more important in order to continue the discourse. In initiating the conversation, Rintel and Pittam (1997) report that repetition is a necessary part of conversation. They also suggest that the use of capital letters are important aspects of the discourse. In this data, the same strategy is found to be applied by the participants. Capital letters were used to either draw attention or to emphasize a point. Several repetitions also are aimed at drawing attention and initiating conversation.

(Log 6)

70 Jey: HELLO EVERYONE  
72 Saturn: WHAT DID YOU ASK?
On IRC, the perception and reflection of feelings are reported to be highlighted by the use of textual symbols such as exclamation marks, possibly used with greetings. In a 3-D virtual chat environment, typing is a mode of communication that is applied by the interactive users. In addition to this, the software enables the users to reflect their feelings of "anger," "happiness," "sadness," and physical response for appreciation through avatars. The following example shows the similarity between two chat environments.

(Log 3)
162 Angel: booooooonnnnnngggg...
160 Angel: hmmm...<yawn>
35 Sun: ^___^
Stage 1: Server drops you off at the Gate
Stage 2: Exchange of exploratory/initiatory linguistic tokens - repetition is necessary.
   a. Greetings (personal information in relation to gender, age, and location)
   b. Statements/questions (locutionary and illocutionary statements are explicitly used, whereas perlocutionary forces were hardly identified)
Stage 3: Textualized exchange of conventional nonverbal contact gestures of greeting as well as visualized exchange of nonverbal contact of gestures.
Stage 4: Transitional strategies for moving to the appropriate speech act based on the appropriate context.

BRINGING INTERACTIVITY TO THE WEB: THE JAVA SOLUTION

Richard H. Knee  
Florida Atlantic University

Ralph Cafolla  
Florida Atlantic University

Java is the object-oriented programming language that has taken the Internet by storm. Java’s popularity lies in its ability to create interactive Web sites across platforms. Because of Java, the Internet no longer need remain a static vehicle. It becomes a truly interactive tool for the user.

The most common Java programs are applications and applets. Applications are stand-alone programs, such as the HotJava browser. Applets are similar to applications, but they do not run stand-alone. Instead, applets adhere to a set of conventions that lets them run within a Java-compatible browser. Applets are essentially embedded in HTML pages for Web viewing (Musciano & Kennedy, 1997).

Java was first “brewed” in 1990 when a handful of developers at Sun Microsystems set out to build a device that could control everyday consumer appliances ranging from coffee pots to VCRs. Soon the vision expanded to include a device that could potentially serve as an interface to the Internet. Late in 1991, an object-oriented programming language called Oak was developed (Scott, 1997).

Sun wanted to build a system that could be programmed easily without a lot of esoteric training. While the developers found the existing programming language, C++, to be unsuitable for their needs, they designed Java as closely to C++ as possible in order to make the system easier to understand. In January 1995, just as it began to attract serious attention from the greater Internet community, the Oak programming language was renamed Java.

Java is fast becoming an essential subject matter and teaching tool within corporate and academic settings. Corporations are sponsoring Java classes for their diverse employee pools. Universities are integrating Java into curriculums as a result of the increasing demand for Java developers. Primary and secondary schools are using Java technology to teach students everything from physics equations to biological processes. Java could very well become one of the foundational tools for the classroom of the future, one that allows for a rich, interactive education. Integrating the Web into the curriculum is greatly enhanced when the interface to the Internet is interactive. Java is making that a reality. In this paper, we will explore the growth of the Java language as a tool for use in teacher education as well as the K-12 classroom.

Bowen (1996) states that “The Java programming language is gaining popularity in university and community college curriculums as a first programming language, as a general programming language better suited to conveying advanced concepts such as concurrency and distributed objects, and as an Internet-related toolset important in continuing-education programs.”

The term “object-oriented” is generally used to describe a system that deals primarily with different types of objects. The actions you can take depend on what type of object you are manipulating. For example, an object-oriented draw program might enable you to draw many types of objects, such as circles, rectangles, triangles, etc. Applying the same action to each of these objects, however, would produce different results. If the action were Make 3D, for instance, the result would be a sphere, box, and pyramid, respectively (Musciano & Kennedy, 1997).

Java and JavaScript

Up to now we have looked at Java applets, which are small programs that are separate from the browser and the HTML document. Java applets run in their own space via a separate execution engine. JavaScript is different! JavaScript is a scripting language that taps the native functionality of the browser. You can sprinkle JavaScript statements throughout an HTML document and JavaScript-enabled browsers interpret and act upon the JavaScript statements (Musciano & Kennedy, 1997).

JavaScript was developed to fill the considerable gaps in functionality between HTML, CGI and Java. JavaScript is well suited to enabling users to interact with HTML pages. JavaScript code can respond directly to user interaction with <FORM> elements like text boxes, buttons, check boxes, drop-down selections lists and more. It is excellent for client-side image maps and hypertext links. It can also be used to “spice up” Web pages with the date, time, status bar messages and scrolling banners.

What about ActiveX?

One of Java’s great advantages is its inherent security. Because it was created to run applications over the Internet, its designers were very concerned about security. They had to be careful to make it impossible for malicious programers to build Java applets that could reach over the Internet.
into users' machines to steal passwords, shut down systems, or perform other unfortunate hacks.

To guard against this, Sun developed the “Java sandbox,” (referred to as a virtual machine) inside which Java applets are forced to run. This virtual machine blocks all access to potential danger zones on your computer, such as the hard disk and serial ports. While the sandbox makes Java very safe, it also makes Java work slower and somewhat less efficiently than native applications that run directly on your machine without any intermediary processing (Rowley, 1995).

The sandbox security model is one of the most important political differences between Java and its nearest competitor, Microsoft’s ActiveX. ActiveX allows access to these “danger zones” and relies on a model of trust, simply telling users that a given Web site wants to run an ActiveX control and asking if this is okay. Simply asking for your permission to introduce foreign, potentially malignant files is viewed by some people as inadequate security protection. As of this writing, Java applets are installed on approximately 1,000 times more Web sites than ActiveX (Scott, 1997). Security assurances are one big reason why.

Java in Education

There is a challenge involved in integrating Java into traditional education programs: Java is not a static technology—yet. It is not “written in stone” the way Pascal and C++ are. Instructors and students must be prepared for changes both in the technology and in the way that it is taught. In his Java Report article “Using Next Generation Technology for Java Education Holger Opderbeck, CEO of MindQ Publishing, puts it best: “It’s about time we started using the power of modern computing to more effectively teach the complexities of modern computing” (Opderbeck, 1997).

Java is an exciting, dynamic technology that is challenging to teach. With new specifications, new classes, and general updates, one must accept the fact, when teaching Java, that the course will never be the same because the subject matter is in a never-ending state of change. In the past, programming classes were created using the model of “develop the course and then teach.” The teaching cycle was typically much longer than the course development cycle. In today’s technological environment, curriculum development must be iterative; in other words, it is an ongoing repetitive process that is required due to the constant change of the subject matter and the technology. In order to be Java-compliant, we must follow Sun specifications, which are continually changing. Today, new releases of host-based products are issued every few months, so class material will probably need to be updated on a regular basis.

At Florida Atlantic University, we decided that graduates of the Educational Technology program should have nine graduate hours of programming exposure and its application for education. There are a significant number of institutions of higher education that have made the Java language a core course required prior to C or C++. (McCauley & Manaris report as cited in Culwin, 1997.) Our second course is centered on Java. The purpose of our course was to provide educators with the Java skills to meet their instructional objectives. It takes a lot of planning to put together a course of this nature. We suggest the following outline:

1. Draw up a detailed outline for the class
2. Create a template for content, demonstrations and projects
3. Research content for topics that apply to education – note change
4. Configure technological environment – know your lab and its limitations
5. Design technology demos – use of student work from previous courses
6. Develop the lecture content
7. Develop a resource list of tools, Web sites and projects
8. Develop student and instructor notes via presentation tools
9. Create a plan for updating course materials
10. Develop a list of student objectives or outcomes

We adopted the concepts of object-oriented programming in our course design. Demos are used because a single demo can replace many screen captures. Each new demo file corresponds to a new chapter or topic, and dependencies between chapters and between labs are kept to a minimum. Creating self-contained modules (just like creating objects or reusable components in programming) means that topics can be written independently and rearranged or altered with minimal impact to the other sections of the course.

An FTP site was created for the course so that material can be shared and updated by the students. Student work can be put on the server for all to explore as the course develops. Java students also developed a Web site as a project, an exciting way of using the medium to teach the medium.

Apple’s EOE - Educational Object Economy Web site (Apple Computer, 1997) is a community of educators, learners, developers, and businesses, focused on the creation and collaboration of educational activities which include pieces of Java software in them. The EOE is also intended to help educators and learners access this material and the creators of the applets. The EOE has a library of over 1000 pointers to Java applets, over 25% of which make source code available. Working together, the educators, learners, and developers can collaborate to enhance existing material and produce new innovations. Educators with little or no programming background have access to an ever growing library of interactive applets to
use as stand alone teaching tools or as enrichments to Web-based instruction.

The EOE has an exciting future for the educator. Educators are providing information about their favorite applets that they use in their classrooms, what applets work best with the textbooks they are using, hints about lesson plans and materials used to effectively use the Java applets to achieve learning objectives. Teachers also make suggestions for what applets they would really like to see created (teacher’s wish lists). The EOE also encourages partnerships between teachers and university Java programming classes, so that teachers have access to programmers and developers who are creating the kinds of learning material the teachers need.

EOE provides an excellent scenario of a fifth grade teacher who finds an applet to teach her class a botany lesson. By working with the Java programmers on the listserv she is also able to have the program modified to fit her specific needs within four days. Java is making the Web an interactive pedagogical tool within the reach of all educators’ especially those with no programming experience (Bastaan, 1997).

Who is building Web sites today? Entrepreneurs, writers, hobbyists, educators and students from the elementary grades and up are building them, not Java programmers. In fact, very few Web sites are actually built by professional programmers. That is why programs like Lotus BeanMachine are important: It brings the power of Java to non-programming Web-builders like teachers and their students.

There are three groups of parts that come with BeanMachine. There are Multimedia parts, such as Animation, Audio, Ticker Tape, and Text. There are Networking parts, such as a Database component, a URL Link for linking to other Web pages, and an e-mail part. The third category of parts is called Controls, which includes all the basic things you need to build data entry forms such as buttons and text fields. Anyone that has experienced a Modest amount of Visual Basic will find himself or herself at home with this software but we stress once again, no programming knowledge is required.

Every JavaBean has a certain set of properties, methods, and events. Properties describe the part, its speed, its width and height, etc. Every bean has a different list of properties that makes it unique. Beans are active objects, as they know how to do things. Animations can play and stop. Buttons can show and hide themselves. Again, every kind of bean has a different set of actions it knows how to perform; these actions are referred to as methods. Events help a bean interact with other beans. An event is a signal that something important has happened: a button was clicked, a transition has finished, or a ticker tape was refreshed. In BeanMachine, every part on the palette is a JavaBean, so it has properties, methods (which BeanMachine calls actions), and events (Lotus, 1997). The BeanMachine is just one example of software that will allow you to "brew a perfect cup of Java" for your next Web page without really learning how to program in Java.

Conclusion
Java is becoming a basic skill for a wide range of students and teachers, not only for programmers. Educators are beginning to recognize that today’s students need to learn logic, or “higher order process skills,” at an early age. Java helps students develop their logical or “object oriented cognitive skills,” an understanding of how, for example, the “objects” of car, truck, and sports car relate to each other. This notion of objects and their relationships, of classification and sub-classification, is important in disciplines ranging from art to chemistry, and it is fundamental to the Java environment. The skills it teaches are crucial, for logic is the essence of cognition, and language is its tool (Spöhrer & Wolpert, 1997).

In an era of increasing international economic competition, the quality of America's elementary and secondary schools could determine whether our children hold highly compensated, high-skill jobs that add significant value within the integrated global economy of the 21st century or compete with workers in developing countries (Shaw, 1997).

On June 29, 1956, President Eisenhower signed the Federal-Aid Highway Act of 1956 into law. President Eisenhower had tried for a number of years to get an Interstate Highway bill through Congress. Senator Albert Gore, Sr. of Tennessee, who was chairman of the Senate Subcommittee on Roads, had also worked diligently for a federal Interstate System and was instrumental in getting the Federal-Aid Highway Act of 1956 approved by the United States Senate. This one act continues to have immeasurable impact on the economy of the United States and was considered one of President Eisenhower's favorite domestic program. Eisenhower's 1963 memoir, Mandate for Change 1953-1956 (Weingroff, 1996), explained why:

More than any single action by the government since the end of the war, this one would change the face of America.... Its impact on the American economy - the jobs it would produce in manufacturing and construction, the rural areas it would open up - was beyond calculation.

Exactly 40 years later Congress approved another historic highway act. This time the visionary champion was Vice President Gore, son of Senator Albert Gore, Sr. History may document that the new Global Highway System, the Information Super Highway, will have a greater impact on the economy of the Unites States than the concrete and steel national Interstate Highway System that was started in 1956. In February of 1996, President Clinton signed the Telecommunications Act of 1996 into law. This new Telecommunications Act contains many components that will allow the Information Super Highway to flourish. An important universal service amendment of the Telecommunications Act of 1996 was the Snowe-Kerrey-Rockefeller-Exon Universal Access Amendment to the Telecommunications Act of 1996, which required that elementary and secondary schools and public libraries be provided affordable telecommunication services.

On May 7, 1997, the Federal Communications Commission (FCC) issued a ruling on Universal Service that would provide $2.25 billion a year in telecommunication discounts to K-12 schools and public libraries. This historic FCC ruling has the potential to make a significant impact on the quality of graduating high school students. Due to the expanding global economy of the United States, graduating students must possess the skills needed for the United States to continue to be competitive. The FCC’s ruling approved the Education Rate Discount Program or E-Rate that will significantly discount the cost of providing Internet connections to over two million classrooms in approximately 106,000 schools in the United States and thousands of public libraries.

Chairman Hundt of the FCC described the E-Rate discount program as: “the biggest single national effort to change education in K-12 classrooms in the history of our country” (Hundt, 1997). Vice President Gore stated that the FCC decision was historic and America “...has taken a great step forward in closing the gap between the information have and the information have-nots” (Gore, 1997).

In addition, Chairman Hundt stated that many years ago the seeds for Universal Service were planted during a conversation with then Senator Al Gore. Former Senator Gore stated that he wished that all students could be provided the opportunity to learn from the limitless resources of the Library of Congress without being barred by time, distance, or money (Hundt, 1997). As a result of this initial and informal conversation between then Senator Gore and Chairman Hundt, a national vision of connecting all American classrooms to the Internet developed. Chairman Hundt also stated that Vice President Gore actually coined the phrase, Information Highway (Hundt, 1997).

Thanks to the efforts of thousands of dedicated professionals, the national vision of connecting every classroom in America to the Global Information Highway is going to become reality. Additionally, because of the FCC’s E-Rate discount program, many of America’s classrooms will be
connected to the Internet by the end of this century. Credit
for the E-Rate initiative not only goes to Vice President
Gore and Chairman Hundt, but also to President Clinton,
other dedicated officials of the FCC, the U.S. Department of
Education, Senator Snowe of Maine, Senator Rockefeller of
West Virginia, Congressman Markey of Massachusetts, the
National Education Association, the National School
Boards Association, and to 30 national education and
library organizations in the Education and Libraries
Networks Coalition.

**Major Components of E-Rate**
The FCC Education Rate discount program was
implemented on January 1, 1998 and is projected to
continue to discount telecommunication services for K-12
schools and public libraries indefinitely. The FCC is
scheduled to complete an in-depth review of the E-Rate
program five years after implementation. The following is a
summary of the major components of the E-Rate discount
program as described in the FCC’s Report and Order that
governs the E-Rate program (FCC 97-157, 1997).

**Eligibility Criteria**
All state and federally funded elementary and second-
ary schools and public libraries in the United States are
eligible to receive E-Rate discounts. In addition, many
private elementary and secondary schools may also qualify
for discounts. Private schools must be non-profit and can
not have endowments in excess of $50 million. However,
Institutions of Higher Education are not eligible for E-Rate
discounts.

**How E-rate Works**
The E-rate program is not a federal grant program. Also,
the E-Rate discount program does not require matching
funds. Instead, eligible elementary and secondary schools
and public libraries will receive telecommunications
services at significantly reduced rates. Formal applications
and other certification requirements must be completed by
all schools and libraries requesting telecommunication
discounts under the E-Rate discount program. Schools or a
consortium of individual schools must also annually
submit their requests for eligible services for competitive
bidding at the national level.

The funding period will be each calendar year and
schools and libraries will only be required to pay their
portion of bills for telecommunication services after the
discount has been applied. For example, a school that is
eligible to receive a 70% discount will only be required to
pay 30% of the bill. Each service provider or contractor will
submit invoices directly to the Administrator of Universal
Service for reimbursement of the remaining 70%. The FCC
has designated the National Carriers Exchange Association
to manage the E-Rate program.

(FCC 97-157)

**E-Rate Program Discount Rates and E-Rate Funding**
The discount percentage level may be figured by
individual schools or by school districts. Eligible libraries
receive the same percentage as the school district in which
they are located. The discount percentages will vary from a
low of 20% to a high of 90% and are based upon two
factors, the percentage of students eligible for free or
reduced price lunches under the National School Lunch Program and a pre-determined rural or urban status of
schools or school districts (see Table 1). The FCC projects
that many schools will be eligible for 70% or 80% dis-
counts.

Funding for the E-Rate program will be collected from
all telecommunications carriers that provide interstate
telecommunications services in the United States. A total of
one billion dollars will be available in 1998 and $2.25
billion will be available annually starting in 1999.

**Eligible Telecommunication Services**
The FCC wanted to assure that schools and libraries
have maximum flexibility to design and purchase the
telecommunication services that best meets their needs. As
a result, all costs associated with providing telecommunic-
ation services to schools and individual classrooms are
eligible for E-Rate discounts. Included are costs associated
with rental of digital Internet access lines, Internet access
charges, regular phone line charges, file servers, routers,
terminal servers, wiring, wiring connections, wireless
connections and associated equipment, networking
software, and all maintenance associated with maintaining
computer networks.

**Telecommunication Services Not Eligible for E-
Rate Discounts**
Teacher training, computers (unless used as file servers),
content related software, fax machines, electrical system
upgrades, remodeling of building to accommodate newly
acquired technologies, and asbestos removal are not
covered under the FCC’s E-Rate discount program.
Two Major Challenges of E-Rate

The E-Rate program is by no means guaranteed to become a national success story in the majority of K-12 schools in America. The very nature of E-Rate requires a great deal of effort by all educators, both from K-12 schools and from Institutions of Higher Education to impact the quality of graduating students. All administrators must realize that important challenges are packaged with the E-Rate program. The administrator’s role in changing the school to a more technological based learning environment that provides connectivity to all students is critical for E-Rate to become a success story.

The Major Challenge for K-12 Educators

Administrators of all K-12 schools must assure that their priorities in networking classrooms and schools to the information highway are carefully analyzed. The most important variable for successful integration of Internet and other technologies into classroom curriculums is teacher training. The E-Rate program will save schools significant funds that would otherwise have had to be spent on networking and other Internet related costs. School administrators need to assure that some of these savings will be redirected into formal teacher training programs. All teachers not only need to be taught how to use Internet and other computer technologies, but they must be taught how to use technology as a transparent tool to facilitate learning of the required basic skills and other core subjects.

The Major Challenge for Colleges and Schools of Education

The following quote is from the 1997 Report to the President on the Use of Technology to Strengthen K-12 Education in the United States (Shaw, 1997), ...even in states with a technology-related certification requirement, new teachers typically graduate with no experience in using computers to teach, and little knowledge of available software and content. The Office of Technology Assessment summarized the current situation concisely: Overall, teacher education programs in the United States do not prepare graduates to use technology as a teaching tool.

The President of the National Council for Accreditation of Teacher Education (NCATE) has stated that, “...most schools of education have not yet fully integrated technology into their programs for preparing teachers. There is a long road ahead” (Wise, 1997). The time is now! Schools and Colleges of Education must start properly preparing pre-service teachers to use Internet and other technologies in their future classrooms.

Conclusion

The Federal-Aid Highway Act of 1956 dramatically impacted the economy of the United States by putting rural areas on the map and connecting cities and people. The E-Rate program was created from the Telecommunications Act of 1996 and has the potential to have an even larger impact on the United States because for the first time, students from all over America will have instant access to global sources of information. However, unless the two challenges described above and other educational challenges are not met head on and conquered, the potential impact of the E-Rate program will be disappointing to say the least.

No longer can we prepare students without classroom connectivity to the multitude of informational resources of the world. The World Wide Web will be the tool of students and adult learners of the 21st Century as the printing press was used as a tool by previous generations. The E-Rate Discount Program makes it possible for all schools to make the connection between new teaching techniques, great resources, and innovative learning environments.

A growing number of schools in Germany are being connected to the Internet. This goes along with an increasing use of the World Wide Web (WWW) in schools. The Internet is mostly used as a means for searching the WWW or for getting into contact with pupils from other schools by e-mail or other communication facilities, such as bulletin-boards or discussion forums. Furthermore, Internet-based learning environments that provide tutorial components as well as communication features are made use of (Cremers, Lüssem, & Sünderkamp, 1997).

With the increasing number of connections to the Internet, network security is a growing concern in schools. The frequency and severity of violence in primary and secondary schools is best documented by the attention this topic has gained in the media. Bearing this in mind, the national and international attempts to enrich the education at an early stage with networked computer-based information technology are a mixed blessing. On the one hand, programs promoting the connection of schools to the Internet are necessary and desirable to keep up with today's technical reality. Information on the Internet and connections to the Internet are no longer confined to specialised fields. On the other hand, the potential for misusing the Internet is becoming more and more apparent (Lüssem & Spalka, 1997).

Although the connection to the Internet can, in some cases, cause many security problems, additional jobs for system administrators are not planned. Consequently, more and more teachers have to deal with the tasks of a system administrator, i.e., they are responsible for the security of computer networks in schools. But only a few of the teachers responsible for the development of secure school-networks are experts in this field (Knaak, Lüssem, & Spalka, 1997). As we have found in a recent survey, often these teachers cannot sensitise their colleagues to security issues (see Figure 1).

This leads us to two interdependent kinds of measures. Thus, security policies must be developed that are easy to understand, as well as effective. And, additional computer security training should be integrated into teacher training.

**The Threats**

First we give some examples of the situation at schools by presenting two possible scenarios.

**Scenario One**

Suppose e-mail has become an indispensable part of the foreign language lessons in school A, for which contact to foreign schools is a new and important opportunity. Outer-school experts are consulted for advice on special problems and much of inner-school communication is done via e-mail. A breakdown of the e-mail server can be caused deliberately if a sufficiently large number of e-mails are sent to e-mail addresses of the school. This can lead to severe disturbances of the lessons.

**Scenario Two**

Suppose at the beginning of a new school term, the pupils of a computer course at school B are given e-mail...
accounts, all of which can be entered with the same password before the pupils start to work with accounts. Many pupils do not regard changing their password as necessary because most of the data on their accounts do not seem to be worth protecting. Thus, pupils are able to break into the system using another pupils' name: a harmless example of abuse is the sending of funny e-mail under wrong names, whereas the distribution of harmful material will definitely lead to far reaching consequences.

As mentioned in the second scenario, on the Internet one can as easily publish harmful material as one has access to it. In addition to violating a state’s constitution and laws for the protection of minors, many sites on the Internet endorse, if not glorify, violence of all kinds. The violation of the rights of individuals, e.g., unauthorised communication of personal data and electronic harassment, is another problem that arises. Thus, we have to deal with the following questions:

- How can these security risks be avoided or minimised?
- How can we protect the rights of individuals?
- What measures can be taken in case of security violations?
- Whom can teachers consult in such a situation?

Only integrated security policies and sufficiently trained teachers can help to answer the above questions. Only they will solve these problems and will make pupils familiar with security mechanisms they are likely to meet in the future as employees.

Until now the steps taken to protect pupils from the Internet's harmful information can be characterised at best as singular and spontaneous. There is hardly any doubt on their insufficiency. They can be subverted without much effort (often unnoticed given that the pupils' technical skills frequently exceed those of their teachers) or they obstruct the proper use of the Internet.

We are convinced that these problems will not be solved until a comprehensive concept for securing networked information systems deployed at schools is devised. It must be explicit and comprise all levels of abstraction and detail. At the top level, a security policy must state the protection demands and the responsibilities of all stakeholders. From this, a set of concrete rules and measures, technical as well as non-technical, must be derived. The most important technical component is a suitable computer security model. This security policy must accommodate both a school’s organisational structure and the particularity of its computer systems. Lastly, these provisions must be supported by security measures for the operating system and the hardware. The level to which we pay the least attention is most likely to be exploited for illegal purposes.

Conducts for the connection of schools are called for that provide structures which can be adapted to the needs of the school not only by experts but even by teachers. Security mechanisms have to be integrated, user-friendly and transparent for pupils and teachers as well as sufficiently effective.

**Security Concepts**

First of all, we must recognise that prevalent security concepts were developed for and targeted at commercial and governmental institutions. Although there is, at present, no alternative, their applicability and effectiveness in schools is questionable. To give an example, the connection of a school computer to the Internet requires a redefinition of a protection unit. Whereas traditionally, a unit of protection must be protected from unauthorised access by users, at school, the pupil must be protected from accessing Internet pages comprising unauthorised content (Cremers, Lüssem, & Spalka, 1997).

Due to the world-wide extent of the Internet, there are currently no effective preventive security mechanisms. Protection products, such as PICS (World Wide Web Consortium, 1997), rely on a co-operative behaviour of the content providers - and for their shallow resistance to subversion, on the technical ignorance of the users. In view of the problem's nature, neither one can be taken for granted.

Thus we must resort to the next lower class of restoration security measures. Here, auditing systems which monitor, record and signal specific events, play a central role. To ensure that access prohibitions are respected several steps must be taken: inform the pupils about the prohibitions, check for violations and sanction the violators. The effectiveness of this procedure depends on all links of the chain. The first and the last one obviously do not concern the computer system, but still have to be a part of a comprehensive security policy.

The final, and least satisfactory, class of security measures are those limiting an ongoing damage, e.g., intrusion detection monitors. Their effectiveness is generally subject to a real-time action of a system administrator. Due to most schools' pitiful financial situation, this full-time job is simply unaffordable. Reasonably, we can only expect the teachers to exercise vigilance.

**Teacher Training**

The training of the teachers in the field of computer security should be twofold. We have to create awareness among all teachers for the above-mentioned problems. Educators should not only be sufficiently informed about the risks resulting from the usage of computer networks. As they have an advisory and catalytic function with respect to the parents, they should also have a fundamental knowledge of how to deal with security problems. In addition, they have to be able to understand the underlying concepts of their school's security policy (Lüssem, & Spalka, 1997) and to establish parental control systems.

Teachers working with the Internet should regularly acquire additional skills. Apart from understanding the
concepts of the security policy, we would like to invite them to participate in the design of this policy (see figure 2). Only if teachers are involved in this process, will the security mechanisms applied at school be accepted by them (Safian, 1995). Basic knowledge of the security mechanisms is fundamental for appropriate teaching the pupils in this field.

**Conclusion**

We have shown that a school’s connection to the Internet creates many new problems for which no satisfactory solutions exist. For that reason we believe that the development of a security policy targeted at the schools’ requirements is a vital step. To create awareness and enhance acceptance, teachers should be involved in this process. Lastly, only appropriate training of the educators in the field of computer security minimise the problems resulting from the usage of computer networks.

As the field of technology in teacher education grows, it becomes increasingly important to address the theoretical foundations of the field. For it is this theoretical foundation which gives us a sense of direction as to where we’re going and why we are going there. Without a solid theoretical foundation, we cannot fully comprehend the effects of technology on teacher education, or how to implement it into our curriculums most effectively.

This year’s Theory section covers the range of possibilities, from offering approaches for implementing learning theory to an overview of these theories, themselves. While the content in this area may be somewhat deeper than in some of the other areas, it is no less important and should not be overlooked by the reader as “boring” or “stuffy” for these papers are neither.

We begin with Peter Albion and Ian Gibson’s look at problem based learning. They address some of the issues surrounding problem based learning, including some of the reasons why it has not been more fully adopted in teacher education. Then, they turn to their attentions to possible ways that instruction through multimedia, an activity which tends to center on the individual, can be combined with problem based learning, which tends to center on the group. By adopting some of their ideas we can change the way that teachers are taught, and have a significant impact upon the generations to come.

Next, Marino Alvarez looks at the use of an online vee diagram as a metacognitive tool. While many of us are familiar with the use of paper-based vee diagrams, Alvarez has adapted and applied this to a Web-based situation. His has developed an approach which assists students in the development of new ways of approaching and thinking about concepts, in an effort to help them to help themselves in understanding concepts, as well as in planning and carrying out research.

Nada Dabbagh takes a slightly different approach in her overview of concept mapping. Like the vee diagram, the idea is to get students to visually represent their thoughts as projects and assignments develop. Unlike Alvarez’ more structured vee diagram, the computer applications, L:iration and Semnet, addressed in Dabbagh’s paper give students considerable freedom and flexibility in their approaches to a project. Dabbagh addresses the use of these programs as Mindtools, which can help students look more deeply and critically at the information presented to them.

Charles Dickens takes us to a “middle ground” between applied and foundational theory with his look at multimodal and multiordinal communication. He addresses the relationship between the access and creation of knowledge and the significance and meaning of the expression created. By grounding in work in the earlier works of Korzybski and Kaelin, Dickens demonstrates that the role of the instructor is influenced and shaped by theory, and the need to ground instruction in a solid theoretical foundation.

The next paper, by Steve Harlow, takes a look at what is meant by learning and knowledge, and technologies impact upon each. Harlow recognizes technology’s critics and concedes that technology may not be the answer to all problems. He briefly looks at learning from both Popper and Bruner’s points of views. He then postulates how information technology might be improved by taking a more narrative view of learning as described by Schank. In a later paper, Mimi Schutloffel looks at many of these same questions from a totally different point of view. Schutloffel takes a more critical look at the same issues, and looks at such things as who gains by new technologies, what is lost when new technologies are adopted, what is the problem we’re trying to solve with technology, and what new problems does technology create.

Hoskisson, Ritchie, Hoffman, and Roddy have prepared a panel presentation which everyone with an interest in instructional technology should be encouraged to read. They provide a very good overview of four different schools of thought: objectivist, generative, constructivist, and problem based learning. The basic tenets of each theory, as it applies to learning, is examined. More importantly, each section is followed by a short lesson plan,
designed and implemented according to the foundational beliefs of the theory under scrutiny. These lesson plans all utilize the same basic concept: teaching preservice teacher to use the Internet. By looking at this one lesson from four different points of view, Hoskisson et al. help the reader better distinguish the differences between each of the four theories. This provides a review for those who may be a little rusty in their theoretical foundations.

Gulsun Kurubacak's paper on critical thinking takes us back to application theory. By taking the stance, "When thinking critically and reflectively, we become active and productive people," Kurubacak leads us through some very convincing arguments of ways that computers could be better utilized as classroom Mindtools. As a research foundation, he describes two courses, one graduate and one undergraduate, both with strong online components in the coursework. By looking at how the online nature of assignments affected student output and performance, we begin to gain some insight as to what the future may hold as we inevitably move toward more online, distance education.

Michael Land and Mary Ann Coe take a critical look at the concept of teaching technology. They raise the issue as to why are we separating the tool (technology) from the subject matter. They point out that the tool is not the end, but the means to an end. We do not build our own automobiles, so why should we expect teachers to program their own computers. They advocate better integration of technology in the curriculum as a whole, modelling for prospective teachers ways of using technology effectively.

Avril Loveless and Michelle Selinger bring us a British perspective with their papers on pedagogy. New laws in Britain have affected the way that instructional technology is approached. Loveless and Selinger describe programs at the University of Brighton and Warwick University, respectively, and how these programs have been impacted and, in turn, influenced the pedagogical foundations of teacher education in Britain.

Finally, Cameron White takes a critical look at the role of technology in teacher education. He addresses the issues of empowerment and access. Can technology really empower the disenfranchised? Or, does it simply widen the gap between the haves and the have nots. As we move from a modern to postmodern age, how to do transform education, in particular teacher education, to enfranchise both students and teachers. Part of teacher education should be helping teachers develop an awareness of the issues of access and equity and how technology can be used to improve the status quo.

As you can see, there is a wide range of philosophies presented in this year’s Theory section. While most of the papers do focus on application theory, there is enough foundational theory presented to give a broad overview of those theories most popular in teacher education today. We can take this theoretical foundation and apply it to issues that are encountered throughout teacher education, and, more importantly, they can be used to help ensure that we continue to strive to reach the fullest, brightest potentials that technology offers us.

Polly Mumma is a doctoral student in Curriculum and Instructional Technology at Iowa State University, N162 Lagomarcino Hall, Ames, IA 50011. Voice: (515) 294-3724. E-mail: pollym@iastate.edu
In response to the advent of personal computers in schools, the energies of teacher educators have generated successive waves of activity in which they have variously sought to assist teacher education students towards computer literacy, to encourage the integration of computer software across the curriculum and to model the use of computers in their own teaching.

Students entering teacher education programs from secondary school are now likely to have been exposed to computers from their earliest years and to possess at least basic skills. Many of them expect technology to play a significant role in their educational experience. The next wave formed by the combined energies of teacher educators must be directed towards using these technologies to improve the quality of processes and outcomes in teacher education.

One component of this wave must focus on incorporating quality teaching processes into a variety of media not dependent upon face to face teaching but designed to support the increasing interest in flexible, open and distance learning options being offered by higher education institutions. These options are especially relevant to the needs of those who by reason of distance or work commitments cannot readily attend classes and who seek access to opportunities for professional development or to new careers. Moreover, the same flexible options are relevant to the needs of students in traditional face to face courses who seek a richer range of learning experiences amidst demands placed on their time by family and other commitments. In the face of these developments students today are developing attitudes and skills relevant for a lifetime of learning.

One educational approach which has gathered momentum because of its relevance to these trends is Problem Based Learning (PBL). PBL has been adopted for the preparation of professionals in fields as diverse as medicine, engineering, law and business. Its characteristic focus on the presentation of authentic problems as the starting point for learning has resulted in a measurable increase in the motivation of students and in their ability to integrate knowledge from foundation disciplines in pursuit of a solution.

This paper describes the design and preliminary evaluation of an interactive multimedia package based upon PBL principles and intended to develop the capacity of beginning teachers to solve problems inherent in integrating technology into their teaching. The package is an outgrowth of successive developments within a teacher education course which has incorporated a problem based learning approach to solving a variety of problems contained within realistic teaching scenarios.

Learning to teach with technology

Although computers are now widely available in schools, their educational impact has been limited. Only a small proportion of teachers actively integrate information technology in their teaching (Plomp & Pelgrum, 1993) and it has been estimated that as few as 3% could be regarded as exemplary in their use of computers for teaching (Becker, 1994). According to US and Australian studies of experienced computer-using teachers (Hadley & Sheingold, 1993; Sherwood, 1993), the principal barriers to computer use include limited access to computer hardware and software, perceived inadequacies in training, lack of support and lack of time for preparation.

Contrary to expectations, newly graduating teachers may be no better prepared for technology integration than their experienced colleagues. Fewer than 25% of graduates from US institutions considered themselves "adequately to thoroughly" prepared for using computers in instruction (Handler, 1993) and Western Australian beginning teachers rated themselves lower than experienced colleagues on computer usage (Oliver, 1993). Studies of computer use by preservice teachers (Albion, 1996; Downes, 1993) suggest that, despite positive dispositions toward computer use, they lack confidence in their ability to integrate technology in their teaching.
If teachers are to be successful at integrating technology, it will not be sufficient for them to develop the capacity for confident personal use of computers. They will also require an understanding of how to adapt curriculum and pedagogy to incorporate technology and it is this dimension which presents the greater challenge to teacher education programs.

Support from like-minded peers is a significant factor in the development of teachers who succeed in integrating technology (Becker, 1994) and teachers value opportunities to share the experience of colleagues who have succeeded with computers (Sherwood, 1993). This evidence suggests that examples of effective practice with technologies may assist teachers to acquire the insights which will enable them to adapt their own practice.

Learning and reasoning from examples are important components in the development of expertise (Chi & Bassok, 1989; Dreyfus & Dreyfus, 1986) especially in ill-structured domains (Spiro, Feltovich, Jacobson, & Coulson, 1991) where problems are ill-defined and there may be no single solution. Teaching exhibits these characteristics, and there is interest in examples or cases as a means of expressing knowledge in the field and as an integral component of teacher education (Carter & Unklesbay, 1989).

The importance of teacher educators providing examples of technology use through modelling has been noted elsewhere (Parker, 1997; Zachariades & Roberts, 1995). However, even if such modelling were practised widely and well, it would still be beneficial for students to encounter examples of good practice in contexts similar to their future employment. Field experience is the logical venue for such examples but it is difficult to ensure that students are exposed to uniformly good examples. Approaches which ensure that all student teachers have access to suitable exemplars are required.

**Problem Based Learning**

Problem-based learning (PBL) developed in response to concerns that the academic discipline focus of a conventional university education might not be the most effective preparation for future professionals. Since originating in North American medical schools in the 1950s PBL has spread to many countries and fields of professional education (Boud & Feletti, 1991).

According to Boud (1985), a PBL encounter typically begins with an authentic problem of practice without any prior preparation by students. Following initial analysis of the problem which is usually undertaken in a small group, areas of learning are identified for individual study and the knowledge and skills acquired in this way are applied back to the problem. The final reflective phase, provides opportunity to summarize what has been learned, and to integrate it with the student’s prior knowledge. Among the advantages claimed are increased motivation and better integration of knowledge across disciplines.

A variation has been described by Gibson and Gibson (1995) in the context of teacher education. Students were initially presented with a one page printed scenario describing a situation typical of the beginning years of teaching and required to analyse the scenario and develop three alternative plans for action with projections of the likely consequences of each. During face to face tutorial sessions following the generation of individual written responses, students were involved in a variety of group processes designed to increase the benefit of interaction with colleagues in the context of seeking solutions to the problem.

In focusing on the solution of authentic problems as a context for acquiring a range of relevant knowledge, PBL methodology accords well with the theories of expertise proposed by Dreyfus and Dreyfus (1986). They argued that the performance of experts tends to be characterised by non-propositional knowledge and proposed that skill acquisition at and beyond the third of the five stages they identified in their description of the development of expertise may be best served by construction of sequences of situational case studies. Such cases ought to include rich contextual information and should engage students in discussion and interpretation based on experience of previous cases.

Compared to other professions, PBL appears to have had relatively little impact on teacher education. Chappell and Hager (1995) reported that although “professional courses around the world, including nursing, design, engineering, optometry, architecture, law and business” were using problem-based approaches they were aware of no instance where this was occurring in teacher education. Although limited implementations of problem-based learning in specific components of teacher education courses have been reported (Gibson & Gibson, 1995; Ritchie, Norris, & Chestnutt, 1995), as yet there appear to be no instances of wider application to an entire course.

It is not clear why PBL has been less widely adopted in teacher education than in other professional courses. One explanation is that case-based approaches to teacher education (Shulman, 1992) are meeting the needs of teacher education programs for relating professional preparation to the experience of practitioners. However, problem-based learning should not be confused with case methods (Bridges, 1992) and deserves to be considered for the unique contribution that it might make to the professional education of teachers.

**PBL and Multimedia**

Hoffman and Ritchie (1997) found no published articles describing how multimedia might address problems with the delivery of PBL courses. In their view, the key benefits of multimedia in PBL would include fidelity, representational richness, time and timeliness.
individualisation, assessment, efficiency and increased power of agency.

A variety of other approaches to using computers to facilitate and enrich the experience of PBL have been described and at least two (Mackenzie, Kitto, Griffiths, Bauer, & Pesek, 1997; Ronteltap & Eurelings, 1997) include provision for supporting collaborative problem solving in distance or flexible learning modes.

In contrast to PBL, interactive multimedia is most often viewed as a technology which promotes opportunities for individual rather than group learning and it may be this aspect which has mitigated against its adoption for PBL. However, many professionals, including teachers, find that much of their work is performed in circumstances where they are required to act alone. Multimedia produced with a PBL approach may offer opportunities for students to engage in individual work both in traditional courses and in flexible or distance mode.

It is against this background that the project described in this paper was developed in response to the need of beginning teachers to “experience” the challenges associated with integrating technology into their teaching and to obtain access to exemplars of appropriate practice.

Project background

Over the past several years, the final unit in curriculum planning taken by University of Southern Queensland students preparing to be primary school teachers has used a problem based learning approach to heighten students’ appreciation of the realities of practice. Early iterations of the unit introduced print based scenarios in which students are presented with a teaching problem which might be encountered during the first years of teaching. Students are required to clarify the problem and to prepare three possible solutions for the problem, giving due regard to professional and ethical issues and to relevant educational theory.

During 1994, interactive television was introduced to afford students the opportunity to observe and interact with teachers on remote sites (Gibson & Gibson, 1995). By linking the interactive sessions with the problem based scenarios, students were able to gain a deeper appreciation of the realities of teachers’ work. Students especially valued the opportunity to observe teachers and to hear their comments on the teaching process.

Designing PBL Multimedia

Interactive television sessions present significant logistical challenges, and, despite their popularity and evident success with students, it is doubtful that funding would permit their use on a routine basis. Videotapes of the sessions were made for use in subsequent years, but video does not offer the same opportunity for engagement as was available to the original group of students.

The multimedia CD-ROM project arose from a desire to present students with video and other materials in a framework which would support engagement through direct interaction rather than passive viewing. Prior success with PBL approaches in the context of the unit led to speculation about the possibilities of merging multimedia and PBL to maximise the benefits of both.

The design of interactive multimedia based on PBL principles presents particular challenges in that, while the nature of interactive multimedia encourages individual use, PBL most commonly involves groups of learners interacting. In bringing these two threads together it was necessary to preserve the essential characteristics which lend each its peculiar efficacy.

Development of the design model and the way in which the different modes of operation of interactive multimedia and PBL were reconciled has been described in detail elsewhere (Albion & Gibson, forthcoming). Briefly, there is evidence (De Grave, Boshuizen, & Schmidt, 1996) that a significant role of the group interaction in PBL is to effect conceptual change through cognitive dissonance, and the design intent in the multimedia product is to use examples prepared by a panel of experienced teachers to challenge the initial ideas of the user.

Users of the CD-ROM are invited to play the role of a teacher in a succession of situations, each of which presents a problem related to planning for the integration of technology into teaching. Each problem begins with an activation task in which the user prepares a brief statement relevant to an employment selection criterion. A series of planning tasks follows and the problem concludes with a final task designed to encourage reflection and integration of what has been learned. As each task is completed users have opportunity to compare their response with the responses prepared by a panel of experienced teachers.

A teachers desk equipped with, among other things, a laptop computer, notebook and resource materials is used to provide a consistent interface throughout the problems. In addition to the responses from the teacher panellists, users have access to a variety of documents based on those found in schools, demographic data about classes, web sites and video interviews with technology using teachers.

Evaluation

The original plan for formative evaluation of the CD-ROM anticipated that a group of final year teacher education students (n = 30) would have up to four hours in which to interact with a complete working version of the first of the four problems envisaged for the package. The software was to include the problem scenario and associated tasks together with a variety of relevant resources and model responses from a panel of teachers.

Delays in the development schedule and the other commitments of students beyond the originally scheduled evaluation dates resulted in a smaller group of students (n = 14) having no more than 2 hours to interact with a very
early prototype of the software. Nevertheless, it was decided to proceed with the evaluation in the expectation that it would provide useful data for the development process.

Despite the difficulties of working with an incomplete version of the software, the reaction from students was strongly positive. On a 5-point scale indicating agreement with a series of statements they recorded an average score greater than 4 for statements about the relevance of the software to the work of teachers and about improving their capacity to integrate technology into teaching.

Students reported that they had gained fresh insights into aspects of teaching referenced in the materials they used, including physical arrangements of classrooms (13 responses), teachers' knowledge of technology (12), teachers' self-organisation (12) and classroom management (10). Several commented favourably on the video interviews with teachers talking about their experience with integrating technology and on the inclusion in the software of a segment which permitted direct manipulation of graphic elements to simulate placement of furnishings in a classroom.

Unfavourable comments were generally restricted to interface issues which were mostly associated with the developmental state of the prototype at the time of testing.

Although limited by the developmental stage of the prototype and the small number of students involved, the preliminary evaluation tends to confirm the general direction of development in this project. Students evidently see value in accessing examples of good practice by teachers and report learning from it. Based on the favorable responses of students to the graphical manipulation of the classroom plan, additional exercises using different layouts will be included in the final version and a similar manipulative approach will be used for timetable planning.

Comments from students were also applied to refining the user interface and making the flow of the problem more readily apparent to the user. Based on their comments, changes were made to provide more explicit directions at points where responses were required and to permit easier access to the variety of resources available on the CD-ROM.

**Conclusion**

The folk wisdom of teacher education asserts that "teachers teach as they were taught". Clearly this cannot be absolutely and universally true else there would be no development in teaching approaches over time. However, there is sufficient truth in the statement to impose an obligation on teacher educators to ensure that their approaches to teaching, including the use of technology, provide examples of practices worthy of emulation.

Synergistic combinations of effective approaches to teaching with new media have the potential to enhance the learning opportunities for teacher education students both directly through their combined power and indirectly as examples of good practice. Results from the preliminary evaluation of this interactive multimedia CD-ROM based on problem-based learning principles indicate that this may be one of the combinations which will contribute to the next wave of improvement in the preparation of future teachers for teaching with technology.

INTERACTIVE VEE DIAGRAMS AS A METACOGNITIVE TOOL FOR LEARNING

Marino C. Alvarez
Tennessee State University

Technology is influencing the ways in which students are using metacognitive tools for learning. Changing paper-and-pencil modes of communicating in favor of electronic interactions that are more efficient and foster collaborative dialogues. Teachers and students are using the Internet not only to access information, but also to show creative compositions and share reports (Alvarez, 1996). An innovative use of one such metacognitive tool for students to self-monitor their learning is the development of the Interactive Vee Diagram. This tool is an electronic version of present uses of vee diagrams that are used either as a teaching tool to clarify concepts, evaluate documents, or to plan, carry out and finalize research investigations. This paper focuses on two of its uses: as a way to evaluate documents, and as a tool to plan, carry out, and finalize research investigations.

Much school learning consists of rote memorization of facts with little emphasis on meaningful interpretations. For example, students are often asked to solve scientific problems and conduct laboratory experiments in a rote rather than in a meaningful way (Novak, 1988, 1990). Often scientific knowledge is assumed to be absolute and students are viewed as passive recipients of information (Driver & Oldham, 1986). In such instances, reading assignments are given, lessons are reviewed, and question-answering is equated with producing “right” answers. Under these circumstances, knowledge construction is reduced to factual knowledge production with little regard for critical thinking, problem solving, or clarifying misconceptions. Texts are often written to support acquisition of factual knowledge. The language of the textbook or laboratory manual is often vague with ill-defined concepts, or with lists of facts that are not situated in a context that encourages students to relate new concepts to their prior knowledge. Seldom are these facts related to students’ everyday experiences, or to other disciplines (Donham, 1949; Erickson, 1984; Eylon & Linn, 1988; Sarason, 1990). Further, Novak, Gowin, and Johansen (1983) show that students lack or misconstrue links between text concepts resulting in a failure to assimilate and accommodate new knowledge in their cognitive structure.

Gowin’s theory of educating (1981) focuses on the educative event and its related concepts and facts. This theory is helpful in classifying the relevant aspects of the educative event. In an educative event, teachers and learners share meanings and feelings so as to bring about a change in the human experience. This theory stresses the centrality of the learner’s experience in educating. Recently, strategies have been reported in which students are active in constructing their own concepts (e.g., Driver & Oldham, 1986; Fosnot, 1989; Pines & West, 1986).

Vee Diagrams

The Vee heuristic was developed by Gowin (1981) to enable students to understand the structure of knowledge (e.g., relational networks, hierarchies, combinations) and to understand the process of knowledge construction. Gowin’s fundamental assumption is that knowledge is not absolute, but rather it is dependent upon the concepts, theories, and methodologies by which we view the world. To learn meaningfully, individuals relate new knowledge to relevant concepts and propositions they already know. The Vee diagram aids students in this linking process by acting as a metacognitive tool that requires students to make explicit connections between previously learned and newly acquired information. The Vee diagram is shaped like a “V” and elements are arrayed around it. The left side, conceptual or thinking side, of the Vee displays world view, philosophy, theory, and concepts. The right side, methodological or doing side, has value claims, knowledge claims, transformations, and records. Events and/or objects are at the point of the Vee. Both sides are interactive; not exclusive (see Gowin, 1981; Novak & Gowin, 1984; Explorers of the Universe: http://coe2.tsuniv.edu/explorers).

The need for instructional tools, such as the Vee diagram, to enhance conceptual learning has been stressed by Novak (1990). In a study with seventh and eighth graders, Novak, Gowin, and Johansen (1983) found that students could understand and use Vee diagrams in science.
classrooms, and that science teachers could use this strategy as a part of their everyday teaching/learning practice. The results of their findings, as well as others (e.g., Alvarez, 1987; Alvarez & Risko, 1987; Alvarez, Risko, Waddell, Drake, & Patterson, 1988; Gurley, 1982; Leahy, 1986; Taylor, 1985), suggest that Vee diagrams can aid students by focusing on the salient role of concepts in learning.

While the aforementioned studies used the Vee in the conventional paper-and-pencil format, this was the first attempt to design and use an Interactive Vee Diagram electronically on the Internet. The research question was “Do Interactive Vee Diagrams appearing on the Internet aid college graduate students in analyzing research documents, and in planning research investigations?” The purpose of this paper is to demonstrate how an Interactive Vee Diagram is used by college graduate students in two ways: first, to evaluate documents, and second to plan their research investigations.

Method

Twenty-nine college graduate students enrolled in an Educational Research class taught by the author, who was the teacher/researcher, participated in this study. The Interactive Vee Diagram was developed for the Internet by the researcher and represented the first time a Vee Diagram has been used interactively and electronically.

A Web site was established for the research class, and was placed on a Web server (Alvarez, 1977a, 1977b, 1977c, 1977d; 1995; Alvarez & Rodriguez, 1995). To insure confidentiality and outside tampering, a password was given to the class of students for access.

Interactive Vee Diagrams

The shape of the Interactive Vee Diagram appearing on the Web site was the same as the one advocated by Gowin (1981). The elements arrayed on the Vee were identical to those that appeared on the paper version. The only addition was a space for students to either write suggestions or problems they may be encountering in their analysis of their research article or the planning of their research study. The Interactive Vee Diagram on the Internet is menu driven and asks for the students for their name, school address, and e-mail address. Also included are instructions for entering information on the Vee. Other features include a link to a paper on the uses of a Vee and an action research plan, both written by the researcher, a visual of a Vee with explanations of the epistemic elements, a movie clip of a student discussing his Vee with the teacher, and an animation of the components of the Vee. There is also a share folder compiled by this researcher by which information of a general nature can be accessed by teachers and students. Clicking on the respective field of the arrayed elements enters data. Once the fields on the Vee template have been completed, the student can review the entries and then electronically submits the information to our base site. There is also a space for students to type suggestions or problems they may be encountering in their study for submission (see Figure 1).

![Interactive Vee Diagram Template](image-url)

Figure 1. Interactive Vee Diagram Template.
The graduate class was given the assignment of developing individual Action Research Plans on a topic of interest in their teaching field and/or major area of concentration. These students used the Interactive Vee Diagram in two ways: (1) to analyze a research article they self-selected for analysis; and, (2) to plan their Action Research Study. Each Vee was electronically transmitted via the Internet; analyzed by the professor (the researcher). Feedback was provided through the same medium. A database was established that tabulated each of the elements on the Vee for comparison and extent of rethinking of ideas that occurred for each transmission and revision. In this instance, two measures were taken for each way the Vee was used: interpreting a research article; planning their individual Action Research Study.

The researcher trained the students in using the Vee. Students were shown examples of Vee diagrams constructed by paper-and-pencil. A skeletal Vee diagram that contained these headings: focus or research question event/object, concepts to be investigated, world view, philosophy, records, transformations, knowledge claims, value claims, theory, and principles appeared on the Internet. These terms were explained and demonstrated with examples for their meaning. They used Gowan’s (1981) Q-5 Technique as a questioning strategy to guide students’ notations on their Vee diagram. These questions comprised the Q-5 Technique: (1) What is the telling question? What does it tell on or is about?; (2) What concepts are needed to ask the question?; (3) What methods/procedures are useful in answering the question(s)?; (4) What answers are produced?; and, (5) What value do these claims have? The purpose of these questions is to guide the learner’s inquiry of a topic under study by focusing attention to the components arrayed around the Vee. Scoring procedures of student Vee diagrams followed the protocol suggested by Novak and Gowan (1984). Individual Vee diagrams were scored on a quality point scale (0-4) with a maximum score being 18 using the following criteria (point values in parentheses for each of the categories): focus question (0-3), objects/events (0-3), theory, principles, and concepts (0-4), records/transformations (0-4), and knowledge claims (0-4).

Findings

Initially, most of the students had difficulty entering their information of their analysis of the research article into the electronic format. Many of these students were not familiar with using the Internet for interactive communications, such as e-mail. Additionally, the inputting of information on the Vee for submission electronically was a first attempt at using this heuristic. We also experienced some difficulty receiving their analyses due to transmitting difficulties. However, once these transmission complications were resolved, the students entered their analyses and they were received and coded in our data bank. Each individual Vee diagram was reviewed and students were given feedback.

When Vees were used in the planning of their Action Research Plan, students again monitored their understanding with their chosen topic by completing its preliminary elements. Students completed their Research Questions, Events, Concepts, Records, Theory, World View, Philosophy, and how they planned to Transform the data. As a metacognitive tool the Vee diagram aided students in monitoring the concepts, events, and facts needed to answer their focus or research question(s). These elements, combined with the other components arrayed on the Vee, were revisited by students during the planning of their investigation and enabled them to search their prior knowledge of the targeted concept under study and extend this knowledge through the formulation of graphs, hierarchical concept maps, knowledge and value claims, and by linking principles to a plausible theory. Conceptual understanding of the targeted concept was also enhanced by conversations emanating with other members of the class and the teacher as their investigations progressed. These cooperative inquiries and resolutions were achieved under the guidance of their teacher who facilitated this exchange of ideas.

Conclusion

Vee diagramming is a way to help students penetrate the structure of knowledge they seek to understand. Being able to get the “right” answer is sufficient in many school evaluations, and too often only rote recall is needed to answer questions. Teachers when versed in Vee diagramming seem to be receptive to this learning strategy in order to achieve meaningful rather than rote verbatim learning, and see this strategy as an independent learning aid to be used by the student (Novak, 1990; Novak & Gowan, 1984; Novak, Gowan, & Johansen. 1983). Involving students in collaborative thought using Interactive Vee Diagrams on the Internet institutes meaningful conceptual change in the ways in which knowledge is viewed.

A conceptual change approach to teaching should include explicit ways for students to become aware of their own beliefs and to come to understand the nature and construction of knowledge (Bransford & Nitsch, 1985; Brown, 1975; Fosnot, 1989; Siegel, 1988). Interactive Vee Diagrams that are shared on the Internet provide the learner with this type of a metacognitive tool by which facts and ideas can be learned meaningfully through reflective thought. This study indicates that online Interactive Vee Diagrams are increasing student awareness and knowledge of research practices, and allowing them to share and communicate their findings with others in ways that are meaningful and noteworthy. These interactive communications and rethinking of ideas resulting from collaborative meaning-making with the Vees are aiding students and teachers in mutually understanding conceptual relations in a meaningful forum.

Knowledge representation refers to how we represent information in long-term and working memory (Gagne, Yekovich, & Yekovich, 1993). Knowledge representation can take many forms (mental representations) depending on the type of knowledge learned and the cognitive strategy used in acquiring that knowledge. For example declarative knowledge which is best described as “knowing that something is the case” (Gagne, Yekovich, & Yekovich, 1993) is represented in the form of propositions. Propositions are knowledge units often referred to as schema (Jonassen, 1988). A schema is a propositional network that is comprised of arguments (topics and attributes) and relations that constrain those arguments (Gagne, Yekovich, & Yekovich, 1993).

For example our schema for “school” is comprised of arguments such as teachers, students, classes, grades, classrooms, and books and relations that constrain those arguments such as “teachers teach students”, “students learn from teachers”, and “grades measure students’ performance”. Procedural knowledge on the other hand is “knowing how to do something” and is represented in the form of productions or IF-THEN contingency statements:

If figure is two-dimensional
and figure is three-sided
and figure is closed
Then
classify figure as “triangle”.

Productions are condition-action rules that enable people to solve problems, make decisions, and develop plans (Gagne, Yekovich, & Yekovich, 1993; Jonassen, 1988). In other words they “produce” an action or a mental or physical behavior. Productions can be interrelated to form a production system which can lead to a complex behavior. Developing production systems for different types of knowledge enhances inference-making and critical thinking skills.

Declarative knowledge and procedural knowledge are interdependent (Jonassen, 1996). Although one might think that acquiring propositional knowledge is a prerequisite for forming productions, in some cases acquiring procedural knowledge can lead to the acquisition of declarative knowledge and applying declarative knowledge can lead to the acquisition of production systems. The interdependence of those two types of knowledge is largely dependent on the cognitive (or metacognitive) strategy that the learner is using while acquiring the knowledge. Concept mapping is a mindtool (a computer application that engages the mind in critical thinking) that can enhance the interdependence of declarative and procedural knowledge to produce yet another form of knowledge representation known as structural knowledge (Jonassen, 1996). Structural knowledge is best described as “knowing why something is the case”. It helps learners integrate and interrelate declarative knowledge and procedural knowledge by activating the perceived static nature of declarative knowledge and by increasing the awareness of why one knows how to do something. Concept mapping requires that students think about a knowledge domain in meaningful ways in order to represent what they know (Jonassen, 1996). By using this computer tool as a cognitive or learning strategy, learners can sharpen inference-making and critical thinking skills and can avoid the acquisition and accumulation of inert (unusable) knowledge.

Computer-based Concept Mapping Tools

Inspiration and Semnet are computer-based visual thinking environments that allow users to create concept maps (also known as semantic networks or nets), webs, outlines, graphic organizers and much more. They are easy-to-use and multi-platform. The basic elements of concept mapping software are nodes and links. Learners use nodes to represent ideas and links to represent relationships that connect ideas. Applying these elements to our earlier example of the schema for the concept “school”, students and teachers would each be a node in the concept map and students learn from teachers would be a link. As the nodes...
and links become interrelated, a structural knowledge representation emerges paving the way for a meaningful understanding of the knowledge domain depicted. In order to build a concept map, the learner must interact with the knowledge domain and organize the information so that it is personally relevant. Prior knowledge and experience play an important role in this learning task ultimately creating a reorganization of existing schemata into a new knowledge structure that is useful and pertinent.

The main advantage to the development of computer-based concept mapping tools such as Inspiration and Semnet is that they remove the drudgery and mess of revising paper-based concept maps (Anderson-Inman & Zeitz, 1993). Electronic concept maps can be modified dynamically and this makes it possible for learners to reflect their improved understanding of a content domain over time by making revisions to their concept maps quickly and easily. Those revisions can also be guided by teachers which renders concept mapping effective as a means of assessing student learning (Sonak, McClure, & Suen, 1995). Electronic concept maps can also be used as planning tools to organize a project or a learning activity.

Inspiration supports the following learning strategies: Outlining, Webbing, Planning, Organizing, Writing, Knowledge mapping, Brainstorming, and Concept mapping.

It is evident from the above functions of this mindtool that its classroom uses are extensive. Students can use this mindtool as a learning strategy to identify important concepts of a content domain and the interrelationships amongst those concepts. This process serves the same purpose as outlining a chapter but requires a more thorough analysis of the content (Jonassen, 1996). Students are engaged in generating a semantic network (concept map) that mirrors their understanding of the content under study. This spacial representation of ideas and relationships becomes a scaffold for acquiring new knowledge (Spoehr, 1994). When used as a pre-instruction exercise, concept mapping allows teachers to inspect students’ knowledge structures to identify misconceptions and therefore adapt instruction to facilitate learning (Sonak, McClure, & Suen, 1995). Students can also use this mindtool as an organizer to plan a research paper or a group project.

**Technique**

When you first run Inspiration, it opens to an untitled diagramming window with a main idea symbol in the middle of the window awaiting the user’s input. A main menu and a tool palette also appear. You begin by typing your main idea (concept) or any idea in the highlighted area inside the symbol. If your ideas are unconnected and you are in the process of brainstorming a topic or a learning task, you continue by pointing and clicking anywhere in the grid area of the open window to create new symbols and type more ideas in these symbols, one idea per symbol. When you are ready to link ideas or organize them in a specific order, you use the drawing link feature. Simply, highlight the symbol you wish to link, and click and drag one of its diamond-shaped handles until you grab the symbol that you wish to link to. A line will be drawn between the two symbols hence linking those two ideas. You can control the direction of the link by adding directional arrows to the line using the tool palette. You can also type in relationships between ideas, as you become more familiar with your topic and the ideas/concepts constituting your topic. To indicate a relationship between two ideas/concepts, select the link (line) and type the text of the relationship in the rectangle that appears. When you are done typing and you hit enter, the rectangle will disappear and the text indicating the relationship remains.

The following diagram illustrates the above events.

![Figure 1. Courtesy http://www.inspiration.com](http://www.inspiration.com)

Inspiration also has a rapid fire feature that allows users to get down their ideas as fast as they can think of them without having to create symbols each time. After typing in the first idea/concept in the main symbol, press the F9 key and type in the next idea in the same symbol. The F9 key generates a marker in the form of a small red box that separates ideas. If you press the F9 key after every idea, Inspiration will automatically break down those ideas into separate symbols with links in between.

Another important feature is the outline view. At any time during the creation of your concept map you can select this view from the main menu and view your concept map in outline format. The outline view provides a hierarchical structure of the concept map based on your links. You can use this view to add new topics, insert subtopics, and arrange priorities and organizational structure. You can also type notes in outline view under...
each topic or subtopic to help convert your outline into a document. Everything you do in outline view is reflected in your diagram view and vice versa. The following diagram is a story web of the book The Secret Garden created in Inspiration:

![The Secret Garden Story Web](http://www.inspiration.com)

**Figure 2. Courtesy http://www.inspiration.com**

Below is the outline view of The Secret Garden story web. It was automatically created by Inspiration.

Other features of Inspiration include: Changing symbol shapes, Creating new symbols, Zooming, Flowcharting, Layering documents by creating a master (family) view and a child view.

It is not difficult to visualize the effectiveness of this concept mapping tool in facilitating student learning and teacher planning. Students can use it as a study aid to organize thoughts, create outlines, plan research papers, and examine content domains by extracting main concepts and ideas, and realizing the interconnectedness of those ideas. Teachers, on the other hand, can use this tool as a planning aid to create lesson plans, generate ideas, develop graphic organizers for content, organize curriculum plans, and adapt instruction to students’ needs by monitoring students’ use of concept mapping to develop key concepts of a content domain.

![The Secret Garden Story Web](http://www.inspiration.com)

**Figure 3. Courtesy http://www.Inspiration.com**

The other visual learning tool being investigated in this paper is Semnet. Semnet software can be used to represent knowledge domains much in the same way as Inspiration does. It allows users to organize ideas about any topic in the form of a semantic network linked by named relations. The main difference between Semnet and Inspiration is that Semnet creates a hypertext environment that allows the user to navigate between concepts through the named relations rather than providing a view of the entire concept map as is the case with Inspiration. Semnet also has additional features such as allowing the user to elaborate ideas with pictures, movies, text, charts, and sounds; and providing a continuously updated quantitative analysis of the knowledge structure being created.

Semnet supports the following learning processes:
- Collaborative thinking
- Personal organizer tool
- Study tool
- Collecting information and resources.

As a collaborative thinking tool, Semnet “can support collaborative endeavors such as curriculum development by teams of professionals or building a community of learners among students. Collaboration leads to conversation which results in clarification of ideas” (Semnet Research Group, http://apple.sdsu.edu/logan/SenNet_Collaborate.html). As a personal organizer tool, Semnet allows individuals to organize their lives and plan...
their activities based on the metaphor of a clock. Users can organize their days, weeks, and years with the points of the clock and build links between and among their lives' events. Below is an example:

Figure 4. Courtesy http://apple.sdsu.edu/logan/SemNet_PO_Tool.html, Semnet Research Group

As a study tool, Semnet allows users to create concept maps in much the same way as Inspiration does. However, Semnet emphasizes the concept-relation-concept in the construction of the knowledge map. This is based on the principle that concepts are ideas that can usually be described by a word or phrase, and that concepts can be understood through their relations to other concepts. For example, the concept dog can be understood through the word “dog” and also through its relations to other concepts: domestic, wild, worldwide, mammal, 2-350 pounds.

Figure 5. Courtesy http://apple.sdsu.edu/logan/logan_SemMan1.html

Those relations are elaborated using the subject-verb-object, which is the basis for normal sentence construction as can be seen in the diagram below. A concept-relation-concept is known as an instance.

While students are constructing semantic networks or knowledge maps, they are actively seeking information to describe concepts by naming them and naming relationships that link two or more concepts together. In the process, they are creating an information map of their knowledge structure and this is much more useful than rote memorization. Below is an example of a semantic network (a net) created by a student about the concept music.

Figure 6. Courtesy http://apple.sdsu.edu/logan/logan_SemMan1.html

The dots appearing next to the related concepts emotion, balance, life, style, form, rhythm, melody, harmony, etc., imply that the user has created an individual net or knowledge structure for each of those concepts. By clicking on a related concept above, Semnet will show the user the individual net in which the related concept becomes the central or core concept.

Figure 7. Courtesy http://apple.sdsu.edu/logan/logan_SemMan1.html
The last learning process that Semnet supports is collecting information and resources, in particular World Wide Web (WWW) information. It allows users to organize WWW information into an interactive multimedia database for presentations, lectures, study, research, and a myriad of other uses. This function serves as an organizational or planning tool with the added feature of being able to import and export text, graphics, pictures, and other multimedia forms from and to various applications. Individual nets (maps) can also be merged together and linked to other nets to create nets of any size (theoretically up to 32,000 instances).

Conclusion

Concept mapping is a powerful and effective instructional tool that encourages students to organize their knowledge about a content domain and to be explicit about the nature of relationships between ideas (Spoehr, 1994). Concept mapping forces students to think about the content domain in order to identify and verify important concepts, classify those concepts, describe the relationship between concepts and assess its meaning, analyze the nature of the relationship, and form the link or connection which engages the most critical thinking (Jonassen, 1996). Inspiration and Semnet are computer-based tools that facilitate this process.

In the broadest sense, information technology has had a role in the instruction of teachers for generations. For education, the most significant revolution in information technology prior to the current century was the advent of moveable type. The printing press made it possible to preserve and distribute information as text to the general populace and, arguably, made literacy a necessity rather than a luxury. The pervasive influence of this technology accounts for two of the three “R’s” of reading, ‘riting, and ‘rithmetic. Today we are encountering a technology that is, at least, as pervasive and powerful as printing was centuries ago. Education, in the accepted sense of schooling,” is predicated on the belief that the young must be taught to comprehend the messages embodied in technologically grounded objects of information. The pervasive information technology today is electronic and digital and requires reconsideration of what is considered appropriate schooling to achieve the goal of a literate people.

**Objects of Complex Communication**

Recent developments in electronic digital information technology permit the transmission of information using multiple modes of knowledge representation. Expressions of ideas, i.e., representations of knowledge, may now be communicated over a global network of digital devices (the Internet) using graphics, sound, and video in addition to textual representations. The term **multimodal** is used to characterize this feature rather than the more common multimedia. The rationale for this shift in terminology is that multimedia refers to source rather than object entities. As Korzybski (1933) asserted, “A maps not the territory it represents,...” Whether the source representation is text, sound, or picture, its form for electronic communication is digital and therefore a single medium.

This kind of communication is also **multiordinal**. Multiordinal terms are ambiguous and infinitely-valued, “becoming specific and one-valued only in a given context, or when the orders of abstraction are distinguished.” (Korzybski, 1933) While Korzybski’s descriptions were in relation to linguistics, this notion can be extended to include multimodal representations. The facility with which individual representations, in whatever mode, can be dynamically associated by linking, adds yet another order of complexity when describing the context.

Multimodality and multiordinality are the fear-tes that characterize these objects of complex communication. To participate in both the access and creation of knowledge as complex communication, it is necessary to be able to describe and interpret the structure of the total context. The multiordinality of terms in a linguistic expression requires more than a collection of definitions (which are themselves linguistic expressions) to derive the significance and meaning of the expression.

**Assessing the Significance of Complex Objects**

What seems to be needed is an expanded method of establishing significance in complex communications, or aesthetic communication. Kaelin (1962, 1968) develops an existentialphenomenological view of aesthetics that seems to be suited to the task. In his description of aesthetic communication, Kaelin develops a model that places artist and audience on the same side as the work itself. Through manipulation of materials in-the-world, the object is brought into being by the artist. Through an analogous action, the significance of the work as it embodies an expression, may be perceived, described, and judged. The communication is a dialogue between artist and audience, or creator and appreciator, which is mediated by the aesthetic object.

Kaelin (1968) develops four postulates for the interpretation of aesthetic significance, which can be paraphrased:
- All significance is context bound.
- The context is composed of counters and their relations. In the aesthetic context, these counters can be separated into surface, the direct result of the manipulation of the materials that form the object, and depth when objects are represented.
• No counter has absolute significance. It is the relationship among counters within the context that creates significance.
• The significance of the context is the “felt expressiveness of all the counters as they fund, or come to closure in a single experience.”

By the manipulations of materials (the artist’s medium), the expressive object is created, making it available as a phenomenal object, i.e., perceptible to the audience. In the act of perception the object then mediates in the communication process between its creator and an appreciative audience. So, too, the objects of complex communication, multimodal and multiordinal, share similar features with expressive objects created by artists, a painting, sculpture, dance, musical composition, etc.

Not all “prospective members of the artist’s audience are prepared ... to participate in the aesthetic communication” (Kaelin, 1962). The critic’s role in aesthetic communication, being prepared by experience and education, is to “lead the audience to the fulfillment of the aesthetic communication” (Kaelin, 1962). In analogous fashion that teachers stand in a similar position to assist students in their ability to participate in the complex communication that technology has made possible. And further, that the educational process also empower students to create their own expressions (knowledge representations) through the use of information technology.

Critic and Facilitator Roles

Kaelin’s commentary on the critic’s job in the context of aesthetic communication also has direct parallels in the teacher’s job as a facilitator of learning in the context of complex communication, and a basis for the role of information technology in the preparation of teachers to fulfill this function.

The job of the critic, therefore, is not to state what the work of art means, but rather to show how it is constructed and of what it is constructed, so that a third person may grasp its significance in an act of integral perception. What the critic must possess is not a series of categories, which result from the classification of previous art works, but if they can be found, the structures which are implicit in the organization of the present art work (Kaelin 1962).

Just as a part of the preparation of the critic in Kaelin’s scheme is a “sound education in the expressiveness of materials,” (1962), so media education should be a part of the preparation of teachers. But education in the manipulation of materials is not enough. It should be combined with a philosophy which allows for the elaboration of appropriate criteria for making judgments about the significance of such expressions or representations of knowledge.

An Educational Technology Program

It is from this standpoint that efforts in teacher preparation, principally in graduate courses in the educational application of technology, are being directed. The Master of Education in Curriculum and Instruction at Tennessee State University added a new concentration in educational technology in the spring of 1996. The target audience for this concentration is principally teachers who have access in their school and classrooms to the information technology. The state has proven a strong commitment to the integration of technology into classroom practice, first by funding the Twenty First Century Classroom initiative, and more recently the Connect-Ten project which provides virtually every school in the state with ISDN Internet access.

Prior to the creation of this concentration, one course was offered at the graduate level for classroom applications of technology. The concentration now makes four courses available to graduate students in curriculum, and two additional, related elective courses are available from other departments. The content addressed by these courses has rapidly moved from single computer applications and evaluation of “educational” software to the creation of original projects using multimedia and hypermedia applications. It is already evident that the present program needs expansion to adequately prepare teachers. It is also evident that initial teacher preparation, which we have at both undergraduate and post baccalaureate levels at Tennessee State, incorporate more of the use of technology for information access and creation than is presently the case. New emphasis that both state guidelines and national accreditation standards are placing on the appropriate use of technology as an integral part of regular classroom practice are encouraging.

By introducing teachers to these concepts and engaging them in creating and evaluating their own efforts at complex communication, we are gradually developing a paradigm that we believe to be appropriate as the information technology continues to change. New tools have made the creation of multimodal objects more accessible. Hypermedia and Web authoring applications have taken on greater significance in our classes than was formerly the case, replacing much of the instructional time previously spent using general applications and productivity software. Time remains a significant constraint. Creating and evaluating complex objects is still a time intensive task and must be balanced against other instructional concerns. While there remains great value in more traditional approaches, this model has efficacy even when applied to less complex expressions.

INFORMATION TECHNOLOGY AND THE SEARCH FOR COHERENCE

Steve Harlow
University of Nevada Reno

"Without stories there would be no events."
Frank Smith, To Think

Jerome Bruner has stated that “in certain respects, how the mind works is itself dependent upon the tools it has at its disposal.” Information technology offers a variety of rapid and extensive media that engage the learner in active ways. At best, the computer places the individual in the locus of control as a learner. The learner is able to gain access to a variety of sources.

Theodore Roszak (1988) in his book The Cult of Information has taken dead aim at the computer as a model for the human mind and as an instrument for teaching. While his complete criticism of the computer goes beyond the scope of this essay, the gravamen of his book is that information processing loses sight of the reality that “the mind thinks with ideas, not with information.” The computer is the consummate machine in dealing with the world as information. To Roszak information represents “discrete little bundles of fact, sometimes useful, sometimes trivial, but never the substance of thought.” Postman (1996) makes a similar point in his work Technopoly. “Computer technology,” he writes, “functions more as a new mode of transportation. It moves information—lots of it, fast and mostly in a calculating mode.” Postman holds that information is both ephemeral and by nature unorganized. To both Roszak and Postman the computer is best at sorting and assembling facts. The net effect of information technology then leads to fragmented learning. That is to say, learning that does not cohere into what has been termed by Roszak and Postman “knowledge.”

While I hold that critics of computer technology, like Roszak and Postman, demonize information technology, and in the process lose the potential positive contribution of the computer in education, they do remind us that the mere presence and use of information technology does not in itself result in coherent knowledge. To give the critics their due, they ask advocated of information technology to address the question of what we mean by learning and knowledge. They press us to examine the effects of technology on the learning process.

In the remainder of this essay, I will briefly deal with the relationship among technology, learning, and knowing. In conclusion, I will offer an epistemology of the narrative that permits us to evaluate the effects of information technology on the educative process.

The Naive View of Epistemology

The idea that we form our notions of the world directly by letting them seep through our senses and mind is considered to be the position of naive epistemology. Popper (1985) referred to this view as the “bucket theory of the mind.” Reality is poured into the mind by “buckets” of outside stimuli. The mind is seen as a mere receptacle of the outside world. There is an immediate correspondence between what the mind takes in and what is actually “out there.” Note that there is a passivity of mind implied in this view. A further implication of naive epistemology is that the teacher’s role is to lead the student more or less directly to a correct set of experiences that yield truth.

Novak and Gowin (1984) expose a severe weakness of naive epistemology by citing Dewey, who stated that “there is nothing on the face of a fact that tells us what it means.”
In other words, facts do not announce themselves. There is a need for interpretation, background, and context.

**The Constructivist View**

Popper views the learner as actively testing his understanding of the outside responding world. To Popper (Hunt, 1982), "all observation is an activity with an aim." The results of such testing, to Popper, are provisional and inconclusive; the best the learner can hope for is closer and closer approximations of the way things work. Accordingly, the learner must continually acquire, and through observation and active testing, correct her understandings of the surrounding world.

**Bruner’s View**

To Bruner, our very way of knowing is shaped by our entrance into a specific cultural milieu. Bruner goes on to state:

> When we enter human life, it is as if we walk on stage into a play whose enactment is already in progress—a play whose plot determines what parts we play and toward what denouements we may be heading. Others on stage already have a sense of what the play is about, enough of a sense to make negotiation with a newcomer possible. (1990).

Language and narrative (story) become the connective epistemological tissue from culture to the individual. In learning language, Bruner (1990) states that "the child is not learning what to say, but how, where, to whom, and under what circumstances." As the child develops facility in language, he begins to use language as a part of forming narrative and stories about how the world works as well as how he fits into this world. Bruner (1990) points out that there is "a readiness of predisposition to organize experience into a narrative form, into plot structures and the rest."

**A View That Emphasizes the Importance of Narrative in Learning**

Taking the idea of the narrative as a way of knowing, Roger Schank, a major presence in the area of artificial intelligence, holds that "story" is the major and most efficient mode of human knowledge and learning. Story is the way we encode the data of everyday life and make that data meaningful and significant. The scope of stories should be conceived in a broad fashion. Pedagogically, for example, a science experiment could assume the structure of a story. If it did not become a story, to Schank, it would not become a part of the knowledge base of the learner. A product of art, say a painting, can represent a story. It is not merely an aesthetically pleasing item, but translates experience into understandable narrative. Where school succeeds, it does so by stimulating the learner to construct stories, stories that embrace and fit the situation at hand. Information technology then can be assessed epistemologically by its capacity to develop stories.

As educators, we need to be aware of our beliefs about how people learn and we need to select tools that: are consistent with those beliefs, fit the needs of the learner, and match the purpose of the learning situation. This means that we need to have a large tool chest of models and associated strategies from which to choose. To help educators collect tools and select from them, four theories and accompanying models of instruction will be briefly explained, and a short lesson based on each model will be presented.

We have included the following four theories/models: Objectivist, Generative, Constructivist, and Problem-based learning.

**Objectivist by Dale Hoskisson**

**Basic Assumptions**

There is an objective reality which can be imperfectly known and shared with others. Reality is idiosyncratic, i.e., no two are the same, although there is enough overlap for communication and achieving mutual goals.

The elements of successful learning situations are: redundant, systematic and organized. Redundant means that there are multiple ways to learn the target material. Systematic means that everything needed for the success of the learner is planned for. Organized means the learning material is put together into an orderly, functional, structured whole.

**The Model**

I have chosen a generic instructional systems design model. I have chosen this because it allows me to create material based on the existence of a body of knowledge (an objective reality) that can be learned, analyzed, and shared with others in a redundant, systematic and organized way.

The purpose of instructional design is to aid the learning of the individual (Gagné, Briggs and Wager, 1992). Instructional design is a systematic, orderly but flexible approach to helping the learner that integrates all components of the learning situation and includes an analysis of the components in logical order and coordinates the overall process among those involved (Briggs, 1977).

**How the Model Affects the Instructional Design of the Lesson and Choice of Technology**

The learner should be actively engaged in the learning situation, not just passively listening or reading (Dick and Carey, p. 9) Learning should be placed in a meaningful context (Gagné, Briggs, and Wager p. 198) The designer should choose media that match the needs and abilities of the learner (Gagné, et al, p. 213). “This systematic method is termed instructional design. It is based on what we know about learning theories, information technology, systematic analysis, and management methods” (Kemp et al, 1994, p. 6).

**Brief Description of the Lesson**

The purpose of the lesson is three fold: 1) to give the students a chance to work in groups; 2) to take on at least some of the role of an actual classroom teacher and work with real children in a real classroom setting; 3) to learn how to integrate the Internet into the classroom.

The students will be divided into groups of four. Each group will be assigned a classroom teacher to work with. The goal of each group will be to produce a unit that the classroom teacher can use to teach his or her students to effectively use the Internet. The students will be given a list of suggested books. The students will have four weeks to produce the unit. The students will implement, evaluate, and revise the units before submitting them for the final grade on the project. A full description of the lesson and how it was developed using the model is included on the CD-ROM or from the author.

Generative Learning by Donn Ritchie

Assumptions
Most educators begin at the same point. They want to create an environment in which their students will learn. But what does it mean to learn something? To some, learning is simply a biological response to external stimuli. To others, learning means constructing a personal interpretation of reality. Between these two extremes are a myriad of interpretations as to what learning involves, and how to facilitate learning.

In 1974, Marvin Whittrock proposed the idea of generative learning, which has been updated over the past quarter century, and continues to evolve as does our understanding of how people learn.

The basic assumption of generative learning is that for learning to occur, active mental participation of the learner is required. Mental connections occur as new information from the environment is integrated into existing mental structures in one of three ways. As the information from the environment is processed through the senses, learners: (a) reorganize their existing mental structures into new frameworks; (b) elaborate existing knowledge structures to become more inclusive; or (c) reconceptualize their understanding to gain a more exact or detailed understanding of the information.

Each of these three processes requires learners to actively engage in mental processing as they "create" new understandings. There are a variety of strategies that require students to actively process information to create new structures. Grabowski (1996) identifies 17 different strategies which facilitate generative learning. The groups are divided by the type of processing required by the student, with each ensuing level requiring a deeper level of processing. They all require the learner to examine new information, mentally process what is being observed, and construct (or generate) a new interpretation of the information. When students generate this new understanding, then learning occurs.

An Example
In a generative learning classroom, the instructor does not talk the entire period. When students are not actively engaged in generating new mental connections, the information is not transferred into long-term memory. If a lecture format is mandated, learning can be enhanced by activities which require active mental processing, such as generating rhetorical questions to direct and engage thought. The instructor is attuned to facilitating the learner's construction of relationships between the new information and their existing knowledge structures.

Suppose you had a group of preservice educators, who need to be taught to explore and search the World Wide Web (WWW). The instructor presents an overview of the WWW. Students take notes during the presentation, and at the conclusion they create an outline of the information presented. They write questions for the instructor, and a statement predicting how this system might be useful for educators. After a demonstration of the Web, students summarize the navigational process by creating a diagram of how pages are linked together.

Students work in teams to explore sites and materials. By synthesizing the new information with prior knowledge, students create a metaphor describing the Web. The teams exchange metaphors, and one at a time, they analyze their creations, and evaluate which metaphor they believe to be most accurate.

One class session would seldom contain each of the strategies. The selection of strategies often depends on the topics and the students' level of understanding. In this example, all of the strategies required the learner to do the generation.

Relationships to Other Theories
In the original work by Whittrock (1974a; 1974b), generative learning was shown to consist of four components. These components included: enhancing a student's motivation by selecting topics based on their interest; focusing the learning processes by using materials that pique the learner's attention; analyzing the beliefs, preconceptions, and metacognition strategies of the learner to enhance the knowledge creation process; and, helping in the generation of knowledge by establishing relationships between the environmental information and knowledge previously held by the learner. In recent years, Whittrock (1992) has focused on identifying ways to facilitate personal relationships between existing knowledge and new information.

This pedagogy can be blended into, and strengthen, other theories of instruction. For instance, in problem based learning, the role of the instructor is to facilitate learning by providing relevant, real-world problems for students to solve. The instructor can ask students to outline the information, paraphrase their solution, or create a concept map at the conclusion of the activity.
Problem Based Learning by Bob Hoffman

Basic Assumptions

Learning is a fundamental response of organisms to their ongoing interaction with the environment. We learn continuously from before birth, and we do so in order to succeed as individual organisms, and to contribute to the success of our species.

The design of formal learning environments is as much an exercise in people’s natural impetus to learn as it is focusing and magnifying their learning efforts. There is no such thing as teaching without learning. Given the pragmatic character of these assumptions, there is Problem Based Learning (PBL), which incorporates elements based on several theoretical models.

Explanation of the Model

Edwin Bridges (1992, 1995) describes the characteristics of PBL as:

- The starting point for learning is a problem
- The problem is one that students are apt to face as future professionals
- The knowledge that students are expected to acquire during their professional training is organized around problems rather than the disciplines
- Students, individually and collectively, assume a major responsibility for their own instruction and learning.
- Most of the learning occurs within the context of small groups rather than lectures (Bridges, 1992)

In terms of a cognitive theoretical rationale for using PBL, Bridges (1992) cites activation of prior knowledge, encoding specificity, and elaboration theory. PBL designers attempt to choose and sequence problems so that students apply their existing knowledge base to the acquisition of new knowledge.

Encoding specificity refers to the situation in which students will apply their new skills and knowledge. By crafting problems that closely resemble those that learners will face in the “real world”, PBL strives to create a functional context that will help students transfer knowledge from the classroom into target arena.

In PBL learning environments, students actively discuss problems and potential solution strategies with each other, teach each other, and document their thinking about the problem. Each of these activities help students elaborate their knowledge.

How Might This lesson Look in a PBL Classroom?

Let’s look at our sample lesson, aimed at showing future teachers how to help their students use the World Wide Web. The course instructor distributes the following to the class:

- Background materials
- Learning objectives
- Guiding questions
- The problem to be studied
- Assessment tools
- Bibliography of relevant materials

The students are divided into small groups. The task is to design a lesson to teach students how to search the World Wide Web. A learning strategy must be selected, and materials drafted to implement it. The course instructor is available to observe and consult with the groups.

How the Lesson Fits Learner Needs and Learning Goals

In this situation, learners need to know not only how to teach their students to search the Web, but also how to design and create effective instruction. The learning goals include not just “how-to” but “why-to”. Why they would want their students to be able to search the Web, and how it might fit into their curriculum.

This PBL unit allows these pre-service teachers to experience and practice the kinds of tasks they will encounter in their profession. It provides a realistic activity in a safe environment. Their prior knowledge about instructional objectives, learning activities, lesson plan development, and assessment all contribute as they tackle this task.

PBL appears to motivate learners by giving them authority to manage their own learning to varying degrees, and by providing them opportunity to enhance their status as educators by doing what “real” educators do.

Pros and Cons

The time needed to select appropriate problems, draft objectives and guiding questions, and to gather relevant resources in PBL may be comparatively greater than preparing some other methods of instruction.

A common objection to using PBL is that, since students must spend time and energy organizing the learning process itself, they may not achieve the same grounding in basic concepts as their non-PBL counterparts.
(Friedman, et al., 1992). This appears to be mitigated by improved durability of retention and somewhat better initial on-the-job performance.

Constructivism by Mark Roddy
There is an external reality that is the basis for our experiences. This reality can be known, and meaning derived from experience can be shared with others. This is the basis for learning and teaching.

Explanation of the Model
One of the reasons that constructivism has been so widely embraced is the self-evident notion that learners “construct” their understanding as a result of experience.
For the nonconstructivist, knowledge is seen as a match between internal representations and external reality. The closer the match, the more perfect the knowledge. If we correctly sequence the right set of experiences, learners are will construct a good match between their own ideas and expert knowledge derived from external reality.
Constructivists formulate the learning process somewhat differently. They look closely at the process of perception. They acknowledge the importance of the senses as a filter between the external world and the internal representations that are constructed as a consequence of experiences. They also acknowledge that the learner interprets experiences in light of what is already known.

The Role and Nature of Sense Experiences
von Foerster (1984) begins with the assumption that we are internally driven to make sense of the world. Our brains seek order and control over the stimuli that we encounter in our experiences. He discusses the evolution and structure of nervous tissue and presents a model of the functional organization of a living organism. This organism receives sensory input, interprets this experience, and if a goal is perceived, acts in such a way as to try to achieve the goal. In so doing, it affects further sensory input and so acts upon itself. The loop is repeated until a stable sensory input is perceived.

Our contact with the external world comes to us only through our imperfect sensory experience. We cannot directly experience the world in itself. We act when we perceive a goal, when we see that something needs doing. At that point we act until an acceptable response is obtained. This constitutes our experience of the world. The physical nature of the stimuli we encounter is not encoded directly by our nervous system. This is a crucial tenet of constructivism.

The Role of Past Experiences
Perceptions are strongly influenced by past experiences. What I am prepared to “see” is greatly affected by what I have seen in the past. Experiences and expectations play an important part in the formation of our perceptions and reactions to the stimuli we encounter.

Applications of Constructivism
von Glasersfeld (1987) and others (e.g. Steffe, 1983) have proposed a “teaching experiment” in which the teacher works with the student to develop a viable model of the student’s understanding of the concept in question. The teacher then leads the learner through a set of experiences designed to give the learner opportunities to encounter conflicts between his or her notions and a more viable set of ideas and understandings.

Of course, such “experiments”, while theoretically sound, cannot be implemented on a daily basis. In reality, what a constructivist teacher takes from this is a commitment to take into account what student bring to the classroom as a starting point, and to create a set of experiences that provide as many opportunities for the student to encounter new ideas in situations where they can be used to solve problems perceived and valued by the student.

Thompson (1985) states that the task of the constructivist curriculum developer is “to select problematic situations that provide occasions for students to think in ways that have a generative power in regard to the objectives of instruction”. He advocates the use of situations in which students are encouraged to generate their own feedback with regard to a problem situation. Confrey (1987) supports this notion and gives it structure by recommending a set of questions that will help students to become autonomous problem solvers. These questions are helpful for the constructivist teacher because it helps the teacher develop a model of the student’s understanding. It also puts the responsibility for the solution process back into the hands of the learner.

Conclusion
Constructivism in various forms has been embraced by many and its influence has been felt in every content area. Its full implications as a learning theory have been largely neglected. While the banner of constructivism has been invoked by many, connections between constructivism and various teaching methods have been poorly drawn. The power of this model of learning, with its emphasis on personal experience, the relationship between the learner...
and the teacher, focused reflection, and communication, remains strong.

The world is rapidly changing with society becoming more technologically complex. As a result, students need to be educated differently than in the past. The educational system should prepare students to become people of this changing society, and to adapt to the changing world.

Today, critical thinking has become an increasingly important movement in the educational system, as an approach to supply students with the skills to live in the new world. Unlike traditional educational systems, the new educational system has tried to base itself on how students think, how they discover facts on their own, and how they utilize information (Halpen, 1984).

Although the idea of thinking critically is quite old, it has been extremely important for psychologists since the beginning of this century. Psychologists have tried to answer how humans think, and how to improve human thinking skills during the 1900’s. However, it has only been a few years since educators have been designing educational programs based on critical thinking.

One course based on the idea of using selected instructional applications to improve students’ critical thinking skills as cognitive tools is call Mindtools (Jonassen, 1996). Mindtools are intellectual partners that enhance the students’ ability to think critically.

What Is Critical Thinking?

In our daily life, we can behave impulsively, so that we become unreflective and non-critical thinkers, who do not have the opportunity to improve our lives.

When thinking critically and reflectively, we become active and productive people. Critical thinking is necessary for everyone in today’s dramatically changing world.

Critical thinking is the process of assessing a conclusion based on evidence (Eggen & Kauchak, 1996). It is the higher-order thinking that is the forming of conclusions. Critical thinking involves the dynamic and mental processes that are used to evaluate information, and to reach logical conclusions in meaningful and useful ways. When thinking critically, we evaluate, analyze, and connect statements, events, ideas, data, and experiences.

Scriv and Paul (1996) described critical thinking as “...the intellectually disciplined process of actively and skillfully conceptualizing, applying, analyzing, synthesizing, and evaluating information...” They emphasized that the information for this process was gathered from “…observation, experience, reflection, reasoning, or communication...” in our daily lives.

According to the glossary of the K-12 handbook, critical thinking is “...the art of thinking about our thinking while we are thinking.”

In sum, critical thinking is an intellectual process that involves higher-order skills to improve our quality of thinking based on universal intellectual values. It depends on a person’s ability to think deeply, as well as the quality and quantity of experiences.

Mindtools for Critical Thinking

Using Mindtools in the learning environment will help students construct their own organization and representations. It requires students to think in meaningful ways.

On one hand, Mindtools engage students in the reflective thinking that leads to their knowledge constructions, while on the other hand, it requires external supports, such as books, slides, overheads, VCRs, computers, other people, etc.

Mindtools disagree with the idea that students are passive receptacles for the information that the teacher or instructional media impact on them (Jonassen, 1996). Mindtools are based on “constructivism” that supports students to be constructors and producers of personal knowledge. Moreover, Mindtools are not only constructivist and cognitively oriented, but they also create more intellectual responsibility in students.

Computers as Mindtools

By the 1990’s, instructional computer applications and learning environments had been adapted and designed as mindtools. Computers as Mindtools are both mental and computational devices that support, guide and extend the critical thinking process of students.

Computers as Mindtools guide students to construct their own knowledge rather than memorize the knowledge
of teachers. Thus, the process of how students construct knowledge is based on constructivism, which helps them organize and represent what they know.

However, in the 1970's, the basic use of computers in classrooms was to apply computer-assisted instruction (CAI) that included drill and practice, tutorials, and intelligent tutors on a limited scale (Jonassen, 1996). It represented learning from computers that were programmed to teach students to direct their own activities. In the 1980's, educators were aware of the usefulness of micro-computers in the classrooms. It was believed that computers were important instructional tools.

**Instructional Computer Applications as Mindtools**

There are several different computer applications, like Mindtools, which can be used to improve students' critical thinking skills. Using computers as Mindtools can provide a wide variety of critical thinking situations to students in a short time. The most common computer applications, using critical thinking activities, are databases, spreadsheets, the Internet, and multimedia.

**Databases and Spreadsheets**

Databases are special purpose programs that are designed to meet the specific needs of a particular application or general-purpose program (Kemp, 1996). Most database programs allow students rapid retrieval of information in an independent manner. Students organize and reorganize the information to answer questions by using the database as a Mindtool. Moreover, it is the sort of function that analyzes and enters subject matter. It provides file management capabilities that allow learners to create and define new database files.

Spreadsheets are computerized, numerical, record-keeping systems that are general purpose programs for processing numerical textual data (Jonassen, 1996). They are powerful tools for solving a wide variety of problems engaging a vast array of mental processes by using and filling in values and formulas. Thus, students use existing rules, create new rules, organize information, and think more deeply when using spreadsheets.

The process of deciding when to develop a database or a spreadsheet to most improve students' critical thinking skills is difficult. Both computer applications require analytical tasks and a number of planning activities while creating and accomplishing in learning.

Barlak's (1995) and Trumpeter's (1994) research show that database and spreadsheets enable one to analyze ideas and experiments, and to come to conclusions without previously having to acquire higher-order skills.

Learners can work in groups, then collect and analyze data from various sources, create relevant questions, and prepare written reports together. This process encourages learners to use higher-order skills. Oshima's research (1996) indicates that a database system, in which learners collaboratively construct the knowledge presented to them, helps users to represent higher-order skills.

Databases can be applied to either quantitative or qualitative social sciences, sciences, or mathematics. Rooze (1986) and Russ (1986) have shown that the database is an important tool for teaching thinking and developing skills of inquiry, problem solving, and critical thinking; as well as many of the skills needed not only in school, but also life outside of school. However, spreadsheets are not very useful for social sciences. They are most useful in the quantitative areas of mathematics and sciences. Neuwirth's (1996), Kharab's (1995), Hall's (1995), and Larrieu's (1995) research show that spreadsheets can be useful tools in helping learners gain a greater understanding of mathematical structures, formulas, numerical solutions of sciences, graphical forms, and statistics.

**The Internet**

The Internet is the world's largest computer-based communication network (Merrill, 1996). This global communication system allows computers to share and exchange data. The Internet provides vast resources for educators to create enriched learning environments.

The Internet has the potential of offering sources, which provide up-to-date information for teachers, and instructional activities for students (Hill, 1996). The Internet offers a wide range of resources that expand and change the boundaries of school and the vast roles of the teachers and students.

Learning on the Internet is more concrete than learning by traditional instructional tools; because learners can acquire knowledge in different ways on the Internet while constructing their own learning scaffold. Students can gain unlimited information about any area in a very short time.

According to Harris (1994), the use of the Internet as a Mindtool in the classroom includes independent learning, one-on-one coaching, large group demonstration with both independent and assisted practice, hands-on labs situations.

Retrieving information is an online activity, especially for supporting research papers. Students study alone in this activity. E-mail provides a useful medium for collaborative writing activities between groups of students from various cultural and socio-economic backgrounds. Bulletin boards and Usenet newsgroups provide individuals the opportunity to read, reply and copy messages focusing on a specific area of interest. Web sites allow users to store documents and multimedia resources. Computer conferencing creates virtual classrooms that are communication and learning spaces located within a computer system. There are two types of computer conferencing. IRC (Internet Relay Chat), which allows users to see what is typed on other users' screens; and, video conferencing, which allows users to send and receive video images from people all over the world. One of the newest learning activities is virtual
realities, which gives users the impression of three-dimensional interaction. It is important that these instructional activities foster the use of the Internet for learning, by designing lesson plans around off-line resources.

Although there are many advantages to using the Internet in the classroom as a Mindtool, learners may become overloaded with information. It has been shown that users learn better when they apply certain strategies to learning tasks consciously so that the learning task directs their thinking and encourages them to monitor and evaluate their progress (Tsikalas, 1995). It is important for learners to develop learning strategies that allow them to know how to access information.

After teachers design their strategies for using the Internet as a Mindtool, there are numerous databases, which can be found on the Internet, to teach students how to access, analyze, and evaluate information. It allows users the opportunity to access information in different ways (Ryder & Hughes, 1997), so that learners can construct their own knowledge, and explore a subject while communication directly with experts or peers around the globe.

If we want to use the Internet efficiently as a Mindtool, all schools and faculties should have access, and individuals with few technology skills should be encouraged to improve those skills.

Today, we need classrooms with high levels of communication, interaction, and collaboration. The Internet can be a valuable tool in academic settings to enhance active, cooperative learning through interaction with people around the world (Smith, 1996). At this point, teachers have a very important role to play in the development of Internet applications for the classroom.

It is quite clear that the Internet will break the walls of the traditional classroom concept in the future. Moreover, instead of attending the conventional classroom, we will teach and learn with our own computers in our homes, and interact with people who live around the world. This is the unique value of the Internet as a Mindtool.

Multimedia

The use of multimedia in instruction is becoming increasingly popular. The concept of multimedia has been around long before there were computers. It was defined nearly two decades ago to describe instructional methods.

Today, multimedia is a buzzword whose specific meaning changes depending on the perspective of the users (Baumbach & Bird, 1996). While specific use varies in emphasis, the basic elements, such as the combination of text, sound, graphics, and video remain much the same. Kinraman (1995) emphasizes that multimedia technology can bring authentic settings into classrooms, but it is only recently that processing power, telecommunications speed, memory capacity, and CD-ROM based software applications have been integrated into desktop computers. This combination of interactive multimedia actively involves students in acquiring the knowledge, and allows them to regulate the way that information is being presented. It has great potential for learning due to the high degree of freedom.

Arnett (1995) stated that the application of multimedia technology in the classroom has the potential to help enhance and support the instruction of all students and provide tools for students to use in creating their own knowledge. It is easy to use multimedia-authoring programs, such as HyperStudio or Kid Pix, to allow students to create programs and combine multimedia elements for specific purposes.

Multimedia can be the focus for building instructional activities related to any trends and topics in curriculum and instruction, such as active learning, constructivism, learner-centered curriculum, cooperative learning, collaborative learning, etc. Thus, the dynamic use of instructional multimedia systems will help to promote enthusiasm and curiosity among learners. Moreover, it will have the potential to extend and transform the curriculum easily.

Conclusion

Critical thinking should be the most important practical goal and value of today’s school and daily life. When thinking critically, we become active, productive, hopeful, and psychologically healthier people.

Due to the lack of critical thinking skills, students get confused inside and outside of their school lives. However, becoming a critical thinker is not easy. It takes a very long time, and a powerful, patient, and huge effort.

Today’s teachers want the use of the new computer applications, such as Mindtools, because they supply new learning environments for students who are trying to become critical thinkers. Thus, teachers should determine how computer applications could be best used as Mindtools in the classroom.

The way we teach, learn, transmit, and access information remains largely unchanged; the basic way that students learn has not changed for centuries, while around us communications technology is transforming the way we live and conduct business.

The following conditions exist today in American education:

Faculty use the “talking head” approach to convey information; students are usually the receivers of information rather than active participants in learning.

The textbook remains the basic unit of instruction; the memorization of its contents tends to be the primary measure of educational success.

Teachers work largely in isolation; most other professionals collaborate, exchange information and ideas, and develop new skills on a continuing basis.

While technology is often found in educational institutions, its instructional use is often limited to that of an expensive electronic workbook or page turner.

The Problem

Why do we still have a technology curriculum from K-12? Haven’t we learned that mandating a technology curriculum isolates the technology from use in the basic curriculum areas of math, language arts, science, and social studies? The inference is there, but inferring the use of technology within the curriculum areas is not what works - we know that from the past 18 years or more of teaching about the technology - not with the technology. But, we are still writing and dictating the use of technology curriculum. We see it at the state and local levels. It isn’t that there is not some attempt to integrate the use of technology into the learning environment - but - what do we read first when the “new” technology curriculum appears on our desks? Not how we can use it to help assist students learn about solving problems in everyday life, not how we can use the Internet to get in contact with our local government officials, not working with classes in various parts of the world in learning about different cultures. We read in the first few pages, “the student demonstrates knowledge and appropriate use of hardware components, software programs, and their connections; start and exit programs as well as create, name, and save files;” “initiate disk;” “load paper properly;” “connect computer to CD-ROM.” Somewhere towards the end of the document we may read some ideas on integrating these skills into the curriculum. Is it too late, have educators read from the beginning of the document and tried to implement the objectives written there before reading the back section where the ideas for integration may be written?

How did this problem originate? During the 1980’s in the public schools, there was great emphasis placed upon teaching all students programming skills and teaching about the computer. Most educators today believe that the computer literacy movement was ill-advised, at least partly because the arguments for its justification were flawed. One of those arguments was that students needed to know how to program computers in order to get and keep a good job. This reasoning was illogical for a variety of reasons. For instance, there are only about 20,000 programming jobs in the United States and 40,000,000 students. In addition, not many successful programmers program in BASIC and Logo. Suppose 19 year-olds (6th graders from 1990’s “literaracy classes”) wanted to apply what they learned in those classes? Here’s what they might be able to do: use an Apple IIe or IIgs or demonstrate a variety of DOS commands. Or perhaps name some of the parts of a computer.

The rationale for teaching students about technology is that such training provides preparation for a technological society, for a vocation, and for further academic study. Since computers play an enormous and rapidly expanding role in our society and in many of the jobs and professions our students will have in the future, doesn’t it seem reasonable for them to know what a computer can do and how to use it? The gap between the time students received their training and when they could expect to use their skills almost guaranteed there would be no need for the skills they had acquired.

While it may be appropriate for electrical engineering and computer science majors to pursue the computer as an object of study, it may be highly inappropriate for non-majors to approach technology in this manner, if their goal
is to learn how to use technology in their discipline. One doesn't have to know RAM from ROM in order to use a computer effectively in most disciplines. In what appears to be a paradox, as computers and technology become more complex, users in fact may actually know less, rather than more about computers.

If you wanted to design an automobile from scratch, one of the individuals you would probably consult would be a mechanical engineer who had specialized in the design of automobiles. If you wanted to design a new computer from scratch, you would probably need the services of an electronic engineer and/or computer scientist. If you wanted to consult with someone about major repairs on your car, you would consult a mechanic; on your computer, you might consult a computer repair specialist. If you wanted to consult with someone about learning how to drive a car, you might consult a driver education specialist. If you wanted to get some ideas about how to use technology in your teaching, you might consult an instructional technology specialist. We must make this distinction among whom to turn to for guidance or run the risk of the misplaced expert syndrome. One consequence of this approach was the misplaced emphasis, especially in the public schools during the 1980's, placed on teaching technology as the object of instruction as contrasted with something to learn with rather than about.

Whenever a new technique or tool is introduced into an organization, the "old-wine-in-new-bottles" syndrome frequently occurs. The individuals in the organization have a tendency to bend the new tool to fit the old way of doing things rather than exploring or learning how the new tool might be used to perform additional tasks. While this approach may be an appropriate response under some conditions, it is an inappropriate response under most conditions.

One of the major questions posed by teachers and administrators is "How do we fit computers into the curriculum without lengthening the school day?" If technology or computer education is viewed as a new area of study that must be taught in addition to the regular curriculum, then it is difficult to find the time for a computer program without shortchanging another area of study. But if computer-related activities are designed to support the regular curriculum, they won't distract from it, but will enhance it.

**Now What?**

During the last ten years, the emphasis in computer education has gradually shifted from an emphasis on programming and the study of the computer itself to the use of applications or tool software. We have observed that not many teachers and students apply programming skills to solve real-world problems. However, applications software is easier to learn than programming and almost everyone who learns to use it sees an immediate application in her or his own work. Consequently, the computer becomes a practical tool that teachers and students can use in all areas of education.

A different approach to curriculum planning is to review each objective that is already in the school's curriculum and plan how technology can be used to enhance the attainment of those objectives. The rationale is that the technology is a teaching tool and that students should be taught with computers and other technologies when such strategies provide advantages over more conventional methods. One of those advantages is that students who use the technology in this way are using technologies in the same ways that people in the world of work are using them—persons in business, industry, manufacturing, education, and the military are using computers as a tool to make them more productive in their job or profession.

Technology as a tool works best when learning includes the process of finding data, information, or artifacts; making decisions based upon data; and communicating those findings to others. Technology as a tool works best when teaching includes the management of a learning environment that sets up environments in which students can work individually and in groups in data collection, decision-making, and communicating within the context of real-world tasks.

Examples of what Instructors/Teachers/Professors might try, include:
- Keep records of grades, absences, advisees, former students in program, syllabi (including online versions), credentials (including on-line versions).
- Confer with colleagues and other experts worldwide.
- Access information in online libraries.
- Manage instructional tasks.
- Access, collect, and use data and instructional resources.
- Prepare and use slide shows with classes.
- Give electronic tests- give, score, and report electronically.
- Make assignments available electronically.
- Make provisions for students to hand in assignments electronically.
- Consult expert consultant to local schools, as in Dr. Math, Dr. Art, Dr. History.
- Access up-to-date information in your specialized field.
- Stay informed on a topic.
- Participate in collaborative projects via the World Wide Web or e-mail.

Examples of what students might participate in could include:
- Acquire and become skilled in computer and telecommunication skills important for the world of work.
- Learn how to locate, access, assemble, and evaluate a wide range of data and resources in one's area of study.
• Communicate with other students and experts, world-
wide, in one’s field of study
• Access information and other resources in on-line
libraries (full text in some cases)
• Access databases not otherwise available.
• Access to a wide range and assortment of resources not
available at any one University.

A tool is not an end in itself, but a means to an end. Tools themselves do not teach; neither should they be the object of instruction. A tool is a means to an end, so it makes sense that technology as a tool should be integrated throughout the school’s curriculum. In a technology-integrated curriculum, there is no need to add new technology-related objectives to a school’s curriculum. Rather, schools examine the traditional curriculum and determine when it may be appropriate to develop computer-related learning activities for existing curricular objectives. An additional benefit of teaching with technology is that students learn to use tools that are commonplace in the work force. Students learn these skills in a relevant and useful context.

We are in the midst of the Information and Communications Age. Our total collected body of knowledge is expanding so rapidly that most of us have difficulty staying up-to-date, even in our own fields of specialization. In this era, knowledge of facts is not as important as the ability to find information when it is needed, to analyze and synthesize it, and to apply the conclusions to new situations. With the technology as a tool, students can focus more on thinking.

WHERE DO YOU STAND TO GET A GOOD VIEW OF PEDAGOGY?

Avril Loveless  
*University of Brighton*

As teacher educators in the UK with a commitment to the use of Information and Communication Technology (ICT) in teaching and learning, we live and work in 'interesting times', in which the cultural and political contexts of education and schooling raise challenges to many practices and beliefs. There is the potential for ICT to be the catalyst for significant change in pedagogy, yet the picture painted and the policies proposed are not yet reflected in the experience of many classroom teachers. What role can research play in providing a 'view' of pedagogy, both current and potential? How can knowledge and understanding of pedagogy with ICT be constructed by teachers, researchers and policy makers to promote effective teacher education in this field?

The purpose of this paper is to contribute to the discussion of 'ways of knowing' in the research process, for both teachers and researchers. The discussion will consider a question which has underpinned a research and development project focusing on teachers' pedagogy with ICT in the media arts. The initial inquiry focused particularly on the understanding of literacy within the contexts of both the media arts and the general use of ICT in education. The influences of culture, subject knowledge and pedagogy on the development of classroom practice were identified and presented within a framework which differentiated between 'mere' practice and 'good' practice.

After further research and reflection, however, it was acknowledged that this framework did not reflect the complexity of the interaction of these themes in developing pedagogy, nor enable the production of a satisfactory description of the experience of the teachers in trying to meet the many requirements placed upon them in the use of ICT in their work. The research paradigm needed to encompass both an interpretivist approach to the teachers' experience and action, and a critical theory approach to the constraints and contradictions of the requirements placed upon teachers by political and structural systems.

**The Initial Research Inquiry**

'What is the interaction between teachers' knowledge of pedagogy and their knowledge of ICT in teaching and learning?' This line of inquiry arose out of a desire to understand how the knowledge that underpins teachers' pedagogical practices interacts with the knowledge that they bring to their uses of ICT in learning environments. The nature and complexity of describing 'teacher knowledge' is recognized, particularly in a national context in which 'teacher knowledge' is increasingly defined and prescribed. The effective use of ICT in classrooms is, however, linked to teachers' theories, beliefs and understandings of the subject domain, as well as access to, and competence with, resources (Watson, 1993). It is this range of theories and beliefs that fuel action in the classroom and models of teacher education for continuing staff development should acknowledge and challenge these in supporting the development of pedagogy.

**The development of ideas in the Brighton Media Arts Project**

**Phase One.** The project set out to examine the notion of 'visual literacy' in Primary school children and the ways in which this could be developed in the digital arts. Its aims included the design and dissemination of curriculum materials which teachers could adopt and adapt to support their pedagogy.(Loveless, 1997). The children's use of image manipulation tools to develop their ideas in the digital medium reflected Street's 'ideological model' of literacy which is embedded in cultural practices, rather than an 'autonomous model' in which sets of skills or competencies are developed separately from the situations in which they are used. (Street, 1993).

Teachers responded to the work produced by the children in such project settings both positively and with anxiety. They celebrated the children's achievement, yet expressed concern about their own lack of ability to continue such work in the daily classroom context without the support of an 'artist in residence'. They described 'generation gaps' in their understanding of the ways in which children received and constructed meaning in contemporary media culture; they expressed lack of subject knowledge in the visual arts and the use of computers; and they perceived a lack of experience and understanding in their pedagogy which contrasted with the representation of knowledge of the practising artist working with the children.
The three themes of culture, subject knowledge and pedagogy were developed beyond the notion of ‘visual literacy’ and applied to the broader considerations of ‘information literacy’ in teaching and learning. The debate about what it means to be literate in the ‘Information Age’ is still developing. Street’s models of literacy are useful in differentiating between a skills or competence model of about what it means to be literate in the ‘Information Age’ and critical pedagogy were developed beyond the notion of ‘visual effectiveness of practice in children’s learning. (Alexander, 1996)

Phase One reflected a view of research in which the factors which influenced pedagogy in a particular context could be observed, described and presented to teachers in order to support their practice. During the course of the project, it became clear that this approach to research and dissemination was unsatisfactory, both in providing accessible exemplars of practice for teachers and in describing their experience of ‘coming to know’ how to develop teaching and learning with ICT.

Phase Two. In designing the second phase, it was felt that the focus should shift to the teachers’ experience of developing subject knowledge, ICT capability, classroom practice and critical awareness of the context of their work, supported by the practising artist and a researcher over an academic year. This shift in emphasis to the learning experiences of the teachers entailed a revisiting of the understanding of the different cultures impinging upon the teacher and the development of change in pedagogy. The research paradigm would also need to shift in order to provide means to describe the teachers’ experiences as well as the wider contexts in which they were working.

Revisiting Culture in the classroom: Tectonic plates?

Teachers are influenced by many cultures which differ in their origin, demands and impact. The images of the purposes and progression of ICT in the wider society are reinforced by the priority given to ICT in education policy, both national and local. These contrast, however, with other education policies which describe the curriculum to be delivered, the nature of subject knowledge required of teachers and the teaching strategies prescribed for the raising of standards. The school and classroom may have limited ICT resources, inappropriate for the range of teaching strategies recommended, often contrasting unfavorably with those resources found in some of the pupils’ homes. The potential for ICT to enhance, extend and change the role of the teacher can be perceived as an exciting opportunity or a confidence-crushing threat.

Amongst these contrasting cultures within the national and local educational systems, there is the teacher’s own sense of professional purpose, competence, values, relationships and emotions.

The demands for innovation and change can therefore be difficult, contradictory and confusing. The model of the development of pedagogy is not one of the teacher located at the center of a number of outside influences, calmly reflecting upon the way forward for effective action. It resembles more the meeting of tectonic plates, jarring and grinding against each other, creating mountain ranges and sliding faults.

Perceptions of the culture of ICT

The debates about the impact of ICT on our culture are well rehearsed. Our society recognizes the impact of ICT in the economic, educational, social and personal lives of its members and much use is made of terms such as ‘The Information Society’ and ‘Virtual Culture’. The definition of these terms are not always clear and the images and expectations that they evoke are problematic, addressed in debates about new literacies, new relationships and new visions of the post-industrial society. Anxieties are expressed about the ways in which ICT can be used for controlling information, surveillance, marketing, invading privacy and models of intelligence. Virtual Culture is, however, also celebrated as providing opportunities for communication and collaboration between communities and previously marginalized groups; for blurring the boundaries of communities and individual identities, and providing new representations of knowledge. The information age is usually presented as good, desirable, inevitable and embodied in our children.

Policy for ICT in Education

Government policy for education in the UK embraces this positive and progressive view. The Stevenson Report, urged government to proclaim its priority to increase the use of ICT in schools (McKinsey, 1997). The White Paper, Excellence in Schools, highlighted the modernization of the comprehensive principle through a ‘National Grid for Learning’ (NGFL) (DfEE, 1997a) and the consultation for the Grid proposed on-line learning and teacher development materials for life long learning(DfEE, 1997b). All teachers will be expected to show evidence of specific standards in their ICT capability. These reports and developments for legislation reflect a political push for access to information and learning for all citizens. It seems to be assumed and uncontested that the first will lead to the second.
Policy for teaching and learning in schools
Against the backdrop of open access and flexible learning spaces is a contradictory rhetoric and policy about the nature of knowledge and pedagogy. The National Curriculum and Assessment framework in England and Wales presents a model of clear subject boundaries and content which can be assessed objectively in order to provide indicators of school effectiveness and performance. The nature of ‘teacher knowledge’ is addressed in current UK policy in the definitions of standards of subject knowledge and teaching strategies. There is a detailed model of a Teacher Training Curriculum and Standards, both in subjects - English, Mathematics, Science and Information Technology - and in general professional practice. This, however, has been recently questioned by a report which describes how effective teachers of numeracy were distinguished from other teachers, not by the level of previous subject qualifications, but by a particular set of beliefs and understandings, both about the pupils’ learning and the subject itself. (Askew et al, 1997)

Teachers’ experiences of their role and purpose
Teachers’ perceptions and experience of their purpose and practice in the ‘turbulent times’ of educational reform need to be considered. There has been a number of key studies which focus on Primary teachers’ personal and professional experience whilst coping with multiple innovations and change in their interpretation of autonomy and professionalism. Indeed, Hargreaves argues, while policy rhetoric stresses knowledge and technique as central to good teaching, I draw attention to the importance of purpose, passion and desire. Seeing teacher development in this light, I argue, highlights the central place of moral, political and emotional issues in the field. (Hargreaves, 1995, p9)

Revisiting Pedagogy: interaction and transformation
Pedagogy is often described as ‘the science of the art of teaching’, and addressed in teacher education as the development of specific teaching strategies and skills. It can, however, be described as a cultural practice (Giroux, 1997) and defined as the ‘transformation of consciousness that takes place in the intersection of three agencies - the teacher, the learner and the knowledge they together produce’ (Lusted, 1986, in Luther, 1990, p15). ICT could be considered to be a fourth agency, acting as a catalyst for the interaction between teacher, learner and knowledge (Loveless, 1995). Such a view does, however, highlight contradictions and tensions between the pedagogical practices required of teachers in current educational policy and the changes in practice made possible by the use of ICT.

Teaching in the Information Age
What’s new? There are interesting and challenging claims made for the potential of ICT in teaching and learning. The purpose and role of the teacher can be clarified and refined in the context of using ICT (Scrimshaw, 1997a). Integrated Learning Systems, whilst reflecting a behaviorist model of learning, have been demonstrated to provide opportunities for teachers to develop their use of diagnostic tools and change their practice (Underwood et al, 1997). Scrimshaw notes that the National Grid for Learning has the potential to change the relationships between teachers and learners, parents and other teachers, as well as provide access to a wider range of human and material sources of information (1997b). The contexts in which teachers practice may also be changed by the use of ICT, both in terms of place and time. Teachers may become ‘portfolio workers’ in which they play a role many contexts - home schooling, electronic conferencing and managing flexible learning spaces. (Davis, 1997, Kenny, 1997, Meisalo et al, 1996).

What’s not new? ICT can enhance existing pedagogy, from providing opportunities to develop composition in writing to developing graphing skills. The presence of the ICT resources and applications in themselves are not sufficient to promote or challenge understanding, and effective capability with ICT depends not on skills, but on the context in which the experience is embedded. Indeed, innovative teachers use ICT in innovative ways. (Watson, 1993)

Tensions. There is a long research tradition in the UK focusing on teaching skills and classroom management to promote higher order interactions between learners and teachers. The current focus is on interactive whole class teaching, which is more teacher-centered and directed. These developments, whilst providing the opportunity to look afresh at ‘fitness for purpose’, contrast with the picture of flexible learning associated with a constructivist approach to the use of ICT.

A Revised Framework for Research
The design of the first phase of the project had been an attempt to represent pedagogy in an ‘autonomous’ model of techniques and strategies which were not embedded in the cultural context in which values and tensions were made explicit. The position of the researchers looking for a ‘good view’ of pedagogy also had to change, from the observation and interpretation of an outsider, to a more constructivist stance of engagement with learners’ experience and the provision of ‘scaffolding’ to support the development of action and meaning. In short, the research question changed from ‘How does ICT support the development of visual literacy?’ to ‘What is the interaction between teachers’ knowledge of pedagogy and their knowledge of ICT in teaching and learning?’
Although the methodology used is similar - a qualitative, interpretive approach employing ethnographic techniques, the lens through which the data is seen and interpreted has changed. The cultural, political, emotional and moral experience of the teacher engaging with teaching and learning in the digital arts is admitted. The tensions and contradictions in the cultures that influence classroom practice are made explicit and the political structures recognised. The models of knowledge which underpin the practice are made explicit and the political structures and contradictions in those demands. The implications of the research do not take into account the contexts in which teachers are being asked to bring about these changes, nor the contradictions in those demands. The implications of the research for teacher training and continuing professional development are acknowledged.

The research paradigm of the project is shifting from realism to relativism. The image of the teacher constructing pedagogy from the tectonic grinding of different cultures developed from Rorty’s discussion of the impact of acculturation, which can be transcended when ‘our culture contains … splits which supply toeholds for new initiatives’ (Rorty, 1991, p13). These tensions throw up the ‘unfamiliar’ ideas which can lead to the making of alternative practice. Smith also focuses on research as a practical and moral act -

To … think, … in terms of the images of a world made as opposed to found, has very serious implications for inquiry. If nothing else, such thinking places front and center our moral responsibility for the worlds we construct. Our judgements about inquiry … must be framed by free and open dialogue and a sense of human solidarity (Smith, 1997, p27)

Riddle: Where do you stand to get a good view of pedagogy?

Answer: Find a toehold and change your spectacles.

ENGAGING EDUCATORS IN ASKING THE RIGHT QUESTIONS ABOUT TECHNOLOGY IMPLEMENTATION

M. J. "Mimi" Schutloffel
The Catholic University of America

In order to understand the purpose of this article, it is necessary to give the reader some background understanding of its roots. In the fall of 1997, I participated in a conference at Pennsylvania State University entitled, "Education and Technology: Asking the Right Questions." The conference was billed as an opportunity to honor the works of Jacques Ellul and Ivan Illich, and their works were discussed in light of the current environment of technology implementation in education.

There are themes in the work of Illich and Ellul that resonate with my world view of education. I wanted to learn more about the thinking of those who question where technology is leading us.

For nearly ten years I have investigated how technology is or is not infiltrating school settings and for what purpose. I have tried to figure out who is guiding the decision making on technology and what is their ultimate objective. I have encountered a few crazed technocrats unwilling to acknowledge the limitations of technology, nor the complexity of its implementation into educational settings. My experience at the Penn State conference raised within the me awareness of the futility of miscommunication between these two groups, or the worst possibility, the complete indifference of these groups toward their coinciding inquiries.

My intention here is to raise the possibility that there are mutual issues between the two extremes, which requires a conversation, due to their mutual interest in the improvement of education. For the purpose of opening the discussion, my comments will describe, and, in some sense, respond to the questions raised by Neil Postman during his presentation at the Penn State conference. I choose Professor Postman as the starting point because his discourse was balanced and reasonable. While some may consider him representative of some out of touch minority of anti-technical educators, his own presentation was clearly more open-minded than some of his critics. The questions he asked challenge each of us as educators and citizens. We are compelled to respond if we are to construct a discipline of education that resides in the real world and reacts to the issues of living human beings.

What is the problem to which this technology is a solution?

When first raised, the question appears uncommonly straightforward. Yet we all are aware of those instances where technology has actually complicated our lives. The point may be elaborated in this way: as a pragmatist, interested in solving problems, in what way can [insert any device] as a technology assist in the solution of [insert any problem]. With this understanding, the first step in technology implementation becomes identifying the problem.

There is the assumption that all technology does is solve problems, or that all technologies solve problems. Our first question requires us to rethink that assumption.

As educators, we must summon ourselves to answer this question regarding the implementation of technology into schools. What problem does technology solve for schools? There are some exciting answers. Technology affords students the opportunity for sophisticated simulation lessons in areas impossible within traditional classrooms (O’Neil, 1995). Technology opens students to huge quantities of knowledge through the Internet. Technology helps students learn the skills of technology, thus making them better prepared for a world permeated with technology. The technology of distance learning provides coursework to those who lack convenient access. The possibilities for creative educational software have barely been tapped (Dwyer, 1991).

Whose problem is it?

Assuming that there are problems related to communication, access to knowledge, and occupational preparation, who owns these issues? Who will benefit most from a solution to these problems? A cursory reply states that we
all benefit, students and society as a whole. But let us reflect more carefully on the benefactors of technology implementation. It is widely accepted that Bill Gates has benefited. And certainly other corporate technology giants have reaped the financial rewards of the soaring popularity of technology.

Hardly an educational official or school administrator does not stagger under the pressure to get more technology into their schools. School brochures are replete with students working on computers, or talking about their school’s Internet connection. The assumption is that technology in the school computes to progress and a good education. Policymakers benefit by the positive political ambience of technology. Technology is a feature of American culture. Woe to the school person who questions the investment into technology. They are viewed as “resistant,” “living in the past,” and “unable to adapt” (Cummings, 1995).

But perhaps these resisters are concerned with this second question. Perhaps they want to know who will pay for the benefits that others are reaping. Perhaps they wonder what message the schools are sending about teaching and learning (Johnston, 1995). When graduate students are confronted with the convenient access offered by distance learning, they tend to be philosophical about the costs versus the benefits (Schuttloffel, 1997). They recognize their compromise; the personal interaction of a graduate seminar for the proximity of the convenient classroom.

Do students pay a price in the quality of education they receive with and through technology? Clearly the answer to that question is dependent upon the quality of technology used, the training and knowledge base of the teachers involved, and the balance of other opportunities for learning. (Van Dusen & Worthen, 1995). It is possible to build a case either for or against technology as a solution to learning problems. But each case is individual in context, tasks, teachers, and learners. Policymakers who decide about the implementation of technology are reminded to think of these when answering “whose problem is it?” which leads to the question “who will benefit and who will pay for using the technology (Schwab, 1973)?”

**Suppose we solve this problem, what new problems will be created?**

If problems exist with communication, access to knowledge, and occupational preparation and are solved through technology integration in schools, what new problems might be generated? This is not a nuisance question. Most administrators will attest to the fact that solving one problem, often creates new issues more problematic than the original. For this reason, administrators tend to tread carefully through the decision making process so as not to make their lives more complicated. The example of Internet access is interesting, due to the fact that most school districts are scrambling to get students on-line. Once the difficulty of getting the hardware and software in place is solved, several new problems emerge. Typically teachers are not prepared to integrate on-line materials into their coursework. With the exception of teachers with prior knowledge, they are often at a loss at how to best make use of this new resource. Teachers also have the problem of trying to prevent students from accessing inappropriate areas of cyberspace. And finally, there is the problem of the vastness of the Internet, itself. Access is not the final problem with the Internet. Access just opens the door to a multitude of decisions that must be made concerning paths and routes. Time can be easily spent on the Internet with little to show for the effort.

While much focus is placed on how crucial technology is to prepare students as the future work force, often less effort has been given to prepare the current group of teachers. Teachers today see their profession changing in ways they did not imagine or anticipate. Most teachers lack the educational preparation to analyze software, investigate the Internet, and design new technology integrated lesson plans. These teachers are not Oppositional to the technology, they just do not have the technical skills. Recognizing the situation with in-service teachers, it is enormously crucial to provide technology learning experiences to our preservice teachers (Zachariades & Roberts, 1995). Too often course requirements do not adequately prepare students to actually integrate technology into their teaching in the content areas. As we prepare teachers for the school of the twenty-first century it is imperative that veteran teachers are not left behind as the toll paid for technology progress.

**Which people and what institutions might be most harmed by this technology?**

This question does not disparage the positive contributions of technology to modern life. There is little chance that many of us would leave our modern conveniences for “the good old days.” Everything from the telephone to the dishwasher has become a staple of our modern life style.

These items support the lives we are able to live. The telephone serves as good examples of the intent of this question. The telephone has effectively closed the distance gap. To visit with friends and family around the world via the telephone is commonplace. As a child of the 50’s, the long distance call had an ominous quality, usually relating the passing of a distant relative. Today, my children make and take international calls casually. Generations of family members have the ability to stay close in spite of the mobility of modern life. The telephone has generated the global economy.
Has anything been lost? In one sense the art of letter writing is on the verge of becoming a piece of antiquity. The telephone has replaced letters as the prominent form of communication between friends, family members, and business associates. The ability to construct prose for a letter is fading. I suspect there is little mail that will make a future text of love letters. The telephone often removes the desire or obligation to visit distant relatives and friends for a thorough conversation. But at another level the telephone has become a dominating feature of our daily lives. We wait for phone calls. We jump up to answer the telephone. We make present persons wait while we talk on the phone to others. And if that bit of discourtesy was not enough, call waiting has provided the means to disrespect two individuals simultaneously.

Possibly the institution most changed by the advent of technology is the American family (Elkind, 1995). The television changed family life forever. One can argue that the content of some television is worthwhile, but it is more difficult to argue in favor of the vast amounts of time American children spend facing the screen. It seems the only cure for the situation was the advent of another screen, the computer monitor. The issue is both one of the quality of the activity on the screen, and the activity away from the screen that the viewer is missing.

The institution confronted by this is the educational system. Is it possible that technology implementation could create problems for the survival of the American school? Or as some have stated, is technology the means to ensure the survival of the American public school (Papert, 1980; Nickerson, 1988)? The disbursement of public funds for the purpose of integrating technology increasingly haunts American schools. This situation is not unique only to public education, as parochial and private schools feel the social pressures. However, the response of the public schools is pivotal, particularly in those urban districts where resources are scarce and expectations for results are burgeoning. How does an administrator explain to teachers, parents, and students that the Internet connection has been installed, but there will be no textbooks for math or science classes? There are no new building plans or teacher raises in the offering, but new computers are purchased.

What changes in language are gained and lost from new technologies?

The implication that technology is natural and has not changed us culturally is naive. An incident in an elementary school illustrates the change clearly. In a kindergarten class, the teacher set up a record player with a 78 RPM record. As students entered the room after recess there was a great deal of discussion when finally a vocal student asked the teacher, “What is that thing in the front of the room?” The teacher and I looked at each other and smirked a little. We both later commented that we doubted there would have been that reaction to a CD-player. Technology has infiltrated our lives to such a degree it is difficult to know where its impact starts and stops. Kindergarten classes are great for cultural excursions because these children have only known a technological world. Even inner-city children recognize cell phones and CD-players.

The technological impact does not end with our nation, the creation of a global culture is one result. A colleague recently returned from a trip to China where the effect of plunging a country into the technological age is very apparent. She was taken to visit a construction site where she was proudly shown the foundation of a new computer center. But she was struck by the construction workforce. People were carrying cement in jugs suspended from a rod balanced on their shoulders. The crash between technology and underdeveloped countries is loud.

At the same time we cannot but recall the impact globalization had on bringing down the Berlin Wall. It was impossible to maintain isolation with a brick wall or even an Iron Curtain. Technology is capable of transgressing into these barriers. Witness how Saddam Hussein uses technology to bargain his political platform to his people and the rest of the world. Or, think how casually we use the term “spin doctor.” Would that concept even be possible without the new technology?

What sort of people or institutions acquire special economic or political power due to the new technology?

Look again at who gains from the promotion of technology. The stock market is filled with technology companies. Clearly, there is money to be made with technology in schools. Education is a huge marketplace. Publishers know the value of the education market. It does not stop at the schoolhouse. Parents are eager to give their children every advantage and technology items top the list. If Americans are clamoring for technology in the schools, where is the political power to make this transformation happen? It is interesting to note that when President Clinton had his most recent education conference corporate leaders showcased the event. The connection between big business and educational technology is direct. Business has built a case for technology in the schools by declaring that students who lack technology skills will be unemployable (Baines, 1997). The fear of the United States losing its position as an economic super-power drives corporate America to infuse its agenda into education. This is not a new phenomena. Most twentieth century education is predicated on its relationship to the world of work. The utilitarian nature of American education ties nicely to American business.

From this environment, technologies emerge as the power-holder-makers. The premise is, that if students lack
the knowledge to use technology, their future contribution to society and their personal fulfillment is in jeopardy. This assumption places large numbers of American students into a potential state of marginalization. What sort of people or institutions acquire special economic or political power in this situation? First, those that currently have power stand to gain the most. Their position and holdings set the stage for further advancements. Those that have the necessary experience and insight to acquire power benefit with the next increment of influence. Finally, those that currently rely on the benevolence of others in order to experience power-holding are least likely to be promoted by their experiences into powerful influence.

**Asking the Right Questions within Teacher Education**

These questions were directed to education in its broadest sense, but their potency as a standard for teacher educators is tangible. Teacher education is a profession steeped in the pragmatic and practical world of daily life in schools (Rosenholtz, 1989). Teachers espouse their philosophical roots but often do not recognize the connection between philosophy and the decision making that comprises teaching. Teaching is mindful decision making (Zumwalt, 1989). Teaching requires an understanding of how we teach and learn with substantive pedagogy and with intense content knowledge. Teaching also sends a message about what is valued within the classroom, school, and society. Students and teachers interpret the message of the school and allow that message to shape learning.

Finally, teachers must reflect on the why motivating their decisions made within their classrooms, schools, district, society and world about technology. Teachers must lead students to consider those who do not benefit from the encroachment of technology into their fragile culture. Yet technology continues to challenge us with the possibility of bringing all people forward through its potential.

This does not preview a future of negative scenarios wrought upon us by technology, as some might claim. In fact, I am optimistic that we are still the master of technology as long as there are educators who ask the right questions. I am hopeful that teacher educators will recognize the priority of preparing mindful teachers who are capable of asking the right questions and following up with reflective practice. And I am confident that teacher educators will seize the moment to lead in demanding the right answers for the welfare of our students, our nation, and our world.

ogy a natural component of preservice language arts courses substance is provided that is frequently absent in survey courses. Therefore, we begin our course with an in-depth theoretical rationale for the instructional approaches that will be presented. This foundation is then used to build bridges between traditional practices and technology. As an example of how this approach works in practice we introduce CD-ROM talking books to preservice teachers during the unit on children’s literature. In another instance, the pros and cons of skill-based phonics programs, both in print form and on the computer, are presented during study of phonemic awareness. The instruction described in this article has demonstrated how one such language arts topic, young children’s composing, can be approached to include the research background on the topic, knowledge of symbol-weaving using traditional tools, and, finally, how multimedia composing programs can enhance symbol-weaving processes.

Becoming literate is a process of becoming aware, not only of oneself as a reader, but of strategies that help to solve problems that arise during reading (Vacca, Vacca, & Gove, 1995). Young children who are exposed to environments rich in print and language have opportunities to utilize multiple sign systems to mediate the activity by defining and shaping it. In effect, the use of sign systems becomes a means of negotiating their interaction.

Emergent Literacy, Semiotics and Critical Thinking

Through their work on semiotics (how signs work), Siegel and Carey (1989) propose the notion that thinking critically is a matter of reading signs. Harste (1989) notes that our understanding of critical thinking is a construction of signs, which enables us to think critically about critical thinking itself. The role of language in critical thinking is that language allows individuals to name their world, it provides the signs that make thinking public, and it allows language users to distance themselves from their knowing. Ideas can be set aside, looked at, thought about, and evaluated.

Gestures, pictures, monuments, visual images, finger movements—anything deliberately and artificially employed as a sign is, logically, language (Dewey, 1933). Siegel et al. (1989) refer back to Dewey’s description of reflection as involving the movement forward to possible conclusions as well as the more traditional movement back to uncover the grounds or bases for some form of knowledge. The signifying function makes it possible for the simultaneous movement back and forth. Understanding the way in which one thing signifies or stands for another is central to understanding reflection and, consequently, critical thinking (Siegel et al., 1989).

Siegel et al. (1989) discuss the implications and importance of semiosis for critical thinking:
1) Semiosis shows that our knowledge of the world is mediated. We don’t just encounter shapes and sounds; we encounter a world made meaningful through the mediation of interpretants—networks of signs.
2) The triadic nature of the sign suggests that meaning is not reducible to the sum of its parts. Semiosis requires the participation of all three components of the sign where each component serves as a connecting link to the other two.
3) The fact that signs generate interpretants which point to something other than what the sign represents suggests that sense making involves the creation of new ideas. This implies that we can not evaluate knowledge without simultaneously generating knowledge.
4) What’s intriguing about semiosis is that it both conceals and reveals this swirl of interpretants to us. They argue that we do not usually think about how we make sense of our world; we take sense-making for granted, at least until we encounter something that doesn’t make sense, thus offering the possibility of reflection.

It is my belief that the work of Siegel et al. highlights the importance and significance of sign systems in literacy development of young children. They argue that all thinking is critical (Harste, 1989). Critical thinking is what people do in an attempt to understand and act on what they see, read, hear, feel, etc. (Harste, 1989). In effect, young children illustrate what it is to think critically as they use the resources provided by multiple sign systems (e.g. oral, written, and graphic) to negotiate, interact, act, manipulate, and respond to the world around them.

Expanding Our Definition of Literacy

Reinking (1994) states that it is becoming increasingly apparent that educators and educational policy makers must now expand their definition of literacy to include the reading and writing not only of printed texts but of electronic texts. These electronic texts have been available for many years, and they range from simple copies of traditional books to those that are increasingly more complex. For example, the computer can read aloud the story in a variety of voices, change the appearance of text, use background music and sound effects, identify problem words, pronounce words, or even explain the meaning of words (Willis, Stephens, & Matthew, 156). As a result, these electronic texts can serve to reinforce children’s knowledge about written language and how print differs
from pictures, the meaning in print, letter-sound relationships, conventions of print, and the practical uses of literacy.

Reinking (1994) notes that the pedagogic potential of electronic texts is that they provide support that beginning readers need in order to focus on meaning and at the same time help them learn to identify words. Children and their teachers also see that electronic texts can facilitate higher levels of independent reading and understanding. He goes on to conclude that as educators look for new ways to help children become more literate, and as electronic technology becomes more advanced and more available, our ideas about what it means to be literate will almost inevitably expand.

Play at Reading Books

May (1998) states that what children really need is a learning environment that allows for unsteadiness, one that never shoves but only gently nudges them toward greater awareness or self-discovery of the utility and beauty of thinking, writing, and reading. This notion is based on the Vygotskian concept that learning requires apprenticeship experiences (Vygotsky, 1978). A second implication of Vygotsky’s views on apprenticeship learning is that the child-apprentice should gradually take over more responsibility for his own learning (May, 1998). If the novice takes over increased responsibility for the task at hand, then we can infer, retrospectively, that our help was well timed and well tuned, and that the novice was functioning in his or her zone of proximal development, doing first with help what he or she could very soon do alone (Cazden, 1988).

This support provided by electronic texts becomes one way that the child-apprentice can reinforce print concepts acquired during other literacy events, and interacting with this form of text enables children to “play at reading books”. Vygotsky considered play to be the principal activity for the interiorization and appropriation of reality during the first years (Blanc, 1990). Play enables children to stretch their imaginations as they explore the role of reader through literacy interactions supported by electronic texts. As Vygotsky suggests, play, itself, mediates the learning of children (Goodman & Goodman, 1990).

Therefore, one of the most valuable supports offered by the electronic texts is that children are able to participate in independent engagements with literacy. They become more familiar with the stories, which encourages them to eventually attempt to read the texts on their own. In so doing, the emphasis seems to be on the creation of worlds of discourse: Each world has its own rules and possibilities for action and interaction (Scollon & Scollon, 1984). Scollon et al. (1984) call these worlds of discourse microworlds.

Technology as Literacy Support System

The use of technology as part of the literacy support system can be illustrated through a four-year old girl’s (Reghan) interactions with electronic texts. One of the books chosen often as a read aloud favorite was the Dr. Seuss book *Green Eggs and Ham* (1960). The repetition and predictability represented by the text enabled Reghan to read along throughout portions of the text. In the Living Books electronic text format, children are offered two options: 1) Read to Me, or 2) Let Me Play. Reghan was shown how to load the CD-ROM into the computer, wait for the program to appear on the computer screen, select [Run], and then choose between option one or two. After trying both options, she began to invariably select Option Two where she is able to interact with the computer, as opposed to Option One where the story is read from start to finish for her.

In the second option, she determines whether she will go forward or backward a page, click on objects on the page, click on the text to have it reread to her, click on words of the text to have a single word read to her, or click on a picture in the text to have the word it represents read to her. Her choice for an option that allows more control on her part represents her desire to be involved in the discourse that occurs within this interaction. In other words, she has created her own microworld of discourse where the rules and possibilities for action and interaction allow her to have more control and independence. It also gives her more of a role in the interaction as she “plays” at reading the book.

When she initially became engaged in this microworld, she would randomly click around on the screen to have objects (e.g. click on the hat to make a bird fly out) become animated. After a text page had been read to her through the multimedia system, she began to be interested in her ability to make the text talk to her in individual words (e.g. click on a single word in the text) or having the text reread to her completely (e.g. click on the green egg at the very beginning of the text). After she had chosen the second option on numerous occasions, Reghan was asked why she chose it instead of the first option. After much prodding, she finally responded in an exasperated voice, “I like this one that plays. The other one just reads the story.” This response and her actions with the electronic text indicate that she wanted to have more control and choice during these sessions.

In this same session, she was asked what the pictures located within the text meant. She initially responded, “I have no idea—Oh, I know.” She then moved back to the beginning of the text and began clicking on each word while reading along with it, “I—would—not—like—them—here—or—there—I—would—not—like—them—anywhere—I—do—not—like—green—eggs—and—ham—I—do—not—like—them—Sam—I—am.” As she clicked on a picture that represented the text, she would glance over to be sure that the observer had seen the word briefly appear when she clicked on the picture. As demonstrated by this exchange, her knowledge of the text was coupled with her awareness of each word that was represented on the page.
After she had finished listening to the text again, she was asked if she could find the word “green” on the page. She first clicked on ham, and when this proved to be incorrect, she tried eggs. She studied the screen for several seconds, then clicked on the green egg to have the text reread for her. In this example, her actions indicate an emerging awareness of rereading as a strategy for locating information in the text, which was made possible by her interactions with the electronic text.

Reghan also benefited from strategies provided by the observer. At one point, Reghan was told by the observer she could identify “green” because green begins with the “g” sound. Though this was a little beyond her independent ability to identify the word, she was only able to use the word “green” with the aid of the observer. The use of that strategy to locate the word in text is not one that she initiated on her own, but it was the presence of the “other,” as mentioned when discussing Vygotsky’s ZPD, that served to nudge her use of graphophonemic knowledge to verify a word in the text.

Several pages later, when Reghan was asked to find the word “fox,” she used a similar strategy to the one described above to locate the word within the text shown on the screen. In these examples, she demonstrated her developing print concepts including: (a) how print is read from left to right, (b) that lines of text move from top to bottom, (c) individual word representation, and (d) how individual words could be used to access information.

In another example that illustrates the powerful support system offered by the electronic text format became evident when Reghan had finished listening to one of the pages in the book. She moved to the beginning of the text and clicked on the individual words as she listened maintaining a pace that was only a bit slower than the computer’s reading of the text. During this process, she inadvertently left out the word “eggs” so that the computer read, “green and ham.” She looked at the screen and paused for a second, and then she went back to the beginning and repeated the process so that “eggs” would be included. When asked why she had done it twice, she responded, “I accidentally (clicked on the wrong key)...I didn’t punch that (word)” while pointing to the word “eggs.” By listening to the text, Reghan recognized that a word had been left out, and she used the strategy of rereading with computer assistance to rectify the mistake. Reghan also demonstrates metacognitive awareness (Lundsteen, 1990) when she points out her failure to click on eggs.

Technology as a Means of Empowering Literacy

As illustrated by these examples, Reghan has used multiple literacies and sign systems to mediate her own emerging literacy development. The role of the computer through use of the electronic text format served as a means of empowerment for her. Empowerment grows out of the fact that the individual learner can experience some direct, visible outcome of a physical action (e.g., lively pictures and audio sequences resulting from the click of the mouse) (Meskill & Swan, 1995). The microworld (Scollon et al., 1984) in which Reghan chose to participate was one where she had more control of these possible interactions.

It was during this time, that Reghan’s growing metalinguistic sophistication became evident as she utilized her growing knowledge of print concepts to read the text.

Reghan also utilized metacognitive strategies as a means of monitoring her reading of the electronic text which was illustrated by her use of rereading to monitor comprehension of the text. In the last example, not only did she recognize that she had left out a word, but she took steps to correct the error. Teale and Sulzby (1988) discuss that a characteristic of young literacy learners is that they learn through active engagement, constructing their understanding of how written language works (Teale et al., 1988). Through these examples, Reghan illustrates her own active engagement with the text, and her growing understanding of how written language works. Technology as a literacy in its own right served as a support in her developing understandings of written and oral language. Bertram (1990) states that we cannot begin to understand the role of technology in literacy if we set it apart as “only a tool;” instead the picture is more one of multiple literacies, each employing a wide range of technologies that overlap with those of other literacies.

TEACHING THE ESL CHILDREN WITH THE HYPERMEDIA PROGRAM

Fuqiang Zhuo
West Virginia University

With a rapid advance in development and application of technology in education, computer instruction in education, such as computer-assisted instruction (CAI) and especially hypermedia-aided instruction (HAI), has an increasing important role in English as a second language (ESL) teaching, learning and acquisition. Though there are controversial results of the use of CAI for ESL instruction, the positive effects of CAI can not be ignored. Technology is important in our modern life and so schools have tried to embed multimedia, the internet and even hypermedia in their language curricula in order to teach English to ESL learners.

Background
This is a follow-up study to the investigations aiming to discover the effect of the program on actual ESL instruction and learning. A hypermedia program was developed from a program that was originally in print form. The project was in use at the Children as Authors Project at Central Elementary School, Morgantown, West Virginia, in which ESL students from nine different countries attend during 1996. Before putting the paper-form children’s story into a hypermedia program by an instructional technology graduate student, the Literacy Group members, consisting of five university faculty and public school teachers, evaluated educational software and determined preferences of their students. When the program was complete, they brought the students in to make a final evaluation. Though simple, it was an English-Chinese hypermedia program which integrated text, colorful graphics, sound and animation, with the ease of navigation and interaction of buttons on the screen. Every story page contained at least three animations associated with the three vocabulary words or phrases from the text at the bottom of the screen. English words and narration would come before the corresponding Chinese characters and narration. After each click on a hotspot a colorful graphic appeared that described the words. Users could listen to the whole texts or vocabulary as many time as needed, navigate to the identical Chinese pages aimed at aiding Chinese ESL learners, as well as creating their own stories to be stored onto a floppy disk.

Literature Review
The widespread use of computer and other technology in education has become prominent. The advantages of computer-assisted instruction have appeared in various types of research literature. Motivation is an important effect of CAI in ESL instruction and learning. Greatly motivated and deeply engaged, the children actively interacted with computers (Cohen, 1993), willingly repeated their computerized assignment (Bowman & Plaisir, 1996), thereby learning the content more thoroughly. Another important feature of CAI is individualized instruction or privacy. ESL learners learned independently. With these programs, students didn’t worry how many errors s/he made or what difficult level s/he was (Lalas & Wilson, 1993; Radencich, 1994). The computer was also patient, able to conduct simulations, to provide instructions on demand, provide immediate and meaningful feedback, and record keeping and interaction (Wang & Chan, 1995). CAI also created a positive learning situation fostering good personalities such as self-learning and self-organization, self-esteem, concentration, memory, methods of work and the pleasure of working in addition to providing a large amount of information and opportunities of self-correction and plenty of information (Cohen, 1993). If CAI were used, it would encourage excellent attendance (Bowman & Plaisir, 1996) since while using the program they would feel like authentic writers (Wrigley & Guth, 1992). Cooperation also an important feature of CAI. Through sharing their skills and knowledge, the learners learn the new materials and solve the problems together (Wrigley & Guth, 1992).

Research has describes enriched verbal exchanges through comments and discussions supported by text, graphics, and voice. The students improved their elaboration of the pictures exposed to them, enlarged their vocabulary, and bettered their sentences with the help of their teacher. They solved normal problem of writing which they could not tackle with a pen or pencil (Cohen, 1993). Besides providing interactive opportunities of English language learning and acquisition, new technology guided the learners to inquire about information, express their emotions, and utilize their first language (Lalas & Wilson, 1993).

Many teachers and researchers have blamed poor quality of software on the lack of integration of existing software into curriculum and the inability to achieve ideal
teaching and learning outcomes. Of the software evaluated for the ESL population, 58.5% was drill and practice, 24.8% tutorial, 5.5% simulation, 12% problem solving, and 10.8% game (Mansoor, 1993). In the area of ESL grammar software, drill and practice occupied even a larger proportion. Current CALL software is very limited and disappointing because most products were not created by experts in education (Baker, 1995; Hunter, 1996).

Besides the problems of technology and software development, inappropriate use of technology is another recognized problem. Many educators used technology as a "baby-sitter" under the disguise of "learner-centered", entertainment and drill and practice (Green, 1995). Not surprisingly, many educators considered that some application software (e.g., word processing, database, and spreadsheet) could generate better results than the available educational software for literacy teaching (Wrigley & Guth, 1992). Even with great educational software, instructors and researchers should have the ability to evaluate and select the appropriate courseware according to the learners' needs, characteristics, goals and interests, and efficiently use the equipment. Without considering the above factors, technology could be used very poorly, especially as a single method to teach literacy (Mansoor, 1993; Wrigley & Guth, 1992).

Hypermedia, while possessing all the advantages of general computer-assisted instruction discussed above, has its own unique strengths consisted; namely: (1) Hypermedia uses the power of computer and multimedia to present huge amounts of information: (2) Hypermedia displays information in chunks which are linked to one or various nodes; (3) Hypermedia provides contents in a non-sequential way at a high level of learner-control so that users can access the information using different paths according to their needs, interests and/or choices (Liu, 1994; Meadow, 1996).

The role of native language is not always considered to be positive in second language learning because of first language interference, although there is a long history of the use of native language used in the grammar-translation method. At present, many language teachers and linguists have been reconsidering the role of the native language in second language and language instruction and learning.

**Purpose of Presentation**

The purposes of this presentation are three-fold: (1) What is the effect of the hypermedia program "There Was A Rabbit Named Bunny" on teaching the young ESL learners English language: (2) What do the ESL children think about the hypermedia program, the role of their native language, and their attitudes toward computer use in education? (3) What should preservice language teachers be concerned about in terms of the application of hypermedia-based instruction to ESL learners?

**Design of Study**

**Participants**

The sample was comprised of eight public elementary ESL students with limited English proficiency (LEP): two girls and six boys including one Japanese first grader and one Korean kindergartner. They were selected from among the international children in the small elementary school in which the "Students as Authors" Project was located.

**Materials**

The story that arose from the "Students as Authors" project in both the hypermedia program and paper form was used to teach the ESL children. The hypermedia program with its alias on the desktop was installed on a Macintosh computer, whereas the colorful book-form story had three versions: English, Chinese and Picture. Blank paper, pens, pencils and other stationery were also available to the learners during the instruction and learning.

**Procedure**

The ESL learner was taken away from his or her classroom and brought into the reading teacher's office, a familiar place to all the students, with the instructional equipment and materials available there. All the ESL children experienced four 20-minute sessions: book session, hypermedia session, writing session, and vocabulary testing session. Following the session was a 10-minute interview, but it could be shorter, depending on those young students who had or little response to some questions.

During individualized instruction, the whole story was separated into two parts—three pages a session. Randomly divided, the children might learn any half section of the story through the hypermedia program or the book so that this presenter could examine the different learning results due to different instructional environments instead of different teaching strategies or content. The students were required to examine a picture of the "Bunny" story either on the screen or in the book, and then told their stories. When being taught through the hypermedia program, they could view the animation along with the sound or music, listen to the narration of the text, and/or click the spots where the mouse cursor changed to learn the vocabulary words. When they learned the other section in book version, the ESL learners could neither see the animation nor hear the sound or narration; instead, I read the text to them and taught the vocabulary words identical to those embedded in the program. To avoid the confusing results due to the different teaching approaches rather than the two instructional environments, I implemented context-based approach to both teaching periods without letting the computer or the book be the sole controller.

In regard to writing or recreating their stories, the ESL students were required to write a short and creative story based on what they had learned. They had to write about a
story page randomly chosen from a section so that they had two pages in total to write if they could, because there were two sessions: hypermedia and book.

In the testing vocabulary recognition session, all the ESL learners came to the auditorium and sat far away from each other. After the instructor repeated the story twice per page and then the words in a random order, the students had to recognize the vocabulary words among a group of unordered words. There were no pictures or other cues involved as visual aids during the test.

Data collection and analysis

The methodology of this study was qualitative including observation and interview. Observation was conducted during instruction and learning, so that whenever possible the key words were recorded and later expanded. Interviews with each ESL learner were taped after the instruction and testing. Chinese language was allowed for the students who encountered difficulty expressing their opinions, and the interview questions were repeated a few times or broken into simple sentences until they understood them. The interview data on the tapes was transcribed later, coded, sorted, and then analyzed later with the observation data according to the themes. The data from the story creation that was taken down in my notebook while the students were writing was analyzed according to the number of words in each sentence, the completeness and meaningfulness of a sentence. Analyzing vocabulary recognition data was through comparison through tabulation.

Table 1.
The ESL learners wrote better and more complete sentences relevant to the sections of hypermedia instruction than the group of students underwent instruction with book materials. The results from Table 2 showed that the ESL learners achieved 28 correct out of 66 possible counts in the book section, while 33 correct out of 62 possible counts in the hypermedia section. Examined individually, majority of the learners performed better in the section that they were taught through the hypermedia program than the one that they were instructed in the book version.

Table 2.
Vocabulary Recognition According to the Story Page Narrated by the Instructor (English Version)

<table>
<thead>
<tr>
<th>Program</th>
<th>Book</th>
<th>Hypermedia</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total</td>
<td>106</td>
<td>101</td>
</tr>
<tr>
<td># of Words</td>
<td>66</td>
<td>62</td>
</tr>
</tbody>
</table>

Note. (1) 28 out of 66 subtotal counts in the book sections were correct, but 33 out of 62 subtotal counts in the HAI sections were correct. (2) P referred to program and B referred to book.

Table 3.
Vocabulary Recognition According to the Story Page Narrated by the Instructor (Chinese Version)

<table>
<thead>

<tbody>
<tr>
<td>Total</td>
<td>333</td>
<td>321</td>
</tr>
<tr>
<td># of Words</td>
<td>66</td>
<td>62</td>
</tr>
</tbody>
</table>

Note. (1) * indicates that the words had not been counted as the ESL learner looked at the dimmed title bar of the hypermedia program. (2) ** refers to the case that the learner first tried to write the story on a piece of paper with a pencil, and later tried to write a story about the same picture on the hypermedia program.

Findings

Story Writing

The following table records the ESL learners' story writing according to a specific page of the entire story. Although all of the "created" stories based on the pictures were very close to the repetition of the original story, there were differences in degree of meaningfulness, quality, and length in their writing samples. The ESL learners wrote better and more complete sentences relevant to the sections of hypermedia instruction than the group of students underwent instruction with book materials.

Even though all of the ESL learners involved in this study were from Asian countries and their native languages derived from Chinese characters, they did not incidentally learn any Chinese words (See Table 3). The exception is student R, a newcomer from China who had been learning Chinese for three years so that he had known all of the Chinese in this story; while student X whose mother taught her Chinese at home recognized about one hundred Chinese characters including some of those Chinese characters in the story but she figured out only one correct Chinese vocabulary in the context.

Data from Interview

The following data was derived from the taped interview conducted after the instruction and the testing.

1. Do you have a computer at home?
2. What do you do with your computer at home?
   Games: 8   Learning: 3
3. Do you do anything like typing or writing on the computer at home?
   Yes: 1   Sometimes: 5   N/A: 2
4. How long or how often do you spend typing and writing on your computer?
   2 times a day: 1   I don’t know: 6   N/A: 2
5. When you write something, do you like to write on a computer or with a pen and paper?
   Computer: 8   Pen: 0
6. Do you like to write on a computer? Why?
   Yes: 7   Fast: 1   Convenient: 1
7. Do you use computer at school too?
   Yes: 8   No: 0
8. What do you do on the computer at your school?
   Typing: 3   See words: 2   Listening: 1
   Play Games: 2
9. Do you like to write something on a computer or with a pen?
   Computer: 7   Pen: 1
10. If you write your story for the first time, which will you like to use, computer or pencil?
    Computer: 8   Pencil: 0
11. If you are going to write something, do you like to write it yourself or with someone else?
    Self: 1   Someone: 7
12. Which form of Bunny story do you like, the computer program or paper book?
    Computer Program: 8   Book Story: 0
13. Why do you like or dislike the story on the computer program?
    Like: 8   Read by itself: 4
    Chinese and English: 1   Sound: 3
    Don’t need to flip the pages: 1
    Colors: 3   Typing: 2
    Moving: 5   Button: 1
14. Do you like computer or not?
    Yes: 8   No: 0
15. In future, will you like to use computer more or less?
    More: 8   Less: 0

Discussion
The findings from the selected ESL students' interaction and learning with the program show that the outcomes of the hypermedia instruction sections are more promising than the book instruction sections, with more complete sentences and words in their writings. In terms of "incidental" vocabulary recognition, the ESL learners obtained a 53% correct rate in the hypermedia sections but only a 42% correct rate in the book sections. This study supports the previous findings that CAI or HAI is more effective than conventional instruction. All ESL learners had their turns to learn a half portion of the story in the environment of conventional instruction and the other in hypermedia-assisted instruction. The teaching strategies and contents were identical; therefore, the difference resulted from the teaching and learning environments.

All the ESL learners' attitudes toward the hypermedia program are very positive. They willingly repeated working with the text and vocabulary words. Student X refused to learn the story after flipping through the book and stayed on the hypermedia program for 15 minutes and repeated some words or sentences. Another interesting finding occurred when, student H, who was told to write his story based on the picture of Page 5, produced only a three-word sentence with a pen and paper, but a 16-word sentence on the hypermedia program. They clearly expressed their opinions that they liked to work on the computer program rather than the book story even though they could not type fast. The findings support the previous discoveries of self-exploration and interaction with the program that the learners spent more time interaction with the program and wanted to explore more content and words than what had been designed in the program (Zhuo, 1997).

This study also confirms that a native language can be very beneficial to second language acquisition or foreign language learning when used appropriately. Used just as learning aids, Chinese sounds and characters help the Chinese learners, especially student H and R who had been in the country for about a month, understand the content. The results of this study matches the findings in the previous self-exploration study that the Chinese ESL learners spent less time to view and listen to Chinese pages and navigated to the Chinese text when they needed help. Therefore, teachers can use learners' native languages to help instruction and learning when necessary, and should use as little as possible.

How This Study Informs Teacher Training
Pre-service teachers should receive training in a wide range of areas. For example, they should become aware of the children’s positive attitudes toward computer which can increase learning. The ESL students in this study all agreed that they enjoyed using the computer. As the word-processing software makes editing easier and the learners preferred to work their first draft on the computer instead of pen and paper.

In this study, two young students, a Japanese and a Korean, talked less about the pictures and expressed much less about their opinions in the interviews than the Chinese students. Sometimes, the Chinese students could ask or answer questions in Chinese in addition to the Chinese text and sounds in the software, so that they felt more comfort-
able than those two non-Chinese students in during instruction and interview. On the way between their classrooms and the staff room, the Chinese students talked with me in Chinese too.

Other findings may help prepare pre-service teachers so that they can integrate hypermedia or CAI into second language teaching and learning. Although authenticity of the child's work is very important, sometimes their drawings, for example, may not clearly depict an object. With the help of animation and sounds, the children had no problem at recognizing the car in the story, but some of the learners mistook it as a computer when they tried to tell the story from the picture in the book form. There was not, however, a problem after they were exposed to the animation and sound of the hypermedia program. Similarly, a child, at one point, considered that the children went back home instead of going to school. After learning the story, the learners repeated the story in their writing. To yield the best learning outputs, pre-service teachers should be taught how to encourage and prepare their future students how to master keyboarding skills so that the learners can spend most of their time on interaction and learning.

Pre-service teachers should also receive instruction on how to select or create software that provides writing and note-taking opportunities so that learners can learn through more sensory channels rather than just clicking forward or backward. In addition, pre-service teachers should be taught whether a holistic approach is effective for their specific ESL learners or not, especially when time is limited. Pre-service teachers should be shown how to guide and facilitate users' interaction with a hypermedia program, so that computers are not used for busy work. Such guidance and facilitation should also reduce navigation confusion and cognitive overload.

Cooperative peer-mediated instruction where students serve as instructional agents for classmates is an old idea (Gerber and Kauffman, 1981). Peer teaching has been in existence since the 1800s. Research in non-computer learning situations supports cooperative approaches. Johnson and Johnson (1989) reviewed over two hundred students and found support for cooperative approaches. Research concerning peer-mediated instruction has also revealed the importance of peer interaction in work on computer problem solving (Joiner, Messer, Light, & Littleton, 1995). Newman, Griffin, and Cole (1989) point to the educational richness of collaborative computer work.

Some posit that student interaction may be responsible for the benefits of collaborative work. However, when considering interaction in technological contexts, besides interaction with peers one must include interaction between peers and the computer. In addition to or in lieu of interaction, peer presence may also be beneficial. Johnson, Johnson, and Stanne (1995) demonstrated that cooperative peer-mediated computer assisted learning was superior to individual or competitive approaches. In examining computer assisted literacy instruction among junior high school students, Mevarech, Stern, and Levita (1987) found that students who learned in pairs were more prosocially oriented toward their teammates, had stronger positive attitudes toward cooperative learning, and scored higher on achievement tests than those who learned alone.

However, little research in the literature has focused on peer-mediated computer instruction in preschool students. Chang, Rossim, and Pan (1997) report from their observations that when young children encounter problems that they are frequently directed to other children in the classroom. They advocate that timely adult developmentally appropriate intervention is also needed to prevent frustration and facilitate program use. Clements, Nastasi, and Swaminathan (1993) indicate that young children prefer working with partners. Virtually all of the research done in cooperative or peer-mediated learning has been school rather than home oriented. No study of sibling-mediated home computer instruction was noted in my review of the literature.

Benefits of Sibling-Mediated Instruction

Home literacy computer time should not be viewed as an alternative but as a supplement to other home literacy activities such as lap time reading. It is a worthy alternative to vapid videos and non-educational television viewing. One obvious advantage of siblings working together on the computer is that it makes what was an individual activity into a family activity.

Observation Outcomes

To apply some of the literature findings in a concrete setting, imagine a five year old girl was observed working independently on the computer. Initially a lack of reading and computer skills leads to difficulty in using the computer and general frustration. Later, when her eight year old...
brother assists, changes surface in her interaction with and use of the program. Here are some of the possible benefits:

1) Less negative affect and frustration occurs with the sibling presence.
2) Greater persistence and longer periods of time are committed to each program. Meskill and Swain (1994) note that multimedia computer programs increase attention span. Also, as parents teach children the sibling mediated approach, the benefits of assisted performance are enhanced.
3) More directed program appropriate activity occur (less random mouse clicking); less activity is directed solely toward stimulation without regard to programmatic questions or goals. Sibling assistance resolves some similar difficulties noted by DeVoogd and Kritt (1997).
4) A general increase in computer skills and ability to resolve problems independently is observed.
5) Greater knowledge is gained from the program. Initially, the older sibling is instructed to give help only on computer problems and allow the younger children to make their own program mistakes. Once the parameters for appropriate assistance were clear, the facilitated learning experience enhanced achievement.
6) The older sibling consolidates to become able to verbalize his computer skills and knowledge when providing explanations to the younger sibling.

These benefits appear to transcend different literacy programs and various program types. Recent theorization concerning peer-mediated learning tends to take a Vygotskan or Piagetian perspective (Joiner, et al., 1995). These perspectives posit benefits from the interaction of peers concerning the instructional content. Another benefit accrues from an increase in what Vygotsky (1978) would call the zone of proximal development (ZPD). DeVoogd and Kritt (1997) emphasize that software should be chosen in the ZPD, the distance between current and potential functioning what the child can do with assistance. This goes beyond meeting students where they are toward posing problems just beyond what they can currently do alone.

The computer alone can functions as a scaffold to support student work at a higher level than they are able to achieve by themselves, peers or siblings at home can provide the required assistance to serve as a bridge to potential functioning. Sibling assistance enables younger siblings to appropriately use a wider range of software. This facilitated use includes programs in which the younger child responds directly. Also, the siblings took turns using their favorite literary programs. The reinforcing nature of this companion learning is such that the younger sibling elect to stay and observe while the older sibling used more advanced programs. Thus the younger sibling further benefited from vicarious learning and the older brother's modeling on programs just beyond or at the outer limits of her ZPD.

Call for More Research

In a time when both parents work outside of the home and are as busy in the evening as they are during the day, it is likely that siblings frequently mediate home computer use. Formal empirical investigations should be undertaken to determine the parameters and benefits of sibling-mediated instruction. It would be interesting to contrast sibling-mediated computer instruction with parental and other peer mediated instruction.

While not empirically verified, it is likely that sibling-mediated instruction works best with siblings who get along well enough to play and work together without excessive conflict. There is some likelihood that positive interaction among siblings on the computer will transfer to other sibling activities, since classroom research indicates such transfer of skills with unrelated peers (Mevarech, 1987). Empirical research in the area of sibling-mediated instruction could lead to the development of guidelines for parents to structure optimal sibling-mediated computer learning experiences, conflict management, and software selection.

INSTRUCTIONAL TECHNOLOGY: ANOTHER PERSPECTIVE FOR PRE-SERVICE TEACHER TRAINING

John Ronghua Ouyang
Kennesaw State University

Instructional technology has been emphasized in teacher education programs all over the United States. Federal government, state administrators, and local authorities have realized what an important role technology plays in today's instruction and learning in schools. NCATE has plugged the technology into the teacher education program review process. Many thousands of tax dollars have been granted to provide computers for schools, provide training for pre-service and in-service teachers, and conduct collaborative projects for the implementation of technology in education. According to the national survey report, 100% of all schools own computers and the ratio of computer to students has become 9:1 in the United States (Electronic Learning, 1993; Office of Technology Assessment, 1995). Abrams (1996) believed that there will have about 30 million CD-ROM drives sold by the year of 1999, and at least 2,000 CD-ROM, videodisc packages will be titled for education. The Education Department has projected that all children in the United States will have access to Internet in their classrooms by the year 2000.

The use of technology for learning starts from the elementary school, continues in the junior high school, and becomes sophisticated in senior high school. All these no doubt are positive, exciting, and enthusiastic. On the other hand, the course credit hours of technology training for pre-service teachers are limited, reduced, and even eliminated from some of the pre-service teacher education programs. It is thought that our pre-service teachers have been well prepared in technology when they graduate from high schools and so it is reasonable to believe that having a required instructional technology course in the program becomes redundant. What is the reality? Which direction should we go forward? Should there be more emphasis on technology training in teacher education programs or leave the technology training aside? The purpose of the study is to examine the truth of these statements.

Background
The presenter conducted a qualitative as well as a quantitative study at senior high schools within the state of Georgia and in Jiangsu province of the People's Republic of China in the year of 1996-1997. The state of Georgia and Jiangsu Province have a friendship dating back to 1985. The Governor of Jiangsu province visited Georgia in 1995, and a delegation of the University System of Georgia was invited to Jiangsu in 1996. Both the state of Georgia and Jiangsu Province are similar in many ways. Both are located in the southern parts of their countries, and have like climates. Both are experiencing rapid economic growth, with new construction and city revitalization. More importantly, to the teacher education communities, both realize and are promoting the use of technology to improve teaching and learning. The presenter was granted opportunities to interview principals and program coordinators, tour computing facilities, and investigate the use of technology with students in both ninth and twelfth grades in the state of Georgia and in the Jiangsu Province, China.

Three of the six schools were identified in the Jiangsu province of People's Republic of China. The other three were selected from the Cobb county, Georgia. Three identified schools in China are nationally recognized key middle high schools (7th to twelfth grades). Two schools are located in Nanjing, the capital of Jiangsu province, and one in a city about 100 miles away from Nanjing. Three schools selected in Cobb county, Georgia are located about 25 miles northwest of Atlanta, the capital of Georgia. All of them are academically considered good schools with higher SAT scores.

Methods
The subjects of the study were randomly selected from six senior high schools within the state of Georgia and in the Jiangsu province of People's Republic of China. 351 students in total were involved in the survey. One third of them were ninth graders and two thirds were twelfth graders. Eight administrators from the same six schools were interviewed. Five of them are principals and three are program coordinators and teachers. The survey questions
were centered on the students' level of computer literacy, and the time they spent using computers and watching TV. The interview questions were focused on the number of students and staff at each individual school, the number of computers available for use at those schools, and principals’ perspectives of the use of the technology to improve the teaching and learning.

A descriptive statistics is adopted in this study. Median and range were used to calculate the time of use computers in school and at home. Mean and standard deviation were calculated for the amount of time students were watching television. The data from the interview were summarized for discussion.

Results

The results of the survey showed that 38% of 157 students in China use computers in school, and 19% of them use computers at home. 79% of 194 students in the United States spend time at computers in school, and 81% of them work at computers at home. The time that Chinese students use computers ranges from 0.1 to 24 hours with a median of 1 hour per week in school, and from 0.3 to 48 hours with a median of 3 hours per week at home. The time that American students spend working at computers ranges from 0.1 to 25 hours with a median of 1 hour per week in school, and from 0.1 to 50 hours with a median of 3 hours per week at home. About television time, 154 out of 157 students in China have televisions, and on an average they watch 4.77 hours per week (M = 4.77, SD = 4.32). 193 out of 194 American students watch televisions, and on an average they watch 11.21 hours per week (M = 11.21, SD = 10.43).

In China, students mainly use computers to learn keyboarding, programming, and word processing in school. All of these are mandatory in the ninth grade curriculum. All ninth graders are required to take a technology introductory class, but very few students in the twelfth grade have time to work at computers. At home, they use computers to practice keyboarding, calculate, do homework, writing assignments, and play games. In the United States, students mainly spend time at computers learning foreign languages, writing papers, and practicing keyboarding skills in the language labs, and conducting experiments in the science labs. At home, they spend time at computers playing games, searching information through the Internet, and completing homework assignments. The students, according to the survey, do not know much about instructional technology. The majority of them either spend time playing games at computers or completing writing assignments.

The data results from the interview showed that among three Chinese middle high schools, all computer labs are equipped with high quality computers, 486 and 586 IBM compatible computers. Some can run advanced CD-ROM software packages and multimedia applications. Only one school has one computer lab that is equipped with 286 IBM compatible computers. All teachers are required by the Jiangsu Province education commission to pass a preliminary computer competency test. Teachers pursue their training opportunities and take written and hand-on examination during the academic year or in the summer vacation. All students in the ninth grade have to take a required technology introductory course in the computer labs. Keyboarding, word processing, and basic programming skills have integrated into the ninth grade curriculum. While asked to give their perspectives of technology use in schools, Chinese principals and teachers are mainly concerned about the establishment of network, tests database, and management system. One of their short-term goals is to have one computer for each teacher and classroom, and to raise the ratio of graduates to pass national college and university entrance examinations.

From the interview with program co-ordinators and principals, and the tour of the computer facilities in three Cobb county high schools, the presenter found that there are more computer labs in these schools than in Chinese schools. However, more 286 IBM compatible computers sit...
Computers in school, and the range of 0.1 to 50 hours with a computer for learning. Few students have put a great effort into using computers in the labs. They are more concerned about preparing for pen and paper exams than using computers. However, the technology skills they obtained when they were in the ninth grade will no longer help them fit into the high-tech society of the future.

Discussion

For several reasons, the presenter is more dismayed than delighted with the argument that our pre-service teachers have been well prepared in technology when they enter teacher education programs. First, not all students in high schools are frequently involved in the use of computer technology for learning in school and at home. The results of the study showed that only 79% of 194 American students spend time working at computers in school and 81% at home. Although there are more students who use computers in and at home in the United States than in China, we still have about 20% students who do not know how to use computers at all.

In the three middle high schools of Jiangsu Province, China, every Chinese ninth grader is required to take a technology introductory course in school, learning keyboarding, programming and word processing skills. The reason few Chinese students in twelfth grade use computers in school and at home is that they are facing an extremely competitive national university and college entrance examination before graduation. They are more concerned about preparing for pen and paper tests than using computers. However, the technology skills they obtained when they were in the ninth grade will not doubt help them fit into the high-tech society of the future.

Second, most computers in the schools cannot meet the needs of sophisticated educational software packages. Touring the computer facilities of three high schools within the state of Georgia, the presenter found that most of the computers in the labs are 286 PC compatible or MAC IIc computers that cannot run sophisticated window and MAC applications. There are no computers in the classroom yet in Chinese schools, but in the school labs they have more advanced computers that can run newly developed educational software packages.

Third, not many students spend enough time using computers for learning. Few students have put a great effort to use computers in school and at home. The results of the study indicated a statistics of the range of 0.1 to 25 hours with a median of 1 hour per week for students using computers in school, and the range of 0.1 to 50 hours with a median of 3 hours per week at home. The study also showed us that among 194 students, the average time of watching TV is 11.21 hours per week. It is much more than the time of working at computers. The majority of students only spend 1 hour in school and 3 hours at home per week working at computers. Besides, we should realize that students use computers mainly for keyboarding drill and practice, word processing, and playing games. Few students have spent time using computers to learn about the computers, such as, programming, problem solving, and integrating technology for learning.

Conclusion

Technology-based systemic reform in pre-service teacher education is hard in part because our ways of thinking about the readiness of implementing technology in classrooms are often flawed. It is thought that pre-service teachers are well prepared in technology when they graduated from high schools. In fact, they are not! Most high school graduates do not know much about educational technology, nor have they had much practice and training in technology when they enter universities and colleges. With the limitation of computer facilities and time spent on the computers in high schools, they will definitely feel frustrated with the challenge of using computer technology for effective teaching and learning.

For the 21st century, it is important for us to put more emphasis on a curriculum guided technology training for pre-service teachers instead of limiting, reducing the training hours, and eliminating technology training class from teacher education programs. Reality reveals that there is a necessity to have instructional technology training more heavily stressed in teacher education programs. Meanwhile, flexible modules of training should be explored to meet each individual’s needs.

A Web Link for the Teaching Mathematics in Early Childhood Education

John Ronghua Ouyang
Kennesaw State University

Integrating technology into the classroom has become one of the priorities of redirection in education for effective teaching and learning. In the United States, the Department of Education has developed an ambitious national technology plan. According to the plan, the nation must commit itself to achieving three major goals by the year 2000: (a) all 2.9 million teachers in America will have received technology training, (b) all 110,000 schools in the nation will be equipped with computers that are connected to the National Information Infrastructure, and (c) all schools will have access to affordable, high-quality, technology/content based software for achieving high academic standards (Office of Technology Assessment, 1995). The National Council for Accreditation of Teacher Education (NCATE) has also set the use of technology as a fundamental part of the teaching, learning, assessment, evaluation and productivity process (Hoadley, Engelking, & Bright, 1995). While it is true that teacher educators, teachers, and students need to know more about technology to achieve these goals, it is not clear exactly what assemblage of knowledge each group needs to know. To be more specific: (a) What does the World Wide Web mean to the teachers and students? (b) What is available on the Web for teaching mathematics in early childhood education? and (c) How can a teacher implement the Web resources into classroom instruction and learning effectively?

World Wide Web To the Teachers and Students

The World Wide Web, more than any other component in our lives, is showing the way of the future. According to Cafolla, Kauffman, and Knee (1997), the number of Web sites is growing exponentially and the number people using the Internet is doubling every year. The statistics show us that (a) there are 27 personal computers for every 100 people in the United States, (b) the number of WWW sites doubled every 53 days, (c) an estimate of the number of WWW sites as of July 1, 1996 has reached 17,956,841, and (d) .74% of the world’s population, approximately 44,238,061 people, are on the Internet predicted by July 1, 1996.

As teachers and students, we now have the capacity to get on the Internet and to expand our intellectual lives to make our teaching and learning better than before. World Wide Web opens up a whole new world for teachers and students. Almost every institute in the world has its own Web site. In the United States, most universities, federal and state government agencies, public and private schools are now online. Through a Web browser, for example Netscape, teachers and students can point and click their way around the world. They can visit different places, collect information, experience visual and audio stimulants, communicate with others, see the future, and extend the intellectual world beyond the walls of the classroom (Cafolla, Kauffman, and Knee, 1997). The goals of 2000 encourage teachers to weave WWW into our curriculum and classroom.

The Internet access has become available. To a certain extent, the training has also become available. However, all those are mainly in the form of showing teachers and students the benefits of this information-rich medium (Caruso, 1997). Searching and identifying relevant sites through the Internet for specific subject teaching are extremely time consuming. Obtaining and capturing desired informative and applicable teaching ideas and activities from World Wide Web require even more endeavors. However, making internet access available in schools is not enough! Teachers and students need to know about the vastness of the information available to them. They must learn that many reputable sites and lots of unreliable sites exist on the Web at the same time. Then, what is available on the Web for teaching mathematics in early childhood education?

Available Web resources

Based on a search and evaluation, the author presents the following sites which may be helpful for teaching
mathematics in early childhood education classified into five categories:
1. lesson plans and instructional resources
2. literacy for teaching mathematics
3. children's learning online
4. teachers' forum
5. CD and software information.

Sites of lesson plans and instructional resources
The sites of lesson plans and instructional resources contain formal and informal lesson plans, instructional ideas, and procedures of classroom activities. Teachers who teach mathematics in early childhood education can copy, print and adopt those lesson plans, ideas, and activities for their own classroom use.

http://www.eduplace.com/math/mathcentral/gradeK/kscal.html This site provides kindergarten teachers with an activity plan of teaching counting numbers. In this activity, children will write numbers on worksheets with picture of apples, and then show their understanding of the number's value by writing the corresponding number of seeds on each apple.

http://www.kconnect.com/kc-domino.html This site provides teachers with an activity plan using dominoes to teach counting numbers. More ideas and activities can be linked with the click at the linking word, dominoes, at the bottom of the Web page.

http://www.eduplace.com/math/mathcentral/gradeK/koca2.html This site provides teachers with ideas of teaching triangles, squares, and hexagons. In these activities, children will cover a picture with correct pattern blocks and then sort the blocks into groups of the same shape. Children will then make statements about the patterns using comparison words.

http://www.eduplace.com/math/mathcentral/gradeK/knca1.html This site provides teachers with an idea of using cube to make a cubes train in Kindergarten classroom. Children can learn to count numbers with this activity.

http://www.eduplace.com/math/mathcentral/gradeK/knca2.html This site provides teachers with an idea of using pictures and domino cards to teach numbers 1-9. Children will match the picture and domino correctly in the classroom activities.

http://www.missouri.edu/~c575812/mts/math/_link.htm This site is created by Shu-Chen Jenny Yen. She provides teachers with the ideas and activities to teach mathematics. The numeration section is very good for kindergarten teachers to adopt in the kindergarten mathematics classroom.

http://www.eduplace.com/math/mathcentral/grade1/101w1.html This site provides a coloring worksheet for first graders. Teachers can print out the worksheet for children to color and write numbers 1-12.

http://www.xs4all.nl/~spaansz/Domino_Plaza.html This site is the site to provide ideas and activity procedures for teachers to teach second grade mathematics. With these ideas and activities, children learn to add and subtract through playing domino games.

http://www.eduplace.com/math/mathcentral/grade3/301io.html This site provides a math center activity procedure for third-grade teachers to teach chart and graph concepts.

http://www.eduplace.com/math/mathcentral/grade3/302io.html This is an activity resource for third grade teachers to teach addition and subtraction with selling and preparing snacks.

http://www.klutz.com/treefort/travel/nim/nim.html This site provides an activity resource of playing NIM. Teachers can adopt the activity to teach addition and subtraction in the third grade classroom.

http://geo.arc.nasa.gov/esdstuff/jskiles/top_own/how_tall_that_is/how_tall_is_that.html This site provides an activity idea for teachers to teach estimation of the height of an object.

http://forum.swarthmore.edu/alejandre/magic.square/loshul.html This is a story and addition activity site. Teachers can bring stories to class and have students do mental math to find out the magic sum with the numbers in a square mat.

http://forum.swarthmore.edu/teachers/ This is a site particularly suitable for elementary school teachers, from pre-kindergarten to grade 5. It is a good resource site of lesson plans and teaching activities that are classified into Pre-K, K-2, and 3-5 academic levels.

http://www.eduplace.com/math/res/parentbk/phs4.html This is a site to provide math activities for parents to help young children learn mathematics in real life environments (grocery story, restaurant etc.). However, it is also a good resource site for teachers to design and prepare homework assignments.

http://www.eduplace.com/math/res/parentbk/phs5.html This site consists of math puzzle activities to help children learn mathematics from grades K-6. Teachers can assign students different mathematics puzzles as homework assignments.

http://www.eduplace.com/math/res/parentbk/phs2.html Although this site is designed to provide parents resources and ideas to work with children in mathematics, teachers can cooperate with parents to create an outside learning environment for young children here. The resources are categorized into grades K-2 and 3-6 levels. At grades K-2 level, the links include: (a) numbers and estimating, (b) measurement, (c) shapes and patterns, (d) computation, (e) data and graphs, (f) numbers. At grades 3-6 level, the links embrace: (a) Computation and Estimation, (b) Fractions, Decimals, Ratio, and Percent, (c) Data and Graphs, (d) Measurement and Estimation, (e) Geometry.
http://www.srl.rmit.edu.au/mav/PSTC/general/index.html This is a site named as Mathematics Problem Solving Tasks Center. At this center, teachers can view the monthly mathematics problems started from the December of 1995. It also consists of wide links related to mathematics problem solving on the Web.

http://www.bobvila.com/conversions.htm This is a resource of conversion with measure, weight, metric system and English system, etc.

http://www.capecod.net/schrockguide/math.htm This site provides mathematics teachers with a link list to explore the Web resources.

http://www.cs.uidaho.edu/~casey931/mega-math/ This site contains unusual and important mathematics problems for teachers to implement into elementary school classrooms, so that young people and their teachers can think about those mathematics problems together.

http://www.aimsedu.org/puzzle/puzzleList.html AIMS puzzle corner is a site to provide teachers with monthly mathematics puzzles that were started from May 1995. Instructional suggestions, materials of activities are included.

http://forum.swarthmore.edu/elempow/solutions/index.html This is a site to provide teachers with weekly mathematics problems and solutions dated back to the October 1995. Teachers may explore the previous weeks’ problems and implement them in their classrooms.

Sites of literacy for teaching mathematics

The sites of literacy for teaching mathematics provide teachers with the resources of books that can be read to the children in the mathematics classroom.

http://www.eduplace.com/math/res/parentbk/phs6.html This site provides the literacy resources for teachers and parents to read to children categorized into K-2 and 3-6 grades levels.

http://members.aol.com/eff570/operation.html This is a reading resource about the mathematics symbols, including the history of each symbol.

http://www.eduplace.com/math/mathcentral/index.html This site contains good biography links for children’s literacy of mathematics from kindergarten to six grade.

Sites of children’s learning online

The sites of children’s learning online give children opportunities to practice their learning with hands-on activities online. Playing on the Web, children will solve mathematical problems, join the discussion and engage in drill practices.

http://bright-productions.com/kinderweb/tri.html This site is a game for kindergarten students to identify shapes.

http://www.gold-pages.com/math/ This is a site for children to practice addition and multiplication skills by playing baseball. Three levels (easy, medium and difficult) give children choices and challenge. At the end of game, the score of each player is provided.

http://www.stack.nl/~raymond/nim/ This is an on-line game of play with Nim. Players can take turns to remove stones from the piles, and the one who removes the last stone wins the game.

http://www.eduplace.com/math/brain/index.html These activities are categorized into grades 3-4, 5-6, and 7+ levels. The site includes previous week’s mathematics problems, the solution to that problem, and current week’s mathematics problem. Students can practice with on-line help and view solutions to the problems.

http://www.lifelong.com/lifelong_universe/AcademicWorld/MonsterMath/default.html The monster mathematics home page is designed to introduce and review a variety of basic math concepts such as counting, addition, and multiplication. Activities online allow the children to become problem solvers.

http://www.wwinfo.com/edu/flash.html This is a site of on-line mathematics flash cards. They allow students to setup their own levels for practice with addition, subtraction, multiplication and division.

http://forum.swarthmore.edu/dr.math/drmath.elem.html This is a site named “Ask Dr. Math.” Questions and answers are all related to the elementary mathematics with multiple topics. Children can explore and post their own questions and get help from others all over the world.

Sites of teachers’ forum

The sites of teachers’ forum allow teachers to share expertise with other teachers and students, and to post questions and answers for the effective teaching and learning mathematics in early childhood education.

http://forum.swarthmore.edu/dr.math/drmath.elem.html This site allows teachers to post math questions and answers for sharing with colleagues all over the world.

http://www.pacificnet.net/~mandel/index.html This site provides teachers opportunities to help teachers. The site is dated back to September of 1995. In the Mathematics section, teaching materials and activities are posted on the basis of grade level and subject area.

Sites of CD and software information

The sites of CD and software information provide teachers and students with the information of current available CD and software packages on the market. Most of them are hosted by software companies.

http://store1-3.broderbund.com/products/fs-kids.html Hosted by Broderbund company, this site provides teachers and students with the company’s latest information about the valuable mathematics and science software packages.

http://www.solutions.ibm.com/k12/solutions/tlc/math/mtn.html This site is hosted by IBM. It is a software package, “Measurement, Time and Money,” that promotes
children's problem solving and thinking skills by building on three levels of understanding (K-4, 3-4, and 5-8).

http://www.forum.swarthmore.edu/shareware/shareware.by.topic.html This site provides teachers information about shareware, freeware, and commercial software packages for teaching mathematics both for Mac and IBM computers. The topics of “Arithmetic” and “Geometry” are particularly helpful.

http://store1-3.broderbund.com/ This site is about a software package, “Mouse Math.” “Mouse Math” is a verbal mathematics drill program for Windows. It is a package with setup options that allow teachers to select problem ranges appropriate for young children, older kids, and teens.

An EASIER approach

Assuming mathematics teachers and students in early childhood education know how and why to navigate the Internet, and can get access to the WWW, what is next? To know what is available on the Web is important. However, more important is how teachers can integrate the Web resources into the classroom instruction for the effectiveness of teaching and learning. The presenter is likely to share an EASIER approach with teachers. The EASIER approach consists of E Explore, A Adopt, S Setup, I Implement, E Evaluate, and R Re-construct.

Explore

Unless one explores the Web resource, he or she cannot really understand the four "Ws" of the Web site validation. Four "Ws" include 1) who wrote the site? 2) What are they saying on the site? 3) When was the site created? and 4) Where is the site from (Caruso, 1997)?

Adopt

Exploring the Web, one will find which site is really useful for his or her teaching, and which information can be adopted for classroom use. If the information is selected, the teacher can make a copy or print out or add a link to his or her own Web page. He or she can have valuable Web resources adopted for use in classroom teaching and learning.

Setup

Clear and specific instructional objectives will help one to implement the Web resource effectively. A teacher should be able to have the curriculum to drive the Web resources. The Web resource should be implemented into the curriculum and for the improvement of teaching and learning.

Implement

With a specific instructional objective and valuable Web resources, a teacher can plan an implementation of Web into the classroom teaching, and determine when, where, and how to use Web resources to enhance their teaching.

Evaluate

Evaluation include two sides: 1) students' learning achievement, and 2) teacher's teaching effectiveness. The former is to see whether students improve their learning with the implementation of Web resource, and the later is focused on the assessment of the strategies of applying Web in instruction and learning.

Re-construct

Re-construction of procedure suggests we need keep our resources updated. Teachers should explore and adopt new and updated Web resources, revise the instructional objectives, modify the implementation strategies, and redesign assessment tools to meet the needs of teaching and learning.

Putting the EASIER approach into practice is not easily achieved. It needs a teacher's initiative to get access to the Web, spend time to explore the Web, evaluate and select the Web resources. It requires a teacher's creativity to setup clear, specific and measurable instructional objectives and design implementation strategies. It expects a teacher's self-motivated criticism to assess students' learning and his or her own teaching, and reconstruct his or her teaching with reputable and informative Web resources.

1314 — Technology and Teacher Education Annual — 1998
Even though the democratic values of thoughtful and diverse expression are not developed in our teacher education classes, the use of technology and a commitment to these values in theory and practice can provide students greater access to expression and diverse thinking for preservice and inservice teachers. Of our most precious treasures, is our democratic heritage that claims the rights to participation and freedom of expression for all. Though we claim to cherish these values in word, neither teacher education nor PK-12th grade education have demonstrated a strong desire to nurture the development of these democratic values in practice.

**Limited Sources of Knowledge in an Information Age**

Traditional classrooms of the past and present are places where students' sources of knowledge have been limited to teacher lectures and reading from a single textbook. Even the physical structure of the classroom has been shaped to reflect the importance of teacher and textbook knowledge to exclusion of other sources of knowledge. In universities as well as in other schools, classrooms have been shaped with desks separated and facing the front to minimize student conversation and maximize attention to the teacher (Cuban, 1984) and to books. The students' purpose was to soak up as much information as possible from the teacher and the text. However, this type of education has been referred to by reformers as passive and dull (Cohen, 1988; Freire, 1970; Goodlad, 1984). In John Goodlad's (1984) book entitled *A Place Called School*, researchers saw students passively listening, reading textbooks, completing assignments, and rarely initiating anything despite stated school goals that stressed curiosity and involvement.

Other researchers similarly report that telling and accruing information dominates the classroom (Cohen, 1988; McDiarmid, Ball, & Anderson, 1989). This traditional approach incorrectly views the concept of "knowledge" as something that is static, unpersonal, and without perspective. By treating knowledge as a static, unchanging entity, teachers are really misrepresenting its true character. Knowledge is actually revisionary and pluralistic in nature (Schwab, 1978). The revisionary nature of knowledge is evidenced when individuals change their minds or develop a new theory which alters the old knowledge. Knowledge is also pluralistic in nature. Not only do people revise their individual knowledge, but they also may read and understand texts and experiences from different perspectives. We don't expect people of different philosophical, educational, cultural or socio-economic backgrounds to interpret the same text in the same ways. Even the most conservative critics would have to admit for example, that Catholics, Quakers, Pentecostals, Calvinists, Amish, and Eastern Orthodox churches have all interpreted the Bible in ways that make their worship different from each other. A flexible understanding of knowledge is very difficult to explain to students in a "telling" style of teaching. To gain a flexible multi-perspective understanding of knowledge student have to work with the knowledge, create it, and relate it to other types of knowledge and yet this activity is limited even in teacher education.

This relationship of teacher and textbook monopoly over knowledge and power in schools has persisted throughout this century. For example, Cuban (1984) discusses how stable teacher-centered practices were in his book detailing the stability of classroom practice from 1890 to 1980. He described a professor who studied rural schools in Texas in 1922 and found that in 88% of the classes the textbook and teacher were the primary sources of information. Typical dialogues between teacher and student consistently followed a similar pattern: teacher question, student answer, and teacher evaluation (Cazden, 1985; Mehan, 1988). Although Cuban finds that for short periods of time educational movements shifted educational practices away from teacher-centered instruction, his conclusion is that there has been no significant change in teaching practice this century. In other words, the measure of the students' goodness is the amount of facts they know, even though standardized tests are criticized for only being able to demonstrate what a student knows and not how he/she knows it.
Limiting Knowledge as a Way of Mediating Power Over Students

Controlling knowledge in a school is also a way of mediating the relationship of power by the teacher over the student. For some educators, the purpose of schooling is to teach a particular collection of knowledge, as claimed in Hirsch's (1987) book Cultural Literacy(1987) and Bloom's (1986) book The Closing of the American Mind. Many times these particular compilations of knowledge imply value systems that are not shared by all individuals because of their culture, socio-economic level, or religious background. These sets of knowledge are culture-bound and particular cultural groups have an advantage in schools where the content of the knowledge the parents teach matches that of the school (Heath, 1983).

In universities and schools, so often we, as teachers and professors, demand students accept our version of the truth or we impose a textbook version of the truth to the exclusion of the child's personal knowledge and personal voice, and to the exclusion of other voices that are not mainstream enough to qualify for inclusion into textbooks. We have wanted students to accept the power the printed word has over them (Scollon, 1988). Students of all levels often get the impression that what is written in the textbook is more authoritative and relevant than that which they have heard spoken by their friends or relatives. Because of the authoritative style in which we present and test students on textbook and teacher knowledge, the sanctioned school knowledge has supremacy over student knowledge.

In schools we expect students to accept a position of submission in respect to content in classrooms, but this forced relationship does not have to exist. Constructivists have a vision of schooling where inspired students use personal knowledge in the classroom and express their voice as an equal scholar in the classroom (Cognition and Technology Group at Vanderbilt, 1992; Dwyer, Ringstaff, & Sandholtz, 1991; Newman, 1990; Papert, 1993). They claim that teachers should not just transmit information that students receive. These theorists emphasize student construction and coordination of effective problem representations (Daiute, 1985). Students need repeated opportunities to engage in in-depth exploration, assessment, and expression of their ideas over extended periods of time.

With constructive approaches, students who engage in generative rather than passive learning activities recall that information more readily because the information is created and used. In contrast, teachers who simply transmit knowledge to students will find that their ideas are inert and not as easily recalled. In a classroom where construction is important, information from various sources are constructed as they integrate with student voice and personal student knowledge.

Four Reasons for Allowing the Personal Voice

In search for this vision of schooling that promotes the democratic value of voice, four issues are central. First, when teacher and textbook information are used to the exclusion of student knowledge, a richness of knowledge that reflects personal knowledge and diversity that otherwise would not be present is missed.

Secondly, student voice and self-expression are concepts that allow the student to maintain a sense of identity and uniqueness while they are learning specific content. The student voice affords students a sense that they can connect school content with their goals and purposes in life. Dewey (1938) emphasized the role of individual knowledge and experience. Most knowledge in schools is imposed from outside the experience of students in a static, matter of fact way. What Dewey calls the "traditional approach" does not invite the student to challenge, edit, or modify information presented.

Third, duplicating teacher and textbook knowledge is a passive process that only teaches students to be docile and obedient to authority. As a method of learning, this passive process trains our young people to be dependent learners who need the direction of the teacher to progress. This type of thinking keeps students from constructing personal divergent thoughts that are important to a liberal education. Passive learning is also unexciting (Goodlad, 1984) and does not provide the sense of personal freedom and creativity that is vital to foster a feeling of ownership with the learner. That sense of ownership involves the learner to give them the critical element of motivation necessary to learn complex strategic processes (Paris & Oka, 1986). In constructive learning, students gain the will to do the skill.

Finally, when students accept teacher and textbook knowledge they often merely duplicate the teacher's schema while holding onto their own schema. Some call this duplication of the teacher's schema as replication, as opposed to an integration of personal and school knowledge, called restructuring (Roehler, 1989). Students accommodate the school schemas to help them survive the educational rites of passage and then revert back to their own schemas when they leave school. Knowledge in a child's life becomes unnecessarily compartmentalized and students find it difficult to access their prior knowledge dependent upon the context they are in. School knowledge is used at school; church knowledge at church; knowledge about friends with friends; practical knowledge is used in other places. School knowledge does not become integrated into personal experience coming from other contexts. Hence, copying school schemas leads to only temporary and not truly educative experiences.

Contemporary educational reformers believe that students should not passively accept information from the
teachers and textbooks. Instead, they should constantly monitor that information against their own existing knowledge and integrate the synthesis of those two into their own schemas (Garner, 1988). Some reformers look for teachers to provide adventuresome teaching (Cohen, 1988) or perhaps adventuresome learning that allows for students to initiate projects, drawing on many sources and constructing new information from what students and their classmates experience (Gardner, 1993). As students and teachers learn to use the computer to construct knowledge this way they provide avenues for educational reform (Papert, 1993).

In this section, some of the reasons why it is important for teachers to include personal knowledge and multiple voices in the schools instead of simply asking students to accumulate facts were discussed. College instructors can serve as good models when they ask students to consider knowledge critically. The next section provide an overview of a study in which college students in a graduate teacher preparation class used many sources and reflected many voices in the course of their online class.

The Study

This paper reports on some findings analyzed as a part of a larger forthcoming study that seeks to describe elements of learning that reflect democratic values in an online class. Ten graduate students took the introductory course in early childhood education in an online class over the course of a five week intensive summer course. With the exception of three face to face introductory meetings and an end of the semester summation meeting, four days a week we met asynchronously online through a series of email messages on the same day. A schedule of readings and activities were posted on the web as part of a syllabus.

In the larger study, student postings, student interviews, the researcher’s log, the syllabus, and online discussion all served as data to describe the online teaching experience for these students. The data was analyzed using the constant comparative method (Glasser & Strauss, 1967) and with qualitative methods drawing on ethnographic research (Bogdan & Bilken, 1982; Erickson, 1986). Through readings and using software entitled Nudist, categories of data emerge and are tested for triangulation and with disconfirming data. The larger report is written to describe in rich detail the breadth and depth of the experiences found in the data.

For the class these beginning graduate students were required to participate in a range of activities on and off line all of which contributed to sources of knowledge they were able to post on our listserv. Students were required to read four books (one on the project approach, one on the workshop approach, one on thematic and one concerning the lived experience of a first grade teacher) and all the postings on the listserv. They were also required to spend 20 hours visiting classrooms to understand a range of what teaching means to different teachers. The videotapes of workshop and project approach which were to be viewed in the library, gave students a visual and practical understanding of those innovative methods. Students were also required use the project approach to teach children skills in context of the project experience. Finally, students had to post a two page critical response and two one page responses which most students did at home. The web page also provided several outside sources of supplemental information with web page links, examples of past student work, and other scholarly resources. So, in addition to the online portion of the class, students performed in a variety of ways which were designed to contribute to their understanding of teaching young children.

One of my objectives of the course was to develop an appreciation for scholarship that originates from several different sources including personal sources. To achieve that goal, students were asked to critically respond to: (a) the text readings, (b) their personal thoughts, (c) their field experience, (d) their viewing of videotapes of early childhood classrooms, (e) comments I, as the instructor, posted on the listserv, (f) ideas that I posted on the web page for each day corresponding to each of the day’s readings and (g) each other’s postings. Instead of responding to only the teacher and the text, which is typical in many teacher preparation classes, I asked students to respond to many sources.

Students responses to each other’s posts created a sort of online discussion which was archived on a web page so anyone could follow the critical posts and the students’ responses to the posts. I valued the texts which gave the discussion some focus and insight which was not available from the other sources of knowledge mentioned above. When I was planning the course, I also felt that the readings lend a depth and rigor of thinking that was not available in the other sources of knowledge. Even so, while keeping students responsible for daily critical essays responding to the readings wasn’t enough. To truly engage students in a critical response to ideas in the text and outside of the text, I encouraged multiple voices originating from the student’s personal experiences, field experiences, videotapes, other listserv comments, and myself.

The Data: Multiple Voices as a Democratic Value

Space for this article does not allow for the entire analysis of the multiple voices that emerged from the online class, however, for the purpose of illustrating some of the finding, I will examine one post written by Linda, one of the students in the class. Having pursued an unappealing career in business, Linda with no experience in the schools was attending class to become a teacher of young children. In her mid twenties, she had strong opinions which I had not noticed in the previous class which I had run in a more traditional lecture/student presentation style. This was her second class in early childhood education.
As you read the section below, look for evidence of the origins of multiple voices such as other listservs, Linda’s own thoughts, Linda’s experience, and an invitation to hear other voices on the topic.

From: “Linda” <Linda@uh.edu>

Re: Welcome to PBLNEWS: #3 Einstein and Project Based Learning. This article starts off with a quote from Albert Einstein: “Imagination is more important than knowledge.” How true this is. A person can acquire all the knowledge in the world, but if they do not know how to apply that knowledge, then what is the point in knowing it. The problem with this type of person is that they were taught in such a manner that they never had to use the information that they were learning. Their purpose for learning was so that they could regurgitate the information on a test. Last semester, I had to work closely with this type of person. She aced tests, created great projects, and did very well academically. However, when it came time to apply what she had learned in a real life situation, she was unable to do it. I wondered how can a graduate student be so smart and then not be able to perform. I came to the conclusion that this was a skill that she had not been taught in her education. She had been taught that information used to perform successfully at academics, not to be used in real situations. As educators, we must teach our students to use the knowledge that we are teaching them. The article (I read points out) that this is a skill that we must “develop” in our students. One of the approaches mentioned in the article for developing this skill was projects. I have not read much about this approach. Has anyone used this approach or seen it done? I would like to know more about how this develops the skill of analyzing problems and developing solutions.

I want to highlight three pieces of information coming from the posting from Linda above that provide evidence that Linda was using multiple voices as sources of knowledge for this online class. At the beginning of Linda’s post the entry listed after from (Re: Welcome to PBLNEWS: #3 Einstein and Project Based Learning) indicates that Linda responded to a post from another listserv called PBLNEWS that was posted to our own class listserv for all in the class to consider because the post related to the topic of project based learning. This difference source, not commonly found in traditional university classrooms, found a voice inside of our class when it was posted, read, and responded to by Linda.

The second piece of evidence of multiple voices comes from Linda’s reference to a fellow student whose knowledge from university courses so static and inflexible that she could not apply the information in real life. This bit of information, drawn from Linda’s real life experience, gives voice and examination to an experience that might not have otherwise been considered in a traditional class which severely limits student opportunities to express their ideas. Unlike the spoken word in class, the written word online allows students more time and space to develop a well thought out argument. In contrast to papers turned in and to be read only by the professor, Linda’s comments become public to be read by the professor and other students in the class. These thoughts are meaningful not only in the sense that they influence the student and the professor’s thoughts, but also in the sense that they influence the ideas of other students in the class.

Thirdly, Linda requests help from others who might have understanding of this approach (which was to be studied later in the class). The shift in authority and power relations implicit in her queries is profound. Linda shifts from one who is required to learn a narrow range of information from the teacher and the text which is common in traditional university classes, to an inquiry orientation that requires her own initiative to ask and solve. Linda asks other students if they would provide information which also engages the rest of the class in inquiry. This learning shifts the student role from passive recipient of information to creator and investigator of knowledge (Freire, 1998). Not only does this sense of curiosity and control of one’s knowledge promote democratic values of voice, inquiry, and independent judgment, it also fosters the value of lifelong learning.

As a professor that seeks to empassion students about early childhood teaching in class, it was exciting for me to read the passion in Linda’s voice that had been missing the previous semester. I don’t believe it was so much Linda that had changed as much as it was the vehicle for communication in the class. The online class provided space and time for Linda, who seemed shy in a traditional setting, to give voice and passion to issues that were hidden in the more traditional classes.

**Conclusion**

This paper provides some background of traditional classrooms in which the range of content and voice is limited to that of the teacher and the text. Diversity in voice and information is a democratic value that is important not only because teacher education classes should be democratic in nature, but also so that teachers can live a model of democratic learning in their own future students.

Online classes, by their structure, providing time and space for diverse student voice and by the instructor’s encouragement, can serve to promote democratic values. In the case presented, Linda’s post gives the reader a window into the use of three different sources of information she uses to emerge as a knowledgeable teacher. Her comments online reflect ownership, voice, independence, and a sense

1318 — Technology and Teacher Education Annual — 1998
of inquiry that is not evident in traditional classrooms. If democracy is a value we cherish in our country, we need to encourage the norms and ways of being that reflect a democratic character in our own classrooms. Wise use of technology can play an important role toward that end.

Future papers will report more on giving voice as well as other democratic values such as the importance of time, styles of learning, active engagement in the subject matter, and modes of thinking and expression.

VOLCANOES TO “VIRTUAL TOURS”: BRINGING MUSEUMS TO CHILDREN VIA VIDEOCONFERENCING

Timothy Barshinger
Purdue University

Museums are taking on a more active role in the education of children. Teachers have become more aware of this role and the benefits that informal settings can provide (Martin, Brown, & Russell, 1991). Science museums and other informal science centers such as zoos, aquaria, and environmental centers have increased in popularity because they provide opportunities that extend beyond the traditional static museum. These types of environments provide direct, interactive experiences with relevant materials that enhance students’ curiosity and wonderment about science (Falk, Koran, & Dierking, 1986). According to Ramey-Gassert, Walberg, and Walberg (1994): “Museum learning has many potential advantages: nurturing curiosity, improving motivation and attitudes, engaging the audience through participation and social interaction, and enrichment” (p. 351). Thus, educators are incorporating participatory science museums and other non-traditional classroom settings into their curriculum to provide kinesthetic and visual experiences that cannot be duplicated in the regular classroom with the same outcomes (Falk, Martin, & Balling, 1978; Flexer & Borun, 1984).

With this growing utilization of informal environments, the assumption would be that the canon of research supporting their use has increased as well. However, Schauble and Bartlett (1997) concluded in their search for research-based museum designs that there is an incredible discrepancy between research on museums as an actual learning contexts compared to studies on exhibit evaluations within the museum. They state:

Although more and more museums are incorporating research, too often research is framed by museum staff and funders as “evaluation,” that is, as a way of demonstrating the success of a completed project, and not as a compass for guiding the unfolding design (p. 791).

They also note that even though there are many current sub-fields organized around school learning, such as educational psychology and instructional psychology, there is currently no sub-field that is generating the constructs and methodologies associated with informal learning.

Whereas research on galleries designed with appropriate pedagogy is limited, there is a significant amount of information on the behaviors children exhibit while attending informal science settings. In particular, the behavioral reactions to setting orientation and novelty influence has been examined extensively. This has led some researchers to be concerned that the novelty, or excitement of a field trip, may interfere with task-directed learning. Children spend more energy orienting themselves with the environment than trying to understand the scientific concept being presented (Falk, 1983a). In fact, some studies suggest that extreme novelty could even lead to less exploration and fear (Falk & Balling, 1982; Falk et al., 1978; Martin, Falk, & Balling, 1981). Researchers have conducted investigations to determine if purposeful novelty reducing procedures such as advanced organizers, or pre-visit, post-visit and on-site visit materials affect students’ conceptual learning. Falk (1983b) researched whether orienting materials could be useful in producing more successful learning of museum information. These orienting materials include: logistical layouts and agendas given pre-visit, information panels placed anterior to museum exhibits, teacher pre-visit discussions, cognitive preparation materials related to the exhibits, and slide-tape presentations given pre-visit.

Technology Use in Museums

This last form of novelty reduction provided the catalyst for a research study. Kubota and Olstad (1991) introduced a pre-visit novelty reducing treatment via a slide tape presentation of the logistics and highlights of a science center. Their positive outcomes suggest that two-way audio-visual interactive learning (2WAVIL) technology could produce similar results. This relatively new form of communication has traditionally been used in the business sector as a type of videoconferencing. However, it is beginning to emerge in educational uses, starting first in Europe at the university level (Bork, 1995). The majority of research on 2WAVIL use focuses on this implementation.
throughout the university realm. Few projects investigate applications at the high school level and virtually none exist for the middle or elementary school (Evjemo, Eidsvik, & Danielsen, 1995). Many of the studies report on cooperative ventures among schools in which one district hires a teacher to broadcast lessons via satellite or cable telephone lines to other cooperating schools. This is often accomplished in a very didactic manner with little interaction from the students (Bork, 1995).

The Children’s Museum of Indianapolis is an institution that possesses 2WAVIL technology. As part of Ameritech’s Advanced Video Network’s “Vision Athena Project”, it serves as a distance learning content provider to schools, businesses, and other community organizations throughout the state. As with most museums that possess this technology, the distance learning curriculum is implemented without a firm body of research as its foundation. Therefore, some informal learning environments have begun collaborative efforts with university institutions to investigate the possibilities of this technology.

The remainder of this paper is broken into two parts. The first addresses the research study that is currently being implemented at The Children’s Museum of Indianapolis regarding the use of 2WAVIL technology as a medium for preparing students for a visit to the museum. The second portion of the paper includes descriptions of various school programs and initiatives that are currently being implemented by the museum. These programs use the 2WAVIL technology as a means of sharing museum resources and exhibits with elementary students.

The Research Study

Purpose

The purpose of this study is to examine how children and their classroom teacher interpret a visit to an informal science museum (The ScienceWorks Gallery of The Children’s Museum of Indianapolis) following a two-way audio-visual interactive learning (2WAVIL) link. This “Virtual Tour” via video conferencing technology is meant to serve as an advanced organizer for children, whom, according to research, often find an experience in museum settings overstimulating. This overstimulation often prevents an appropriate orientation to the new setting; such an orientation would help children focus on the concepts being presented by museum exhibits. This study intends to add to the literature by examining the influence of a 2WAVIL link on children’s “lived” experience at an informal science setting.

The Research Questions. Specifically, this study addresses the following questions:

1. What are children’s interpretations of their experience in a novel science museum setting and the 2WAVIL link which preceded it?

2. What is the classroom teacher’s interpretation of those children’s experience?

3. How do the children’s and teacher’s interpretation of this experience compare?

Design & Procedures

This interpretive study involves four fifth grade children and their classroom teacher as key informants. Data is gathered through interviews with the key informants, as well as through observations, field notes, and researcher reflections. Data will be interpreted through the development of common themes generated from the interviews and will be synthesized into assertions about the nature of the experience. These assertions will be triangulated with the other three types of data to strengthen the nature of the study. Member checking techniques will be employed with the classroom teacher as a further means to verify interpretations.

This study follows a phenomenological theoretical tradition. According to Patton (1990), the central question of phenomenological research is “What is the structure and essence of experience of this phenomenon for these people?” (p. 88). The research questions for this study fall within that question as the participants interpret the experience of their interaction with technology and with the museum environment. Interviews are utilized as the primary data source. An interview is conducted with the key informants following the initial observations but prior to the 2WAVIL link. A second interview occurs immediately following the 2WAVIL link but prior to the museum visit. The third and final interview sessions occur following the experience at the museum.

The classroom and the key informants are observed at least once prior to the visit. This helps provide general background knowledge on the dynamics of the class, the students, and the teacher. The key informants are also observed during the 2WAVIL link via a video recording of the procedure. Tracking of the key informants (a form of observation employed by museum personnel) is utilized during the actual visit to the museum. Key informants are tracked from a non-obtrusive distance by assistants. These assistants record data such as: the path of movement throughout the gallery, exhibits that were explored (“attraction”), amount of time spent at those exhibits (“holding power”), interaction with other visitors or classmates, and comments made related to the exhibit. Key informants are made aware of the tracking procedure to avoid anxiety that could be produced if children felt they were being “watched” by a stranger. Assistants are provided with a stop watch and a set criteria for how to track the key informants.

The data obtained from the tracking procedure are used as field notes. Also included in those notes are observed behaviors of the key informants in the other phases of this
Results & Findings

A qualitative approach to this project was utilized to provide information regarding the nature of the experience as interpreted by the participants. Final results and conclusions, at this point, are still pending. However, preliminary review of student and teacher interviews would suggest that the technology was effective in orienting the students to the gallery environment. While the degree of orientation varied from student to student, all four expressed that they felt the link was a positive experience. All agreed that one of the biggest benefits was that the technology enabled them to be aware of the types of exhibits that were in the gallery. They also felt the explanations of possible means of interaction and explorations, which were shared in the link, were helpful. When asked to compare the 2WAVIL link with a video-taped tour of the gallery, all emphasized that the ability to ask questions and interact with the tour guide "on the spot" would make a 2WAVIL link more motivating. These same reflections were shared by the classroom teacher who also believed that this was one of her most successful field trips. She believes this is so because many of the students came prepared with a plan of action for their visit.

The final results and conclusions of this project should help provide a better understanding of how children think and learn in informal science settings. It will also help extend previous studies done on novelty reducing preparation in informal learning environments. Additionally, this particular project will also serve as one of the few studies that examine the outcomes of 2WAVIL technology use in a classroom and in an informal setting.

The conclusions drawn from the project will have implications for the educational establishment's current push toward the integration of advanced technology in the classroom. It will provide a basis for further studies that implement distance learning technology. It will also provide information for schools and museums that are just beginning to equip their buildings with 2WAVIL technology.

Videoconferencing School Programs

Developing 2WAVIL Programs That Follow Constructivist Epistemology

Bitgood, Serrell, and Thompson (1994) highlight the advantages that informal learning environments have over the traditional classroom. These sites are often able to meld affective and cognitive learning experiences as academic enrichment occurs via recreational interactions. Another advantage is that "time-on-task", while usually short, episodic and more intense than a traditional classroom, is controlled by the learner. Thus, participants are more apt to pursue those exhibits which possess science content that is relevant and meaningful to them. Schauble and Bartlett (1997) explain that this constructivist notion provided the theoretical framework for the design, construction, and educational programming of the ScienceWorks Gallery. Exhibits were created that could "build upon and extend activities first encountered at the museum into other contexts, such as the child's home, school or backyard" (p. 784). In addition to the physical design, the museum recognized that to truly encourage a constructivist approach, involvement with the exhibits must occur with mediation. This mediation needed to expand beyond the built-in components of tools, signs, and layout to include the even more important element of human interaction. Gallery interpreters are encouraged to be sensitive to the manner in which children think and learn while visiting exhibits. Less emphasis is placed on dissemination of factual content, with a greater significance being directed toward the pedagogical methods necessary to guide children toward science understanding. In short, the museum wanted to apply classroom constructivist methodology to an informal science environment.

While the museum has experienced a great deal of success executing these beliefs for their on-site visitors, the addition of audio-visual videoconferencing as a means of presenting museum resources adds another, more complex layer. Can an informal environment, built upon a foundation of free-choice exploration with guided interpretations, promote meaningful and relevant experiences for school children via electronic means? This notion of independent exploration would not seem feasible in a situation that requires students to remain mostly stationary and fixated to a central object of information presentation, the TV monitor. However, Jones and Knezek (1995) state that one of the true benefits of 2WAVIL technology is the "interactive" nature of the system. It provides a level of intimacy in communication that is not apparent in other forms of distance learning. Colbert, Voglimacci, and Finkelstein (1995) highlight that another strength of the technology lies in its synchronous nature; the teacher and learners experience parallel delivery and reception of information without a time delay. Finally, Jonassen, Davidson, Collins,
Campbell, and Haag (1995) suggest that a constructivist epistemology can indeed be implemented through 2WAVIL technology. They state:

Two-way real time video transmission of information implies a new definition of real-world context. Although video-mediated, constructivist learning environments could potentially include the actual environment or a close facsimile with which the learner could remotely interact. The collaborative problem-solving situations enhance knowledge construction through the addition of visual information and remote interaction with other learners. The video transmission of authentic, realistic contexts add a significant dimension to anchored instruction and situated learning environments (p. 18).

Technology Capabilities at a Children's Museum

The Children's Museum of Indianapolis possesses the capabilities to provide the actual museum environment in realistic contexts. Many institutions utilize a stationary audio/video set-up isolated in a single conference room. While the museum does have a dedicated distance learning classroom, it also possess a mobile camera and monitor unit. This unit can be plugged into fifty-four different receptacles located throughout the five-story gallery spaces and collections department house in the basement. These receptacles are wired to an in-house cable network located on the third floor. This central network serves as the head-end from which all broadcasts are received and transmitted via fiber optic phone lines. This has provided the museum the capability to broadcast and receive transmissions from almost anywhere within its 250,000 square foot facility. Thus, any of the museum environments can be brought virtually to schools or classrooms that own the appropriate equipment.

Creating 2WAVIL Programs at a Children's Museum

Possessing the capability to provide the museum environment to remote locations does not guarantee that interactive teaching techniques will be executed in a manner consistent with constructivist epistemology. Appropriate mediation would need to occur to avoid a didactic approach or "talking head" mode of presentation. Therefore, the museum is currently in the process of creating and adopting various distance learning science programs that can be transmitted to elementary and middle schools. These programs attempt to combine museum resources (such as gallery exhibits, collections and museum personnel) with a theoretical framework that models constructivist classroom teaching. What follows in the final portion of this paper are brief descriptions of some of the 2WAVIL school programs currently offered by the ScienceWorks gallery. These programs are approximately one hour long and are geared toward an elementary and middle school audience, with most emphasis in the 2nd-6th grades. In addition to explaining the content presented, a description of the manner in which these programs encourage guided exploration is included.

Lots-n-lots of Fossils

As one of the first programs designed by ScienceWorks staff, this lesson utilizes the gallery's twenty foot fossil wall which is modeled after a limestone outcrop from southern Indiana. Imbedded within the Paleozoic rock layer are realistic invertebrate fossils such as: gastropods, crinoids, blastoids, horn coral, and trilobites. Actual examples of these fossils can be found in the limestone quarry directly beneath the wall. For this presentation, the gallery camera becomes the eyes for the remote site. The fossil exploration can be controlled by the distant students who direct the on-site camera "to the left, up a little, now zoom in". With interpreter mediation, these fossil samples can be compared to the data sheet that has been faxed to the remote school prior to the link. Additional comparisons are made to a "What They Looked Like" wheel located near the wall. This spinning manipulative contains illustrations of the fossil life form as it looked when it was living. Interpreters are encouraged to promote discussion among the remote site students by having them share their ideas of the fossils that they discover in the wall.

Volcanoes: An Explosive Experience

Manipulation of tactile objects and "real" science equipment is imperative to fruitful interaction for on-site visitors. In developing distance learning programs, museum staff felt that remote students needed to be provided with these same opportunities. For this program, kits which contain samples of volcanic rock and materials necessary to "produce" volcanic eruptions are prepared and sent-out to participating schools. The program begins with a discussion of the basic geologic eruptions of the earth. An explanation of the various types of volcanoes and a demonstration of volcanic eruptions then follows. The interpreter provides step-by-step instructions to the students who are placed in 3-4 cooperative groups. A variable is changed for each group which produces a difference in the type of eruption. Students discuss the reason for the variance in reactions among their groups and with the interpreter. The program continues with the presenter guiding students in an investigation of the physical properties of the rock samples. Students record observations of their samples (i.e. color, texture, mass, buoyancy, etc.) and compare them with observations highlighted by the presenter. Once again, interpreters are encouraged to emphasize the process of data collection over the actual identification of the rock samples.

Rocks & Minerals (But Mostly Minerals)

The greatest strength of this program is the manner in which a "resident scientist" aids in the investigation of
some common minerals and their properties. Like the volcano and earthquake programs, this lesson is enhanced with a manipulative kit which contain samples of minerals, various tools for examining their physical attributes, and two sets of data sheets. The first data sheet is fashioned in a grid pattern with mineral properties (ex. "hardness", "luster", "cleavage", etc.) placed at the top of each column and alphabetic letters along each row. The teacher distributes the minerals to the students, assigning each sample a letter in place of the mineral name. The role of the resident scientist is to define the various properties. He also demonstrates how to test for that property using larger and more pristine samples. After completing these series of tests, the students are provided with the second data sheet that contains a hierarchical graph of each mineral's properties. Students must deduce the identity of each mineral sample from the data they collected on their sheet. Finally, they share their results and rationales with the scientist who verifies their identity.

Put on Your Hip-Waders: Exploring a Pond Habitat

While this program is the most technologically challenging, it also exemplifies an immersion experience. The interpreter broadcasts while standing in the 500 gallon pond located in the ScienceWorks gallery. The focus of this lesson is to help students understand the necessities all living creatures need to survive in their environment. The remote site is provided with a series of cards which include various examples of the four basic requirements of a habitat: food, water, shelter, and space. The presenter directs student attention to a chart with a list of animals and their coordinating basic habitat requirements. Students must work within their group to provide the matching set of cards. Once completed, the interpreter takes students on an "up-close" tour of the pond and surrounding wetland. Using a hand-held camera, the presenter showcases the various kinds of fish, turtles, frogs, amphibians and plants that are living in the pond environment. From this point, the interpreter suggests that students select one or two creatures they observed and then discuss in groups the four basic habitat requirements for that organism.

Technology continues to evolve. Young children and their teachers now have many use options other than traditional instructional software, paint programs, and LOGO programming tools, even though these were the perceived options just a few year ago (see Clements, 1993). Some new options today include software which: (a) reads the text of a book, (b) allows for visual representation of complex ideas using concept maps, and (c) allow the user to develop multimedia presentations. The content and formatting of the World Wide Web are also continuing to evolve to a point at which a young child might soon be able to use it without too much help. Due to their recent price drops, digital cameras are now widely available. Similarly, the cost of videoconferencing equipment is decreasing while the quality of the transmitted images and sound is improving. This last possibility, the use of videoconferencing in an early childhood school setting, is the focus of this paper.

This discussion is grounded in the author’s experiences with related, ongoing technology planning for the Early Childhood Development Center (ECDC) at Texas A & M University—Corpus Christi (TAMU-CC). The ECDC features a public school attended by pre-kindergarten through third grade students. Inclusion in the planning of the College of Education’s newly revamped, field-based teacher education program adds to the complexity of the planning effort.

A Rationale for Videoconferencing

Use of videoconferencing is founded on the premise that providing teachers and students with opportunities to communicate with others who are external to the ECDC school is desirable and effective. While some scholars speak of leveling the playing field as a way to provide equal education, an issue of concern at TAMU-CC is one of broadening the playing field or increasing a child’s opportunities to communicate with others. The ideas is to enrich students’ learning in selected curricular areas while—maintaining a developmentally appropriate approach—helping them to develop communicative and collaborative skills. Videoconferencing also affords teachers with new opportunities for professional development and collaboration with other teachers. Under the “companion classroom” conception, teachers and students can collaborate on projects with each other, guided the whole while by a university faculty person who is involved on an ongoing basis.

Current views regarding constructivism also contribute to the rationale for use of videoconferencing. Constructivism holds that learning is grounded in experience and requires the active construction of new knowledge based on that experience. Social negotiation—the idea that learners should be allowed to collaborate to derive personally meaningful conceptions of ideas and experience—should be well supported by students’ involvement with other students via videoconferencing. Other constructivist ideas concerning the need for student-centered approaches and active learning should also be addressed through videoconferencing. Further, aiding learning through provision of multiple perspectives should also be supported insofar as students will be able to readily share in each other’s differing views on given problems and topics.

The faculty and teacher education students are also to be involved in use of videoconferencing. One intriguing related idea concerns classroom observation whereby teacher education students can use the equipment to observe teacher—student interaction in participating, remote classrooms. Given a sufficient number of participating sites, this strategy will greatly enrich education students’ opportunities to see what is happening in classrooms in varied settings.

Currently envisioned users and uses of the video system for the ECDC are summarized in Table 1. The strategy is intended to maximize efficiency by allowing for use by multiple groups.

The Planning Effort: Some History

Most human endeavor is marked by complexity. Use of videoconferencing in a place such as the ECDC is no different. Planning to this point may be characterized as a slow, complex process.

A number of systems have been considered thus far. Originally, college of education planners felt that use of a high quality V-Tel system would work best. This approach called for installation of a V-Tel hub at the local Region 2 Educational Service Center. Working in partnership with the faculty, the Region 2 staff were to schedule and implement videoconferencing sessions with other K-12 schools and appropriate professional organizations. The involved schools—led by the Coastal Bend Center for Professional Development and Technology housed in the college of education—were to comprise a consortium which would participate in ongoing strategizing and use of the system to support teaching and learning, including education students. It was later decided that high-end V-Tel systems were cost prohibitive and, accordingly, would not allow for a sufficient number of sites to be involved.

Planners also gave thought to utilizing the inexpensive C-U SeeMe desktop video application which runs over the Internet. After conducting a few “try-outs” of this application, planners determined that it provided insufficient audio and visual quality to be useable. Subsequently, new self-contained videoconferencing equipment providing acceptable quality has appeared in the market costing approximately only $3,000 per site. Depending on the exact equipment, costs for phone lines may also have to be budgeted. Although purchases have not yet been made, it appears that planners will opt for the new, moderately priced equipment, pending further research and try-out.

Planners have learned a number of lessons thus far. They include:
1. Clarify the purposes of system use at the beginning of the project.
2. Design the system beforehand to provide adequate audio and visual quality and to accommodate all potential users.
3. Try out the equipment before purchasing it.
4. Verify that proper telecommunication wiring is in place before purchasing it.
5. Identify required personnel for system operation before purchasing it.
6. Beware of hidden, ongoing costs such as those for phone lines.

While some of these lessons may appear as blatant common sense, they are worthy points to keep in mind, especially for those lacking extensive experience with videoconferencing systems.

Planning for Videoconferencing:
Essential Considerations

The following lists summarize essential considerations for planning a school-based videoconferencing system. The summary utilizes a traditional instructional systems development model as an organizing scheme. It should be useful to individuals in other locales who are interested in similar kinds of planning:

**ANALYSIS Issues**
1. Procure funding.
2. Establish team and project director to coordinate and guide videoconference use.
3. Identify goals of system use.
4. Identify sites, users, and their locations.
5. Identify system coordinators at remote sites.
6. Research appropriate videoconferencing hardware and software.
7. Identify candidate hardware and software.
8. Verify availability of telecommunication wiring required for candidate system(s).
9. Arrange try-out of candidate system(s).
10. Select and procure system components.

**DESIGN Issues**
1. Select curricular areas of emphasis.
2. Identify goals and objectives for videoconference use.
3. Design support materials for users.
4. Identify required training objectives for system users.
5. Write, review, revise usage plans with project team and users.

**DEVELOPMENT Issues**
1. Finalize goals and objectives for videoconference use.
2. Develop support materials for users.
3. Develop required user training.

**IMPLEMENTATION Issues**
1. Conduct user training.
2. Begin videoconferencing.

**EVALUATION Issues**
1. Measure attainment of goals and objectives.
2. Identify possible attainment of unintended goals and objectives.
3. Measure videoconferencing users' opinions and attitudes toward the project.
4. Summarize operational problems.
5. Write and disseminate evaluation report.

**Closing Thoughts**
Having been in existence for less than two years, TAMU-CC's ECDC stands as a wonderful locale to explore uses of technology with young children and their teachers. Currently, faculty and administrators are planning for the procurement and use of video conferencing in the ECDC and companion classrooms. It is hoped that teacher education faculty and students will use video conferencing as a classroom observation tool. Implementation of the system will no doubt provide exciting, ongoing opportunities to evaluate and research exactly how video conferencing impacts learning and professional development of those involved.

From the mass media to the scholarly press, a common theme in the last several years has been that educational practice must change. Learning must become more learner-centered; educational offerings must be more flexible, more individualized; teachers must move from being "sages on the stage" to "guides on the side" with new roles such as "learning facilitators and knowledge brokers" (Tuckett, Jones, & Thomas, 1997). In addition, higher education in particular must become more responsive to the needs of lifelong learning, but probably within the constraints of less funding. And just, changes in teaching and instructional practice are notoriously difficult. Various reasons for the as-yet limited impact of ICT on educational change in higher education are well known: research, not instructional innovation, is what is valued in terms of quantifiable indicators of scientific productivity; output financing discourages risk-taking in instructional practices; the relative autonomy of instructors, of departments, of faculties, and of universities with respect to educational practice means economies of scale and critical masses of experience do not develop; the time and effort investment required of the instructor who wishes to implement ICT into his instructor practice are not only high, but frequently lead to negative experiences. Student course-evaluation forms, for example, rarely present choices relating to qualities such as "effort spent by the instructor to innovate" or "willingness of the instructor to use ICT to change his instructional approach". Instead, the instructor is rewarded for qualities such as being "well prepared" and "clear", qualities which are easier to convey when teaching in a traditional way with well-used materials than when grappling with the frustrations of unfamiliar ICT use.

As a key to the puzzle of how to do more with less, information and communication technologies are generally mentioned in the same context as the need for change (Massy & Zemsky, 1997; Moonen, 1994). New technologies, particularly those involving networking, will not only need to be integrated more into traditional teaching and increase the demand for more access to open and distance learning but their effective and efficient use will also become "an obligation" for schools and universities (Langlois, 1997). However, a particular problem associated with technology and educational change is that the impact of the use of technology in our teaching is difficult to measure. Accompanying this difficulty are unrealistic or unmeasurable expectations: using technology (or these days, the Internet) should lead to transformation of the institution, to new forms of teaching and learning, to structural innovation of the whole study process (De Haan, Fisser, & De Wolf, 1997). These are expectations which probably will never be met, nor is it clear that all forms of teaching and learning need to be transformed. Also, the impact of "small things", such as the casual and frequent communication which students have with instructors via e-mail, are apparently not easy to measure in terms of quantifiable impact indicators, but such small things are in fact quietly and incrementally contributing to quite substantial changes in the educational culture and certainly in the time expenditures of the instructor.

Thus there is a gap between vision and execution. Parallel to the calls for change are systematic analyses of barriers confronting change related to technology in schools and universities. Implementation problems relate to the difficulty in changing embedded practice, cost factors, lack of adequate support, lack of adequate staff training and on-going help, lack of planning adequate for
multifaceted change, lack of political or social will, lack of clarity of how to proceed, lack of reward structures, lack of adequate organizational and even system-wide changes, lack of time, lack of adequate access to hardware and network connections, lack of appropriate learning-related resources, lack of ideas for how to integrate new technologies into teaching, lack of fully worked out technical considerations, lack of awareness of usability issues relating to computer-based and network-based materials, lack of adequate technical preparation among instructors and students (among many sources of references to support this list of problems, see at the conceptual level, Fullan, 1991, and Langlois, 1997; at the higher-education level in particular, see Massy & Zemsky, 1997, Richards, 1998, and Seminoff & Wepner, 1997; at the level of a specific program or course, see Montgomery & McGovern, 1997, and Takle & Taber, 1996). When the many different analyses of barriers confronting implementation efforts in schools and higher education with relation to change and the use of technologies as part of change are synthesized, the following recommendations seem to occur most consistently:

- Managed change should not be technology-driven, a clear, obtainable goal and rationale for the change process must be agreed upon and technology should only come into the picture when it is obvious that technology is needed to reach the goal. Goals such as "preparing for the future" or "improving our education" are not specific enough to focus a change process. There should be a problem which all can agree needs to be addressed.

- Staff development is critical, both in terms of handling the technologies involved but also in terms of how to adapt to new instructional emphases such as learner centeredness and increased interaction among learners.

- Change is multifaceted and multiplayer, and all aspects need to be integrated, at the institutional level, the instructor level, the student level, the supporting-staff level, the technology-infrastructure level, the curriculum level, the user-interface level, the procedural level via which the managed change is to occur.

- There needs to be a mixture of both top-down (leadership, policy, vision, incentives, pressure, coordination, funding, infrastructure provision) and bottom-up (acceptance of the value of the innovation by the individual involved, willingness to move through initial difficulties as well as the unavoidable "implementation dip" that accompanies having to deal on a personal basis with the small and large problems of change and technology, adequate personal skill, access and insight to continue productively).

The pressures on a Faculty of Education to respond to changes in teaching and learning and to overcome implementation barriers are considerable. As faculties in higher-education institutions, all of the problems confronting any faculty are also felt by us. We must publish; we must obtain research funding and carry out empirical research; we may have inadequate access to the technical support needed to attempt innovation in our teaching; we are evaluated in our teaching on the basis of student satisfaction and course completion, goals not always compatible with attempting innovative practice; our attempts at innovation, when they do occur, may not fit the organizational practice of our institutions; we may not perceive ourselves any relevance in all these calls for change within our own courses. And yet we are supposed to be educating our own students to become professionals in the new type of educational environments that we do not even know how to demonstrate ourselves. We need to practice the change that we are preaching, if we even are preaching it. Who do we look to as models for ourselves?

At the Faculty of Educational Science and Technology of the University of Twente in The Netherlands, we are involved in a comprehensive change-implementation initiative, involving attention to all aspects of the change process, in which we are not only developing a new model for our education (which we call C@MPUS) that involves both "pedagogical re-engineering" but also the appropriate combination and use of different didactical methods and technologies, that we think might provide a model to other faculties of education. Among the keys to the process are (a) our own history and context, which has brought us to the point where managed change can begin, gain acceptance, and be carried out; (b) the TeleTOP initiative, which has the leadership role in managing the change process; and (c) our balance of attention to the three key features of our core principles of learning and teaching, staff engagement, and comprehensive technology design. In this presentation, I briefly describe our history and context and then the TeleTOP initiative as implementation manager for our current re-design of our educational practice. After this, more specific attention to our staff-engagement methods will be given. I will conclude with two major questions, not only for us but for all faculties of education.

**History and Context: Technology and Teaching at the Faculty of Educational Science and Technology in The Netherlands**

The University of Twente is one of three "technological universities" in The Netherlands, established within the last 40 years to focus specifically upon technical subjects. Thus these faculties have no arts and humanities faculties and no traditional faculties of education. The University of Twente itself however has a Faculty of Educational Science and Technology, which focuses on educational technology in the sense of both products and methods. We emphasize an
“engineering approach” to educational problems. Our students typically go to work in the training departments of large organizations, in companies and agencies designing and delivering educational resources and services, and often as members of multidisciplinary teams involved with the design and development of computer-related materials. In our faculty, we do provide this training for candidates wishing such a certificate for mathematics, chemistry, and physics. However, we work intensively with schools and teachers as a partner on many inservice projects, on research projects, and as partners in consortia of various sorts. We are engaged by the Ministry of Education to evaluate or stimulate educational-change initiatives in schools. One of our departments, called ISM (for “Educational Instrumentation”), has an international reputation in terms of its research and practice with respect to the use of technologies in learning. Through an on-going variety of international, national, and intra-university projects, the Department ISM has gained considerable experience in the applications of older media (such as video and single-machine computer-based learning) and newer media (such as different forms of computer-based communication, the WWW, video- and desktop conferencing, and other applications of high-speed networking). In our Department, we have been among the pioneers in the use of the WWW in teaching, starting in 1994 (see an overview of four years of experience of one particular course in Collis, 1997c).

From such pioneer activities, we have moved to what might be called a “1,000 flowers blooming phase”, where more than 15 of our courses, not only in the Department ISM but across the faculty, have come to make extensive use of the WWW and many other courses use other forms of technologies (for a review, see Collis, 1997a; see also a hyperlinked listing of the courses at http://to-www.to.utwente.nl/TO/project/telecop/exampl.html). All students have generous network access, free from their on-campus residences, free for the first 300 minutes of dial-up telephone charges if they live off campus. In our building, there are many computer rooms, available to students almost all the time, and students have generous access to printers, to multimedia-related hardware, to professional software packages, and to all innovative WWW-related applications. We have approximately 20 technical support staff, with high levels of skills. We have two lecture halls with presentation platforms, where computers with network connections are always available to support presentations and ceiling mounted projection devices are installed. We have a critical mass of students that are well acclimated to working in (and producing) WWW environments, to working collaboratively with each one via the networks, and to using computer communication of various sorts as part of their on-going daily routines. An organizational culture has developed for network-related computer use in our instruction, particularly WWW environments. All faculty make daily use of e-mail, and all institutional communication flows through e-mail, and increasingly, via WWW sites. PowerPoint support is commonly used in our lectures, and many students do their final masters’ level projects around the design and development of computer-based, and now WWW-based learning resources.

However, despite its many achievements, our university and faculty are facing problems with regard to funding and to number of students. The university’s strong technical orientation is a disadvantage in a time of a decreasing number of students coming out of secondary school with the strong preparation in mathematics and science that we require and the fact that the government has recently introduced cut-backs in student funding which bring financial difficulties to students if they are not able to move quickly through their studies. Our location in the relatively rural eastern part of The Netherlands is a disadvantage compared to the appeal of Amsterdam and other larger cities in the west of the country in terms of appealing to the sense of adventure in young students. Due to a reorganization, many of our traditional base of students are now enrolling in a new Department of Communication Sciences within the university. And, at the national level, the government has tied funding to universities very strongly to the number of students who complete a degree program, and has cut funding in general. Because the Dutch language is not much known outside of The Netherlands and Flemish Belgium, we do not have an easy way to compete internationally for beginning students (although we have a separate Master of Science Programme in Educational Training and Systems Design which is offered in English and which is doing very well, but which operates separately in terms of funding). In short, we have a problem. We need more students in our regular program. There are two general ways to find them: among those leaving secondary school meeting the entry requirements for our university but who do not wish to move to our (far-away, by Dutch standards) city, and among those who already have a degree from a teacher training or equivalent institution and who may be working in the field anywhere in the country but who would like to have the additional experience in educational technology that we offer.

It is in this context that we have moved into a period of managed change. Our faculty administration has taken the step or moving from providing a good support environment for the “1,000 flowers blooming” to the more-proactive phase of stimulating all staff, in a systematic way, to move to a new, more-flexible form of educational delivery in which we can integrate these new intakes of students with
our on-campus students in a top-quality educational program. It is the decision of the faculty administration to move from creating an opportunity climate where the interested individual can move forward to enrich his or her teaching with technology, to the more proactive position of putting forth a strategy, with funding, for stimulating managed change that creates the transition. The TeleTOP initiative is a major tool in this managed-change phase.

**Becoming More Flexible: The TeleTOP Initiative and C@MPUS**

The goal of TeleTOP, started in August 1997, is to systematically support the professional development of the faculty in terms of potential applications of telematics in their teaching, and to carry out the re-design of approximately 38 courses in during the 1997-1998 academic year so that our education becomes more efficient, more enriched, and more flexible via innovative and appropriate applications of telematics, particularly WWW-based tools and environments. The Mission Statement of TeleTOP can be seen on its homepage, at http://to-www.to.utwente.nl/

Not only because making one's education more flexible is a way of reaching more students but because it is critical to the individualizing of education on a more conceptual level (Massy & Zemsky, 1997). We had already studied a variety of ways in which education can become more flexible and identified more than 25 dimensions on which a student could be offered choices in the way he or she experiences a course (Collis, Vingerhoets, & Moonen, 1997). The most familiar choice is that of flexibility in location, whereby students can choose to participate in a course from a distance or by being resident, or combinations of these. Other flexibility dimensions include choices in timing and pace (when a course can be started, how much time can be taken to complete the course); choices in instructional approach and methods (including in media used in a course as well as in didactics); choices in the social organisation of a course (including the choice of working individually or as part of a group); and choices in forms of assignments and ways of being assessed. We have found that some of these choices are incompatible with each other, for example, the choice of studying at one's own pace may require giving up the options of group work and collaborative learning as instructional organisation choices within a course. We also are aware of human limitations on flexibility. We are a typical university faculty, where each staff member must not only carry out teaching responsibilities but also do research, supervise graduate students, and participate in internal tasks and committees as well as maintain professional identities outside the faculty. We must carry out all aspects of our own teaching, from creating to carrying out our own courses, having no layer of tutors to take over communication and evaluation tasks with our students. It is not possible to offer highly personalized education to our hundreds of students, for reasons of human constraints.

Nor do we want to. We believe that our strengths as educators lie in how well we are carrying out our "old values", particularly those of good teaching, of the development and guidance of experiences for our students in working as part of collaborative learning groups through our emphasis on design projects throughout our curriculum, and of providing the atmosphere in which our students gradually become professionals through interacting with us and with the field in both well-organised and informal ways. Also, although in the "outback" of the country, we have a very pleasant campus, the only university in The Netherlands with its own large natural setting complete with ponds, ducks, lovely trees and lakes as well as sports facilities and even an open-air amphitheatre. Furthermore, we have excellent technical facilities on campus, As we become more flexible, we do not want to lose the benefits of what we already have, but rather, we want to extend them. We do not want to become virtual.

We believe we can offer some aspects of increased flexibility while maintaining our old values (Collis, 1997b). This is what we mean by our C@MPUS Approach. In particular, by September 1998 we will be offering many of our courses to combinations of the following different cohorts of students: (a) the regular students in residence at the University of Twente; (b) part-time students, from throughout the country who maintain their own working lives and remain in their own homes; (c) students who follow our courses via real-time technologies in an "interactive classroom" in Friesland (a province in the north-west of The Netherlands); and (d) foreign and Dutch students of our Master of Science Programme in Educational and Training Systems Design. The way we can make this possible, keeping our number of teaching staff constant, is our approach to flexibility, of which the following principles are central:

- **Teach once, but adapt within** All students participating within a course follow the same general timeframe and share in certain key aspects of a course while being able to carry out other aspects in a variety of ways best suited to their own needs and backgrounds

- **Use good combinations of technologies and instructional strategies**: Including the blend of face-to-face and telematics, as seen in the requirement for our new first-year programme that all students be present at our physical site one day every two weeks and otherwise actively participate in our courses via different telematics environments, such as via video-conferencing for the Friesland students in the north-west of the country

- **Focus on maintaining the strengths of our good teachers and on the methods we have developed for group work and collaborative learning**: Provide the
support they will find attractive and helpful to develop new ways of extending what they already do well in the teaching and learning process. Support the group process via technology when group members do not see each other face to face.

- Manage all this change through an integrated combination of policy, faculty-wide strategy, recognition and appreciation from the administration, top-quality human and technical infrastructure and support, experienced leadership, and a specially chosen team. The latter is the TeleTOP team.

Key to this strategy is the idea of “pedagogical re-engineering” (Collis, 1997c; Collis & Fisser, 1998), where each course is examined in terms of opportunities to provide more flexibility while retaining its strengths. Table 1 show some aspects of the analysis process.

**How TeleTOP Works**

To make this pedagogical re-engineering happen, TeleTOP has the following staffing, principles of staff engagement, procedures and strategies:

**The TeleTOP team and their tasks**

The TeleTOP initiative is chaired by the author, who is a senior academic (the Professor of Tele-Learning in the faculty, and at the university level, the Senior Researcher for Telematics Learning Technology for the inter-faculty research Centre for Telematics and Information Technology (CITIT; see http://wwwcitat.utwente.nl/); a member of the President’s Task Force on tele-learning policy and strategy; and also someone with extensive personal experience in the re-engineering and teaching of courses via the use of the WWW (see also Collis, 1996). The daily responsibility for TeleTOP is shared with the Director of the faculty’s computer laboratory, a person with extensive experience in project management and in directing a state-of-the-art multimedia laboratory. Strategic and financial decisions are made in collaboration with the Board of the faculty. The faculty member responsible for the overall undergraduate educational program is closely involved in the planning and execution, particularly of the new approach to the first-year, and in communicating the new approach to potential students. A researcher studying the role of telematics in the changing university supports the research orientation of the project. There is a Steering Committee representing all departments in the faculty and an external evaluator has been engaged.

The team also includes five full-time educational technologists, all with a Masters degree (the Dutch equivalent) from our faculty and all having previously been students in the courses they are now redesigning. Four of the team have also previously completed a teacher-training program and all have already had successful experiences in the workforce or in other higher-education settings, several outside of the country. In addition, there are three persons employed in TeleTOP with technical responsibility: a full-time Webmaster, a part-time Webmaster, and a full-time database specialist. Graphic-design specialists and multimedia specialists from our computer laboratory are available to the project, as are members of the faculty’s technical helpdesk. The team is supported by a secretary.

**The technical facilities**

There is a well-equipped working area whose furnishing is flexible so that small meetings can take place. A portable projection device is available to be made use of during meetings and consultations so that persons do not have to huddle around a computer screen. Each member of the TeleTOP team has a good multimedia computer, equipped for desktop videoconferencing. TeleTOP makes use of a Silicon Graphics WWW and video server, and uses an Oracle database environment.

The interactive classrooms in both Enschede and the west of the country are linked via ISDN and ATM network technologies. Each has room-size and desktop videoconferencing. The Enschede classroom has 15 networked computers on an intranet using the Silicon Graphics computer as WWW and video server. The Friesland classroom has six networked computers. All computers can support desktop videoconferencing and application sharing. All students have generous access to multimedia computers, and Internet and intranet network connectivity from their homes or residences. Through several smaller projects, we are also developing teaching materials involving video to make available on demand via the video server.

**Principles underlying staff engagement**

We know as researchers as well as practitioners that staff engagement is the critical component of the initiative. Not only must the teaching staff accept the innovations involved, but also it is the instructors involved who must teach in the new ways and handle the new technologies. Their competency and commitment are the key factors. Also, our support staff, such as those who work with the student administration and handle student questions, complaints, and mentoring must be equally well informed and committed. Our technical support personnel will face substantial new problems and calls on their services. Our administration must respond to the new issues and challenges that will occur, such as funding for laptop computers for all part-time students so that they do not suffer a technical-access disadvantage compared to our Enschede and Friesland and Masters Programme students. The culture must be ready, in terms of staff who have adequate experience and confidence (McCartan & Hare, 1996). Thus, staff engagement is critical, involving commitment, skills, and willingness to change. The following principles are among those that underlie our staff-engagement strategy:
Higher education faculties do not respond well to top-down steering. Decision making and the change process need to have the characteristics of a learning process in which participation is voluntary and everyone feels himself represented (Mintzberg, 1990). Although the overall decision to change to more-flexible teaching means that the instructor will not have a voluntary choice in terms of dealing with the different cohorts of students, the many different staff-development sessions and meetings which we offer are on a voluntary basis, and those who wish to adapt their courses without help from TeleTOP are free to do so.

Parallel to this, some administrative stimulants are valuable for a change process to move forward (Kluytmans, 1994). Each department is receiving financial compensation for each course being re-designed in cooperation with the TeleTOP team. Also other forms of recognition (for the instructor individually as well as his group) can result from participation; the administration has created the impression that being involved with this initiative is valuable and valued.

Coordination within the faculty is valuable, so that cooperation can increase, ("from individually inventing the wheel to being able to make use of available solutions"); Boon, Janssen, & Cox, 1997, p. 43

The incentive to invest time in re-designing one's teaching is not only for pragmatic reasons, but also coupled to the opportunity to also make one's own teaching better in terms of enrichment, and of being able to try out some new possibilities to deal with previous problems in particular courses. The instructor's efforts are not to the disadvantage of his or her research productivity, as a number of research opportunities are available in associated with the fact that the chair of the project is also the chair of a research area in tele-learning in the faculty. This confronts the familiar difficulty in higher education of not having enough time for research, if one invests time in teaching improvement (Seminoff & Wepner, 1997).

As much as possible, the instructor is being sheltered from technical problems, and scaffolded in his or her familiarization process with the aspects of technical competency that will need to be acquired (Juge, Hartman, & Truman, 1997).

We are fortunate in our good instructors; we want to build on their strengths, not ask them to abandon them. New ways of teaching more flexibly do not mean that the instructor needs to loose the social and communicative contact that he or she now enjoys with students (Collis, 1997b; Langlois, 1997).

**The TeleTOP method and staff engagement**

During the first two months of TeleTOP, seven different open sessions were offered to staff, led by the TeleTOP chair, in which a variety of examples of new teaching strategies and WWW-based tools are being used within courses in the faculty. (See the TeleTOP site, at http://to-www.to.utwente.nl/TO/project/teletop/appideas.html) for the way the pedagogical re-engineering ideas were organized and demonstrated. Participation was voluntary, and good. Between 20 and 40 staff members came to each session. Some time was spent in giving staff some introductory lessons in how to change a word-processed file into a html file and how to change a PowerPoint file into a set of html files. Meanwhile, different informational meetings were held, and formal visits were made to the administration of each department in the faculty, to discuss issues involving staff involvement.

The actual method used for course re-design is also innovative and based on the above principles of staff engagement. A decision-support tool (DST) was built which is WWW based and integrated with a database environment (De Boer & Hamel, 1998; De Boer, Strijker, & Collis, 1997; Fisser, De Boer, Peters, Verheij, & Collis, 1998). The DST tool is designed as a tool for support of a structured interview involving the TeleTOP chair, at least one of the design team, and each instructor whose course is being re-designed. The tool and procedure were pilot-tested in December 1997, after which some intensive revisions were made. During January 1998, the tool and procedure are being used with the instructors of all the 38 courses being adapted. During this one-hour interview, the instructor is asked a series of questions about what he or she would like to see added or changed in his or her course, following the pedagogical re-engineering framework shown in Table 1. For each possibility, a link is provided via the DST to a WWW-based example of what the possibility looks like in current practice in the courses in our faculty which already make use of the WWW for course support. The members of the TeleTOP team interact intensively with the instructor, trying to identify which ideas and approaches are most likely to be acceptable and interesting to his or her, and to respond with ideas and suggestions, as well as to skip suggestions which do not seem like they will be comfortable for the instructor. When the instructor indicates he or she finds a feature interesting, it is selected via the decision-support tool (DST). When the interview is completed, the DST automatically generates a WWW page for the instructor in which he or she can further examine the choices that were made via any WWW browser or by studying the printout.

Within a few days, the TeleTOP team members visit the instructor in his office, and walk through the first prototype of his course WWW site. This fast turnaround is possible because of the way that the DST is linked to an underlying database, and our own, possibly unique, method of rapid prototyping. The instructor's first prototype represents all the structure and functionalities that could be available in
his eventual course site, but without any content other than minimal example material, and with only minimal attention to the visual aspects of the user interface. The TeleTOP team members and the instructor walk through this site, and discuss possible additions or deletions. (Changes can be continued to be made for a number of months). All of these first prototypes are available as links through a closed shared workspace, accessible only to those involved in TeleTOP. This process of interview and use of the DST to develop a first prototype is taking place for 38 courses and will be completed by the end of January 1998.

The second phase of the TeleTOP Method, comprising about three months, consists of three parallel activities. One of these is continual staff involvement and professional development, based on weekly hands-on sessions for TeleTOP instructors only, in which the instructors will learn to work with their own sites and handle the amount of content-entering and minor site modifications (i.e., to the wording of a page, adding some notes, etc) that we have found to be necessary in practice. Parallel to this, is the on-going development of the course WWW sites, evolving from the first to second prototypes. Linking these first two activities is the device of using the instructors’ own evolving sites as the media for their hands-on activities. Based on what options the instructors are most interested in, we will tailor each week’s session to focussing on those options and how the instructors can be comfortable with using them within a WWW site and for teaching. The third of the parallel activities is also important: we have invited instructors who are interested in developing new approaches to lesson presentation, especially approaches that make use of real-time collaboration and interaction among students both here and at a distance, to join us in a “Working Group” to study together the new didactics that we want to use. For example we are interested in strategies to capture the major moments of an instructor’s face-to-face presentations or class sessions and make these available via the course WWW sites via synchronized multimedia available on demand to the students whenever and wherever they want to review a presentation. But we know that instructors will need time and practice to be comfortable with these techniques. Thus the Working Group will be an opportunity to invite staff to join in on the development of our new didactics, as well as to practice in advance. To demonstrate these new pedagogical approaches and the use of the technology involved, the Chair will volunteer one of her own courses (from March-May 1998) as a demonstration basis for the rest of the faculty. Faculty will be invited to participate, to drop in, to take part in de-briefings, and to discuss among themselves which of the pedagogical approaches they find most feasible for their own styles and subject areas. Faculty engagement is major aspect of our strategy.

Does the TeleTOP Approach Generalize?

The TeleTOP project is only in its first year, but the interest of the faculty, the university and from interested people outside the university is already high. We see TeleTOP as a strategic step towards a new model for the traditional university, that of extending its strengths with telematics-enhanced courses. The portability of the TeleTOP method to other settings is however, one of our on-going research questions. These include:

- To what extent is the evolution from tolerating the pioneer to non-structured support of volunteers to systematic management for change an evolution that each faculty must go through? Can a phase be skipped? What about a unit with no highly-motivated pioneer? What about a faculty with no supportive culture for computer-related educational change?
- Our faculty is biased from the start, certainly toward technology, but also with many academic staff members whose research and professional identities relate to innovative use of new technologies in education. What about faculties of education without this bias? Can the TeleTOP approach generalize to such faculties? What aspects would need to be modified?

In any case, pressures for change in terms of course delivery in higher education will continue, faculties of education will be expected to model what they are preaching, and information and communication technologies will be part of both the problem and solution. The rapid emergence of WWW-based environments since 1994 offers a heightened variety of ways, both technical and pedagogical, to accompany educational change in faculties of education, but strategies for support and engagement of all the staff at the faculty (or institutional) level will be critical in winning the needed commitment and skill. Changing one’s teaching has been likened to “rowing against the stream” (Boon, Janssen, & Cox, p. 10) or even worse; without integrated and managed change strategies, faculties of education will not be able to prepare teachers for such change, or model such change in their own teaching.

NOTICE

REPRODUCTION BASIS

This document is covered by a signed "Reproduction Release (Blanket)" form (on file within the ERIC system), encompassing all or classes of documents from its source organization and, therefore, does not require a "Specific Document" Release form.

This document is Federally-funded, or carries its own permission to reproduce, or is otherwise in the public domain and, therefore, may be reproduced by ERIC without a signed Reproduction Release form (either "Specific Document" or "Blanket").
